CLINICAL RESEARCH

What is obesity and why?

0001

Appetite regulation (acute)

D. Richard[1]
[1] *Institut universitaire de cardiologie et de pneumologie de Québec, Médecine, Quebec, Canada*

The escalating prevalence of obesity together with the rising awareness of the detrimental impact of this condition on health and health costs have considerably stimulated research related to the etiology of excess fat deposition. Regulation of fat mass (hence body weight) is determined by controls exerted on both food intake and energy expenditure. The brain is critically involved in those complex controls, which are achieved through the harmonized crosstalk between autonomic (hypothalamus and brainstem) and cognitive/limbic (hippocampus, amygdala, striatum, and cortex) brain circuitries. The control of food intake and energy expenditure, is insured by interconnected neurons expressing varied receptor types and producing diverse peptides or classic neurotransmitters that have been grouped into "anabolic" and "catabolic" mediators. Those mediators are found in nuclei such as the arcuate nucleus of the hypothalamus, paraventricular hypothalamic nucleus, lateral hypothalamus, nucleus of the tractus solitarius, nucleus accumbens, ventral tegmental area, amygdala and cortex. The "autonomic" and "cognitive/limbic" brains work inseparably in regulating energy balance as most of their nuclei are tied to each other to form pathways that control the intake as well as the expenditure of energy. They comprise neurons that produce energy-balance-influencing mediators such as neuropeptide Y, agouti-related peptide, alpha-melanocyte-stimulating hormone, cocaine- and amphetamine-regulated transcript, melanin-concentrating hormone, orexins, endocannabinoids, opioids, dopamine and serotonin. The production of these diverse molecules is modulated by short- and long-term signals that inform the brain about the status of the energy stores and energy fluxes. Whereas leptin and insulin are recognized as the main long-term tonic signals, the gastrointestinal hormones ghrelin, peptide tyrosine-tyrosine, cholecystokinin, and glucagon-like peptide 1 are known as short-term or episodic regulatory signals. Circulating nutrients, including glucose, lipids and amino acids, are also sensed by brain "catabolic" and "anabolic" neurons. The understanding of the complex controls exerted on food intake and energy expenditure appears essential to decipher the etiology of obesity and to envision proficient behavioral or pharmacological strategies to prevent or reverse excess fat deposition.

Regulation of energy expenditure

B. Wisse[1]
[1] *University of Washington School of Medicine, Division of Metabolism Endocrinology and Nutrition, Seattle, USA*

Energy homeostasis is defined by the relationship between energy intake and energy expenditure. The last ten years have dramatically increased our understanding of the peripheral and central signals that regulate energy homeostasis – and animal studies have been essential for much of this progress. However, in some ways, firm conclusions related to the regulation of energy expenditure, have been harder to substantiate than those related to energy intake. Given the proliferation of mutant mouse models with body weight or body fat phenotypes – it is surprising that very few of these models demonstrate significant differences in energy expenditure. Part of the challenge lies in the technology and methodology. 'Between mouse' variance in calorimetry studies tends to be high relative to the expected 'between group' variance in energy expenditure needed to account for phenotypic differences. Part of the challenge lies in interpretation – and even now the best method to normalize oxygen consumption to body size or body composition remains disputed making it difficult to determine whether an obese mouse is truly hypometabolic or a lean mouse truly hypermetabolic. Nonetheless, progress has been made in identifying the central pathways that control energy expenditure and identifying the physiological signaling pathways and their impairment in pathological conditions. More importantly, studies in humans and rodents continue to suggest that energy expenditure – and specifically non-resting energy expenditure – may be a regulated variable that could be modified by pharmacological interventions.

0003

Central vs peripheral regulation of metabolism

T. Lam[1]
[1] *University of Toronto, Physiology and Medicine, Toronto, Canada*

Recent work has cast a spotlight on the brain as a nutrient-sensing organ that regulates the body's metabolic processes. In this lecture, I will discuss the physiological and molecular mechanisms of brain lipid sensing and compare these mechanisms to liver lipid sensing. A direct comparison between the lipid-sensing mechanisms in the brain and liver reveals similar biochemical/molecular but opposing physiological mechanisms in operation. We propose that an imbalance between the lipid-sensing mechanisms in the brain vs. liver may contribute to obesity-associated type 2 diabetes.

0004

The role of the adipocyte

F. Giorgino[1]
[1] *University of Bari School of Medicine, Department of Emergency and Organ Transplantation, Bari, Italy*

With excess energy storage, obesity develops, leading to increased risk for type 2 diabetes and cardiovascular disease. The current epidemic of obesity has caused a surge of interest in the study of the mechanisms regulating adipose tissue formation. It has been observed that adipose tissue contains a pool of adult stem cells with multipotent properties, which provide for the physiological cell turnover, and can be isolated and potentially utilized for tissue engineering and regenerative medical applications. These "stromal" cells exhibit pre-adipocyte characteristics, can be isolated from adipose tissue of adult subjects, propagated in vitro, and induced to differentiate into adipocytes. Different populations of multipotent precursor cells can be isolated from human fat fragments. Thus, adipose precursor cells are a heterogeneous cell population, consisting of fibroblast-like multipotential stem cells generally termed adipose-derived stem cells (ASCs). The basic biology of ASCs may provide important implications for the understanding of metabolic diseases in humans. The distribution of body fat appears to be also a major determinant of the metabolic and cardiovascular impact of obesity, even more important than the total amount of fat. Abdominal and, in particular, visceral adiposity is strongly linked to insulin resistance, type 2 diabetes, hypertension, dyslipidaemia, sleep apnea, and other complications of obesity. Visceral adiposity, manifested as a high waist circumference, is now accepted as a major component of the metabolic syndrome. However, the biological mechanisms underlying the adverse impact of visceral fat accumulation remain to be established. It is possible that even precursor cells may possess specific biological features according to their fat depot location, and that visceral fat precursors may be already committed to become more dysfunctional under conditions of excess nutrient intake.

The discovery of insulin: history, science and controversy

A. de Leiva[1]
[1] *Universitat Autonoma de Barcelona, Medicina, Barcelona, Spain*

The discovery of insulin was a multi-step process shared by many investigators. On 1906, Georg Zuelzer (Berlin) injected subcutaneously his pancreatic extract to dogs and men, reporting beneficial effects on the excretion of sugar, and

ketone bodies ***(1).*** In 1912 the US Patent, ***acomatol,*** was licensed.
Nicolae C. Paulesco (Bucharest) published in the ***Traité de Physiologie Médicale*** (1920) (2), July 23, 1921 issue of ***Comptes Rendus de la Societé de Biologie (París) (3***), and ***Archives Internationales de Physiologie*** (August, 1921) ***(4)***, that he succeeded in obtaining an active extract from dog and beef pancreas, effective in lowering blood glucose in both pancreatectomized and normal dogs. The product also exhibited antiketogenic properties. On April 1922, the patent ***pancreíne*** was registered.
Frederick G Banting and Charles H Best, working at JJR Macleod's lab (Toronto) first tried the duct ligation to induce atrophy of the exocrine pancreas; later, they developed active extracts from fetal and adult ox pancreas, without the need of duct ligation. They published the leading article on animal research in the ***Journal of Laboratory and Clinical Medicine*** (February 1922) ***(5).***
The collaboration of J B Collip allowed the purification of the extract. On January 23, 1922, the first successful administration of the new extract to a diabetic subject occurred. The antidiabetogenic substance was named ***iletin*** first, and later ***insulin.***The first succesful clinical trial was published in the ***Canadian Medical Association Journal*** in March 1922 ***(6).*** In December 1922, the Collip/Best patent application included both the process and the product.

TEACHING LECTURE

How does culture impact on diabetes education?

0006

How does culture impact on diabetes education?

M. McGill[1]
[1] *Royal Prince Alfred Hospital, Diabetes Centre, Camperdown, Australia*

Much of the predicted global explosion in diabetes prevalence will occur in developing countries. Paying for essential diabetes medicines, transport to hospital and the doctor's fee can render the person and family to abject poverty. Compounding the situation are limited access to learning self care behaviours and the influence of myths and culture on the cornerstones of diabetes management; medications, food and physical activity. In some instances, families lose everything on the "promise" of a cure. For the past 9 years the IDF Consultative Section on Diabetes Education has had a very strong focus on upskilling health professionals to increase access to evidence-based diabetes management whilst at the same time appreciating the important influence of culture on behaviour. Education strategies include the development of i) International Standards for Diabetes Education that enable diabetes services to benchmark their work practices against evidence; ii) educational tools such as the International Curriculum for Health Professionals and CD modular package of over 800 powerpoint slides and lesson notes, translated into the world's common languages and iii) multidisciplinary health professional workshops. In addition, the Section has implemented an IDF Recognition Program for institutions conducting their own education courses. A further exciting development and to build capacity worldwide, is the designation of Centres of Education in local institutions experienced in providing education. The institutions will form a global, collaborative voluntary network to initiate, facilitate, conduct and coordinate high-quality education for healthcare professionals. The successful Institutions will be announced during this presentation. World Diabetes Day celebrated on November 14th reached an estimated audience of a billion people in 2008 and the theme for the next 5 years is Education and Prevention offering further opportunities to improve outcomes. Only through this multifaceted approach will the lives of people with diabetes be improved no matter where they live.

HEALTHCARE AND EPIDEMIOLOGY

Redefining diabetes? what tools? what is it anyway?

0007

HbA1c variability: fact and fancy

D.B. Sacks[1]
[1] *Brigham and Women's Hospital and Harvard Medical School, Pathology, Boston, USA*

Detection of increased glucose concentrations has been used to identify individuals with diabetes mellitus for over 3,500 years. Measurement of glucose in the blood, the most widely used test to diagnose diabetes, is limited by several factors. These include the need for the subject to be fasting, large biological variability and a lack of reproducibility of glucose tolerance tests. Glycated hemoglobin (Hb), most commonly measured as HbA1c, has an integral role in the management of patients with diabetes. Large prospective clinical studies have clearly documented that HbA1c is both an indicator of long-term glycemic control and predicts risk for the development of microvascular complications. These attributes, combined with low intra-individual variability and the lack of influence of food ingestion (a fasting sample is not necessary), make HbA1c appealing for the diagnosis of diabetes. The recent adoption of HbA1c for diagnosis increases the need for further understanding the reliability of HbA1c results. Conditions that change erythrocyte lifespan (e.g. hemolytic anemia, certain hemoglobin variants and blood transfusion) alter HbA1c. Race and age are also reported to influence HbA1c. Published reports indicate that some diabetic individuals have HbA1c values that are lower or higher than expected based on their clinical presentation and blood glucose results. This has led to a theory of high and low glycators whereby individuals with the same mean blood glucose have different HbA1c concentrations. Factors that influence the rate of glycation of hemoglobin and the implications for interpretation of HbA1c results will be discussed.

0008

Hyperglycaemic states - what is the need when redefining diabetes?

K. Borch-Johnsen[1]
[1] *Steno Diabetes Center, Gentofte, Denmark*

Rationale: Diabetes is a condition characterized by elevated glycaemic levels in combination with an increased risk of developing diabetes specific, microvascular complications as well as macrovascular complications. The diagnostic procedure for diabetes involves fasting alone or in combination with post-challenge glucose measures. Currently the introduction of HbA1c as a diagnostic test is also being proposed. For neither of these three possibilities is it possible to identify a clear cut-point below which the risk is nil, and above which the risk is constantly increased. Glucose behaves as all other biological markers of risk. The risk increases gradually with the level of the risk factor in question. This raises two questions:
Is diabetes a specific disease, or is glucose "just" a risk factor in line with blood pressure, cholesterol etc?
and
If diabetes is a specific disease, what is the the most appropriate measure of glycaemia identifying those at risk
Methods: Based on pooling of large data sets from major parts of the world as done in the DECODE-study, the DECODA-study and the DETECT-2 initiative, the prognostic impact of each measure of glycaemia has been evaluated.
Results: Fasting plasma glucose, post-challenge glucose and HbA1c identify different individuals as "high risk" individuals, but with respect to risk of

developing microvascular complications they perform equally well. In relation to mortality and mortality from CVD, HbA1c and post-challenge are stronger predictors than fasting plasma glucose.
Conclusion: Based on the results of the large scale studies, the possibility of redefining the diagnostic criteria will be discussed, and the rationale for maintaining diabetes as a diagnostic entity will be reviewed.

0009

Redefining diabetes: a role for ß-cell function/mass ?

P. Butler[1]
[1] *Larry Hillblom Islet Research Center, Medicine, Los Angeles, USA*

Type 1 and 2 diabetes are characterized by hyperglycemia as a consequence of insufficient insulin secretion (impaired insulin secretion) to maintain glycemic control. People with type 1 and type 2 diabetes have relative insulin resistance compared to BMI matched non-diabetic controls. In contrast most people with obesity (and insulin resistance) do not develop diabetes, but adaptively increase insulin secretion.
The contribution of regulation and dysregulation of beta cell mass in pathophysiology of type 1 and 2 diabetes will be explored. Mechanisms that distinguish successful versus failed regulation of beta cell mass will be considered. The potential links between impaired beta cell function/mass and insulin resistance in type 1 and 2 will be considered.

No conflict of interest

0010

Redefining diabetes: insulin resistance and metabolic syndrome

N. Sattar[1]
[1] *University of Glasgow, Cardiovascular and Medical Sciences Faculty of Medicine, Glasgow, United Kingdom*

The metabolic syndrome has received considerable focus in the last several years as a means to pick up individuals at risk for diabetes and cardiovascular disease (CVD). Yet, whilst metabolic syndrome is associated with both outcomes, it is clearly more closely aligned to diabetes risk and does not enhance risk prediction for CVD. We recently showed that the criteria are not clinically beneficial for predicting risk of either condition and that separate risk algorithms are needed (1). This view is now increasingly accepted and metabolic syndrome criteria are likely to have a limited role in research but not in clinical practice. As regards insulin resistance, all agree this is a strong risk factor for type 2 diabetes but that its direct measurement is complicated and not amenable to widespread clinical use. However, we know now that simple clinical predictors, both non-lab and lab measures (reflecting upstream and downstream correlates of insulin resistance) can determine diabetes risk with good sensitivity and specificity. This talk will show how such predictors and recent algorithms (being regional specific) have genuine potential for widespread clinical use. The talk will also outline how such algorithms could be dovetailed efficiently with vascular screening programmes and thus be more widely used.

CLINICAL RESEARCH

The renin angiotensin system in diabetes: from islet to kidney

0011

The new biology of the renin-angiotensin sytem

E.L. Schiffrin[1]
[1] *Sir Mortimer B. Davis - Jewish General Hospital McGill University, Medicine, Montreal, Canada*

The renin-angiotensin system (RAS) has been around since the discovery of renin (1898) and later angiotensin (1937). The RAS was until recently believed to be a linear system: renin generates angiotensin (Ang) I by acting on angiotensinogen, and Ang converting enzyme (ACE) generates Ang II from Ang I. Ang II was considered the final mediator of the RAS acting via Ang receptors. However, other enzymes, peptides and receptors have been discovered, such as AT1 and AT2 receptors which mediate effects of Ang II, ACE 2 as a pathway for conversion of Ang II to Ang1-7 (vasodilator and vasculo-protective which may act via the mas receptor), neutral endopeptidase as another potential generator of Ang1-7, Ang III and Ang IV (which may stimulate PAI-1) with their own putative receptors, all of which has changed our understanding of how the RAS maintains BP and body fluid homeostasis. The different components of the RAS have been detected in many tissues, suggesting local generation of Ang II, although renin appears still to come only from the kidney. Aldosterone, whose secretion by the adrenal glomerulosa is stimulated by Ang II, binds to mineralocorticoid receptors in many tissues and exerts effects in interaction with the actions mediated by Ang II via AT1 receptors. A receptor for renin/prorenin has been demonstrated, which increases tissue generation of Ang by renin and prorenin (the latter was thought to produce little or no Ang). Via these renin/prorenin receptors, renin and prorenin also produce Ang-independent effects via stimulation of MAP kinases. Accordingly, our knowledge of how to target the RAS to improve outcomes in humans with cardiovascular disease has increased significantly.

0012

The role of the RAS in diabetic nephropathy

P. Groop[1]
[1] *Folkhalsan Research Center/Biomedicum Helsinki, Department of Diabetes Genetics, Helsinki, Finland*

The development and progression of diabetic kidney diseases is the major preventable predictor of morbidity and mortality in individuals with diabetes. Although we have many tools, effective blockade of the RAS appears to be the most powerful. A number of clinical studies have confirmed the efficacy of RAS blockade in kidney disease in both type 1 and type 2 diabetes. However, these actions are only partially effective, and despite conventional blockade many individuals go on to end stage kidney disease. Although dual or triple blockade offer some improvement, there remains a significant unmet need. New understanding of the RAS and its interactions with other pathogenetic pathways will facilitate the development of new and potentially more effective approaches for renoprotection. In addition, recent strategies to optimise blockade and target feedback via renin inhibition and declining ACE2 activity may further enhance our chances of preventing renal damage in diabetes.

No conflict of interest

0013

RAAS in CVD

E. Lonn[1]
[1] *Hamilton Health Sciences McMaster University, Department of Medicine, Hamilton, Canada*

Cardiovascular disease (CVD) is the leading cause of mortality and a major source of morbidity in people with type 2 diabetes.
The RAAS is involved in the pathophysiology of CVD from hypertension to atherosclerosis, left ventricular (LV) hypertrophy, endothelial dysfunction, LV remodelling following myocardial infarction, congestive heart failure and endstage cardiac disease. The major mediator of vascular and cardiac abnormalities associated with activation of the RAAS is Angiotensin II, shown to increase oxidation, promote inflammation and endothelial dysfunction and to be involved in tissue remodelling and plaque rupture. A variety of the cellular receptors and mediators, in addition to the AT1 receptor and Angiotensin II are important in RAAS activation.
Pharmacological blockade of the RAAS can be achieved with beta-blockers, angiotensin converting enzyme inhibitors (ACE-Is), angiotensin receptor blockers (ARBs), and direct renin inhibitors (DRI). These drugs lower blood pressure and additionally reduce LV hypertrophy, improve endothelial function, retard progression of atherosclerosis and reduce inflammation. Large randomized controlled trials have shown improved outcomes in heart failure patients treated with ACE-Is and ARBs as single agents and combined. Trials in patients with stable chronic vascular disease have also shown improved outcomes in patients treated with ACE-Is. These benefits extended to people with and without diabetes. More recently, the ONTARGET trial demonstrated similar benefits for ARBs. In this patient population, combined ACE-I and ARB therapy did not confer additional benefits. Therefore, combined ACE-I and ARB therapy is currently not recommended in patients with chronic stable vascular disease and without LV dysfunction and/or heart failure. More recently, DRIs have been shown to effectively reduce blood pressure, proteinuria, LV mass in patients with LV hypertrophy, and BNP in patients with heart failure. Ongoing large trials are evaluating effects of DRIs on clinical endpoints.

0014

RAS and the beta cell

P. Leung[1]
[1] *The Chinese University of Hong Kong, Department of Physiology Faculty of Medicine, Hong Kong, China*

Type 2 diabetes mellitus (T2DM) is attributable to more than 90% of diabetes cases globally. It imposes huge demands on the healthcare resources in Western societies and is also now becoming a burden in developing countries such as China. Meanwhile, recent clinical studies have reported that pharmacological blockade of the renin-angiotensin system (RAS) reduces the incidence rate of new onset of T2DM. However, the exact mechanism(s) by which RAS blockade is protective against T2DM have yet to be elucidated. In this context, we have recently identified the existence of a local RAS in the pancreas which becomes upregulated in animal models of T2DM, hyperglycemia and islet transplantation. Locally produced angiotensin II modulates pancreatic islet blood flow, oxygen tension, (pro)insulin biosynthesis and oxidative stress. We also found that inhibition of this pancreatic islet RAS improves islet beta-cell structure, function and glucose tolerance as well as reducing pro-inflammatory factor gene expression and protein production in experimental T2DM. These experimental data suggest a partial regulatory mechanism for the protective effects of RAS antagonism, including those for T2DM, in humans. These findings provide a novel and alternative explanation for the reduced incidence of T2DM observed in large-scale clinical trials applying RAS blockers to individuals at high risk for this disease.

ASSOCIATION DEVELOPMENT

Association development in the context of IDF

0015

Has IDF helped associations in improving diabetes care ?

D. Franco[1], *G. Camara*[2]
The IDF represents the interests of a great number of people with diabetes and those at risk. Their mission is to promote diabetes care, prevention and a cure worldwide. The Federation has been leading the global diabetes community since 1950. In order to discuss from the point of view of an IDF member association we will talk about this relationship and if diabetes care in this association is improving because of that.
In 1999 a Brazilian diabetes association, ADJ joined IDF. From the beginning the association received informative materials about diabetes in the world and we were encouraged to inform about our work at the association. Since then the IDF has given opportunity to get more information on diabetes care and how to improve their knowledge in the treatment and inform laypeople how to fight for their rights.
In 2008 a partnership between ADJ, Brazilian Diabetes Society and IDF was created and an education program was settled and is now being replicated all over the country. Some results of this program will be presented.
A survey about the IDF and Diabetes Associations was done and some of this data will also be presented.

0016

Challenges facing diabetes associations in the real world

E. Morrison[1]
[1] *Diabetes Association of Jamaica, 1 Downer Ave, Kingston 5, Jamaica*

In the real developing world, irrespective of the high ideals outlined in vision and mission statements, persons with diabetes (PWDs) come to associations expecting help, not mere education only; but rather help to access consultations with experts and acquire medications at reduced cost. Associations which fail to deliver on these two, remain aloof and irrelevant.
The 33 years of my experience at the Diabetes Association of Jamaica, has taught me the key role of the peer and lay groups in sustaining and ensuring that the association keeps its focus on the PWDs. Any training afforded a consultant or officer of the association, must be translated and shared with educators and facilitators for the benefit of the PWDs.
A major challenge is funding. Efforts at fund-raising can be frustrating in many small settings especially found in developing countries. Here also, due to economic challenges, governmental support is not forthcoming. Further, pharmaceutical companies assist in very limited ways because of the perceived small market. In addition, these companies put any little support behind doctors, as it is this group that writes the prescriptions from which come the sales. Hence, there is very little resources financially to mount meaningful assistance programmes.
Human resource varies, and too often, the volunteer becomes a cost, whether by way of honoraria, out of pocket expenses etc. Commitment here is directly related to the closeness of diabetes to the volunteer, and even so, in the face of very little support, the interest fades.
It behoves the IDF, to work through its regions to look into these areas of potential fall-out amongst its membership and to use whatever networking possible to shore up these fledgling associations; ensuring their proper organisation and management structure which will best put them on track for self-sufficiency and sustainability.

No conflict of interest

0017

Are the relations between associations and IDF clear enough?

R. Zivkovic[1]
[1] *Diabetes Association of Serbia, President, Belgrade, Serbia*

Why, at all, may anybody ask such a question? What is the meaning, in this case, of the word ***clear?*** Does ***clear*** mean obvious? Or, does it mean something

like, relations are so clear that we have managed, performing IDF instructions and methods to lessen incidence of diabetes? Or, saying: relations are not clear, which side to look at the matter counts - IDF or National Association (NA) side? Does opinion of relevant Authority on national level count as well?
Do more initiatives, documents and instructions from IDF side necessarily mean relations become clearer? Does this ***clearness*** turn into ***turbidity*** if information on the other side is not captured properly within given time. Is the internal structure of the NA capable of coping with this increased number/volume of information provided in highly specialized language and form? If NA were not capable, would the decreased volume of information solve the problem?
Existing activities and relations are identified and assessed. Aiming at care, prevention and finding a cure for diabetes, IDF has made grandiose efforts setting up serious structure which made IDF bodies, functions and communications closer to the base. General Assembly and Congress, cooperation with CE, EASD, ISPAD, EURADIA, project like IMAGE, SWEAT, DIADVISOR, make just a part of IDF functioning.
IDF-Europe, has introduced a post, Association Development Officer. Hence, single NA left without real-time information/interface to any of the above.
To considered relations clear, IDF should simplify forms, procedures, language - NA should raise its internal structure to a level necessary to capture, recognize, process and implement information provided by IDF

Taking diabetes care to the people: the experience from Puerto Rico

E. Blanes[1]
[1] *Asociación Puertorriqueña de Diabetes, Executive Director, San Juan, Puerto Rico*

The Asociación Puertorriqueña de Diabetes was founded in 1988 as a non profit organization with the mission to promote prevention and control of diabetes, as well as to educate patients, their families and the general community. Puerto Rico is a small island in the Caribbean with a population of almost 4 million people and an estimated diabetes prevalence of 12.8%. Therefore, education becomes an important tool to control diabetes and prevent life-threatening complications, especially within underserved communities.
The organization has developed a wide array of educational programs and services that are offered free of cost to the community, which main purpose is to empower the patient to take control of diabetes.
Some of the programs are: ***Health Train: Bringing Health to Every Stop***, education offered at schools; ***Train of Trainers: Educating the Educator***, workshop for school personnel; ***Your Health and Diabetes***, a weekly radio program; ***Nutritional Counseling***; ***Glucose Screenings***; ***Educational Material*** is developed and distributed; ***Internet Diabetes Library***, computers available for students and people without access to internet; ***Diabetes Conferences, Seminars and Workshops; Internet website***; ***EXPO Diabetes,*** the only convention dedicated to diabetes; ***Encaminada*** held during November, diabetes' national month, with an awareness walk; ***Adult Summer Camp "Step by Step: Take Control of Diabetes"***, a four day workshop; ***Public Service Announcements*** are developed to be transmitted in the media.
These efforts have been possible with the support of the community, private and government sector and by fund-raising events. The funds are invested in all the educational services. Also, the organization has created a network with other non profit organizations related to diabetes such as Renal Council of PR, Pediatric Diabetes Foundation, Puerto Rican Society of Endocrinologists, among others. This has provided us with the opportunity to exchange ideas, services and discuss issues that affect the people we serve.

Where now for diabetes genetics?

0019

Type 2 diabetes: whole genome analysis and beyond

M.I. McCarthy[1]
[1] *University of Oxford, Ocdem, Oxford, United Kingdom*

Until recently, progress in identification of the genetic variants influencing predisposition to common forms of diabetes has been slow. However, recent advances in genetics, genomics and informatics have enabled well-powered association scans designed to detect association signals across the entire genome.
For type 2 diabetes (T2D), the genome-wide association (GWA) studies so far performed have extended the number of loci harbouring common variants implicated in susceptibility to 20. Amongst the novel loci identified by this process include variants in/around genes which encode beta-cell zinc transporters (***SLC30A8***) and putative regulators of beta-cell mass (***CDKN2A/B*** and ***CDKAL1***). One of these new-found loci, mapping to the fat mass and diabetes associated (***FTO***) gene, influences individual risk of T2D through a primary effect on fat mass, making this the first common variant known to influence weight and individual risk of obesity.
Analogous efforts applied to continuous glycaemic traits have demonstrated the key role of variants in the melatonin 1B receptor gene in the regulation of insulin secretion: a large number of additional loci are currently being confirmed by large-scale replication. There is evidence that these variants have divergent effects on the regulation of fasting glucose in healthy individuals and on predisposition to T2D in later life.
There are three major challenges going forward. First, we need to understand the mechanisms whereby the associated variants at these signals impact on phenotypic variation and disease risk: this will require careful blending of genetic and genomic approaches. Second, we need to translate the biological insights generated into improvements in clinical care. Third, recognising that the variants so-far identified explain only a small proportion of overall susceptibility to these conditions (<10 percent), we need to develop and implement approaches that enumerate the unexplained variance.

0020

Type 1 diabetes: whole genome analysis and beyond

C. Polychronakos[1]
[1] *McGill University Health Care, Paediatrics and Human Genetics, Montreal, Canada*

Background: the CDCV paradigm. High-density genotyping arrays have enabled the examination of most of the common human genetic variation in large population samples. The results so far permit a reliable estimate of the contribution of common alleles (frequency > 0.01 the) to the $lambda_s$ (sibling relative risk, the most meaningful measure of familial clustering). These alleles, conforming to the common-disease-common-variant model (CDCV) typically confer weak relative risks (<1.5) and, collectively, explain a small part of the $lambda_s$. With larger and larger samples, more loci of smaller and smaller effects will undoubtedly be discovered, their potential total number being in the hundreds, or even thousands.
The future: Rare, highly penetrant variants and personalized medicine. Of the large number of such weaker genetic effects, it is likely that a considerable portion is weak only because of allele rarity. Among those rare alleles, some could have extremely high penetrance. Each of these variants will explain a large portion of the individual risk but only for a small fraction of the patient population, indicating that what appears to be a homogeneous phenotype may have distinct molecular aetiologies, responding differently to a given therapeutic intervention. For type 1 diabetes, we have started with copy-number variations (CNVs) both because they are prime candidates for biological effects and relatively easy to detect. Analysis of fluorescence signals from the ***Illumina*** Infinium array in 1,000 cases and 4,000 controls with the PennCNV algorithm, detected 11 CNV loci with significantly higher frequency in cases than in controls and large odds ratios (>>2). Collectively, these involve 6% of all cases. Confirmation with direct methods is in progress.

If confirmed, this will be a first step towards personalizing diagnosis at the molecular level, a step necessary for the meaningful evaluation of novel (as well as existing) therapeutics.

The future of monogenic diabetes: from research backwater to clinical mainstream

A. Hattersley[1]
[1] *Peninsula Medical School, Diabetes Research, Exeter, United Kingdom*

The key component of monogenic diabetes is that a mutation in a single gene results in diabetes. This means that genetic testing can be used as a specific and sensitive diagnostic test for the particular genetic subtype of diabetes. These subtypes, in contrast to type 2 diabetes, have a common and uniform aetiology resulting in considerable clinical homogeneity. This means it is possible to use the mutation as a predictor of future clinical course and also in unaffected subjects to predict whether they are likely to develop diabetes. Critically it has also been shown that for the commonest forms of Maturity Onset Diabetes of the Young (MODY) and Neonatal diabetes that treatment response differs between genetic subtypes. This means that the diagnosis has important implications for clinical care.
The major genes for monogenic diabetes have been diagnosed between 1992 and 2006 and have rapidly moved into being used as a diagnostic service in many countries throughout the world (see www.diabetesgenes.org). The cost and simplicity of genetic testing is improving rapidly and this will continue such that testing will become a relatively cheap and simple process which will mean that it will not be reserved for those with a high probability of having monogenic diabetes but used universally in children and young adults with diabetes. Given the considerable financial advantage in not prescribing insulin where it is inappropriate (estimated at $60,000 over a lifetime) then the financial implications of performing genetic testing may make it appropriate. However the performing of tests in patients with a low prior probability of having monogenic diabetes will lead to a whole new series of issues which will be discussed.

0022

Pharmacogenetics of diabetes: will we be able to predict response in the clinic?

E.R. Pearson[1]
[1] *University of Dundee, Biomedical Research Institute, Dundee, United Kingdom*

In diabetes, pharmacogenetics is a few years behind traditional case-control or quantitative trait genetics, largely due to the lack of large discovery and replication cohorts. Pharmacogenetics is complementary to these other genetic methods, and offers great potential. There are a few examples from the study of monogenic diabetes (HNF1A, KCNJ11, ABCC8) where identifying the genetic aetiology will guide therapeutic choice. However, in polygenic diabetes there are still no consistently replicated variants that influence response to the common oral agents, so we are a long way short of being able to utilise genetics in patients with type 2 diabetes. However, beyond the distant potential of pharmacogenetics to be used to determine treatment choice for patients with type 2 diabetes, it can be used as an alternative tool to unravel diabetes aetiology, to study biological pathways and to determine drug mechanism. Preliminary data from genome wide association studies (Affymetrix 6) will be presented to highlight this. A variant associated with sulphonylurea response, involved in insulin exocytosis, is also associated with type 2 diabetes risk; two variants in the metformin scan reveal novel mechanisms of metformin and insulin action. In this rapidly moving field, what is certain is that our ability to discover common and rare variants will increase dramatically. Over the next few years we need to establish sufficiently large, cleanly defined cohorts to be able to utilise this technology. This is the biggest challenge.

Diabetes, insulin and exercise - meeting the challenge

A. Farquhar[1]
[1] *Family Practice, Kelowna, Canada*

Good glucose control (A1C <7) and avoiding serious hypoglycemia are only 2 of the many challenges facing those who live with insulin treated diabetes Exercise compounds these challenges, making "control" frustratingly unpredictable and at times downright hazardous.
It is not too long ago that people with T1D were actively discouraged from exercising and indeed much of what medical people now know has been gleaned from the collective experience of many active individuals who, often going against medical advice, determined to "do their own thing". From such a group of people was born the International Diabetic Athletes Association (now known as the Diabetes Exercise and Sports Association) which exists to help and encourage persons with diabetes to be physically active and some to pursue their dreams to be a professional or elite or even Olympic caliber athlete.
For the recreational athlete to exercise safely and for the competitive athlete to achieve peak performance, considerable skill and determination are required to juggle the multiple variables impacting blood glucose levels.
My presentation will draw largely from my own experience as an "MD with DM" - a busy physician living with T1D for over 50 yrs and being variously involved over the decades with track and field, soccer, rugby, racquetball marathons, triathlons and skiing.

Exercise in pregnancy

E. Chandraharan[1]
[1] *St. George's Healthcare NHS Trust, Obstetrics & Gynaecology, London, United Kingdom*

Pregnancy is a 'diabetogenic state' due to the production of anti-insulin hormones (human placental lactogen, growth hormone, oestradiol and cortisol) by the feto-placental unit. Resultant 'insulin resistance' may pre-dispose to gestational diabetes mellitus (GDM) especially after 20 weeks of gestation and may pose difficulties in glycaemic control in women with pre-existing diabetes complicating pregnancy. High body mass index (BMI) and weight gain during pregnancy may further increase 'insulin resistance'. Exercise increases peripheral utilisation of glucose and reduces insulin resistance. It is both safe and beneficial to the majority of pregnant women.
Recreational exercise during pregnancy is known to reduce the stress levels, reduce tiredness, improve sleep and to enhance the overall sense of physical and emotional well being, in addition to improving muscle tone and strength that helps women to adapt to physical changes occurring in musculo-skeletal system during pregnancy. They may also help prevent gestational diabetes, essential hypertension, excessive weight gain and its implications. Walking, swimming and aerobics are recommended to the majority of women during pregnancy, and medical supervision is required in women with cardiac or pulmonary disease, antepartum haemorrhage, severe pre-eclampsia, preterm rupture of membranes or severe anaemia. Contact sports (boxing, martial arts, ice hockey, basket ball) and sports that may affect the 'balance' (cycling in late pregnancy, down hill snow skiing etc.) should be avoided as they may predispose to maternal and fetal trauma. Exercise may increase core maternal temperature and if this exceeds 39.2 degrees Celsius, may be potentially teratogenic in the first trimester. Recently, it has been suggested that the risk of severe pre-eclampsia is increased if a woman excercises for more than 270 minutes/week in the first trimester. Most women would benefit from 30 minutes of recreational excercise every day throughout pregnancy to prevent gestational diabetes and to provide better glycaemic control for established diabetes.

Exercise in school and home

D. Carnero Gonzalez[1]
[1] *Havana University, School of Economy, Havana, Cuba*

Practice of exercise is very important for children and young people with diabetes. In order to understand the benefit of exercise it is important to answer the following questions:

1. Why should children and young people with diabetes practice exercises?
2. What kind of exercises do we need to do?
3. When can we practice exercise and when not?

Exercises in school: It is important that exercise at school begun since the 1st year of school, until university studies. People with diabetes should be included in this program taking in account our particular needs. Generally the exercise program at school is three times in a week.

It is important to incorporate and participate actively with the rest of the students in the different activities, such as sports team.

Exercises at home: We should practice exercise at least 5 or 6 days per week, so we should complete our program at home. Exercise and sports is part of our life, is fun and make us feel closer with our group of friends. Dance is another kind of making exercise; this will also give us lots of pleasure and a group participation.

Precautions: In order to enjoy at most the practice of exercise we should be prepare to prevent Hypos and Hyper, so it is important to make blood test before, after certain period of time and at the end of exercise and act according the situation.

We must always carry on supplies for the occasion.(sugar, soft drinks, honey, insulin, etc)

Exercise is the milestone in the development of children and young people with diabetes that will allow us to incorporate healthy and happy to our society.

If we are correctly trained and prepared for the different possibilities, we will be able to practice any kind of exercise

0026

Should we exercise regularly: how much and how often?

C. McEnery[1]
[1] *IDF, New York, USA*

While exercise is a long-established health consideration for all, it is of greater necessity for patients with diabetes. Not only do the benefits of regular exercise that exist in the general population carry over to patients with diabetes, but there are further positive effects, some that serve to ameliorate the effects of Type 1 and some of Type 2, that result from a regimen of regular physical activity.

Beyond the promotion of a generally healthy lifestyle, the lowering of cholesterol, and other metabolic factors, exercise enables stabilization of blood sugars, and decreased weight and insulin resistance in people with type 1 diabetes. In patients with type 2 diabetes, within which population there is a high incidence of obesity, exercise promotes weight loss and a reduction of components of the metabolic syndrome. Indeed, Type 2 can be wholly reversible when exercise is paired with nutritional changes.

Although the benefits of exercise are widely known, a variety of deterrent factors exist for patients in the diabetes community. These factors can include: difficulty in managing blood sugar with different types of exercise (i.e. anaerobic vs aerobic), motivation, and knowledge regarding medication and exercise interaction.

While the effects of exercise are universally beneficial, the extent of its benefits varies within populations based on risk factors. In those populations with a high genetic predisposition to insulin resistance, exercise may be insufficient to ward off a diagnosis of Type 2 diabetes. Patients without such biological influences who are merely overweight may be able to entirely avoid diabetes through the implementation of a regular schedule of physical activity. The benefits of avoiding the development of Type 2 extend to greatly reduced risk for its accompanying complications.

EDUCATION

Diabetes in indigenous communities

0027

How to implement national diabetes education program

R. García[1], *R. Suarez*[1]
[1] *National Institute of Endocrinology, Therapeutic education and social work, Havana City, Cuba*

Therapeutic education is an essential part of caring for people with diabetes. But how to implement it with efficacy is a question to deal with in our daily work. The purpose of this lecture is to reflect on this subject using our experience with a National Diabetes Education Program. When therapeutic education is designed and planned in a structured program, results are more efficient. First of all, it is necessary to identify the educational needs of participants taking into account their socio-economic and cultural context and the organizational needs of the service. The program will establish general principles with enough flexibility to adapt it, according to regional or ethnic differences. Secondly, philosophy and strategies of the education model must be defined. Third, subject matter must be adapted to the learning needs and evaluation must be part of the program from its design. The design started with a diagnosis research to establish the learning and logistic needs. The philosophy was to focus on a patient-centred approach. Methodologically, dialogue and group discussions were selected instead of classes or lectures. Having evaluated the strengths and weaknesses of the educational process, appropriate changes were introduced, and the program was extended with local adaptations to the different diabetes services. National coverage allows uniformity on diabetes education all over the country and facilitates the evaluation process. Results of evaluations have shown a better understanding of Diabetes in both health care providers and patients. Treatment adherence has also improved in patients, decreasing acute and long term complications. Diabetes education must be planned as an essential part of diabetes care, and a national program facilitates similar education possibilities to people with diabetes all over the country.

Taking diabetes education and care to the Aboriginal communities in North Australia

A. Sinha[1], *B. Davis*[1]
[1] *Cairns Diabetes Centre, Medicine, Cairns, Australia*

Diabetes is much more prevalent in Indigenous Australians than in the wider Australian community. The majority of these individuals also reside in very remote areas of North Queensland. The management of such patients presents serious logistic challenges because of their remoteness from expert medical care and supervision. Clinicians, including specialists, can contribute significantly to the secondary prevention of diabetes and its comorbidities and complications.

Since the early 2000s the Cairns Base Hospital Endocrine unit and the Diabetes Centre have used an innovative approach to outreach diabetes care in disadvantaged communities in Cape York and Torres Strait islands. The service travels to remote areas and provides comprehensive diabetes care to people with diabetes. The team is multidisciplinary and involves working with primary care physicians, remote area nurses and Indigenous health workers. Over the years the training of these individuals in basic diabetes care has evolved using nationally accredited training tools. The education component now constitutes a significant part of the outreach service and is the only way to maintain a sustainable service in these remote areas. More recently we have also introduced telehealth services for managing patients with diabetes foot problems and diabetes in pregnancy. Virtual ward rounds with remote area hospitals and clinics are now a routine part of the service provision.

In remote settings, appropriate management structures and clinical support for people with diabetes including education of nurses and health workers can lead to improvements in care processes, control of blood pressure, and preventable complications that result in reduced hospital admissions. Control of glycaemia and weight are more difficult and require active community engagement. There is a need for a change in our current management strategies for chronic diseases such as diabetes in remote areas.

Indigenous communities in Eastern Europe (Gypsies)

G. Roman[1]
[1] *"Iuliu Hatieganu" University of Medicine and Pharmacy, Clinical Center of Diabetes Nutrition Metabolic diseases, Cluj-Napoca, Romania*

Introduction: Originated from Northern India, Roma population (gypsies) represents a particular ethnic minority in Eastern Europe, with a life philosophy incompletely understood. We aimed to analyze specific aspect of diabetes and diabetes care in gypsy communities in Eastern Europe.
Methods: Data have been collected by searching Medline publications, using the keywords "gypsy", "Roma population", "diabetes" and applying a questionnaire regarding specific data on diabetes care, sent to diabetologists in Eastern European countries. Following aspects were analyzed: demographics, prevalence, education level, social aspects, morbidity, diabetes care, glycemic control.
Results: Prevalence of Roma ethnic population in Eastern Europe ranges from 1% to 10% (10,000 to 1,500,000). The education level ranges from illiteracy in 40-60% to high level in 1%. According to specific health care legislation in different countries, 30% to 100% of Roma population has medical insurance, still diabetes medication is reimbursed. Although limited data are available, the main health problems in adult population seem to be cardiovascular disease, obesity, metabolic syndrome, pulmonary diseases, type 2 diabetes and infections, while in children, infectious diseases. Overall, life expectancy is lower. There is no available data concerning the prevalence of diabetes and its impact among Roma population, the main reason is that affiliation to a certain ethnic group is not mentioned in medical records. However, literature data and general opinion suggest that Roma-population has a higher risk for cardiovascular disease and a poorer glycemic control; the main reasons would be the unhealthy lifestyle and the low education level. Although specific European programs were developed aiming at social and cultural issues and supporting education and integration, majority of Roma population experiences a low socioeconomic status.
Conclusion: Optimizing diabetes care in gypsy ethnic communities involves wider political, economic, social decisions. Specific education and social support programs are needed, challenging economic systems in Eastern European countries.

0030

Diabetes education: challenges and solutions in resource poor countries of sub-Saharan Africa

A. Jalang'o[1]
[1] *Kenyatta National Hospital, Diabetes Clinic, Nairobi, Kenya*

Aims: The aim is to highlight the challenges posed of scarce resources in Diabetes education in resource poor settings and possible solutions to address them.
Method: This is a descriptive survey using questionnaires to identify the resource related challenges and possible solutions in Diabetes education in resource poor settings of sub-Saharan Africa.
Results: Preliminary results indicate that restricted resources; human, financial and educational materials do adversely hamper Diabetes education. In the settings that have responded, the quality and hence impact of Diabetes education is not assured as no standards exist and secondly guidelines for the education process are lacking.
Restricted resources hamper access to training for health care professionals on the one hand and on the other, patients can hardly afford education.
Possible remedies listed are the need to advocate for education, it has an important role in Diabetes care. Others suggest integration of Diabetes care in the mainstream non communicable disease care. Public–private partnership may also address issues of staff training and acquisition of resources. Diabetes Centres can adapt guidelines and education standards from existing ones from the IDF international or the regional office. Partnering with centres of excellence in resource poor countries may provide useful ideas that can be adopted. Audit of education process and outcome would also inform on best approaches to take.
Conclusions: Diabetes education plays an important role in Diabetes especially regarding lifestyle modification and Diabetes self care. It has evolved from a primarily didactic to theoretic empowerment models. The emergence of Diabetes and related non communicable diseases poses a double disease burden to many countries in sub-Saharan Africa. It is therefore imperative that affordable effective approaches to Diabetes Education are identified and put in place to effectively address care needs.

TEACHING LECTURE

LIVING WITH DIABETES

Empowering people with diabetes

0031

Empowering people with diabetes

C. Feste[1]
[1] *Humedico, Minneapolis, USA*

People need life skills in order to put into action knowledge about managing diabetes. GOAL SETTING helps people to be in charge of their diabetes and their life.
PROBLEM SOLVING helps people to resolve the challenges encountered as they pursue their goals. MANAGING the STRESS of diabetes as well as the daily stresses of life helps to prevent problems and further stress. MOBILIZING SUPPORT means receiving the help of healthcare professionals, family, friends, co-workers and the general public. MOTIVATION is needed throughout a lifetime of managing diabetes.
A program teaching these life skills was evaluated and proved to increase self-efficacy, improve attitudes and resulted in a clinically significant improvement in A1c. A PERSONAL PATH TO RESPONSIBLE SELF-CARE was taught through the American Association of Diabetes Educators trained in the program. (DIABETES CARE, July, 1995)
Since self-management plays a critical role in successful diabetes management, there will be a discussion on how self-management education and diabetes education can be integrated to provide life-long support to people and families affected by diabetes.

WORKSHOP

Insulin for all: can we make it a reality?

0032

Accessibility, storage and distribution

M.D. Bhattarai[1]
[1] *National Academy of Medical Sciences Bir Hospital, Medicine with Diabetes & Endocrinology Service, Kathmandu, Nepal*

IDF global surveys have identified problems facing insulin access in developing countries. Insulin per person may cost almost six months of family's income. High costs in private sector, low availability in public sector, withdrawal of cheaper animal insulin, transportation difficulties, inaccessible electricity and refrigerators, and lack of long-term international support are some important problems. Measures proposed or tried are exemption from taxes, making generic products available, price negotiation, differential pricing, pooled procurement, public-private initiatives, RAPIA by IIF, Association Twinning Initiative etc. Insulin can lose its potency during improper transport and storage without cold chain maintenance. Apart from common complications, use of such insulin with decreased potency lead to hyperglycemia with resultant need to increase dose and later on when a new bottle of insulin is started with the increased dose, the patient may develop hypoglycemia. This I had reported as "Hyperglycemia followed by hypoglycemia – Reverse Somogyi – phenomenon".
In essence there are inadequate purchasing and countrywide distribution systems in many developing countries. Private distribution systems selling human insulin operate mostly in urban areas through wholesalers and pharmacies. Availability of cheaper animal insulin is getting difficult due to financial imperatives that drive pharmaceutical business. Considering efficient distribution system, with cold chain maintenance, of Expanded Programme on Immunization in developing countries, IDF collaboration with WHO, international immunization agencies and pharmaceutical industries to supply

animal insulin along with vaccines can solve the problems. Incorporating only animal, not human, insulin seems essential to make the programme feasible. It will also prevent later influences from pharmaceutical sectors to include other products in the programme. Affluent population can get human insulin through private or other distribution systems. International initiatives to collaborate with immunization programme with worldwide bulk supply of cheaper animal insulin can preserve access to animal insulin and make "Insulin for all" a reality.

No conflict of interest

0033

Cost, affordability and availability

R. Williams[1]
[1] *Swansea University, School of Medicine, Swansea, United Kingdom*

For a person dependent on exogenous insulin, access to that insulin is a basic human right and should not be a lottery the result of which is dependent on where they live, their age, gender, economic status or any other factor. This presentation will explore, amongst other aspects of this topic, the questions: Is insulin becoming more affordable and available globally? If not, what are the current barriers? To what extent is cost an issue? If so, how can accessibility be facilitated? What are the roles of government, diabetes associations, the private individual and the commercial sector?
Acute shortage and inaccessibility of insulin as a result of natural or man-made disasters are readily understood. An infrastructure exists to minimise morbidity and mortality in these situations. Chronic inaccessibility, however, is less easily rationalised and cannot be tolerated. Even when cost and affordability are not barriers and when insulin is available, cultural barriers still mean that inequalities are created where none should exist.

No conflict of interest

0034

Insulin for all

G. Ogle[1]
[1] *International Diabetes Federation and HOPE worldwide (Australia), Life for a Child Program, Sydney, Australia*

Almost 90 years since insulin therapy was developed, untold thousands of people with diabetes in low-income countries die because they cannot readily access or afford it. Many more people with diabetes would benefit if insulin were available to them.
In the developed world, insulin is readily obtained through health systems. In low and lower-income countries, some governments provide insulin free or at a low, affordable cost. In others, insulin must be purchased by the individual concerned. The annual cost is US$200-500, which may be more than the family's annual income. Furthermore, despite insulin being recognised as an essential medicine, the supply of insulin through health systems may be intermittent even in cities, and it is often not available at all in rural clinics.
The most common causes of this situation are under-resourced (and sometimes also dysfunctional) health systems. Others causes include taxes and duties on insulin in some countries, problems with ensuring the cold chain, and lack of health professional expertise concerning diabetes. Replacement of types of insulin by newer types which have added benefit, but are more expensive (e.g. human for animal, analogue for human) may also increase prices, as can new delivery devices.
This is an unacceptable situation, and many efforts are underway to address it. These include advocacy by the International Diabetes Federation (IDF) and its member associations to encourage Governments to provide insulin, the IDF's ***Life for a Child*** Program which supports the care of children, Insulin for Life which redistributes unused insulin, the International Insulin Foundation's country studies which identify how availability can be improved, and programs by some insulin manufacturers to make insulin more affordable. An increased number of manufacturers is also leading to lower prices in some regions. These are all positive developments, but comprehensive solutions will be needed before all have access.

0035

Insulin in disaster - supply on time saves lives

R. Raab[1]
[1] *Insulin for Life, (President), Victoria, Australia*

A gap of more than a few days in insulin supply can result in death for those who depend on it. To save lives in disasters requires an immediate response, with the ability to send, receive and distribute insulin very quickly. In reality "disasters" are happening every day because there are many who die because they cannot access insulin.
Insulin for Life (IFL) Australia, with affiliates in Austria, Germany, UK and USA (IFL Global), collects and distributes donated in-date insulin, test strips and other diabetes supplies to recognized organizations, with an agreed protocol, following specific requests.
These are donated following emergencies, and on a long-term sustainable basis to countries in need. A stock of insulin is held for emergency requests, ready to be sent immediately. IFL Global donates approximately 250,000 ml insulin yearly (equal to 25,000 x 10 ml vials, or 83,300 x 3 ml cartridges), and test strips, syringes, glucose meters, insulin pens, pen needles and other supplies.
Emergencies responded to include the Indian Ocean Tsunami (2001); Hurricane Katrina (2005); the Peru earthquake (2007); China earthquake (2008); the war in Georgia (2008); and Zimbabwe (2006-9). Most of these had IDF support for transport and handling costs, as part of an agreement with the IDF to respond to emergencies.
Collection, storage, freight and communications channels need to be ready in advance and be able to be very quickly activated. IFL maintains these systems and is ready to send insulin at a day's notice, with arrival within a very short period, in time to save lives that may otherwise be lost.
More information is at www.insulinforlife.org

ASSOCIATION DEVELOPMENT

Diabetes care and disasters

0036

The role of associations in disaster management

M. Vera Gonzalez[1], *B. Rodríguez*[2], *E. Jiménez*[3], *S. Feria de Campanella*[1], *D. Villarroel*[4]
[1] *IDF SACA Regional Office, Montevideo, Montevideo, Uruguay*
[2] *IDF SACA Regional Office, San Juan, San Juan, Puerto Rico*
[3] *IDF SACA Regional Office, San José, San José, Costa Rica*
[4] *IDF SACA Regional Office, Sucre, Sucre, Bolivia*

History has always shown the enormous destructive power of nature. Up to now man has not been able to create a complete protection against natural disaster. SACA executive committee has faced up the way to be capable and efficient in any kind of natural or man-made disasters.
The basic attention in case of disasters is based on the following principles:
1. Evacuation of the people living in affected areas
2. First aid
3. Immediate epidemiological activities
4. Shelter and food to victims of the disaster

First of all, it is important to give answer to the following questions:
1. How many people live in SACA Region?
2. How many people with Diabetes live in SACA Region?
3. How many natural or man-made disasters have occurred in the last years in our region?
4. How many people have been affected due to disasters in our region?
5. How many people with diabetes could have been affected due to disasters?
6. What is doing our region in order to improve the attention to people with diabetes in case of disasters?
7. What do we propose as SACA/IDF?

Our goal is reduce morbimortality of people with DM in the aftermath of a natural or man-made disaster.
Raising awareness in diabetes will enable: To engage suppliers and allied health related organizations, to address the need for a standardized approach

to diabetes in the disaster setting. To provide education on diabetes treatment in disaster.
In order to reach our goals our Project has 4 target audience: 1- Government, 2 - Associations, 3 - Organizations and health workers dealing with disasters, 4 -Community in general.
It is important to involve as many people as possible and create general consciousness about the severity of the problem.
IF WE DO SO, OUR REGION IS PREPARED.

What can associations do in the face of disasters ?

S. Fraser[1]
[1] *Belize Diabetes Association, Belize City, Belize*

It is estimated that 7% of the world population have Diabetes and large number of the Caribbean population have Diabetes. According to the IDF statistics there are 200 associations operating in 160 countries. In the Caribbean there are 19 Associations scattered across the Caribbean Sea and are faced with a number of disasters every year.
As we are aware, disasters form part of our lives since they occur naturally and are also created by man. Every country in the Caribbean and North America has a Disaster Response Organization which deals with and coordinates disaster effort. But the question is always can they do enough?
Diabetes care takes a lot of planning. So that unexpected events such as floods, tornados, earthquakes and hurricanes make diabetes management more difficult. And as we know despite unlimited resources the Disaster Response Organization cannot by themselves respond adequately to meet the need of Diabetics. This is where the Diabetes Associations can play their part.
The participants will be introduced to what are the problems being faced by the local Disaster Response Organization in respect to diabetics, and to what the Diabetes Associations can do to assist their local Disaster Response Organization when faced with natural and man-made disasters.

SPEAKERS' CORNER

Strengthening structure and communications within IDF

0038

Strengthening structure and communications within IDF

V. Ocheretenko[1]
[1] *Ukrainian Diabetic Federation, chair of the board, Kiev, Ukraine*

IDF has to faithfully assisted member-associations with managing and fundraising strategies, to help them to become better communicators, to foster membership growth and to increase Diabetes Associations' impact.
Aims: Globalization
1. To increase an influence of Diabetes Associations in society
2. To develop a public education strategy
3. To develop an involvement strategy
4. To strengthen horizontal ties
5. To build uniform information network
6. To form new generation

Methods:
1. Analyzing situation in regions
2. Twinning
3. Renewing Diabetes magazines Committee
4. Building data bank of member-associations best practice and resources
5. Enriching resource of IDF and each member-association
6. Decreasing costs by using general resources
7. Leadership for youth
8. Granting newborn DAs
9. Training for DAs' Staff
10. Training on workplaces
11. Leaderships
12. Guidelines for management of DA

BEST PRACTICE
Ukrainian Diabetes Federation's experience
1. Positive example of fruitful twinning between BDA and UDF (1992-1997)
2. Protection of Patients rights together with the national Medical Law Association (from 2004)
3. Continual school for regional leaders (from1998)
4. Creation Ukrainian Union of Patients' Organizations "Health of the Nation" (2006)

Successful example of international horizontal communications
Eastern European DAs' summits - 7 years experience
1. Model Law "On Principles of Medical and Social Protection of Diabetes Patients" adopted 20 December 2004 by IPA of CIS countries
2. Agreement of Governments of CIS Countries about common diabetes policy 14 November 2008

Focusing on Youth projects
1. International Diabetes Youth Festival

"DNIPRO-2006"
"Ukraine-ARTEK-2007"

PRESIDENTIAL ORATION

United we stand - a global diabetes strategy

0039

United we stand - a global diabetes strategy

M. Silink[1]
[1] *International Diabetes Federation, Brussels, Belgium*

History will undoubtedly mark the passage of the United Nations Resolution on Diabetes (UN 61/225) on December 20, 2006, as the turning point in the recognition of diabetes as a threat to world health. The success of the IDF-led campaign for a UN Resolution was made possible by the "diabetes world" coming together under the "unite for diabetes" banner using the blue circle as the symbol of diabetes.
The IDF has grown to be a federation of over 200 national associations in 162 countries. The membership of these associations is in excess of 2 million. The IDF is one of the largest consumer advocacy groups globally but, despite this, the voice of those affected directly or indirectly by diabetes has too often been ignored or not heard.
Much progress has been made over the past 3 years, both at the political and infra-structure level, but much more needs to be done to fulfil IDF's mission of promoting diabetes care, prevention and a cure. The IDF Atlas is now used as the data source by the WHO, World Bank and the OECD. The first IDF Centres of Diabetes Education have now been accredited in several regions of the world using IDF-based standards and curricula. Health economic studies have been undertaken in Africa, China, South-East Asia and Latin-America. The IDF's Life for a Child Program has expanded greatly, with generous donations of insulin allowing over 4,000 children to be supported in 20 countries by the end of 2009, and enough insulin being pledged to support 12,000 children in 2010, 19,000 in 2011 and 25,000 in 2012. Up-to-date versions of IDF clinical guidelines on type 1, 2 and gestational diabetes and Position Statements on screening, metabolic syndrome, and oral health have been released. World Diabetes Day, now a UN World Day, aims to educate, energise and empower and now reaches over a billion people worldwide.
The IDF recognises that global and national approaches are needed for both primary and secondary prevention. The burden of diabetes threatens to subvert the achievement of internationally agreed development programs, including the Millennium Development Goals. The IDF supports the WHO Action Plan for the Global Strategy for the Prevention and Control of Non-communicable Diseases.
At the United Nations, the IDF is campaigning for a UN General Assembly Special Session on NCDs. We are asking for a UNITAID-type program for essential NCD medicines, a single Global Fund for Health, the integration of NCDs into primary health care systems and the broadening of the Millennium Development Goals to include NCDs.
The world has never before had to cope with an epidemic of non-communicable diseases. Non-communicable diseases are now responsible for 60% of global morbidity and premature mortality. The diabetes epidemic now affects over 250 million worldwide with the major burden (80%) in the developing world.

Solutions will not be easy but what is clear is that the "diabetes world" needs to be part of the solution.

CLINICAL RESEARCH

Foot care

O-0040

A new approach for healing stimulation: autologous platelet gel in chronic deep diabetic foot ulcer

S. Clavel[1], C. Denizot[2], H. Agopian[1], M.A. Desbas[1], A. Desserpprix[1], L. Labbé[1], C. Mourey[1]
[1] Foundation Hotel Dieu, Dept of Diabetology, Le Creusot, France
[2] Foundation Hotel Dieu, Prérédiab network, Le Creusot, France

Aims: Evaluate feasibility, safety and efficacy of autologous platelet gel for chronic deep diabetic foot ulcers healing stimulation.
Methods: 100 diabetics (age 66,3±11,3 years) all neuropathic, macroangiopathic (n=66) with deep chronic foot ulcerations (n=115, ulcers duration: 6,1±5,5 months) with extension to tendon, bone or joint. The immediate causes of ulcers are biomechanical stress with abnormal plantar pressure (n=50)(PU), callus, ill-fitting foot wear for the dorsal or lateral side of toe (n=65)(ST). Before any application, good standards of wound care were used: skin, subcutaneous tissue, tendon, bone surgical debridement until the wound is free of infection, infection medical management, medical management of comorbidities and off loading (unremovable below knee cast, removable below knee bi-valve polyester cast, wheelchair, plastazote pressure redistributing insole in appropriate shoes, half shoes). Gel is obtained from patients, blood separating rich (RPP) and poor platelet plasma (PPP) by 2 methods, RPP blended with thrombin from PPP (n=42, Angel system), RPP with thrombin from whole blood (n=58, RegenLab system). Gel is used 1-5 times/ patient. No dressing change during 3-4 weeks only protective compress change at home once weekly except for maceration twice weekly.
Results: PU treated by gel with thrombin n=26: Complete healing n=20, after 1 application n=15, after 2 applications n=4, after 4 applications n=1. Improvement n=6, after 1 application n=2, after 2 applications n=2, after 3 applications n=1, after 4 applications n=1. PU treated by gel without thrombin n=24: Complete healing n=17, after 1 application n=13, after 2 applications n=4. Improvement n=7, after 1 application n=5, after 2 applications n=2.
ST treated by gel with thrombin n=24: Complete healing n=23, after 1 application n=11, after 2 applications n=6, after 3 applications n=4 after 4 applications n=1, after 5 applications n=1. Improvement n=1 after 2 applications. ***ST treated by gel without thrombin n=41***: Complete healing n=34, after 1 application n=20, after 2 applications n=7, after 3 applications n=3, after 4 applications n=4. Improvement n=6, after 1 application n=4, after 2 applications n=2. One lost to follow-up. Improvement was estimated on wound depth, size and bone shock disappearance. Autologous gel separation system can be used by health professionals in traditional health care facilities.
Conclusion: available to outpatient clinic and home care staff, when added to good standards of care, autologous platelet gel enhance diabetic chronic severe foot ulcer healing without adverse events.

O-0041

The effectiveness of the "Step by Step" foot care project in reducing rates of amputation among persons with diabetes-associated foot ulcers

Z. Abbas[1], J. Lutale[2], L. Archibald[3]
[1] AMC / MUHAS, Internal Medicine, Dar es Salaam, Tanzania
[2] MUHAS, Internal Medicine, Dar es Salaam, Tanzania
[3] University of Florida, Internal Medicine, Gainesville Florida, USA

Background: Diabetic foot complications are increasing in Tanzania and are associated with substantial morbidity, mortality, and healthcare costs. Thus, in 2005, the Step by Step Foot program was instituted in 14 regions where rates of referrals of patients with diabetic foot complications were high.
Objectives: We carried out the current analysis to determine the effectiveness of the "Step by Step" intervention in reducing rates of amputation among persons with diabetic foot ulcers who were referred to the diabetes clinic at Muhimbili National Hospital (MNH).
Methods: The "Step by Step" training programme has been described in detail in published literature and is designed to achieve the following: (i) train healthcare practitioners (HCP) in diabetic foot management; (ii) facilitate the transfer of knowledge and expertise from HCP with training to those without; (iii) reduce rates of foot complications by education, early detection, prompt and appropriate treatment; and (iv) develop an infrastructure for support and service development. We monitored secular trends in amputation rates among patients referred to MNH during 2001-2008 (study period). The denominator was defined as the total number of patients with diabetes referred to MNH with foot complications.
Results: During the study period, the mean annual amputation rate among referrals was 17.6%. Before the Step by Step program, trends in rates of amputation were upward and had increased to >1 standard deviation (SD) above the mean by 2005. Following the institution of the program, rates of amputation among referrals significantly decreased to a low of 1 SD below the mean in 2007 and 2 SD by 2008 ($p < 0.01$).
Conclusion: Institution of the Step by Step Foot Project in 14 regions in Tanzania resulted in a significant reduction in overall rates of amputations among patients with foot ulcers referred to a large tertiary centre in Dar es Salaam. These data suggest improved foot ulcer management at the regional level following Step by Step, before referral for specialist care. These data also underscore the importance of surveillance activities for diabetes complications in measuring outcomes of interventions.

Characteristics of diabetic foot in the Western Pacific Region - ASIPAC foot study

S. Kono[1], V.B. Ta[2], E.A. de Jesus[3], E. Yunir[4], K. Altaisaikhan[5], H. Kajio[6], M. Noda[6], T. Himathongkam[7], Z.G. Zhao[8], A.V.M. Foster[9], H. Kuzuya[1], A.J.M. Boulton[10]
[1] Kyoto Medical Center, WHO-collaborating Centre for Diabetes, Kyoto, Japan
[2] National Endocrinology Hospital, Hanoi, Vietnam
[3] Jose R. Reyes Memorial Medical Center, Diabetic Foot Care Clinic, Manila, Philippines
[4] University of Indonesia, Department of Internal Medicine, Jakarta, Indonesia
[5] Health Science University of Mongolia, Department of Endocrinology, Ulaanbaatar, Mongolia
[6] International Medical Center of Japan Toyama Hospital, Department of Diabetes and Metabolic Medicine, Tokyo, Japan
[7] Theptarin Diabetes Center and Hospital, Bangkok, Thailand
[8] Henan Provincial People's Hospital, Zhengzhou, China
[9] King's College Hospital, London, United Kingdom
[10] Universities of Manchester UK and Miami USA, Manchester, United Kingdom

Background: The number of diabetic foot lesions and consequently amputations is increasing in the Western Pacific region (WPR). However, there are no foot care specialists such as podiatrists or chiropodists in WPR and there is much ignorance amongst medical staff as to how to identify and educate those at risk and treat those who develop problems.
Aims: The aim of this study (ASIPAC FOOT STUDY) was to investigate the characteristics of diabetic patients with foot ulcers in 7 hospitals in 7 countries (Vietnam, Philippines, Indonesia, China, Mongolia, Thailand and Japan), and to increase awareness of diabetic foot problems in WPR.
Methods: The study population includes 309 hospitalized patients presenting with a new foot ulcer in 2008. Data on patient characteristics, as well as foot and ulcer characteristics were obtained.
Results: General patient characteristics were different in all countries. Some countries did not show a higher prevalence of foot ulceration in men (Men (%): 42.1 in Vietnam (V), 46.7 in Indonesia (I), 51.2 in Philippines (P), 55.6 in Mongolia (M), 68.3 in Japan (J), and 72.7 in China (C)). Younger patients with shorter duration of diabetes were more affected in some countries (Mean age (years) /duration of diabetes (years): 54.3/4.4 in I, 56.6/7.1 in P, 59.3/2.6 in M, 63.3/7.8 in V, 65.8/20.9 in J, and 66.3/13.7 in C). Poor glycemic control prior to admission was a common problem (Mean HbA1c (%): 13.2 in M, 9.6 in V, 9.4 in I, 8.7 in P, 8.6 in C, and 8.3 in J).
Extrinsic factors of ulceration were trauma, especially on bare foot walking, shoe sore, burn, and ischemia. Neuropathy was diagnosed in 66.7-92.7 % of

the patients, while peripheral arterial disease (PAD) in 24.4-86.3%. Smoking rates were high in most countries (66.7% in M, 45.5 in C, 43.2 in P, 42.3 in I, 38.9 in J and 20.5 in V). Infection was complicated in 59.1-100 %. Many patients came to the hospital late after the onset of the wounds (days until presentation (mean / median): 47.5/20 in C, 33.9/21 in P, 28.5/20 in V, 27.1/28 in I, 27.7/14 in J, and 16.4/14 in M). The amputation rate was 17.1-61.0%, while major amputation was 1.3-48.8%. Revascularization to PAD patients was not performed in V, I, M, and P.

Conclusion: The characteristics of diabetic foot patients in WPR were much different in some points from those reported from other region such as Eurodiale study. Diabetic foot patients with PAD seem to be increasing in this region, while smoking rates are high and revascularization is seldom applied. In order to reduce amputations, it is essential to increase awareness of diabetic foot and tobacco problems, and improve the skills of screening and education of high risk patients and management of foot ulcer through regional professional training program.

First lower extremity amputations among persons with diabetes in Finland (FinDM II study)

S. Koski[1], P. Ilanne-Parikka[1], T. Jarvala[2], I. Keskimäki[3], T. Klaukka[4], O. Nylander[3], A. Reunanen[3], R. Sund[3], K. Winell[3]

[1] *Finnish Diabetes Association, FinDM II study group, Tampere, Finland*
[2] *Finnish Diabetes Association / University of Tampere, FinDM II study group, Tampere, Finland*
[3] *The National Institute for Health and Welfare, FinDM II study group, Helsinki, Finland*
[4] *The Social Insurance Institution of Finland, FinDM II study group, Helsinki, Finland*

Aims: In earlier research the reported incidence of first lower extremity amputations in persons with diabetes varies markedly between countries. We investigated the situation in Finland during 1997-2007.

Methods: The FinDM II - study uses individually linked data from several Finnish national administrative registers. All persons diagnosed for diabetes were identified from five sources: the Hospital Discharge Register (1969-2007), the Health Insurance Registers on reimbursement of antidiabetic medication (1994 – 2007) and on entitlements to elevated reimbursement of the medication (1964-2007), Medical Birth Register (1987-2007) and Register of Causes of Death (1988-2006). All first lower extremity amputations for these persons were identified during the period 1997-2007 with the data from the Hospital Discharge Register.

Results: In the study we identified 637 585 persons with diabetes and 7 906 of them underwent at least one lower extremity amputation during the follow-up. In women the trend was decreasing with both type 1 and type 2 diabetes. The decrease was over 30% in both subgroups (31% in type 1 and 38% in type 2 diabetes). Among men the development was not uniform: men with type 1 diabetes showed no decrease in amputations during the follow-up but among men with type 2 diabetes the rates decreased by 29%.

61,5% of the first amputations were major amputations performed above the ankle. A significant decreasing trend was observed with the first major amputations in persons with both type 1 and type 2 diabetes both in men and in women. For women with type 1 diabetes the decrease in 1997 – 2007 in first major amputation rates was as high as 57%.

Conclusion: The risk of first lower extremity amputations among persons with diabetes has significantly decreased in Finland since the late 1990s. However, our study showed considerable differences in time trends for amputation risks between genders, age-groups and types of diabetes which suggests that Finnish health-care organizations need to meticulously evaluate practices to deliver diabetes care and identify persons with diabetes at risk for foot complications.

The Caribbean Step by Step diabetic foot care programme - a unique collaboration of the International Diabetes Federation and Rotary Club of Ledbury

K. Bakker[1], K. Van Acker[2], S. Morbach[3], J. Greedy[4], U. Morgan[4], A. Perry[4], I. Stoddart[4], L. Piemonte[5], P. Riley[5]

[1] *International Diabetes Federation, Consultative Section on the Diabetic Foot, Heemstede, The Netherlands*
[2] *St. Josefskliniek, Endocrinology, Bornem, Belgium*
[3] *Marienkrankenhaus, Diabetes and Vascular Medicine, Soest, Germany*
[4] *Rotary Club, Ledbury, Ledbury, United Kingdom*
[5] *International Diabetes Federation, External Relations, Brussels, Belgium*

Introduction: In the Caribbean Region the prevalence of diabetes and the incidence of diabetic lower extremity amputations (LEA's) are very high. Ignorance and lack of preventive measures are the main causes of the problem. The International Diabetes Federation (IDF) and the Rotary Club of Ledbury (RCL), working with other UK and Caribbean RC's will carry out foot care programmes across the Caribbean in order to reduce the number of amputations.

Aim: The programmes will be based on the Step by Step model, which aims to improve diabetic foot care in the developing world by providing education for people with diabetes and healthcare professionals in the prevention and treatment of diabetic foot problems.

Methods: In 2008, the International Diabetes Federation approved funding for a joint project between the RCL and the IDF Consultative Section on the Diabetic Foot. Led by RCL, matching funds have been raised by Rotary Clubs, Districts and the Rotary International Foundation. Further funding has been secured from the World Diabetes Foundation. Step by Step has been effective in improving diabetes foot care in a number of developing countries, such as India, Tanzania, and Pakistan. It has set up practical training courses for teams of healthcare professionals (teams of doctors and nurses or other paramedics) and provided them with special educational materials. Built into the project is a session to teach participants how to train other healthcare professionals. They are encouraged to disseminate information through training so that they cascade their acquired knowledge and skills to colleagues in their local settings. The courses are held over a two-year period. IDF and RCL carried out a survey to identify sites in the Caribbean where to hold the first phase of training courses. Five islands were selected: Barbados, St Lucia, St Maarten, St Kitts, and the British Virgin Islands. Site visits to these islands have been carried out, and the programme will start in 2009-2010. A local and international medical faculty will be responsible for the training courses. The project has received the support of the Ministry of Health, local patient associations and Rotarians on each island.

Outcome: The expected outcomes include sustainable improvements to foot care in the target countries; increased awareness of diabetes and its complications; and improved links between civil society and diabetes healthcare professionals. The most important outcome will be reduced amputations and improved quality of life for many people with diabetes in the Caribbean.

Summary: In 2009-11, IDF and RCL will implement a Step by Step programme in the Caribbean to create sustainable improvements in foot care so as to reduce LEA's and improve quality of life for many people living with diabetes in the Caribbean.

O-0045

Charcot neuroosteoarthropathy in diabetic patients after transplantation is associated with diabetic retinopathy

R. Bem[1], A. Jirkovská[1], M. Dubsky[1], R. Koznarová[1], F. Saudek[1], M. Adamec[2], J. Skibová[1]

[1] *Institute for Clinical and Experimental Medicine, Diebetes Centre, Prague, Czech Republic*
[2] *Institute for Clinical and Experimental Medicine, Department of Transplant Surgery, Prague, Czech Republic*

Background and aims: Charcot neuroosteoarthropahy (CNO) is a late complication of diabetes that can lead to amputations of the foot and a decreased quality of life. The risk factors for CNO after pancreas-kidney (PK) transplantation or pancreas transplant alone (PTA) are still unknown. The aim of our study was to evaluate prevalence of CNO after PK transplantation or PTA and get insight into possible risk factors for acute CNO after transplantation.

Patients and methods: From May 1993 to December 2008, 318 pancreas transplants (279 PK transplantation and 39 PTA) were performed at Institute for Clinical and Experimental Medicine in Prague. After transplantation, the diagnosis of acute CNO was based on clinical and radiological findings and confirmed by bone scan. Possible risk factors for CNO were evaluated before transplantation – gender, age at the time of transplantation, duration of diabetes, necessity and duration of dialysis before transplantation, type of transplantation, the presence and grade of diabetic retinopathy (assessed by ophthalmologist with photo documentation), peripheral neuropathy (biothesiometer), autonomic neuropathy (Ewing's tests and spectral analysis of heart rate variability), ischemic heart disease. After transplantation, functioning of graft(s), rejections and glycemic control were recorded. The group of patients with CNO after transplantation was compared with patients without CNO either before or after transplantation. Stepwise logistic regression was used to determine which of the factor(s) are associated with Charcot foot occurrence after transplantation. The mean follow-up period was 71.4±48.4 months after transplantation.
Results: Acute CNO was diagnosed in 23/318 (7.2%) patients after transplantation (6 patients had recurrence and 17 patients had new development of CNO). There were 277/318 (87.1%) patients without CNO either before or after transplantation. In univariate analysis, patients with acute CNO after transplantation were significantly younger in comparison with patients without CNO (38±7.4 vs. 43.1±9.1; $p<0.01$) and had significantly higher grade of diabetic retinopathy (95.7% vs. 73.9%; $p<0.03$); other assessed factors were not significant. Stepwise logistic regression has shown that lower age at the time of transplantation (Odds ratio [OR]=1.07, 95% CI 1.01-1.12) and higher grade of diabetic retinopathy (OR=7.33, 95% CI 0.96-56.3) are significant risk factors for CNO after transplantation; other assessed factors were not significant.
Conclusion: CNO after transplantation was more frequent in younger patients with higher grade of diabetic retinopathy which should be in accordance with more severe microvascular impairment.

Pilot study on the anthropometry and biomechanics of the diabetic foot

H. Patkova[1], I. Galandakova[1], L. Dolezalova[1], M. Kvapil[1]
[1] 2nd Medical faculty, Diabetology, Prague, Czech Republic

Introduction: Available literary sources show no reference of extensive research on the feet sizes of diabetics. In terms of our work, supported by the TANDEM FT –TA3/096 grant, we measured foot lengths and circumferences of our retirement age type 1 and 2 diabetic patients.
Aim: Our aim was to determine the shape of a diabetic patient's foot in four critical sections, and subsequently evaluate these in relation to sex, duration and compensation of diabetes.
Group: Data was obtained from 614 patients, 72% (441 patients) of which were type 2 diabetics, 27% (166 patients) type 1 diabetics and the remaining 1% (6 patients) include other types of diabetics. The group consisted of 51% (314) men and 49% (300) women. The average patient's age was 51 years regardless of his or her sex.
Methodology: Measuring was carried out in diabetology outpatient clinics at the diabetology department of Motol Faculty Hospital. This process was executed using a scanner controlled by specially developed software, enabling quick data evaluation and the displaying of foot dimensions in 3D.
Results: We obtained precise circumferential dimensions of diabetes patients, including the shape of cross-sections in four critical sections. The unpaired t-test confirmed the statistically significant difference in the foot shapes of patients with diabetes according to sex, $p < 0,05$. An ascending linear trend between the width and size of the foot was discovered within the same size groups. The uniqueness of our measurement lies in discovering the cross-sections of the foot differed at the toe joints of randomly selected diabetic footwear in comparison with the cross-section of the diabetic's foot, even though the circumferences were identical.
Conclusion: The 3D scan of our diabetic patients demonstrated the increasing trend of feet size and width, a difference in the shape of feet was proved on patients with diabetes according to sex. We obtained precise circumferential dimensions of diabetes patients, including the shape of cross-sections in four critical sections. The information could support the development of safer footwear for diabetics in the future.

A prospective study on diabetic foot ulcers and mortality: the Nord-Trøndelag Health Study, Norway

M.M. Iversen[1], G.S. Tell[2], T. Riise[2], B.R. Hanestad[2], M. Graue[1], T. Østbye[3], K. Midthjell[4]
[1] Bergen University College, Faculty of Health and Social Sciences, Bergen, Norway
[2] University of Bergen, Department of Public Health and Primary Health Care, Bergen, Norway
[3] Duke University Medical Center, Department of Community and Family Medicine, Durham /NC, USA
[4] Norwegian University of Science and Technology, The HUNT Research Center, Verdal, Norway

Background: It has been suggested that the elevated mortality rate among people with diabetic foot ulcers is related to comorbid disease such as cardiovascular disease and nephropathy or psychological factors including depression.
Aim: The aim of the present study was to assess mortality rates for persons with diabetes with and without a history of foot ulcer (HFU) and for the nondiabetic population in a large population-based study, taking into account the effect of potential confounding factors.
Research design and methods: The study included 1,339 persons with diabetes without a HFU, 155 persons with diabetes with a HFU, and 63,632 nondiabetic persons all followed for 10 years with mortality as the end point. Information on mortality was obtained from the Norwegian Causes of Death Registry using the Norwegian 11-digit personal identity number unique for each resident. Participants with self-reported diabetes were well characterized with regard to their diabetes, and information on demographics, lifestyle, prevalent disease, and depression was available.
Results: Analyses show that 49.0% of persons with diabetes with a HFU died, 35.2% of persons with diabetes without a HFU and 10.5% of the nondiabetic persons died during the study period. In Cox regression analyses, adjusted for demographic and lifestyle factors, having a HFU was associated with more than a twofold (2.29 [95% CI 1.82–2.88]) hazard risk for mortality compared to the nondiabetic group. In corresponding analyses in persons with diabetes, a HFU was associated with a 38% increased mortality (1.38 [1.07–1.78]). The estimated effects of a HFU on mortality did not change markedly when also microalbuminuria, cardiovascular disease, and Hospital Anxiety and Depression Scale depression scores were included in the model.
Conclusion: This large community-based study showed that foot ulceration is a marker of increased mortality risk among persons with diabetes, and underlines the importance of organizing future health care services with follow-up routines that allow for early and tight clinical monitoring in persons with a HFU in primary care.

The fibrosis promoter SPARC and its relation to the collagen-like adipokine adiponectin in human obesity

K.T. Kos[1], S. Wong[1], D. Kerrigan[2], J.H. Pinkney[3], J.P.H. Wilding[1]
[1] Clinical Sciences Centre Aintree University of Liverpool, Department of Diabetes and Endocrinology, Liverpool, United Kingdom
[2] Clinical Sciences Centre Aintree University of Liverpool, Department of Surgery, Liverpool, United Kingdom
[3] Peninsula Medical School and Royal Cornwall Hospitals, Diabetes Unit, Truro, United Kingdom

Background and aims: Circulating Secreted Protein, Acidic and Rich in Cysteine (SPARC, also known as osteonectin) is predominantly derived from adipose tissue (AT) and is a mediator of collagen deposition and fibrosis. We have previously shown that its expression in AT is increased in human obesity and responds to weight change. We also reported upregulation of AT SPARC with insulin treatment in vitro, and increased expression of SPARC in subjects

with insulin resistance. SPARC is proposed to influence the composition of the extracellular matrix of adipose tissue and its collagen content and whilst adiponectin belongs structurally to the soluble-defence-collagen superfamily, the aim of this study was to determine a link between SPARC and adiponectin expression.

Methods: Morbidly obese non-diabetic subjects undergoing bariatric surgery (BMI=46.8±1.9(mean±SD)kg/m^2,n=37) and lean controls undergoing elective surgery (BMI=23.6±0.8kg/m^2,n=18) had serum, visceral-AT(VAT) and subcutaneous-abdominal-AT(SCAT) taken. Serum adiponectin levels were measured by ELISA and AT-derived mRNA expression by Real-time PCR and adjusted to ß-actin.

Results: SPARC expression was higher in SCAT than VAT (0.81±0.06(mean±SE) Signal Units(SU) versus 0.51±0.05SU,p<0.001,n=47) which was similar to the higher expression of adiponectin in SCAT (2.84±0.8SU versus 1.54±0.5SU,p<0.001,n=47). AT-expression of SPARC and adiponectin was similar in men and women, whilst serum adiponectin was higher in women (0.94±0.07ng/ml) versus men (0.81±0.05ng/ml, p<0.05). SCAT-adiponectin but not VAT-adiponectin correlated with circulating adiponectin (r=0.30, p<0.05) and SCAT and VAT-derived SPARC expression showed a positive correlation with fat mass (r=0.4, p<0.01). In contrast, adiponectin expression was lower in obese subjects and correlated negatively with fat mass (SCAT: r=-0.41,p<0.01; VAT: r=-0.43, p=0.003; serum adiponectin: r=-0.45, p=0.001). SCAT-SPARC correlated negatively with SCAT-adiponectin expression (r=-0.3, p<0.05) whilst no correlation was found for SPARC and adiponectin VAT-expression after correction for fat mass.

Conclusion: Similar to adiponectin, SPARC expression is higher in SCAT and whilst adiponectin decreases, SPARC increases in human obesity. SCAT-adiponectin appears to play a bigger contribution to circulating adiponectin levels and whilst SCAT-SPARC and adiponectin are negatively correlated and this independent of fat mass, our data suggests a regulation of adiponectin by SPARC which requires further evaluation by mechanistic studies.

Loss of the Prader-Willi Syndrome candidate gene Magel2 alters appetite and energy balance

R.E. Mercer[1], R. Wevrick[1]
[1] University of Alberta, Medical Genetics, Edmonton, Canada

Our laboratory identified the Prader-Willi Syndrome (PWS) candidate gene MAGEL2 as a circadian output gene expressed in the hypothalamus, a region of the brain important for homeostatic functions including growth and reproduction, sleep and wakefulness, and appetite and metabolism. People with PWS, a genetic disease, have significant appetite and metabolic disturbances, including an early failure to thrive followed by childhood-onset hyperphagia and low metabolic rate. In the absence of strict dietary and behavioral intervention, people with PWS progress to morbid obesity, insulin resistance, and type-2 diabetes. Proposed associations between circadian rhythm and normal metabolic function prompted us to examine appetite and metabolism in transgenic mice lacking Magel2, referred to as ***Magel2***-null.

We have previously shown that as in PWS, ***Magel2***-null mice show reduced weight gain in the pre-weaning period, followed by accelerated weight gain and increased adiposity as adults. This increased weight gain appears to be the result of a dramatic reduction in activity compared to control animals, with only a modest reduction in food intake, leading to a relative hyperphagia in the ***Magel2***-null mice. We now show that mice lacking ***Magel2*** respond abnormally to an acute energy challenge in the form of a 36-hour fast. After the fasting period, ***Magel2***-null animals lost a smaller percentage of their initial body weight compared to control animals. Upon refeeding, ***Magel2***-null mice showed a blunted reflex hyperphagia response, consuming significantly less food than control animals, leading to slower weight re-gain and reduced feeding efficiency.

The arcuate nucleus (ARC) is a key region of the hypothalamus involved in both short and long term energy balance. Key neuropeptides in the ARC include the orexigenic neuropeptide-Y (NPY) and the anorexigenic pro-opiomelanocortin (POMC), which are up- and down-regulated by fasting respectively. To examine if loss of Magel2 affects NPY or POMC levels in the hypothalamus, we are using quantitative reverse transcriptase PCR on both fed and fasted animals. Alterations in hypothalamic neuropeptide levels may explain some of the changes seen in ***Magel2***-null mice. For example, a failure to increase NPY levels upon fasting could reduce reflex hyperphagia.

Circadian rhythm is emerging as an important factor in metabolic function, highlighted by recent studies using animal models of obesity, hypertension, and diabetes. Our work further highlights the role of circadian function in appetite and metabolism, and provides a valuable model to understand how circadian alterations can affect specific hypothalamic pathways involved in appetite and energy balance.

Chemerin is an adipokine related to insulin resistance and decreasing after bariatric surgery in morbidly obese patients

H. Sell[1], A. Divoux[2], K. Clément[2], J. Eckel[1]
[1] German Diabetes Center, Institute of Clinical Biochemistry and Pathobiochemistry, Düsseldorf, Germany
[2] University Pierre et Marie Curie-Paris 6, INSERM Nutriomique U872, Paris, France

Aims: Adipose tissue is an endocrine active organ producing various adipokines including the newly described chemokine chemerin. We could recently demonstrate that chemerin induces insulin resistance in skeletal muscle cells in vitro. The role of chemerin in obesity and type 2 diabetes remains unclear and has not been investigated after bariatric surgery.

Methods: Chemerin plasma levels were measured in 60 morbidly obese female patients (BMI 50.0±1.0, age 43.1±1.5) before surgery as well as 3, 6 and 12 months after surgery. In a subgroup of 27 patients, chemerin levels were monitored for 2 years. At all time points blood levels of insulin, glucose, HbA1c, cholesterol, HDL, triglycerides, CRP, leptin, adiponectin and IL-6 were assessed in addition to weight and BMI.

Results: Chemerin concentrations are substantially elevated in obese patients compared to concentrations for normal weight persons (353.8±18.0 ng/ml compared to approximately 250 ng/ml described in the literature). Preoperatively, chemerin levels are correlated positively with body weight, BMI, CRP, IL-6 and insulin sensitivity (HOMA). Furthermore, chemerin is correlated negatively with HDL levels. After bariatric surgery, chemerin decreased significantly (275.6±17.9 ng/ml after 3 months, 255.9±12.0 ng/ml after 6 months and 253.0±14.9 ng/ml after 12 months) in parallel to leptin levels but different from IL-6 that only displayed a marked reduction 12 months after surgery and adiponectin that was significantly increased after 6 and 12 months. In the subgroup of patients studied for 2 years, chemerin levels significantly decreased between 1 year and 2 years after surgery (preoperative 381.7±28.0 ng/ml, after 1year 290.7±26.9 ng/ml, after 2 years 215.1±14.7 ng/ml). 3 months after surgery chemerin levels only positively correlate with triglycerides, a correlation that was remaining apparent after 6 and 12 months. The prominent decrease of chemerin in the first 3 months after surgery was significantly associated with the increase in insulin sensitivity (HOMA) for this period.

Analyzing diabetic patients (n=20) separately, a correlation of chemerin levels could be found with HOMA and HDL before surgery and with triglycerides 3 and 6 months after surgery. Differently in non-diabetic patients (n=37), chemerin correlates with BMI and IL-6 before surgery but not with HOMA or HDL.

Conclusion: This is the first study to demonstrate decreased chemerin plasma levels after bariatric surgery. The observed decrease in chemerin after bariatric surgery indicates together with our previous in vitro findings that chemerin might be a factor contributing to insulin resistance in obesity and the improvement of insulin sensitivity and other obesity-related morbidities after surgical intervention.

Effects of obesity on ß-cell function in all stages of glucose tolerance

G. Fra[1], E. Colli[1], C. Cerutti[1], F. Corlianò[1], G.P. Carnevale-Schianca[1], E. Bartoli[1]
[1] Clinica Medica Generale AOU "Maggiore della Carità", Dipartimento di Scienze Mediche, Novara, Italy

In this study we analyzed the influence of obesity on insulin sensitivity and secretion throughout the different stages of glucose tolerance.

We recruited 1279 subjects (584 men and 695 women) who were stratified according to body mass index (BMI, kg/m^2), as normal weight (BMI < 25, n = 343), overweight (BMI ≥ 25 and < 30, n = 496) and obese (BMI ≥ 30,

n = 440). We executed a standard OGTT, measuring fasting and 2h-plasma glucose (FPG and 2hPG), to diagnose the different stages of glucose tolerance, and insulin (FPI and 2hPI) to evaluate ß-cell function. We calculated the estimated insulin sensitivity index (EISI) and the first phase of insulin secretion (1fsPH) as OGTT-derived values of insulin sensitivity and secretion, respectively. By OGTT, in agreement with the 2003 ADA criteria, we identified 713 normal glucose tolerant subjects (NGT), 256 affected by impaired fasting glucose (IFG), while 96 were affected by impaired glucose tolerance (IGT), 111 by combined IFG/IGT, and 103 were diabetics.
Within each glucose tolerance group, an ANOVA analysis and post-hoc comparison of ß-cell function variables was computed comparing the values obtained for each BMI range of values considered.
EISI consistently decreased proceeding from normal weight to obesity in each glucose tolerance group, except IGT. Closely associated with this finding, we found a significantly progressive increment of 1fsPH when proceeding from normal weight to obesity in all glucose tolerance stages.
Comparing subjects with similar BMI, but different glucose tolerance steps, both EISI and 1fsPH were significantly higher in NGT with respect to any glucose tolerance group.
Our data confirm that obesity is a metabolic condition where worsening of insulin sensitivity constitutes a common feature; this abnormality is also present in pre-diabetic stages and diabetes. The rise in insulin secretion attributable to obesity is however present not only in NGT but, surprisingly, in pre-diabetic stages as well as in diabetes.
This secondary rise in insulin secretion, when proportionate to insulin sensitivity, constitutes a distinctive feature of NGT; in the pre-diabetic stages and diabetes the significant rise of insulin secretion, that we measured in the present study, is not sufficient to compensate the concomitant worsening of insulin sensitivity.

Low-grade inflammation and depressive symptoms as predictors of developing abdominal obesity

M. Valtonen[1], D. Laaksonen[2], L. Niskanen[2], H. Viinamäki[3], T. Tolmunen[3], J. Kauhanen[4]
[1] *LIKES – Foundation for Sport and Health Sciences, Jyväskylä, Finland*
[2] *Kuopio University Hospital, Department of Medicine, Kuopio, Finland*
[3] *Kuopio University Hospital, Department of Psychiatry, Kuopio, Finland*
[4] *University of Kuopio, School of Public Health and Clinical Nutrition, Kuopio, Finland*

Aims: Growing evidence shows that depression is a risk factor for cardiovascular disease and for the metabolic syndrome. Low-grade inflammation and evolving abdominal obesity have been hypothesized to be the underlying mechanisms linking these impairments of health. We therefore examined the effect of both depression and inflammation in developing abdominal obesity.
Methods: In this prospective study we investigated the relationship between inflammation and depressive symptoms and increased waist girth in 1725 non-diabetic middle-aged men participating in the Kuopio Ischemic Heart Disease Study during an 11-year follow-up. Inflammation was defined as serum C-reactive protein over 2mg/ml and depressive symptoms were assessed by Human Population Laboratory Depression scale. These two variables were combined together for logistic regression analysis.
Results: This study showed that men with both low-grade inflammation and elevated depressive symptoms were at an especially high risk to develop abdominal obesity (waist girth = 94 cm, OR 3.43, 95% CI 0.99-11.85, P<0.001; waist girth >102 cm, OR 4.33, 95% CI 1.68–11.19, P=0.004) during the 11-year follow-up, even after controlling for age, smoking, alcohol consumption, cardiovascular disease, physical activity and socioeconomic status. Similarly, these men were at a high risk for developing the metabolic syndrome (National Cholesterol Education Program definition, OR 3.90, 95% CI 1.37-11.12, P=0.002).
Conclusion: Inflammation together with elevated depressive symptoms may have especially adverse effects on metabolic risk factors in the long term, predisposing to abdominal obesity and the metabolic syndrome.

Depot-specific expression of MMIF, MCP-1 and MIP-1alpha in human adipose tissue in relation to systemic inflammation

K. Kos[1], S. Wong[2], D. Kerrigan[3], J.P.H. Wilding[2], J.H. Pinkney[4]
[1] *Clinical Sciences Research Institute, Diabetes and Metabolism Dept, Coventry, United Kingdom*
[2] *Clinical Sciences Centre Aintree University of Liverpool, Department of Diabetes and Endocrinology, Liverpool, United Kingdom*
[3] *Clinical Sciences Centre Aintree University of Liverpool, Department of Surgery, Liverpool, United Kingdom*
[4] *Peninsula Medical School and Royal Cornwall Hospitals, Diabetes Unit, Truro, United Kingdom*

Background: The systemic inflammation observed in obesity is thought to be mainly derived from the stroma-vascular fraction of adipose tissue (AT) due to macrophage-infiltration of AT in obesity. Macrophages are recruited and trapped in AT by release of chemoattractant-molecules such as monocyte-chemoattractant-protein-1 (MCP-1), macrophage-inflammatory-protein-1(MIP)-alpha and macrophage-migration-inhibitory-factor (MMIF). Whilst little is known about the contribution of chemokines to obesity-related inflammation, the aim of this study was to determine the depot-specific-expression of these chemokines in both subcutaneous and visceral AT and their association with circulating inflammatory cytokines which are typically elevated in obesity.
Methods: With ethical approval, a fasting blood sample, visceral-AT (VAT) and subcutaneous-abdominal-AT (SCAT)-biopsies were obtained from morbidly obese non-diabetic subjects undergoing bariatric surgery (age=44.5±1.4years (mean±SE), BMI=46.8±1.9kg/m^2, n=37) and age-matched lean controls undergoing elective surgery (age=42.3±4.1years, BMI=23.6±0.8kg/m^2, n=18). Chemokine plasma levels were determined by ELISA and AT-derived mRNA expression by quantitative real-time-PCR after correcting for ß-actin.
Results: In our study population we observed the following systemic cytokines were positively correlated with fat mass: hsCRP(r=0.82, p<0.001), solubleTNFalphaR2 (r=0.36, p<0.01) and IL-6 (r=0.52, p<0.001). There was no depot-specific AT-expression of TNFalpha or CD14. However, MCP-1, MIP-1alpha and IL-6 showed higher expression in SCAT (p<0.001) than VAT, whilst MMIF was higher in VAT (p<0.001). VAT-MMIF but not SCAT-MMIF correlated with fat mass (r=0.28, p<0.01), hsCRP (r=0.35, p<0.01) and HOMA-IR (r=0.2, p<0.05) independent of fat mass. In contrast, AT-MCP-1 was unrelated to hsCRP or HOMA-IR but plasma levels of MCP-1 showed a marked correlation with hsCRP (r=0.36, p<0.01). AT-MIP-1 was related to fat mass, and hsCRP and AT-MIP-1 showed a positive correlation with HOMA-IR (VAT: r=0.1, p<0.05; SCAT: r=0.3, p<0.01). AT-expression of MIP-1 also correlated with circulating solubleTNFalphaR2 (VAT: r=0.28, p<0.001; SCAT: r=0.17, p<0.001) and VAT-MIP-1alpha (r=0.28, p<0.01) but not SCAT-MIP-1alpha correlated with plasma IL6. In addition, VAT-TNFalpha (r=0.35, p<0.01) showed a stronger association to hsCRP than SCAT-TNFalpha (r=0.13, p<0.05).
Conclusion: Our data suggests that inflammatory cytokines and chemokines differ in their expression in the AT-depots. VAT-derived MMIF and TNFalpha correlate closer to hsCRP, solubleTNFalphaR2 and IL-6 as markers of systemic inflammation which characterises the obese state. This supports a major role of VAT-derived products in systemic inflammation. However, whilst SCAT may contribute less to systemic inflammation, the SCAT-MIP-1 correlation with HOMA-IR shows that some chemoattractants in SCAT may be independently associated with insulin resistance.

Imaging the brain's response to eating in man using continuous arterial spin labelling functional magnetic resonance imaging

S. Lee[1], Y. Nathan[1], P. Choudhary[1], L.J. Reed[2], M.J. Brammer[3], S.A. Amiel[1], F.O. Zelaya[4]
[1] King's College London, Diabetes Research Group, London, United Kingdom
[2] King's College London, Institute of Psychiatry, London, United Kingdom
[3] King's College London, Brain Image Analysis Unit, London, United Kingdom
[4] King's College London, Centre for Neuroimaging Sciences, London, United Kingdom

Background: Dysregulation of appetite and satiety sensing can result in overeating, obesity and Type 2 diabetes. Central control of appetite is an attractive target for weight-reducing and insulin sensitising therapies. Conventional neuroimaging methods avoiding radiation exposure such as functional magnetic resonance imaging (fMRI) cannot easily be applied to measure regional brain responses to slowly evolving stimuli, such as eating. Continuous arterial spin labelling (CASL) is a method of quantifying changes in regional brain perfusion, a surrogate marker of neuronal activation, which may be applicable to the study of responses to feeding.
Methods: Ten R-handed healthy volunteers (age 26.2±3.1 yrs, BMI 24.1±1.7) were scanned twice using CASL (1.5T MRI scanner) in random order after an 8 hour fast and either a 400Kcal mixed meal or 50ml water (fasted control). CASL was measured before, immediately, 8 and 28 mins after ingestion. Imaging data were analysed using SPM5 (Wellcome Trust Centre for Neuroimaging, UK), comparing the fed and fasted states. Only significant clusters ($p < 0.05$ at the cluster level) were considered. Satiety scores were measured with each CASL measurement.
Results: Food ingestion increased satiety scores ($p<0.0001$); while hunger and desire to eat scored more highly in the fasted state ($p<0.001$, $p<0.0004$). There were no significant differences in the baseline CASL between the 2 study days. The fed state increased perfusion in the thalamus; hypothalamus; precuneus; superior and lateral cerebellum; visual and auditory cortices and the gustatory cortex associated with taste sensation in tongue and lips. Perfusion was less after food in the anterior cingulate and orbitofrontal cortices.
Conclusion: Food ingestion alters neuronal activation in regions known to be involved in appetite control and satiety sensing, nutrient sensing and taste. CASL provides a robust assessment of these responses and can be exploited in the examination of the role of appetite control in the pathogenesis and treatment of obesity and Type 2 diabetes.

Insulin-mediated cortical activity in the slow frequency range is diminished in obese mice, and therefore promotes physical inactivity

A.M. Hennige[1], T. Sartorius[1], O. Tschritter[1], S.Z. Lutz[1], H. Preissl[2], H.G. Rammensee[3], H.U. Häring[1]
[1] University of Tuebingen, Internal Medicine 4, Tübingen, Germany
[2] University of Tuebingen, Institute of Medical Psychology and Behavioural Neurobiology, Tübingen, Germany
[3] University of Tuebingen, Department of Immunology, Tübingen, Germany

Aims: There is sufficient evidence from mouse models and humans that alterations in insulin action in the brain are accompanied by an obese phenotype; however, the impact of insulin in the brain with regard to behavioural aspects like locomotion is unknown.
Methods: To address insulin action in the brain with regard to cortical activity in distinct frequency bands and their behavioural consequences, the insulin signaling pathway was followed from the receptor up to electrical activity, and locomotion. Western Blot analysis, electrocorticogram recordings with intracerebroventricular (icv) application of insulin, and measurements of locomotor activity were performed in lean and obese, as well as Toll-like receptor (TLR) 2/4-deficient mice.
Results: We show that insulin application icv into lean mice was accompanied by a profound increase in cortical activity in the slow frequency range, while diet-induced obese mice displayed insulin resistance. In parallel, insulin icv increased locomotor activity in lean, whereas a PI 3-kinase inhibitor or obesity abolished insulin-mediated locomotion. A potential candidate that links insulin signaling to locomotion is the Kv1.3 channel that is activated by PI 3-kinase, and pharmacological inhibition of Kv1.3 channels bypassing insulin receptor activation promoted activity in lean and obese mice. Moreover, mice deficient in TLR2/4-dependent free fatty acid signaling displayed an increase in cortical activity in the slow frequency range that was correlated with improved spontaneous locomotor activity.
Discussion/conclusion: Our data provide functional evidence for a direct effect of insulin on brain activation patterns associated with locomotor activity in lean, while in obese, insulin-mediated locomotion is blunted and further aggravates physical inactivity.

Admission hypoglycaemia portends a substantially increased risk of mortality in patients with community-acquired pneumonia: population-based cohort study

J. Gamble[1], D.T. Eurich[1], T.J. Marrie[2], S.R. Majumdar[2]
[1] University of Alberta, School of Public Health, Edmonton, Canada
[2] University of Alberta, Faculty of Medicine & Dentistry, Edmonton, Canada

Aims: The relationship between dysglycemia and adverse events for hospitalized patients focuses on elevated blood glucose. Our aim was to examine the independent association between admission hypoglycemia and in-hospital, 30-day, and 1-year mortality in a population-based cohort of patients hospitalized with community acquired pneumonia (CAP).
Methods: From 2000 to 2002, clinical and laboratory data were prospectively collected on all CAP patients admitted to 6 hospitals in Edmonton, Alberta, Canada. Patients with admission glucose > 6.1 mmol/L (n=1996) were excluded from further consideration; the remaining 956 patients were categorized as having admission hypoglycemia (<4.0 mmol/L [n=54]) or normoglycemia (4.0 to ≤ 6.1 [n=902]). Multivariable Cox-proportional hazards models were used to examine the relationship between admission hypoglycemia and all-cause mortality after adjustment for demographic and clinical data (e.g. laboratory findings, comorbidities, functional status, pneumonia severity [PSI]). Examining in-hospital mortality, several further sensitivity analyses were undertaken: a) inclusion of clinical markers of physiologic stress [e.g. HR, Temp, RR]; b) exclusion of patients admitted to the ICU; c) exclusion of patients with known diabetes.
Results: Mean age of the 956 study patients was 65 (SD 20) years, 48% were female, and 15% resided in a nursing home. Most (45%) patients had severe (PSI Class IV or V) pneumonia. Overall, admission hypoglycemia was present in 2% (54 of 2990) of the entire cohort, and in 6% of our study sample (i.e., those with admission glucose ≤ 6.1 mmol/L). There were a total of 89 (9%) in-hospital deaths, 96 (10%) deaths at 30 days, and 247 (26%) deaths at 1 year. In-hospital mortality was higher among patients with admission hypoglycemia [11 (20%) deaths] compared to those with normoglycemia [78 (9%); adjusted hazards ratio (aHR) 2.96, 95%CI 1.38-6.31, p=0.005]. An increased risk of mortality was still observed at 30-days [11 (20%) vs. 85 (10%); aHR 2.88, 1.32-6.27] and remained elevated at 1-year [16 (30%) vs. 128 (14%); aHR 1.80, 1.02-3.17]. None of the sensitivity analyses undertaken altered our main findings with respect to in-hospital mortality: a) inclusion of markers of physiologic stress (aHR 3.30, 1.47-7.43); b) exclusion of 88 patients admitted to ICU (aHR 4.60, 1.88-11.27); c) exclusion of 72 patients with prior diabetes (aHR 2.97, 1.25-7.03). Furthermore, there was no indication of effect-modification by diabetes status (p>0.4 for interaction).
Conclusion: In a population-based sample of CAP patients without elevated blood sugars, we found that admission hypoglycemia was significantly associated with an increased risk of death during hospitalization that persisted up to 1-year. Although uncommon, admission hypoglycemia is easily identified and captures a group of patients at very high risk of adverse events that may need far greater clinical attention.

Patients with increased glycemic variability measured using 2 days of continuous glucose monitoring have an increased risk of subsequent hypoglycemia

P. Choudhary[1], A. Finlayson[1], B. Whitelaw[1], S. Heller[2], S. Amiel[3]
[1] *Kings College Hospital London, Diabetes Department, London, United Kingdom*
[2] *University of Sheffield, Diabetes Endocrinology and Metabolism, Sheffield, United Kingdom*
[3] *Kings College London, Department of Diabetes, London, United Kingdom*

Background: Continuous Glucose Monitoring (CGM) is increasingly being used to characterise glycemic variability within an individual as this may have bearing on risk of vascular complications as well as future hypoglycemia risk. Glycemic variability derived from a month of home glucose monitoring has been shown to predict risk of severe hypoglycemia in the following 3 months. It is not known if shorter (48 hours) exposure to more detailed glucose information available with continuous glucose monitoring(CGM) has similar predictive value. There are a number of different measures of glycemic variability and it is not clear which offers the best assessment of an individual's risk of subsequent hypoglycemia.
Aims: To determine if patients with greater glycemic variability measured using a single sensor (48 hours of data) are at higher risk of hypoglycaemia over the subsequent 9-12 months.
Methods: We analysed the first complete 48 hours of CGM data from 75 patients with type 1 diabetes from the UK Hypoglycemia Study [Mean HbA1c 7.6 (0.9) %; Diabetes duration either <5 years or >15 years] and calculated measures of glycemic variability [Low Blood Glucose Index(LBGI), High Blood Glucose Index(HBGI, Blood Glucose Risk Index(BGRI) and Continuous Overall Net Glycemic Action (CONGA). Each patient also recorded all symptomatic hypoglycemia over the subsequent 9-12 months. We correlated measures of variability and subsequent hypoglycemia risk.
Results: Glycemic variability was greater in patients with longer duration of diabetes and was significantly correlated with HbA1c (CONGA 1, r = 0.35; p=0.003). CONGA and BGRI showed good correlation with each other (r= 0.69; p<0.001) but there was poor agreement between those in the highest quartile of variability measured by both methods (Kappa = 0.3). LBGI calculated from 48 hours of CGM was not correlated with risk of subsequent hypoglycemia, but CONGA 1 was significantly correlated with risk of severe hypoglycemia (r=0.3; p=0016) and symptomatic hypoglycemia (r= 0.4; p<0.001) over the next 9-12 months. There was also a significant correlation between CONGA 1 and capillary glucose readings <3.5 mmol/l (r= 0.4; p<0.001). CONGA 1 >30 predicted increased risk of severe hypoglycemia over the following year.
Conclusion: Patients with increased glycemic variability (measured using short term CGM data) are at increased risk of subsequent symptomatic and severe hypoglycemia over the subsequent 9-12 months. This may allow us to identify more appropriate treatment strategies for these individuals. There is poor agreement between measures of variability and more work needs to be done to evaluate these measures.

Estimating number-needed-to-treat to avoid hypoglycaemic episodes in people with type 2 diabetes: a post-hoc analysis of a prospective randomized controlled trial comparing once-daily insulin glargine with twice-daily NPH insulin

J. Rosenstock[1], V. Fonseca[2], M.P. Dain[3], M. Riddle[4]
[1] *Dallas Diabetes and Endocrine Center at Medical City and University of Texas, Southwestern Medical School, Dallas TX, USA*
[2] *Texas A&M University, Section of Endocrinology Scott and White Clinic, Temple TX, USA*
[3] *Sanofi-Aventis, Paris, France*
[4] *Oregon Health & Science University, Portland OR, USA*

Aims: Studies consistently show that insulin glargine (Glargine) is associated with less risk of hypoglycaemia for a given level of blood glucose (BG) than NPH, especially when close to glycaemic targets. To quantify the potential value of hypoglycaemia risk reduction with the use of Glargine, we reviewed data from a large, long-term study to determine the number of people that need to be treated (NNT) with Glargine vs NPH to protect 1 person from experiencing hypoglycaemia.
Methods: Hypoglycaemia and HbA_{1c} data from a 5-yr study that compared randomized treatment with Glargine qd (evening) or NPH bid (morning and evening), both with oral antidiabetic drugs (OADs), to assess retinopathy progression (reported elsewhere) in patients with Type 2 diabetes (T2D) were included. Patients received basal insulin plus OADs, prandial regular insulin could also be added. 1017 participants previously using insulin for T2D were enrolled (mean age 55 yr, T2D duration 11 yr, BMI 34kg/m^2, HbA_{1c} 8.4%). Stable control of HbA_{1c} was achieved with each basal insulin throughout the study. Hypoglycaemia risks adjusted for change in HbA_{1c} were derived by logistic regression (498 Glargine and 486 NPH patients). The NNT was computed for the following categories of hypoglycaemia: severe (predefined in study), symptomatic with SMBG <36 and symptomatic with SMBG <70mg/dL.
Results: For Glargine qd and NPH bid, total basal insulin dose was 61.8 and 72.3U and HbA_{1c} change was –0.62 and –0.73%, respectively. Compared with NPH, Glargine was associated with a significantly lower risk for all categories of daytime and total but not nocturnal hypoglycaemia. These reduced risks translated into statistically significant and, in most cases, clinically relevant NNT values (<20). Differences in rates of nocturnal hypoglycaemia did not reach statistical significance.
Summary: Glargine qd results in a lower incidence of total and daytime hypoglycaemia than using NPH bid. The NNT to avoid 1 person experiencing an event ranged 13–30 for different categories of total and daytime hypoglycaemia. The NNT for severe hypoglycaemia was 23.
Conclusion: The reduced risk of hypoglycaemia by using Glargine instead of NPH insulin in this population was clinically relevant in terms of NNT.

Fear of hypoglycaemia in adults with type 1 diabetes and its relation to demographic and disease specific factors

T. Anderbro[1], S. Amsberg[1], U. Adamson[2], J. Bolinder[3], P.E. Lins[2], R. Wredling[1], E. Moberg[3], J. Lisspers[4], U.B. Johansson[1]

[3] *Karolinska Institutet, Department of Medicine Karolinska University Hospital-Huddinge, Stockholm, Sweden*

[4] *Mid Sweden University Campus Östersund, Department of Social Sciences, Östersund, Sweden*

Aims: It has been reported that fear of hypoglycaemia (FoH) is as strong as fear of vascular complications among patients with type 1 diabetes. Furthermore, FoH affects quality of life and may also have a negative impact on metabolic control. The aim of this study was to examine the FoH in adult patients with type 1 diabetes and to investigate its association with demographic and disease specific factors.

Methods: Questionnaires were sent by mail to all patients with type 1 diabetes identified in the local diabetes registries of two hospitals in Stockholm, Sweden (n=1347). FoH was measured using the Hypoglycaemia Fear Survey (HFS); the worry-subscale and the aloneness-subscale (measuring fear of aloneness) from the Swedish version of HFS. Demographic and disease specific factors were collected from patients self reports and medical records and included gender, age, duration of diabetes, HbA_{1c}, self monitoring of blood glucose, frequency of severe, moderate and minor hypoglycaemia, symptoms during hypoglycaemia, history of hypoglycaemic unawareness and self reported episodes of "hypoglycaemic symptoms" during hyperglycaemia. Univariate analysis and multiple stepwise linear regression analysis were used in the statistical analysis.

Results: 764 patients participated in the study, 380 men and 384 women, mean age 43.3 years and mean HbA_{1c} 7.0% (normal < 5%). The HFS worry-subscale was significantly associated with frequency of severe hypoglycaemia, frequency of symptoms during minor hypoglycaemia, gender, "hypoglycaemic symptoms" during hyperglycaemia and unawareness of hypoglycaemia, The HFS aloneness-subscale was significantly associated with frequency of severe hypoglycaemia, frequency of symptoms during minor hypoglycaemia, gender, frequency of minor hypoglycaemia, HbA_{1c}, unawareness of hypoglycaemia and visits to hospital due to severe hypoglycaemia. Separate analyses for gender showed that FoH was more prevalent in females and also indicated a somewhat different pattern of factors associated with FoH with fewer significant factors for males than for females.

Conclusion: Our results confirm previous research which identifies the frequency of severe hypoglycaemia as the most important factor associated with FoH. In addition, gender and hypoglycaemic unawareness, "hypoglycaemic symptoms" during hyperglycaemia and HbA_{1c} were identified as significant factors predicting FoH. To our knowledge this is the first study to document gender differences with respect to FoH. This indicates the need of further research.

Fears of hypoglycaemia and complications in insulin-treated patients with diabetes: preliminary results of a multi-center study

M. Nishi[1], K. Okazaki[1], T. Murata[2], K. Kotani[1], Y. Sano[1], M. Narimiya[3], K. Yamada[2], N. Sakane[1]

[1] *Kyoto Medical Center, Department of Preventive Medicine, Kyoto, Japan*

[3] *Nishisaitama Chuo National Hospital, Internal Medicine, Saitama, Japan*

Diabetic patients regarding insulin treatment seem to have many kinds of fear in their daily lives. Especially, fears of hypoglycemia and diabetic complications are considered major concerns. This study investigated which of these fears: hypoglycemia, severe hypoglycemia, blindness, or dialysis is most severe in insulin-treated type 1 and type 2 patients based on responses obtained from a multi-center cross-sectional survey. By the end of February 2008, 554 patients and their physicians at the outpatient department of 15 hospitals or clinics had completed the questionnaire. The response rate was 75%. We developed this original questionnaire to survey the occurrence of hypoglycemia (including severe and nocturnal hypoglycemia); fears of hypoglycemia, severe hypoglycemia, blindness, dialysis; and socio-demographic factors. The strength of fear was measured using a 5-point Likert scale with 1 never feel fear, and 5 feel extreme fear. In this study, severe hypoglycemia was defined as a low blood glucose level that results in a loss of consciousness or requiring the treatment from another person. There were 554 subjects (193 type 1 and 361 type 2, mean age 57 years, male 52%, mean duration of diabetes 16.9 years, mean duration of insulin therapy 7.3 years, and mean HbA1c 7.3%). Fear scores were 3.7 for hypoglycemia, 4.3 for severe hypoglycemia, 4.7 for blindness, and 4.7 for dialysis on a scale of 1 to 5. One way analysis of variance showed that there was no significant difference between the fears of blindness and dialysis. However, there was a significant difference between fears of complications and severe hypoglycemia ($p<0.05$). There was also a significant difference between severe hypoglycemia and hypoglycemia ($p<0.05$). Additionally, using logistic regression analysis, two factors such as an experience of severe hypoglycemia in the past year and age were significantly associated with an increased likelihood of fear of hypoglycemia (odds ratio = 3.5 and 1.0, respectively). Other factors such as gender, type of diabetes, duration of diabetes, presence of diabetic neuropathy and level of HbA1c were not significantly associated with fear of hypoglycemia. In conclusion, insulin treated patients with diabetes had stronger fears of complications than of hypoglycemia (blindness = dialysis > severe hypoglycemia > hypoglycemia). Experience with severe hypoglycemia in the past year was a major factor affecting fear of hypoglycemia. Thus, it seems to be important to take various measures to reduce the incidence of severe hypoglycemia.

The costs and main causes of severe hypoglycemia in diabetic patients visiting the emergency room

J.R. Lee[1], S.A. Kim[1]

[1] *Asan Medical Center, Nursing, Seoul, Korea*

Background and aims: The risk of hypoglycemia is a barrier to intensive diabetes management. If the patient can recognize the hypoglycemia early and deal with it properly, the risk of severe hypoglycemia can be reduced. We performed this study to identify the main factors causing severe hypoglycemia in diabetes patients and treatment costs, when they came to ER.
We also evaluated the patients' or families' capabilities to manage the situation.

Methods: The patients with diabetes mellitus who visited ER of a university hospital with severe hypoglycemia (n = 34) were enrolled for 15 months. Emergency nurse specialists conducted interviews on the patient and family member while a diabetes clinical nurse specialist reviewed the medical record. The interview was based on the questionnaires dealing with various aspects of causes of hypoglycemia and self management (skills) and knowledge of hypoglycemia. We also checked the medical costs when they were discharged.

Results: The average age of the subjects was 68.3±11.0 years(range 36-84yrs, median 69.5yrs). Among the patients, 88.2% (n=30) were taking oral hypoglycemic agent (OHA) and 44.1% (n=15) were taking insulin. The most frequent cause of severe hypoglycemia was irregular eating (85.1%, n=29) with or without overdose of OHA or insulin.
The 55.9% (n=19) of the subjects never had a diabetes education before. Only 12.1% (n=4) of patients or families checked blood glucose level when they were attacked by hypoglycemia at home. Even though they did not check blood glucose at the time of the incident, 42.4% (n=14) tried to eat something sweet. The total medical cost was 212.1(±151.1) US dollar, which was 6.9-fold higher than the average cost of OPD visit.

Conclusion: This study emphasized the importance of regular meal plan to prevent hypoglycemia. Patients and their families should be taught to check the blood glucose level regularly when their food intake becomes irregular. This should reduce the medical costs associated with visiting ER due to severe hypoglycemia.

Determinants of severe hypoglycaemia in community-based patients with type 2 diabetes: the Fremantle Diabetes Study

T.M.E. Davis[1], W.A. Davis[1], S.G.A. Brown[2], I.G. Jacobs[2], D.G. Bruce[1]
[1] University of Western Australia, School of Medicine & Pharmacology, Fremantle, Australia
[2] University of Western Australia, School of Primary Aboriginal & Rural Health Care, Nedlands, Australia

Aim: To determine the incidence and predictors of severe hypoglycaemia (SH) in community-dwelling Australians with type 2 diabetes using robust analytical techniques, including those that account for the majority who should not experience SH.
Methods: We studied 616 FDS type 2 patients from the longitudinal observational Fremantle Diabetes Study (FDS) who were assessed in detail in 1998 and followed to end-June 2006 for episodes of severe hypoglycaemia (SH). SH was defined as that requiring i) ambulance attendance, ii) Emergency Department (ED) services, or iii) inpatient care. Cox proportional hazards modelling was used to determine independent predictors of the first SH episode. Poisson, negative binomial (NB), zero-inflated Poisson (ZIP) and zero-inflated negative binomial (ZINB) regression models were used to identify predictors of SH frequency.
Results: The patients had a mean (±SD) age of 67.0±9.8 years, 52.3% were male and they had been diagnosed a median [inter-quartile range] of 7.7 [5.2-11.8] years previously. Their median HbA1c was 7.2 [6.5-8.1]% and 13.2% were insulin-treated. A total of 104 (9.3%) experienced at least one episode of SH during 7,172 patient-years (mean 6.4±2.1 years) of follow-up with an incidence of 2.5/100 patient-years. The average number of SH events was 1.7 (range 1 to 20). Independent predictors of time to first SH event were insulin treatment (hazard ratio [95% confidence interval] 4.61 [2.60-8.17]; P<0.001), estimated glomerular filtration rate (eGFR) <60 ml/min/1.73m^2 (2.93 [1.69-5.07]; P<0.001) and educational attainment beyond primary level (2.38 [1.10-5.12]; P=0.027). The ZINB provided the best fit of the four models of SH frequency tested. SH frequency was associated with a lower fasting serum glucose (FSG; relative risk 0.86 [0.76-0.98] for a 1 mmol/L increase) and a higher HbA1c (1.32 [1.01-1.75] for a 1% increase), while patients who did not experience SH were unlikely to use insulin (0.06 [0.01-0.40]) or to have an eGFR <60 ml/min/1.73m^2 (0.21 [0.09-0.53]).
Conclusions: Insulin treatment is the strongest risk factor for SH in community-based type 2 diabetic patients. Renal impairment is also an independent predictor, while higher educational attainment might predispose to SH through greater knowledge of the implications of poor glycaemic control and consequently more intensive self-management. Although the relationship between SH frequency and a lower FSG is understandable, that with a higher HbA1c may identify a group of patients with unstable control including unpredictable SH.

Maternal characteristics and neonatal outcome of children born to mothers with Type 1 Diabetes who experienced severe hypoglycemia during pregnancy.

D. Pacaud[1], S. Meltzer[2], A. Edwards[3], L. Donovan[3], S. Crawford[1], D. Dewey[1]
[1] University of Calgary, Pediatrics, Calgary Ab, Canada
[2] McGill University, Medicine, Montreal QC, Canada
[3] University of Calgary, Medicine, Calgary Ab, Canada

Severe hypoglycemia (SH) can occur in about half of pregnancies complicated by type 1 diabetes (T1D). As part of a longitudinal study examining the impact of SH during pregnancy on the neurodevelopmental outcome of the offspring, we explored characterisitcs of mothers affected by SH during pregancy and their neonates.
Aims: 1) To compare the diabetes characteristics of mothers with T1D affected by SH during pregnancy to mothers with T1D without SH 2) to compare the neonatal outcomes of the offspring of mothers with T1D affected by SH during pregnancy, to mothers with T1D without SH and healthy control mothers.
Methods: Pregnant women with T1D were recruited early in pregancy and information on their diabetes history, general health history and habits and demographic information was collected. Diabetes control information such as A1C, SH, frequency of mild hypoglycemia and insulin doses was gathered prospectively throughout their pregancies. Information on the neonatal outcomes of the offspring was collected through maternal interviews and chart review.
Results: 53 pregnant women with T1D (23 with at least one episodes of SH during pregancy and 30 without SH) and 52 control women and their offspring were included in this analysis. There were no differences between T1D mothers with SH and those without SH in terms of age, educational level, marital status, age at diagnosis, duration of diabetes, A1C at first antenatal visit or presence of microvascular disease. However, a history of 2 or more episodes of SH in the 12 months prior to pregnancy was associated with a threefold increased risk of SH during pregnancy (p<0.001). Insulin doses, frequency of mild hypoglycemia, weight gain and A1C throughout the pregnancy did not differ between the two diabetes groups. Mothers with T1D had higher rates of cesarian and induced delivery than the control group (p<0.005). Neonates born to both groups of mothers with T1D were more likely to have at least one blood glucose < 2.0 mmol/l and/or be admitted to NICU for hypoglycemia than the control group (p<0.01). No differences in terms of birth weight, gestational age, Apgar at 5 minutes, and neonatal complications were found among the 3 groups.
Discussion/conclusion: Women with 2 or more episodes of SH in the 12 months prior to becoming pregnant are at higher risk of SH during pregnancy. Women with T1D and at least one episode of SH during pregnancy were no different from the other women with T1D or women without diabetes in terms of maternal demographic characterisitcs, other diabetes control indices and health history factors. The occurrence of SH during pregnancy does not impact immediate neonatal outcome compared to the effects of diabetes alone.

[4] MDRC-CRCHUM Biotech Angus, Departments of Nutrition and Medicine, Montreal QC, Canada

Reduced lipolysis in hormone-sensitive lipase (HSL)-deficient mice is associated with impaired glucose-stimulated insulin secretion (GSIS), suggesting that endogenous ß-cell lipid stores provide signalling molecules for insulin release. Measurements of lipolysis and triglyceride (TG) lipase activity in islets from HSL$^{-/-}$ mice indicated the presence of other TG lipase(s) in the ß-cell. Using RT-QPCR, adipose triglyceride lipase (ATGL) was found to be the most abundant TG lipase in rat islets and INS832/13 cells. To assess its role in insulin secretion, ATGL expression was decreased in INS832/13 cells (ATGL-KD) by small hairpin RNA. ATGL-KD increased the esterification of free fatty acid (FFA) into TG. ATGL-KD cells showed decreased glucose- or Gln + Leu-induced insulin release, as well as reduced response to KCl or palmitate at high, but not low, glucose. The KATP/amplification pathway of GSIS was considerably reduced in ATGL-KD cells. These data in ATGL-KD cells were confirmed by using a transgenic mouse lacking ATGL. ATGL$^{-/-}$ mice were hypoinsulinemic, hypoglycemic, and showed decreased plasma TG and FFAs. A hyperglycemic clamp revealed increased insulin sensitivity and decreased GSIS and arginine induced insulin secretion in ATGL$^{-/-}$ mice. Accordingly, isolated islets from ATGL$^{-/-}$ mice showed reduced insulin secretion in response to glucose, glucose + palmitate and KCl. Islet TG content and FFA esterification into TG were increased by 2 fold in ATGL$^{-/-}$ islets, but glucose usage and oxidation were unaltered. The results demonstrate the importance of ATGL and intracellular lipid signalling for fuel and non-fuel induced insulin secretion.

AMPK activity in pancreatic ß-cells and in insulin-expressing neurons regulates ß-cell mass, glucose-regulated insulin secretion and glucose homeostasis

G. Sun[1], I. Leclerc[2], N. Harun[1], G. da Silva Xavier[1], B. Viollet[3], G.A. Rutter[1]
[1] *Imperial College, Cell Biology, London, United Kingdom*
[2] *Imperial College, Endocrinology & Metabolic Medicine, London, United Kingdom*
[3] *Institut Cochin, CNRS (UMR 8104), Paris, France*

Aims: AMP-activated protein kinase (AMPK) is a key regulator of cellular energy metabolism and a drug target for metformin and thiazolinediones. Whilst changes in AMPK activity in liver and muscle regulate blood glucose directly, hypothalamic AMPK is involved in the central control of glucose homeostasis. Here, we explore the effects of forced-changed AMPK activity in pancreatic beta cells and insulin expressing neurons, in vivo, using transgenic and knockout mice for AMPK.
Methods: Transgenic mice expressing constitutively-active (AMPK CA) or dominant-negative (AMPK DN) forms of AMPK under the control of a 0.6 kb proximal fragment of the rat insulin promoter 2 (RIP2) promoter were generated. Whole body knock out mice for AMPK alpha1 catalytic subunit were crossed with mice carrying a floxed allele of the AMPK alpha2 catalytic subunit and subsequently bred with animals carrying Cre recombinase under the RIP2 promoter to generate RIP-AMPKa2$^{-/-}$/a1$^{-/-}$ mice.
Mice underwent intraperitoneal glucose tolerance test (IPGTT) using 1 g/kg body weight for measurement of blood glucose (Roche, Accuchek glucometer) or 3 g/kg body weight for measurement of plasma insulin (Merchodia, ultrasensitive rat insulin ELISA). Intraperitoneal insulin tolerance tests (IPITT) were performed using 0.75U bovine insulin/kg mouse weight. Glucose-induced insulin secretion (GIIS) from isolated islets was measured after batch incubation with 3 or 16.7 mmol/l glucose. Secreted and total insulin were quantified by radioimmunoassay using I^{125}-labeled insulin. All experiments were approved by UK Home Office according to Animals (Scientific Procedures) Act, 1986.
Results: Male RIP-AMPK CA mice displayed glucose intolerance at 12 weeks (AUC for transgenic, 13.3 ± 0.4 vs. 11.6 ± 0.3 x 10^2min.mmol/L for controls; n=9; mean ± SEM) and 25 % lower ß-cell mass (0.68 ± 0.05 % vs. 0.9 ± 0.04% pancreatic surface in controls, $p < 0.05$, n=3 mice per genotype). Isolated islets from RIP-AMPK CA mice displayed 20 % increase in AMPK activity at 16.7 mmol/l glucose and GIIS (16.7 vs 3 mmol/l glucose) from these islets was reduced to 0.28 ± 0.03 %/ 30 min from 0.59 ± 0.13 %/ 30 min in controls; n =4, p = 0.03.
Whilst glucose tolerance and ß-cell mass were normal in RIP-AMPK DN mice, isolated islets displayed a 30 % decrease in AMPK activity at 3 mmol/l glucose. RIP-AMPKa2$^{-/-}$/a1$^{-/-}$ mice however, displayed grossly abnormal glucose tolerance (AUC for KO, 16.7 ± 0.70 vs. 12.4 ± 0.3 mmol/L for controls; n=3; mean ± SEM) and undetectable insulin secretion ***in vivo***. However, GIIS was normal in isolated islets and IPITT showed increased peripheral insulin sensitivity.
Conclusion: AMPK is indispensible in beta cells and insulin-expressing neurons for normal regulation of glucose homeostasis and insulin secretion, most likely through a central effect. However, sustained activation of AMPK in these tissues impairs insulin secretion and decreases beta cell mass.

Augmented cycling of ß-cell triglyceride stores contributes to enhanced glucose-stimulated insulin secretion in PKCe null mice

J. Cantley[1], G.L. Pearson[1], C. Schmitz-Peiffer[1], M. Leitges[2], T.J. Biden[1]
[1] *Garvan Institute of Medical Research, Diabetes and Obesity Program, Sydney NSW, Australia*
[2] *University of Oslo, Biotechnology Centre of Oslo, Oslo, Norway*

Aims: Deletion of protein kinase C epsilon (PKCe) has been shown to protect mice from high fat diet induced glucose intolerance by enhancing glucose stimulated insulin secretion (GSIS). The amplifying pathways of GSIS allow glucose to increase insulin secretion independently of the K^+ATP channel dependent triggering pathway. Lipid signalling processes such as lipid partitioning, lipolysis and lipid cycling have been implicated in modulating GSIS. Therefore, the aim of this study was to test the involvement of lipid signalling processes in the up-regulation of GSIS in PKCe knock-out (KO) islets.
Methods: Islets were isolated and cultured for 48 hours in DMEM containing 0.92% BSA coupled to 0.4mmol/l palmitate (lipid). Secretion experiments were performed by batch incubation in KRB containing either 2mmol/l or 20mmol/l D-glucose. Diazoxide (100µM) and KCl (25mM) were used to test the amplifying pathways of GSIS. Orlistat (200µM) was used to inhibit lipolysis. Lipid flux was assessed using [^{14}C]palmitate, [^{3}H]triglyceride and glycerol release. Statistical significance was determined by t-test.
Results: We detected an enhancement of GSIS (wt 334 ±42, PKCeKO 1086 ±218, pg/islet/hour, n=10, P<0.01) and amplifying pathway GSIS (wt 3794 ±385, PKCeKO 6206 ±689, pg/islet/hour, n=6, P<0.01) in lipid cultured PKCeKO islets. This enhancement of GSIS was associated with increased esterification of exogenous palmitate into triglyceride pools (wt 2778±184, PKCeKO 3602 ±185, ^{14}C counts per min, n=11, P<0.01), increased lipolysis (wt 247±30, PKCeKO 369 ±40, pmol glycerol released/150islets/hour, n=7, P<0.05) and increased triglyceride lipase activity (wt 733 ±31, PKCeKO 879 ±33, pmol substrate hydrolysed/mg protein/min, n=5, P<0.05). Inhibition of lipolysis by orlistat treatment of islets during secretion experiments completely normalised the enhanced GSIS (wt 357 ±58, PKCeKO 509 ±116, pg/islet/hour, n=9, ns) and amplifying GSIS (wt 4071 ±1070, PKCeKO 3734 ±617, pg/islet/hour, n=9, ns) in lipid exposed PKCeKO islets.
Discussion/conclusions: These data show that lipid cultured PKCeKO islets are a model of enhanced amplifying GSIS. The enhanced GSIS is coupled by enhanced lipolysis and correlates with increased triglyceride formation, indicating increased cycling of lipids through the triglyceride pool. Therefore we provide evidence for a lipid derived signal involved in GSIS coupling, and implicate PKCe in this process. As PKCeKO mice are protected from high-fat-diet-induced glucose intolerance, up-regulation of GSIS by inhibition of PKCe in humans may represent a potential novel treatment for type 2 diabetes.

Knockout of Nck-1 in mice results in important loss of pancreatic islets but enhances beta cell insulin levels

L. Yamani[1], M. Latreille[2], G. Bourret[1], L. Larose[1]
[1] *McGill University, Medicine, Montreal, Canada*
[2] *Institut of Molecular Systems Biology, Medicine, Zurich, Switzerland*

Pathogenesis of type 2 diabetes is characterized by pancreatic ß-cell dysfunction and apoptosis. A better understanding of the mechanisms regulating pancreatic ß-cell function is crucial to develop new strategies to prevent diabetes. Here, we report physiological evidence for an important role for the Src homology domain-containing adaptor protein Nck-1 in pancreatic islets homeostasis. Mice in which the Nck-1 gene has been deleted are smaller than their wild type littermate, but this difference disappears after three months of age. Five month old Nck-1 KO mice are virtually identical to the wild type mice in terms of body and individual tissues weights, and food consumption. Nck-1 KO mice also present normal blood glucose and insulin levels, and no noticeable change in insulin sensitivity in spite of impaired tolerance to glucose in glucose tolerance test ***in vivo***. Essentially, similar glucose intolerance has been observed in mice lacking Nck-2, an Nck isoform that shares about 68% identity with Nck-1. This suggests that both Nck adaptors could have a redundant role in modulating glucose tolerance in mice. Examination of the pancreatic islets reveals that Nck-1 KO mice harbor fewer and smaller pancreatic islets, but have normal architecture of a-cells surrounding a central core of ß-cells. Furthermore, no sign of apoptosis can be detected by TUNEL assay in Nck-1 KO mice pancreatic islets. Surprisingly, Nck-1 KO pancreatic islets contain significant higher levels of insulin and release insulin proportionally to their content ***in*** vitro, thus release higher levels of insulin in response to glucose stimulation. These findings suggest that decreased glucose tolerance in Nck-1 KO mice might not be due only to ß-cell defects. Additional investigations are underway to define the mechanism by which Nck adaptor proteins influence pancreatic islets homeostasis.

GIP and GLP-1 normalize glucose tolerance by normalizing islet adaptation to insulin resistance without increasing glucose effectiveness in high-fat fed mice

B. Ahrén[1], G. Pacini[2]
[1] *Lund University, Clinical Science, Lund, Sweden*
[2] *National Research Council, Institute of Biomedical Engineering, Padua, Italy*

Aims: Insulin resistance is adaptively compensated by increase in insulin secretion and glucose effectiveness. However, these adaptations are inadequate in mice after high fat feeding that yields markedly reduced glucose elimination

after intravenous glucose. We investigated whether these defective adaptations can be normalized by the incretin hormones glucose-dependent insulinotropic polypeptide (GIP) and glucagon-like peptide-1 (GLP-1).

Methods: C57BL/6J mice were fed a normal chow (ND 11%) or a diet with 60% fat for 8 weeks (HD). After a baseline blood sample was taken, a bolus injection of glucose at 35 g/kg with or without addition of synthetic GIP or GLP-1 (at 0.03, 0.3 or 3 nmol/kg) was given intravenously followed by six blood samples taken within 50 (ND) or 75 min (HD) for analysis of glucose and insulin. Data were analyzed with minimal model that provides insulin sensitivity index (SI) and glucose effectiveness (SG). Insulin secretion was assessed as the increase in insulin levels during the first 5 min after injection (dAIR), and glucose elimination was estimated as the percent reduction of glucose (after logarithmic transformation) during the first 20 min after administration (K_G). ß-cell adaptation was calculated as SI×dAIR (disposition index, DI) and ß-cell function as delta peak insulin/delta peak glucose.

Results: K_G was lower in HD fed mice (P<0.001). At 0.03 nmol/kg, neither GIP nor GLP-1 significantly affected K_G in HD; at 0.3 nmol/kg, the incretins significantly increased K_G, but not to normal values. However, at 3 nmol/kg, K_G was completely normalized by both GIP (2.28±0.22, n=11) and GLP-1 (1.96±0.24, n=17). As can be seen in the Table, this was associated with markedly increased dAIR and ß-cell function (p<0.001); S_I was not affected, but the resulting DI was completely normalized. In contrast, S_G, which was increased by HD, was slightly reduced, but not normalized, by the incretins.

	ND (n=48)	HD (n=49)	HD with incretins (n=28)
Body weight (g)	22.1±0.2	35.6±0.9	36.6±1.2
K_G (% min^{-1})	1.96±12	1.35±0.10	2.10±0.20
S_I (min^{-1}/(pmol/l))	1.14±0.09	0.51±0.06	0.56±0.04
dAIR (pmol/l)	1096±69	594±64	2207±151
DI	12.8±1.3	2.8±0.4	12.7±1.2
S_G (min^{-1})	0.040±0.002	0.096±0.010	0.074±0.006
ß-cell sensitivity	134±9	69±7	273±26

Discussion: We conclude that GIP and GLP-1 completely normalize the glucose elimination in severe insulin resistance in mice after high-fat feeding by normalizing the disposition index; this derives from marked upregulation of the islet adaptation to insulin resistance without any effect on insulin sensitivity and with no improvement of insulin-independent mechanisms of glucose elimination.

Angiotensin II type 1 receptor inhibition protects human islets from the effects of glucose on oxidative stress and angiogenesis

S. Dubois[1], A.m. Madec[1], A. Mesnier[1], M. Armanet[2], K. Chikh[3], T. Berney[2], C.h. Thivolet[1]

[3] *Centre Hospitalier Lyon Sud, Laboratoire De Biophysique, Lyon, France*

Aim: Data from prospective studies suggest a significant reduction in the risk of type 2 diabetes after blockade of the renin angiotensin system (RAS). Since RAS has been found in pancreatic islets and the surrounding capillary network, we hypothesized that these beneficial effects could be attributed to direct actions on islet micro vessels. Our study examined the direct actions of glucose and the Angiotensin II receptor blocker Losartan on isolated human beta cells.

Methods: Human islets from 8 distinct donors were studied following 96 hrs in culture in presence of normal (5.5 mmol/l) or high (16.7 mmol/l) glucose concentrations with or without 5 µmol/l Losartan. The levels of specific gene transcripts were studied by real-time polymerase chain reaction and angiogenesis-related protein expression using protein arrays. Expression of CD31 were studied by indirect immunofluorescence and insulin secretion was monitored by IRMA.

Results: Insulin secretion was significantly increased by 8.5 times at 16.7 mmol/l glucose for 4 days when compared to 5.5 mmol/l glucose (55.4 ± 21.4 vs 13.5±11.5 mUI/L/prot (µg/ml), 8 independent islet preparations, p=0.006). Indirect immunofluorescence staining showed that glucose reduces the number of CD31+ endothelial cells. We found that high glucose had significant effects on angiogenic markers such as a decrease in VEGF mRNA and protein expression levels (20% and 64%, p=0.05 and $p=3.10^{-6}$, respectively). Protein arrays showed that high glucose reduced expression of additional factors such as IGFBP2 by 53% ($p=5.10^{-7}$) or IL8 by 24% (p=0.008). Gene expression of NADPH oxidase subunits (Nox2, NDUFa9) and NRF1 was not modified by high glucose; but Ros levels were significatively 60% up-regulated by high glucose (p=0.02). These effects of glucose on Ros levels were partially abrogated (Ros levels decreasing by 52%) by Losartan. Furthermore, Losartan was able to reverse effects observed on protein expression of some angiogenic markers. Indeed while glucose decreased protein expression of VEGF, IGFBP2 and IL8, Losartan partially tended to reverse VEGF reduction (25% reversal increase, p=0.08) and completely reversed reduction of IGFBP-2 (p=0.002) and IL8 (p=0.02).

Discussion/conclusion: These data suggest that glucose reduces islet angiogenesis, and increases oxidative stress. Blockade of islet RAS might prevent these modifications. These data may have important clinical consequences both for prevention of type 2 diabetes and islet preconditioning prior to cell transplantation. In perspective, we will study effects of glucose and Losartan on markers involved in mitochondrial and endoplasmic reticulum stress.

TNF-[alpha] or IL-1ß induced nuclear factor-[kappa]B activation has a pro-apoptotic effect in pancreatic ß-cells

R. Eldor[1], K.H. Baum[1], L. Amior[1], D. Sever[1], R. Abel[1], D. Melloul[1]

[1] *Hadassah Medical Center, Internal Medicine, Jerusalem, Israel*

Type 1 diabetes is characterized by the infiltration of inflammatory cells into pancreatic islets, followed by the selective and progressive destruction of insulin-secreting ß-cells. Apoptosis has been proposed to be the main form of ß-cell death at the onset of T1D and following islet transplantation. Cumulative evidence suggests that the pro-inflammatory transcription factor NF-kB (nuclear factor[kappa]B) could be an important cellular signal in initiating a cascade of events that leads to ß-cell death. To investigate the role of NF-kB in the destruction/survival of ß-cells, the transgenic mouse line TolB (for Tet-on delta I[kapp]B in ß-cells) was generated. In these mice, NF-kB activation is specifically inhibited in ß-cells by the expression of a non-degradable IkB transgene ([delta]NIkBa) in an inducible and reversible manner using the ***tet-on*** gene regulation system. We show that, inhibition of the NF-kB pathway protects isolated islets from cytokine-induced apoptosis ***in vitro,*** and from multiple low doses streptozocin induced diabetes ***in vivo,*** along with reduced intra-islet lymphocytic infiltration.

Aims: To further study the role of the different cytokines IL-1ß, TNF-[alpha] and IFN-[gamma], in inducing ß-cell death or survival. The principal aim is to resolve the controversial issue of NF-kB activated by TNF-a which leads to ß-cell survival.

Methods: Islets isolated from TolB mice were treated with TNF-a (100U/ml), IL-1ß (50 U/ml) or INF-g (1000 U/ml) in the presence or absence of doxycycline which turns on the [delta]NIkBa transgene. We then assessed the NF-kB nuclear translocation by EMSA, nitric oxide (NO) production using Greiss assay, apoptosis evaluated by TUNEL assay and target gene expression by real time RT-PCR.

Results: Exposure to IL-1ß +IFN-g or TNF-a + IFN-g induced NF-kB nuclear translocation, NO production and ß-cell apoptosis. NO production, apoptosis and NF-kB target gene induction where significantly more prominent after exposure to IL-1ß +IFN-g than to TNF-a + IFN-g. Induced islets expressing the [delta]NIkBa protein were resistant to the deleterious effects of both IL-1ß +IFN-g and TNF-a + IFN-g.

Conclusion: Our results show that NF-kB activation is pro-apoptotic in ß-cells when induced either by IL-1ß or TNF-a in combination with IFN-g. Furthermore, this pro-apoptotic effect is more robust after IL-1ß exposure perhaps due to a sustained activation of NF-kB and to the pattern of expression NF-kB target genes. These results underscore the key role played by NF-kB in ß-cell destruction. The effects of temporal NF-kB blockade in the survival of ß-cells in transplanted islets expressing the [delta]NIkBa inducible transgene, is under investigation.

[5] *University of Sydney, Centre for Vision Research Westmead Millennium Institute, Sydney, Australia*

[6] *The Queen Elizabeth Hospital, Endocrinology, Adelaide, Australia*

Aims: To develop and validate a diabetes risk assessment tool for Australia based on demographic, lifestyle and simple anthropometric measures.

Methods: 6,060 participants from the Australian Diabetes, Obesity and Lifestyle study, aged over 25 years without diagnosed diabetes at baseline were followed up for 5 years. Diabetes was defined at follow-up by pharmacological treatment or diagnostic levels for diabetes of fasting and 2-hour glucose from an oral glucose tolerance test. A total of 19 variables were considered for inclusion in the risk prediction model. They were age, gender, country of birth, education, occupation, total household income, consumption of fruit or vegetables, alcohol intake, smoking, leisure-time physical activity, television viewing time, parental history of diabetes, history of high blood glucose, use of anti-hypertensive medications, lipid-lowering treatment, history of angina, heart attack or stroke, body mass index, waist and hip circumferences. The risk prediction model was developed using logistic regression and converted to a simple scoring system. The validity of the tool was evaluated in two independent Australian cohorts using areas under the receiver operating characteristic curve (AROC) and the Hosmer-Lemeshow (HL) x^2 statistic.

Results: 362 people (194 men, 168 women) developed incident diabetes over the 5-year follow-up. Age, gender, country of birth, parental history of diabetes, history of high blood glucose, use of antihypertensive medications, smoking, physical inactivity and waist circumference were included in the final risk prediction model. The AROC of the diabetes risk prediction model was 0.78 (95% CI 0.76-0.81) and HL x^2 statistic was 4.1 (P=0.85). A score of 12 or higher (maximum 35) corresponded to the point on the receiver operating characteristic curve at which sensitivity (74.0%) and specificity (68.5%) were maximised, with a positive predictive value of 12.7%. Using a score of 15 or higher, the sensitivity, specificity and positive predictive value for identifying incident diabetes were 54.3%, 83.1% and 16.9%, respectively. The AROC and HL x^2 statistic in the two independent Australian cohorts were 0.66 (95% CI 0.60-0.71) and 9.2 (P=0.32), and 0.79 (95% CI 0.72-0.86) and 29.4 (P=0.0003), respectively.

Conclusion: This tool provides a simple, noninvasive method for Australian adults for identifying those at high risk of type 2 diabetes who may benefit from interventions to prevent or delay the onset of type 2 diabetes.

A comparison of screening strategies for impaired glucose tolerance and type 2 diabetes mellitus in a UK community setting: a cost per case analysis

K. Khunti[1], N.A. Taub[1], C.L. Gillies[1], K.R. Abrams[1], L.J. Gray[1], S.L. Hiles[2], D. Webb[2], B.T. Srinivasan[2], M.J. Davies[2]

[1] *University of Leicester, Department of Health Sciences, Leicester, United Kingdom*

[2] *University of Leicester, Department of Cardiovascular Sciences, Leicester, United Kingdom*

Aims: Universal screening for vascular risk is to be introduced in the UK in April 2009, for people over 40 years. As this will have a substantial impact on health care resources, it is essential to investigate different methods for pre-screening people at high risk. Currently, there is no systematic or structured screening policy for T2DM in most countries. The aim of this study was to assess effectiveness and cost efficiency of a combination of different screening methods for undiagnosed T2DM and impaired glucose regulation (IGR included IGT and/or IFG) in a multi-ethnic community setting.

Methods: A random sample of people aged 40-75 years from 24 general practices in Leicestershire were invited for a 75g OGTT. Participants provided a detailed medical history, anthropometric measurements and completed the FINDRISC questionnaire.

Clinical effectiveness was compared using sensitivity, specificity, and area under the ROC curve. We compared 17 approaches to screening involving FINDRISC and our own Leicester self-assessment (LSA) and Leicester primary-care-data (LPD) risk scores, in addition to fasting glucose and HbA1c.

The cost-effectiveness of tests was assessed by 'cost per case', i.e. the total estimated cost of screening a specified population, modeling cost components such as nursing cost rates, nursing time, administration and lab test costs. This is then divided by the number of cases identified, as estimated using test sensitivity values from the study sample data. As an improvement on previous screening cost-effectiveness models, these models were run within a Bayesian framework, using a simulation-based approach that incorporates uncertainty around both the estimated costs and sensitivity values.

Results: 6749 individuals participated: the age range was 25-75 years (SA) and 40-75 (WE); mean age was 56.1(SD 10.8), 47.7% were male and 27.5% were of south Asian ethnicity. 6372 individuals (94.4%) had all relevant data recorded and were included in analysis; of these 202 (3.2%) were diagnosed at OGTT with screen-detected T2DM, and an additional 902 (14.2%) were diagnosed with IGR.

Estimated cost implications varied substantially for the 212 screens we considered; results for three screens are shown in the Table.

Discussion/conclusion: The suggested strategies provide a number of tools for screening people for T2DM and IGR. A stepwise screening strategy using self-assessment or practice routine data to calculate a risk score, followed by a FPG or HbA1c is an efficient screening strategy for detecting T2DM and T2DM/IGR in a community setting.

Stage 1	Stage 2	Stage 3	Proportion to OGTT (%)(SE)		Est. cost per T2DM case detected (€/$)(SE)	
HbA1c =6.0	OGTT		22.3	(0.5)	1713/2306	(55/74)
LSA=14	HbA1c=5.8	OGTT	29.8	(0.6)	1245/1676	(51/69)
LPD=5.00	HbA1c=6.0	OGTT	18.8	(0.5)	931/1253	(42/57)

Diagnostic criteria for impaired glucose regulation based on an HbA1c=6.0% lacks sensitivity in White Europeans but not South Asians

D.R. Webb[1], K. Khunti[2], L.J. Gray[2], B.T. Srinivasan[1], S. Hiles[2], S.A. Mostafa[1], A. Farooqi[2], S. Griffin[3], N. Wareham[3], M.J. Davies[1]

[1] *University of Leicester, Cardiovascular Sciences, Leicester, United Kingdom*

[2] *University of Leicester, Health Sciences, Leicester, United Kingdom*

[3] *University of Cambridge, MRC Epidemiology Unit, Cambridge, United Kingdom*

Introduction: HbA1c% may become the preferred screening modality for identifying the glucose-specific determinants of cardiovascular risk and individuals at risk of diabetes. The impact of revised diagnostic criteria using HbA1c% rather than glucose indices to define Impaired Glucose Regulation (IGR) and Type2 Diabetes (T2DM) in a multi-ethnic setting is unknown.

To report sensitivity and specificity for HbA1c% cut-offs defining IGR as =6.0% and T2DM as =6.5% within White European (WE) and South Asian (SA) UK groups.

Methods: We analysed baseline data from a prospective screening study for IGR and T2DM (ADDITION-Leicester). Leicester is a UK urban center with a significant SA Indian (40%) population. A population sample of 36,000 40-75 (WE) and 25-75 (SA) year olds were invited for an OGTT, HbA1c% and cardio-vascular risk assessment.T2DM and IGR (composite of Impaired Fasting Glycaemia (IFG), Impaired Glucose Tolerance (IGT) and T2DM) were defined using standard WHO criteria from OGTT results.

Results: 6,749 (48%Male 25%SA) subjects responded (22% response rate) with age unadjusted prevalences of IGR 19% (WE:16% SA:20%) IFG 5% (WE:4% SA:5%) IGT 13% (WE:11% SA:13%) and T2DM 3% (WE:3% SA:5%).

see table 1

Conlusion: Defining IGR by an HbA1c=6.0% or fasting glucose of =6.0mmol/l lacks sensitivity in WE 40-75 year olds. The higher prevalence of IGT in SAs limits the usefulness of fasting glucose but may enhance the sensitivity of an HbA1c% IGR cut-off of =6.0 in this group. Defining T2DM by an HbA1c=6.5 will result in approximately 30% of those currently diagnosed using an OGTT via WHO not meeting revised T2DM criteria. This may have important implications for micro- and macro-vascular surveillance.

HbA1c and prediction of diabetes: Inter99, AusDiab and D.E.S.I.R.

S. Soulimane[1], D. Simon[1], J.E. Shaw[2], P.Z. Zimmet[2], K. Borch-Johnsen[3], D. Vistisen[3], S. Vol[4], B. Balkau[1]
[1] INSERM U780, 94807, Villejuif, France
[2] Baker IDI Heart and Diabetes Institute, 3004, Melbourne, Australia
[3] Steno Diabetes Center, 2820, Gentofte, Denmark
[4] IRSA, 37521, La Riche, France

Background: In the past HbA1c had not been validated as a diagnostic tool for diabetes, mainly because the assay was not standardized. HbA1c use for diabetes diagnosis is now again proposed as there is a new reference assay. We compare the performances of HbA1c and fasting plasma glucose (FPG) for predicting incident diabetes in three cohort studies.
Methods: Data are from three cohorts: Danish (Inter99, baseline 2000), Australian (AusDiab, 2000) and French (D.E.S.I.R., 1994) with respectively 4630, 5770 and 3858 men and women, aged 30-60 (mean 46 years), 25-88 (51 years), 30-65 (47 years). Diabetes incidences were estimated at five years for Inter99 and AusDiab, and at six years for D.E.S.I.R. Diabetes was defined by diabetes treatment or FPG≥7.0 mmol/l or 2-h plasma glucose (2-hPG)≥11.1 mmol/l excepting for D.E.S.I.R where 2-h PG was not available. In each of the three cohorts, we evaluated the incidence and show smoothed incidence curves, and the positive predictive values for diabetes, of HbA1c, and FPG.
Results: The cohorts were analysed separately. The HbA1c distributions differed: Inter99 (mean±SD, 5.9±0.4%), AusDiab (5.5±0.3%), D.E.S.I.R (5.4±0.4%) in contrast to similar FPG, respectively 5.4±0.5 mmol/l, 5.5±0.5 mmol/l, 5.3±0.5 mmol/l. The incidence of diabetes was 3.0% in D.E.S.I.R, 3.4% in AusDiab, higher in Inter99: 4.5%. For HbA1c, the incidences and the positive predictive values for diabetes differ from one study to another; in contrast, for FPG, the cohorts show similar characteristics. Incidence and positive predictive value increased with increasing HbA1c and FPG.
Conclusion: In each cohort, incident diabetes is associated with HbA1c and FPG at baseline. The distributions of these two glycemic parameters differ between cohorts, more so for HbA1c.

O-0076

Leicestershire self assessment score for impaired glucose regulation for use in a multi ethnic setting

L.J. Gray[1], K. Khunti[1], N. Taub[1], S. Hiles[2], M.J. Davies[3]
[1] University of Leicester, Department of Health Sciences, Leicester, United Kingdom
[2] University Hospitals of Leicester, Department of Diabetes Research, Leicester, United Kingdom
[3] University of Leicester, Department of Cardiovascular Sciences, Leicester, United Kingdom

Introduction: One in five of those screened in the ADDITION-Leicester population based screening study had some form of Impaired Glucose Regulation (T2DM or impaired fasting glucose (IFG) or impaired glucose tolerance (IGT)) (IGR). Modelling studies have shown that early detection of IGR and appropriate intervention can decrease morbidity and early mortality from cardiovascular disease. Self assessment scores identify those at high risk and are particularly useful in populations where response rates to screening programmes are low. To date no self assessment scores have been developed and validated for multi ethnic populations.
Methods: We used data on 6,390 subjects aged 40-75 from the ADDITION-Leicester screening study from a multi ethnic UK setting (76% White European, 22% South Asian, 3% other). All participants were given a 75g Oral Glucose Tolerance Test. We developed logistic regression models for predicting IGR (IFG/IGT/T2DM) using data from self reported questionnaires. Using the best fitting model we developed the Leicester Self Assessment Score. Initial analysis was carried out using complete cases only, then missing data indicators were used as a check for robustness of the modelling. We externally validated the tool using data from 3,298 subjects aged 40-75 screened as part of a second screening study.
Results: The final model includes age, ethnicity (White European versus other – predominantly South Asian), sex, 1st degree family history, antihypertensive therapy or history of hypertension, waist circumference and body mass index. The score ranges from 0 to 47. Validating this model using the STAR data gives an area under the ROC curve of 71% (95% CI 68% to 74%). Using a cut point of 16 to predict those at high risk of IGR had a sensitivity of 82%, specificity of 47% and correctly classified 53% of cases.
Conclusions: The Leicester Self Assessment Score can be used to reliably identify those at high risk of IGR in multi ethnic populations. The score is simple (7 questions) and non invasive.

Prevalence of impaired fasting glucose, type 1 and 2 diabetes in a Spanish working population stratified by occupational categories. ICARIA-DM study

M. Cabrera[1], E. Calvo[1], J. Román[1], M.A. Sánchez[1], A. Fernández[1], R.M. Pozas[1], R.I. Navarro[1], E. Navarro[2], F. Martín[2], A. Goday[3], J. Reviriego[4], E. Caveda[4]

[2] Ibermutuamur Health Surveillance Society, Occupational Medicine, Madrid, Spain
[3] Hospital del Mar, Department Of Endocrinology and Nutrition, Barcelona, Spain
[4] Lilly S.A., Department of Clinical Research, Madrid, Spain

Background and aims: An inverse relationship exists between social position and incidence of diabetes. Yet little is known about the relationship of occupational categories and the prevalence of impaired fasting glucose. One aim of the study was to know the prevalence of impaired fasting glucose (IFG), type 1 (T1DM) and type 2 (T2DM) diabetes, by occupational categories, within a nationwide working population.
Material and methods: This was a cross-sectional study of 375,607 workers, 72.3% male (M), mean age (SEM) of 36.87 (0.02) yr. All subjects underwent a routine medical check up from January 2007 to December 2007 at Ibermutuamur. A structured questionnaire, physical examination and standard serum biochemical analysis were performed. Workers were classified into nine major categories according to the 1994 Spanish national Classification of Occupations: Workers in the first four categories were grouped as non-manual (white collar) and workers in the last five categories as manual (blue collar). IFG was defined as a fasting glucose level between 100-125 mg/dl (without T1DM or T2DM diagnosis); T1DM (previous diagnosis of T1DM); T2DM (previous T2DM diagnosis or treatment or fasting glucose level ≥ 126 mg/dl.).
Results: 84.1% Males (M) and 94.3% females (F) showed a normal glycemic

table 1

		Sensitivity (95% CI)			Specificity (95% CI)		
		Total	**WE**	**SA**	**Total**	**WE**	**SA**
Fasting Glucose (mmol/l)	=6.0 (IGR)	43.2 (40-46)	44.7 (41-48)	44.3 (39-50)	98.7 (98-99)	98.6 (98-99)	99.0 (98-99)
	=6.5 (IGR)	21.0 (19-23)	20.9 (18-24)	26.2 (21-32)	99.9 (99-100)	99.9 (99-100)	99.9 (99-100)
	=7.0 (T2DM)	66.0 (59-73)	65.6 (57-74)	66.5 (54-77)	99.6 (99-100)	99.7 (99-100)	99.7 (99-100)
HbA1c%	=6.0 (IGR)	51.7 (49-55))	45.2 (42-49)	70.5 (65-76)	84.0 (83-85)	86.9 (86-88)	74.43 (72-77)
	=6.5 (T2DM)	70.4 (64-77)	64.8 (56-73)	79.4 (68-88)	96.9 (96-97)	98.1 (98-99)	93.7 (91-95)

profile. IFG, T2DM and T1DM prevalences (%) among M/F were as follows 12.6/4.7; 3.0/0.7 and 0.4/0.2, respectively.
Table 1 shows the prevalence of IFG/T2DM/T1D in the studied population stratified by occupational categories. Percentage (95% CI)

	IFG	T2DM	T1DM
White Collar	**7.3 (7.2-7.5) n=9710**	**1.5 (1.5-1.6) n=2070**	**0.3 (0.2-0.3) n=363**
General managers and government administrators	12.3 (11,5-13.0)	3.7 (3.3-4.2)	0.2 (0.1-0.3)
Scientific professionals, technicians, intellectuals	7.4 (7.1-7.6)	1.6 (1.3-1.6)	0.3 (0.2-0.3)
Support technicians and professionals	7.2 (7.0-7.4)	1.6 (1.5-1.7)	0.3 (0.2-0.3)
Clerks and related jobs	5.8 (5.5-6.1)	1.0 (0.9-1.1)	0.3 (0.2-0.3)
Blue Collar	**12.0 (11.9-12.2) n=29297**	**2.8 (2.8-2.9) n=6908**	**0.3 (0.3-0.3) n=775**
Catering and hospitality, personal and security service workers, and salesmen/women and shop assistants	8.7 (8.3-9.0)	1.8 (1.6-1.9)	0.3 (0.2-0.3)
Skilled workers in agricultural and fishing industries	13.6 (12.2-15.0)	3.9 (3.1-4.7)	0.6 (0.3-0.9)
Craftsmen/women and skilled workers in manufacturing, construction and mining	12.9 (12.7-13.1)	3.1 (2.9-3.2)	0.3 (0.3-0.4)
Machine installers, operators, and assemblers	13.0 (12.7-13.2)	3.4 (3.2-3.5)	0.3 (0.3-0.4)
Unskilled workers	11.7 (11.4-11.9)	2.5 (2.4-2.7)	0.3 (0.3-0.4)
Total	**10.4 (10.3-10.5)**	**2.4 (2.3-2.4)**	**0.3 (0.3-0.3)**

Conclusion: In a nationwide Spanish working population, glycemic profile alterations are common. As in T2DM, the prevalence of IFG is high among workers with low occupational position (blue collar), but general managers, among white collar workers, have similar prevalence to manual workers. This is not true for T1DM. These data could serve as a basis for preventive programs.

The distribution of glycated hemoglobin (A1c) levels among U.S. adolescents during 1999-2006

D.B. Rolka[1], D.E. Williams[1], J. Saaddine[1], A. Albright[1], E.W. Gregg[1], G. Imperatore[1]
[1] Centers for Disease Control and Prevention, Division of Diabetes Translation, Atlanta, USA

Aim: To describe the distribution of A1c among adolescents without diagnosed diabetes in the U.S.
Methods: We used data from the National Health and Nutrition Examination Survey (NHANES) for the years 1999 through 2006. Our sample included 8214 non-pregnant youth 12 to 19 years of age without diagnosed diabetes, 3629 of whom completed a fasting glucose test. We defined impaired fasting glucose (IFG) as a fasting glucose level of 100 to 125 mg/dL. We defined overweight as having body mass index (BMI) greater than or equal to the 95th age-sex-specific percentile, and at risk for overweight as having BMI between the 85th and 95th percentiles. We estimated the mean and selected percentiles of A1c overall and by sex, age, race or ethnicity, weight status, and fasting glucose status.
Results: Among non-pregnant U.S. youth without diagnosed diabetes, mean and median A1c were 5.14%, and 5.11% respectively (see table). A1c levels were higher at all percentiles among males than females, among youth aged 12-15 y than those 16-19 y, and among non-Hispanic black youth than among Mexican American and non-Hispanic White youth. The highest levels of A1c were present among those with IFG (mean 5.27%), non-Hispanic blacks (5.25%) and overweight youth (5.22%). However, among the 8214 adolescents in our sample, only 35 (estimated 0.3% of the population) had an A1c level of 6% or greater. Only 6 of 415 participants (estimated 1.2% of the population) with IFG had A1c greater than or equal to 6%.

Table 2: Means and percentiles of A1c among U.S adolescents without diagnosed diabetes, 1999-2006.

Conclusions: The distribution of A1c varies in US adolescents. Small but significant differences between groups are present at all percentiles of the distribution. Very few adolescents have A1c values above 6%. More research is required to determine the health consequences of A1c level in youth without diabetes.

Type 2 diabetes diagnosed by the oral glucose tolerance test - evidence for a heterogeneous presentation of the disease

G.P. Carnevale Schianca[1], C. Cerutti[1], F. Corlianò[1], E. Colli[1], E. Cornetti[1], G.P. Fra[1], E. Bartoli[1]
[1] Clinica Medica Generale AOU "Maggiore della Carità", Dipartimento di Scienze Mediche, Novara, Italy

Aims: early recognition of high-risk subjects for type 2 diabetes, which is occurring in epidemic proportions worldwide, is a public health goal. Despite attempts to lower FPG cut-off values to diagnose diabetes without resorting to the OGTT, the latter is more sensitive than FPG alone in detecting diabetes or prediabetes. Our goal was to explore the ability of OGTT in detecting sub-groups of diabetics with different clinical-laboratory features.
Methods: we executed OGTT in 1277 non diabetic subjects (583 men and 694 women), who presented risk factors like obesity, hypertension, diabetes, family history of metabolic abnormalities and dyslipidemia. By ADA criteria, 103 subjects (8.1%), 52 men and 51 women, were found to be affected by type 2 diabetes. On the basis of the accepted glycemic cut-off values for diagnosing type 2 diabetes (FPG > 125 and/or 2h plasma glucose, 2hPG, = 200 mg/dl), the 103 newly recognized diabetic subjects were divided in 3 sub-groups. Group A: FPG > 125 and 2hPG <200 mg/dl (n = 22, 7 women); group B: FPG = 125 and 2hPG = 200 (n = 55, 30 women); group C: FPG >125 and 2hPG = 200 mg/dl (n = 26, 14 women). In all these new diabetic subjects we considered age, BMI, waist circumference (WC), diabetes inheritability and calculated the estimated insulin sensitivity (EISI) and the first phase of insulin secretion (1fsPH) by OGTT data combined to associated plasma insulin measurements (FPI and 2hPI).
Results: Age, BMI, WC, diabetes inheritability and sex distribution were not different among the three sub-groups. EISI was significantly lower in group B than group A, 2hPI and 1fsPH significantly higher than that calculated in group C. In group A, 1fsPH was significantly higher than in group C.
Discussion: A diabetic subject with isolated high 2hPG has impaired insulin sensitivity as compared to a diabetic subject with isolated high FPG. When both these glycemic values are high, a crucial worsening of insulin secretion is evident. These data are consistent with a heterogeneous presentation of type 2

table 2

			Percentile				
	Mean	95% CI	10th	25th	50th	75th	90th
All Youth	5.14%	5.13% to 5.16%	4.79%	4.96%	5.11%	5.28%	5.43%
Male	5.16%	5.15% to 5.18%	4.81%	4.97%	5.13%	5.30%	5.50%
Female	5.12%	5.10% to 5.13%	4.77%	4.94%	5.08%	5.25%	5.40%
12-15 y	5.17%	5.15% to 5.18%	4.83%	4.97%	5.14%	5.30%	5.49%
16-19 y	5.12%	5.10% to 5.13%	4.77%	4.94%	5.08%	5.25%	5.40%
Mexican American	5.16%	5.14% to 5.18%	4.85%	4.97%	5.12%	5.29%	5.40%
Non-Hispanic white	5.10%	5.08% to 5.12%	4.78%	4.94%	5.08%	5.22%	5.38%
Non-Hispanic black	5.25%	5.23% to 5.27%	4.79%	5.04%	5.25%	5.41%	5.60%
Normal weight	5.12%	5.11% to 5.14%	4.78%	4.95%	5.09%	5.26%	5.40%
At risk for overweight	5.14%	5.12% to 5.16%	4.80%	4.96%	5.11%	5.27%	5.41%
Overweight	5.22%	5.20% to 5.24%	4.86%	4.99%	5.17%	5.34%	5.54%
Normal fasting glucose	5.13%	5.11% to 5.15%	4.79%	4.96%	5.10%	5.26%	5.40%
IFG	5.27%	5.24% to 5.30%	4.91%	5.07%	5.25%	5.40%	5.59%

diabetes, which is detectable by a simple method like OGTT, thus allowing the possibility of specific treatments. Finally, it is noteworthy that OGTT permitted the diagnosis of a greater proportion of newly recognized type 2 diabetics (55/103, 53.4%) who would have been considered non-diabetic had FPG alone been used. These patients would not have been treated for diabetes. Based on FPG alone, only 26 patients would have been correctly detected without OGTT, whereas 22 had a 2hPG <200 mg/dl, thus requiring a different therapeutic management than true diabetics.

Effective education: process and outcome

O-0080

Best and promising practices in diabetes education

J. Guimond[1], S. Khan[1], A. Kuntz[1]
[1] Canadian Diabetes Association, Research Professional Education and Government Affairs, Toronto, Canada

Background: The Canadian Diabetes Association developed an evidence-based project to identify 'best' and 'promising' practices in diabetes education. An assessment tool identified these practices, and findings were disseminated to diabetes educators, health professionals, government and key decision makers of diabetes education programs.
Aims: The Association's goal is to increase the capacity for the creation of integrated, evidence-based, responsive diabetes education programs and services across Canada by improving awareness and knowledge of best and promising practices in diabetes education.
Method: The first phase of the project focused on selecting an assessment tool to review and identify practices as 'best' or 'promising'. The assessment tool consists of two sets of criteria: effectiveness and plausibility.
During the **second phase** of the project, an extensive search of published literature was undertaken, which provided a snapshot of existing Canadian and international diabetes education practices during a 10-year period (1997-2007).
Nominations were also solicited from all Canadian Diabetes Educator Sections to help identify practices that may not have been identified through the published literature.
In the **third phase** of the project, inclusion/exclusion criteria were applied to the results from the literature search in order to identify practices directly relevant to the search questions.
From the published literature, 258 articles were identified. Based on the inclusion/ exclusion criteria, 143 English- and 28 French-language articles (representing 137 different practices) were considered for assessment.
From the nomination process, 16 English- and 7 French-language nominations were considered for assessment.
Results: Of the 137 practices identified through the published literature and evaluated using the assessment tool, 18 were ranked as 'best,' 27 were ranked as 'promising,' 72 were ranked as 'to be watched' and 20 were ranked as 'do not include.' Of the 23 nominated practices, one was ranked as 'promising.'
Conclusion: Of the 45 best and promising practices contained within the catalogue, only two are from Canada and only one resulted from the nomination process. These results emphasize the need to evaluate diabetes education programs in Canada. The project has successfully contributed to the field of diabetes education by creating an accessible catalogue of best and promising practices that are evaluated and show positive health outcomes.

O-0081

ROMEO (Rethink Organization to Improve Education and Outcomes): A 4-year multicentre randomised controlled trial of Group Care for the management of type 2 diabetes.

M.Trento[1], M. Porta[1]
[1] Univeristy of Turin, Laboratory of Clinical Pedagogy Internal Medicine, Torino, Italy

Background and aims: We showed previously (Diabetes Care 27;670:2004) that type 2 diabetes (T2DM) is managed effectively by continuous systematic group education (Group Care), which substitutes traditional one-to-one visits with sessions centred on hands-on and problem-solving activities, role playing and discussions on motivation, diabetes acceptance, psychosocial and coping strategies. Sessions last 40-50 minutes, are held every 3-4 months and are followed by brief individual consultations with a physician. A multicentre clinical trial was organised to ascertain if Group Care would perform as well in diabetes clinics throughout Italy.
Patients and methods: 815 patients with non insulin-treated T2DM from 13 Italian clinics were centrally randomised to either Group or one-to-one Care. Operators were specifically trained and provided with a detailed operating manual and educational materials. At baseline, the 2 treatment groups were similar by age, gender, known duration of diabetes, BMI, HbA1c, lipids, quality of life, knowledge of diabetes and health behaviours, as assessed by questionnaires. Analysis was by intention-to-treat. 592 patients from 11 clinics completed the 4-year follow-up. Results are adjusted for participating centre, gender, family history for diabetes, schooling, occupation, years of attendance in clinic and baseline values of the relevant variables.
Results: After 4 years, the patients followed by Group Care had lower HbA1c [-1.49% (-1.63/-1.34)], fasting blood glucose [-19.1 mg/dl (-27.1/-11.1)], weight [-3.15 Kg (-4.21/-2.08)], BMI [-1.09 (-1.56/-0.62)], systolic [-4.4 mmHg (-7.3/-1.5)] and diastolic [-3.3 mmHg (-5.2/-1.3)] blood pressure, triglyceride [-44.8 mg/dl (-56.0/-33.5)] and total cholesterol [-25.7 mg/dl (-31.8/-19.5), and higher HDL cholesterol [+5.2 mg/dl (+3.5/+7.0)] than those followed by traditional care. They also had better quality of life [-16.8 (-18.3/-15.2)], knowledge [+10.6 (+8.9/+12.3)] and health behaviours [+4.2 (+3.8/+4.5)]. All differences were significant at $p<0.001$.
Conclusions: Group Care produces better clinical, cognitive and psychological outcomes than traditional one-to-one care when applied within a structured systematic programme. However, it requires re-organization of working practices, which may account for failure of two participating clinics in implementing it. (ROMEO was supported by an EFSD-Novo Nordisk grant for T2DM research in Europe)

A culturally appropriate diabetes self-management education network in community--evaluation of JSIDEM study (a multicenter,randomized and controlled pilot study)

Z.L. Sun[1], K.Y. Cai[2], W.F. Yao[3], W.N. Yu[4], C.G. Wu[5], J. Liang[6], F. Hua[7], C.P. Ju[1], L.L. Liu[1], J. Han[1]
[1] Zhongda Hospital Southeast University, Department of Endocrinology, Nanjing, China
[2] Xuzhou Kuangzong Hospital, Department of Endocrinology, Xuzhou, China
[3] Wuxi Second Hospital, Department of Endocrinology, Wuxi, China
[4] Huaian Second Hospital, Department of Endocrinology, Huaian, China
[5] Zhengjiang First Hospital, Department of Endocrinology, Zhengjiang, China
[6] Xuzhou Central Hospital, Department of Endocrinology, Xuzhou, China
[7] Changzhou First Hospital, Department of Endocrinology, Changzhou, China

Aims: To establish a culturally appropriate diabetes self-management education network in Jiangsu province of China (Jiangsu intensive diabetes education and management study, JSIDEM study) and to evaluate the outcomes such as the levels of diabetes knowledge, metabolic control and self-management skills.
Methods: A total of 664 patients with type 2 diabetes mellitus were recruited from seven hospitals in Jiangsu province of China and were assigned to intensive diabetes health education program (intensive group, n=376) or conventional education program (control group, n=288). The intensive group received diabetes self-management education for 5 sequential days followed by subsequent regular advice based on educational focus (information, lifestyle behaviors, glucose monitoring and self-management skills) by telephone, short messages or internet. In the control group, subjects received education once a week for up to five weeks (whole day each time) followed by regular

advice, and outcomes were classified as knowledge, glycemic control and self-management skills at baseline, 3 months, 6 months, and 12 months, using questionnaires and laboratory data.

Results: There were no significant difference between two groups in age, gender, diabetes duration, education level, work status, type of insurance, HbA1c, blood pressure, BMI and lipid profile at baseline. Over the 12 months of the study, intensive group showed an increase in knowledge scores, improvement in self-management skills, and reduction in HbA1c, BMI, blood pressure and lipid profile. HbA1c level in intensive group was reduced by 2.3% on average. The percentage of patients with HbA1c<6.5% was increased from 15.63% to 58.82% (3 months), 47.45%(6 months) and 40% (12 months) respectively(P<0.05). On the other hand, HbA1c level in control group was reduced by 1.63% on average. The percentage of patients with HbA1c<6.5% was increased from 7.69% to 25%(3 months), 10.34%(6 months) and 10.53%(12 months) respectively(P>0.05). The rate of patients' BMI meeting 25kg/m^2 criteria was elevated from 54.52% to 61.17% (3 months), 60.37%(6 months), 60.9%(12 months) respectively in intensive group(P<0.05). However, there was no significant difference in control group. Comparing blood pressure and lipid profile of the two groups after 3, 6 and 12 months intervention, there were no significant differences.

Conclusions: Evidence supports the positive effectiveness of DSME-net on knowledge, frequency and accuracy of self monitoring of blood glucose, self-reported dietary habits, and better glycemic control was demonstrated in the study with short follow-up (12 months).

O-0083

A specific educational approach aimed at improving lifestyle behaviour and reducing risk factors for 3,000 persons with diabetes in Burundi

V. La Hausse de Lalouviere[1], X. Debussche[2], M. Balcou Debussche[3]
[1] Association pour la Promotion de la Santé, Curepipe, Mauritius
[2] CHD Felix Guyon, St Denis, Reunion
[3] IUFM & University of Reunion Island, St Denis, Reunion

Aims: APSA is implementing an educational program in Burundi for people with diabetes, or at risk of developing cardiovascular diseases. Over a period of 3 years (2007-2010), 3000 people will be monitored in a project financed by the World Diabetes Foundation. An intermediate evaluation of a group of 292 individuals, who attended at least 2 educational sessions, has shown encouraging results.

Method: This approach to educating patients with diabetes is based around a minimum of 3 sessions (The learning nest). Subjects covered include: cardiovascular risks, fat intake in the diet and managing physical activity. With the help of a specially developed manual, patients work in groups of 8 to 10, to acquire the necessary medical knowledge in an effective way, while taking into account individual, social, and cultural environments. Between 2007 and 2008, APSA, in collaboration with its training consultants, trained 27 doctors, 43 nurses and 23 educators from twelve public and private health structures in Bujumbura. Health care professionals work together to provide early detection of diabetes and the metabolic syndrome through targeted screening of risk factors. By March 2009, 1600 individuals had joined the educational network, attending sessions given by trained nurses and educators. During the first educational session, participants' modifiable risk factors were noted in their manuals. Proper monitoring and follow up of eating habits and lifestyle behaviour is possible over a period of 5 years.

Results: Of the 292 individuals who took part in a second educational session on 'how to reduce cardiovascular risks', in the first year, 38% improved their health status, 33% their blood sugar level, 28% their blood pressure, 24% reduced their waist circumference, and 36% stopped smoking. The most popular of the 10 choices of actions to be taken during the first educational session, was reducing fat intake in the diet, the second walking 30mins daily and the third reducing salt intake. During the second educational session participants could alter their choice to suit their daily lifestyle better, and 'reduction of refined sugar' became the 3rd most popular.

Discussion: The results bring a discussion on implementing a therapeutic educational approach that will generate long term compliance towards adopting healthy lifestyle behaviour in participants. This will reduce their modifiable risk factors, and help them avoid diabetes complications, in a country, impoverished by 12 years of war, where medical care and medication are not accessible to the vast majority.

O-0084

The implementation of staged diabetes management in public and private diabetes centers in Brazil

S.A.O. Leite[1], A.C. Forti[2], R.M.C. Fonseca[3], A.O.T. Oliveira[4], E. Strock[5], R. Mazze[5]
[1] Universidade Positivo, Endocrinology, Curitiba, Brazil
[2] Centro Integrado de Diabetes e Hipertensao, Endocrinology, Fortaleza, Brazil
[3] Centro de Diabetes e Endocrinologia da Bahia, cedeba, Bahia, Brazil
[4] Instituto de Ensino e Pesquisa HCV, IEP-HCV, Curitiba, Brazil
[5] Park Nicollet, International Diabetes Center, Minneapolis, USA

Aim: This study assesses the implementation of a systematic approach to comprehensive management of diabetes and its complications. Staged Diabetes Management (SDM) was employed to train health professionals and implement new diabetes management procedures in public and private health care systems. The overall aim was to determine how effective SDM was in improving management of complications associated with diabetes.

Methods: This prospective study was done with the SDM program to assess the impact on standard diabetes care in Brazilian primary care clinics and private health systems. SDM clinical pathways (DecisionPaths) were customized by local experts to account for the unique health care systems in three geographically dissimilar states in Brazil. SDM was customized for family health programs in Bahia state (12 primary care units) and in Ceara state (4 primary care units). Additionally, it was customized for five private diabetes multidisciplinary centers (physicians, nurses, dietitians and psychologists) in five cities in southern Brazil. Baseline and end of study (6 months) data were collected using the PACES audit form (a multi-national standard chart audit that consists of 40 sentinel events (e.g. amputations) that measure both diabetes care processes and outcomes.

Results: Six months after SDM implementation in public health care settings, lower-extremity amputations due to diabetes were reduced by 45% (p<0.001) and hospitalization for hyperglycemia treatment decreased by 63% (p<0.01). Additionally, the SDM program was initiated in five private health clinics using a multi-disciplinary health team model. Changes in quality of care were documented in these health systems with higher numbers of foot examination, screening of chronic complications with microalbuminuria and retinal evaluation. Health professionals in private health systems increased the treatment of dyslipidemia from 40% of patients at baseline to 60% after SDM training (p<0.001). Within private clinics, prior to the SDM program 15% of patients had individual or group education compared to 40% after 6 months (p<0.001), in spite of out-of-pocket expenses.

Conclusions: Diabetes morbidity and mortality depend on quality of care. We concluded that SDM implementation improved quality of diabetes care in both public and private medical centers in three geographically dissimilar states in Brazil.

O-0085

Erratic versus structured self measurement of blood glucose in type 2 diabetes – impact on cost and benefit for the German health care system

C. Weber[1], P. Bachmann[1], F. Heister[1], C. Weiss[1], K. Neeser[1]
[1] Institute for Medical Informatics and Biostatistics, Department of Health Economics, Basel, Switzerland

Background/aims: Diabetes mellitus is now a widespread disease in Germany. Actually, over 7 million people are diagnosed with the condition. Considering the worldwide rising prevalence, the challenges for the German health care system will be considerable, also in economic terms.

The discussion about the value of SMBG in the management of non insulin dependent Type 2 diabetes is still ongoing. In assessing the benefit, it is often ignored that SMBG is only a diagnostic test and can not have – contrary to pharmaceuticals – an intrinsic effect. Application of appraisal methods used for the evaluation of pharmaceuticals can provide misleading results.

Methods: We conducted a cost-effectiveness and budget impact analysis of SMBG using a validated Markov state model to assess the clinical impact and related cost when SMBG is performed by non-insulin requiring patients with type 2 diabetes in a structured manner (e.g. seven-point profile during 3 days monthly). The assumptions of additional clinical effects on blood pressure or lipid levels are based on preliminary data from two ongoing RCTs analyzing the effect of structured versus erratic SMBG. Accordingly, we assumed an improved glycemic control (HbA1c reduction 0.4 %) and an additional improvement of blood pressure and lipid levels by 5% (scenario 2), 10% (scenario 3) and 15%

(scenario 4) of the baseline values. The simulation time was set to 10 years or death of the cohort member. Costs were calculated with a German cost data reflecting a third-party-payer perspective. The impact of different discount rates on costs and life expectancy was investigated in sensitivity analysis (range of 0 and 5 %).

Results:

Scenario	1	2	3	4
Cumulated cost over 10 years (EUR, undiscounted)	22,082	21,169	20,287	19,433
Incremental cost (EUR, undiscounted)	-	- 913	- 1,795	- 2,649
Life expectancy (in years, undiscounted)	8.495	8.585	8.673	8.760
Incremental life expectancy (in years, undiscounted)	-	0.09	0.178	0.265
Cost per life year gained (EUR/ LYG, undiscounted)	-	- 10,144	- 10,084	- 9,996

Budget impact analysis (based on scenario 2, an actual SMBG use by 37 % of non-insulin treated T2 patients and a yearly switching rate of 0.087) yields cost savings of 83.3 Mio EUR within 5 years.

Conclusion: Self measurement of blood glucose (SMBG) can represent a valuable and cost effective element in the therapeutic approach of non-insulin treated diabetes, if some prerequisites are fulfilled.

An adequate use of SMBG by the patients and an assessment of the benefits with appropriate health economic methods will yield potential cost savings for the statutory health insurance.

How to identify and to choose appropriate footwear in orthopedic high risk diabetic patients ?

A. Desserprix[1], M.A. Desbas[1], C. Denizot[2], C. Mourey[1], S. Clavel[1], M.A. Desbrosses[1]

[1] *Foundation Hotel Dieu, Diabetology, Le Creusot, France*

[2] *Foundation Hotel Dieu, Prerediab Network, Le Creusot, France*

Aims: Presentation and evaluation of a preventive educational program for foot complications designed for orthopedic high risk Diabetes Mellitus patients.

Methods: This program of Education and Evaluation is built around an educational tool called "Identifying and Choosing a Good Pair of Shoes" devised by the health care team. The playbox (footbox) contains cards describing footwear (the heel, the outer sole, the insole, shape and quality of a shoe) and invites the patient to compare his own shoes with the information given on the cards and thereby to deduce the qualities and imperfections of his current footwear. Vidéo CD Rom on computer insist on diabetic orthopedic high risk: the what, the why, the whom and the prevention.

92 diabetics all neuropathic with or without arteriopathy follow the program.

The first visit (V1), destined to promote patient awareness, consists of personal risk assessment by foot examination. The footbox is used for baseline assessment of footwear. The second visit at 3 months (V2) consists in group education session about preventing major foot ulcers (self examination, foot care, choosing a shoe) and a second evaluation of current footwear via the "footbox". The third visit at 6 months (V3) consists of a video CD Rom reminder of the main guidelines discussed at V1 and V2 and a third evaluation via the "footbox". The fourth visit at 12 months (V4) consists of an evaluation by foot examination and by footwear.

Results: Study patients attitudes from V0 to V4 showed better adapted footwear: 32 to 58 %, less callus: 49 to 39%, less fungal infection: 24 to 13%, less wound: 29 to 10%.

Discussion/conclusion: This tool helps mainly:

- to quantify changes in habits in the short term
- to measure in the long term its impact in preventing foot injury
- to highlight the impact of education in preventing secondary complications.

These encouraging results incite us to pursue education with this program in all diabetic patients at high risk of foot injury.

A model for diabetes care at schools by Finnish Diabetes Association

R. Koivuneva[1]

[1] *Finnish Diabetes Association, Expert on Social and Health Policy Affairs, Tampere, Finland*

There is a legislative gap in Finland: no one has the responsibility to carry out the measures of diabetes care in school environment. Therefore children have mutually an inequal status totally depending on the school they attend. Part of the children have right to a professional and safe diabetes care during their school day whereas some depend on their parents coming to school to give insulin and count carbohydrates. As a result of the influence of Finnish Diabetes Association, authorities have now 1) launched a national recommendation and a model of diabetes care during school day and 2) started developing new legislation. Finnish Diabetes Association managed in this by producing factual information, contacting key-decision makers, educating and by raising public awareness. Finnish Diabetes Association ran a study in 2006 in order to get a full picture of the problems nation-wide. With the results as evidence, Finnish Diabetes association contacted the Ministry of Education and Ministry of Social Affairs and Health who, based on this, set up a work group. To safeguard the interest of the children with diabetes Finnish Diabetes Association published its own form to serve as an agreement tool for parents and schools while the official form was to be waited. The publishing date was UN World Diabetes Day 2007 and presentation was done both in the main TV news and newspapers. Publicity increased the demand for education, and Finnish Diabetes Association continued consulting both school staff and paediatrics serving as a channel in between the ministry level work group and school world. Parents taking contact straight to the ministries and parliament added very strong impact on ministry level working group. The ministry level recommendation includes general guidelines on who is responsible for each part of a child's diabetes care at school and instructions how to educate a person to be able to perform the task. The form serves as an individual tool for each child with diabetes. The tone of the recommendation is very positive. The purpose is to make the day at school safe and simple not only to the child with diabetes but as well empower the named staff at school the same way. Finnish Diabetes Association has consulted among others the Swedish Diabetes Association with creating a model. The Finnish national ministry level recommendation and model form will be available to public at World Diabetes Congress in Montreal.

Better diabetes care with peer support

A. Jhingan[1]

[1] *Delhi Diabetes Research Center, Diabetes and Metabolic Disease, New Dehli, India*

Improvement in quality of diabetes care is essential for reducing diabetes complications. Simultaneous involvement of primary care physicians, patients, their families and other health care providers is of utmost importance in achieving diabetes management goals.

Aim: To assess the impact of diabetes education to both primary care physicians and patients along with peer support groups on importance of laboratory tests and treatment compliance, and to assess the effect of this intervention in improving metabolic control as measured by HbA1c levels.

Design and methodology: In a two pronged educational programme, a team of diabetologists, dieticians and diabetes educators interacted with primary care physicians and peer supporters. The study was conducted over 2 years and included 650 diabetes patients, 15 primary care physicians and 35 peer supporters.

In a two day workshop lasting 3 hours a day, sensitization about the basics of diabetes, its complications, smoking and alcohol cessation and therapeutic options was done.

Selection of Peer Supporters:

1. To be selected by the primary care physician of that locality, having type 2 DM for > 5 years with adequate understanding of the disease.
2. These role models were trained and organized group meeting with diabetes patients and discussed any treatment issues and encouraged smoking/alcohol cessation.

Results: Out of 650 patients, 50 left before completion of study. The proportion of diabetics getting HbA1c testing at least annually rose from 15% to 38%. Patients undergoing ophthalmology visit increased from 120 to 228. Microalbuminuria testing went up from 33 to 180 and lipid testing went up from 11% to 33%.

Discussion: Peer support plays a crucial role in managed diabetes care. Patients with good understanding of diabetes can be "Role models" for others in promoting awareness and encouraging adoption of a healthy life style. The study proves that diabetes education improves treatment outcomes.

Social relationships and school outcomes among young adults in the Diabetes Attitudes, Wishes and Needs youth study

T. Danne[1], M. Peyrot[2], H.J. Aanstoot[3], B. Anderson[4], K. Lange[5]
[1] *Kinderkrankenhus Auf der Bult, Dept. of General Pediatrics and Endocrinology/Diabetology, Hannover, Germany*
[2] *Loyola College in Maryland, Dept of Sociology, Baltimore, USA*
[3] *Diabeter, Diabetes Center for Children and Youth, Rotterdam, The Netherlands*
[4] *Baylor College of Medicine, Pediatrics, Houston, USA*
[5] *Medizinische Hochschule, Medical Psychology, Hannover, Germany*

Aims: This study assessed the association of social relationships in school with impact on school attendance, performance, and activity participation among young adults with diabetes.

Methods: Data are from a cross-sectional internet survey of independent national samples of patients with diabetes aged 18-25 (N = 1905) from the Diabetes Attitudes, Wishes and Needs (DAWN) Youth Study. Respondents from Brazil, Japan, the US and 5 European countries provided self-report data for all measures. The sample for this analysis consisted of 400 respondents who were still attending school. Social relationships at school included whether teachers and students treated the respondent better or worse than others because of having diabetes, and whether the respondent could get help managing diabetes, if needed, from teachers, students, school nurses, or nobody. Hierarchical multiple regression assessed the significant ($p<.05$) independent associations of school attendance, performance, and activity participation with social relationships at school, controlling for country of residence and respondent demographic and disease characteristics.

Results: School relationships accounted for 16% of the variance in school attendance, 14% of the variance in performance impact, 24% of the variance in activity participation. Teachers treating respondent worse was associated with lower attendance, more impact on performance and less activity participation. Students treating respondent worse was associated with less activity participation, and students treating respondent better was associated with lower attendance. Diabetes assistance available from school nurses was associated with higher attendance and activity participation. Diabetes assistance available from students was associated with higher activity participation. Lack of available diabetes assistance was associated with more impact on school performance.

Discussion/conclusion: Social relationships play an important role in school outcomes among young adults with diabetes. Teacher discrimination against students with diabetes had the strongest and most consistent (negative) impact. Relationships with other students had both positive and negative consequences, depending on whether differential treatment was positive or negative. Potential support for diabetes needs from students and nurses was associated with better outcomes. These findings suggest the need for teacher training programs and student education regarding diabetes, and an increased nursing presence for youth with diabetes in schools.

Measuring diabetes health: a capability approach in the Swedish National Diabetes Registry

S. Gudbjörnsdottir[1], F. Odegaard[2], D. Olsson[3], U.B. Löfgren[4], P. Roos[5]
[1] *Sahlgrenska University Hospital, Department of Medicine, Göteborg, Sweden*
[2] *Richard Ivey School of Business, University of Western Ontario, London ON N6A 3K7, Canada*
[3] *Karolinska Institutet, Medical Statistics Unit, Stockholm, Sweden*
[4] *Linköping University Hospital, Department of Medicine, Linköping, Sweden*
[5] *R R Institute of Applied Economics, Box 20015, Malmö, Sweden*

Aim: To present a method for measuring diabetes related health taking a capability approach (CA). In a health related CA the focus is on an individual's health functionings, such as being in good health, having health knowledge, or ability to overcome health problems. The CA approach in this study is limited to diabetes related functionings.

Method: Using a recently developed diabetes questionnaire (NDR), 4743 Swedish diabetes patients, at 23 diabetes care centres, reported their perceived functioning for: (1) health knowledge (7 questions about self care management of diabetes and quality in the communication with health care personnel), (2) social life and working conditions (5 questions about the individual's ability to overcome diabetes related problems in daily life activities), (3) confidence (5 questions about anxiety for complications and access to diabetes health care services), and (4) self-respect (3 questions about having self-respect in the relationship with health care personnel). All questions were measured on a 5 point Likert scale. These ordinal data have to be transformed into a scalar, or cardinal, measure. We use Item Response Theory (IRT) for the estimation of cardinal scales to each of the 4 functioning variables. IRT allows us to estimate scores for each individual and each functioning. These scores, will then be linked to individual observation in NDR on medical conditions such as HbA1c, cholesterol, blood pressure, BMI, type of diabetes, current treatment etc.

Results: The results show variation among diabetes patients in all of the 4 functionings. On average the results show more problems in overcoming problems in social life and at work and in anxiety among type I diabetes than in type II. For type II patients the results indicate increased problems in social life and working conditions, and more anxiety for patients on insulin treatment then for patients on diet or oral treatment. The result shows variations in patient health knowledge between health care centers. Patients with HbA1c >7.5% show lower (worse) scores in all the 4 health related functionings.

Discussion: To our knowledge this is the first study on diabetes health taking a capability approach. We think that a CA will prove very useful since it takes into account not only medical data on health but also information on individual functioning and ability to overcome diabetes related problems on an individual base. Such will improve the quality in the daily medical decision making. From a health policy perspective, the CA would generally imply that the government should support activities that brings each individual's health functioning as high as possible, given his or her own features. This questionnaire is planned to be used as a part of the online registration in The Swedish National Diabets Registry

The eleven-year results (1997-2008) of the Israeli-Georgian program "diabetes in pregnancy"

N. Asatiani[1], R. Kurashvili[1], M. Dundua[1], E. Shelestova[1], L. Tsutskiridze[1], M. Hod[2], S. Smirnov[3], V. Vlasov[3]
[1] *Georgian Diabetes Center, Endocrinology, Tbilisi, Georgia*
[2] *Rabin Medical Center, Obstetrics and Gynecology, Tel-Aviv, Israel*
[3] *Novo Nordisk, A/S, Copenhagen, Denmark*

The purpose of the present work was to evaluate the eleven-year results (1997-2008) of the program Diabetes in Pregnancy, aimed at approximating pregnancy outcomes in diabetic women to that of the non-diabetic ones.

Methods: In total, 184 women with Pre-GDM (T1DM) (mean age 24$\pm$ 6 yrs, diabetes duration 11.2$\pm$ 6.4 yrs) and 59 women with GDM were enrolled in the study. The patients were divided into 4 groups (Gr.): Gr.1 - 78 patients who received specialized pre-conception care; Gr.2 - 62 patients enrolled in the program at < 10 weeks of gestation (5.6$\pm$2.1 weeks); Gr.3 - 44 patients enrolled in the program at > 10 weeks of gestation (19.5$\pm$6.1 weeks); Gr.4 - 59 women, all with GDM.

Results: At baseline high levels of HbA1c and post-prandial glycemia (PG)

were registered. At conception these indices decreased in Gr.1, while in Gr.2 this decrease was achieved only in the 2nd trimester (tr), and in Gr.3 and 4 in the 3rd tr. In Gr.1 pre-eclampsia(PE) and pre-term delivery (PTD) percent was lower than in the remaining three groups (PE - 4.4%, 12.0%, 26.4% and 24.4% respectively, PTD - 1.4%, 9.6%, 23.5% and 24.4%, respectively). Retinopathy progression was observed only in 8.1% of patients from Gr.3. In Gr.1, despite the lower levels of HbA1c and PG throughout the pregnancies, the percent of macrosomia was higher than in Gr.2 and 3 (16.07%, 12.1% and 15.3%, respectively). The rate of spontaneous abortions was lower in Gr.1 (4.4%) than in Gr.2 (13.4%). Perinatal mortality (8.8%) and fetal malformations (5.8%) were registered only in Gr.3. Two cases of perinatal deaths were registered in Gr.4.

Conclusion: In patients with Pre-GDM and GDM good glycemia control during pregnancy not always prevents macrosomia, though significantly reduces the risk of spontaneous abortions, pre-eclampsia, preterm delivery, fetus malformations and perinatal deaths. No retinopathy progression is observed when women are well-controlled throughout their pregnancies.

Comprehensive approach towards paediatric diabetes management: NGO initiatives in developing country India

P. Sankpal[1], P.S. Vaishali[1]

[1] Health alert Organization of India [NGO], Community medicine, Dhule, India

Issues: In developing nations diagnosis of diabetes brings mental-trauma/depression in family. Focused treatment for pediatric age-group is unavailable in developing-countries. 26% of diagnosed diabetics are children. Adequately trained physicians/nurses in issues of pediatric-diabetes provide continuity of care, relief from depression and smooth transition from diagnosis to treatment. Qualitative collaborative relationship between these makes diabetics life bearable. Our NGO-project highlights significance of relationship between nurses and diabetic-children in community clinic setup of rural India.

For Diabetes, its assumed that depression is inevitable sequel to diagnosis. Retrospective analysis of past studies shows—counselling improves QOL & attitude towards diabetes-treatment.

Aims: To describe care issues in diabetic-children. Observe/modify nature of relationship between nurse and child. To evolve comprehensive treatment plan for patients and families.

Methods: A retrospective analysis of data base from 7 rural health-clinics. Specialized therapy/support to pediatric-age-group not available at any centre. Total 117 children [4-13 years] diagnosed with diabetes. 23 had additional endocrine/metabolic problems. Nursing/medical care plan analyzed. No specialized trained personnel in rural/tribal India. Opinion/needs from patients families collected on feedback questionnaire. Then we trained 10 nurses & 2 physicians for handling pediatric cases [4 weeks training].

Results: out of 117, 41 discontinued Rx due to improper counseling/guidance. 3 died. Patient/family's feedback highlights: Better access to newer drugs-delivery-systems, psychosocial support, follow-up-plan. Nurses/physician be sensitized in pediatric care-issues. Main issues of concern were: [1] illness and coping with their feelings. [2] Initial impact of diagnosis and a search for solution? Expectations for future life & its quality? [3] Concerns of cost of RX [4] Availability of proper follow-up centers in rural areas of developing nations.

Conclusion: Multifaceted Relationship between physician/nurse and Diabetic-child is crucial. This relationship provides better continuity of treatment. We show concerns/difficulties while working in Asian set-up to international experts/seniors at IDF-2009-congress.

Diabetes and pregnancy

P. Ivana[1]

[1] Croatian Diabetic Association, Zagreb Diabetic Society, Zagreb, Croatia

Success of a diabetic pregnancy depends on the quality of pregnancy planning and good regulation of diabetes. This program is trying to work educationally for two groups of diabetic females: those who get pregnant unexpectedly and those who avoid pregnancy because they are not aware of progress in this field. It takes a lot of work to raise awareness about the complications and risks in the event of inadequate glucose regulation and the incredibly good results if a person approaching pregnancy is well prepared and on time. Doctors don't have enough time to devote themselves to each pregnant woman and answer all their questions during their working hours. Therefore, many mothers are confused during their first pregnancy and have a number of unanswered questions. So we tried to organize different approaches in explaining the problem and solving future mother's dilemma. This program is trying to reduce the high cost of treatment due to complications arising from poor regulation of diabetes and is trying to raise awareness of the opportunities of people with diabetes and to lift stigma that diabetes is a big limitation.

The program consists of a lecture on the topic: "Ideal Diabetic Pregnancy" in which doctors explain what is recommended to do before conception in order to drastically increase the chances for bringing a pregnancy to a full term, and what to do in case of an unplanned conception.

Psychological workshops follow after on the topic: "Expectations, fears and facing with pregnancy," which explains that some fears can be useful and constructive, and same which are irrational can reduce the quality of life in such a beautiful period of pregnancy.

Very popular topic "To store stem cell or not?" is presented in the form of a round table discussion which gives insights on the benefits of storage of stem cells from the umbilical cord and also debates about additional reasons for diabetic mothers whether to store stem cells or not.

And perhaps the most important activity for all future mothers is to visit the Department for pregnancy diabetes in the hospital in which future mothers get familiar with the surroundings and staff. Previously there has not been such an insight for diabetic mothers and other future mothers in the Republic of Croatia.

Future mothers who go through this program, resolve their fears and concerns, and bravely decide to get pregnant because of new knowledge and information they have gained. Fortunately for those women they have a great chance of bringing a pregnancy to a full term.

Resistin-induced expressions of visfatin and inflammatory cytokines in endothelial-macrophage co-culture model through NF-kappaB pathway

W.H. Sheu[1], C.M. Wu[1], I.T. Lee[1], S.Y. Lin[1], W.J. Lee[2]

[1] Taichung Veterans General Hospital, Department of Internal Medicine, Taichung, Taiwan

[2] Taichung Veterans General Hospital, Department of Medical Research and Education, Taichung, Taiwan

Aims: To investigate whether resistin, secreted from adipocytes and macrophages, can directly upregulate visfatin, inflammatory cytokines and adhesion molecules in endothelial/macrophage co-culture model.

Methods: Human umbilical vein endothelial cells (HUVECs) were co-cultured with macrophage (PMA-stimulated THP-1 cells) and stimulated with resistin (100 ng/ml) for up to 24 h. mRNA and proteins expression of visfatin, inflammatory cytokines (MCP-1, IL-6 and IL-8) and adhesion molecules (ICAM, VCAM and E-selectin) were determined by Real-time PCR and western blot. NF-kB activity was measured by Electrophoretic Mobility-Shift Assays (EMSA).

Results: We found that resistin upregulated mRNA and protein expressions of visfatin, inflammatory cytokines (MCP-1, IL-6 and IL-8) and adhesion molecules (ICAM, VCAM and E-selectin) in endothelial/macrophage co-culture models at 24 h (all $p<0.05$). Resistin treatment resulted in activation of NF-kB in HUVEC, which further increased significantly when co-cultured with HUVEC and macrophage.

Discussion/conclusion: Resistin induced visfatin, inflammatory cytokines and adhesion molecules mRNA as well as proteins expressions in HUVECs/macrophage co-culture system, probably through activation of NF-kB activity. We suggest that resistin may play certain role in links between obesity, inflammation and endothelial dysfunction.

Asymmetric dimethyl arginine (ADMA) levels are associated with macrovascular disease but not inflammation in type 2 diabetes

A. Akalin[1], M. Celik[2], O. Colak[3]
[1] Eskisehir Osmangazi University, Endocrinology, Eskisehir, Turkey
[2] Eskisehir Osmangazi University, Internal Medicine, Eskisehir, Turkey
[3] Eskisehir Osmangazi University, Biochemistry, Eskisehir, Turkey

Aim: We aimed to determine the relation of asymmetric dimethyl arginine (ADMA) levels to atherosclerotic vascular disease and inflammation markers in type 2 diabetes.
Methods: Fifty type 2 diabetic patients with established atherosclerosis, 50 type 2 diabetic patients without atherosclerosis and 31 healthy control subjects were included in our study. Age, sex, blood pressure levels, duration of the diabetes, treatment types of the patients were recorded. Carotid artery intima-media thickness of each subject were measured. Fasting blood samples were drawn and fasting blood glucose, C-peptide, creatinine, lipid levels, hcCRP, fibrinogen, erithrocyte sedimentation rate, adiponectin, homocysteine(tHcy) and ADMA levels were studied. We evaluated the relationship between ADMA levels and tHcy, adiponectin, inflammation markers and macrovascular disease.
Results: ADMA levels were significantly higher in patients with macrovascular complications than the patients without macrovascular complications (0.52±0.23 mmol/L vs.0.39±0.16 mmol/L,p<0.05) and the control group (0.52±0.23 mmol/L vs.0.32±0.13 mmol/L,p<0.05). In addition, when we compared all of the diabetic patients with control group, we found that ADMA levels were significantly higher than the control group (0.45±0.21 mmol/L vs. 0.32±0.13 mmol/L, p<0.001). Adiponectin levels and homocysetine levels were the most important determinants of ADMA in the presence of macrovascular disease. We could not find any relationship between ADMA levels and inflammation markers.
Conclusion: There is a relationship between ADMA levels and macrovascular disease in type 2 diabetes but, this relation is independent of inflammation. Adiponectin levels are significant determinators of ADMA levels in type 2 diabetic patients.

Plasma nitric oxide metabolite (NOM) concentrations are elevated in the obese and type 2 diabetics and are suppressed by insulin

H. Ghanim[1], P. Dandona[1], K. Korzeniewski[1], A. Chaudhuri[1], S. Abuaysheh[1]
[1] State University of New York at Buffalo, Medicine, Buffalo, USA

We have recently shown that endotoxin injection leads to a rapid increase in plasma NOM concentrations as a part of the acute inflammatory response in normal subjects. In view of the chronic low grade inflammation which exists in patients with obesity and type 2 diabetes mellitus (T2DM), we hypothesized that NOM concentrations are elevated in these conditions. Since insulin exerts an anti-inflammatory effect, we also hypothesized that insulin suppresses NOM concentrations. Plasma NOM concentrations were measured in the fasting blood samples from normal subjects, obese and T2DM patients (24 each) using the Griess reaction. In the second study, a low dose (2U/h) of insulin and 5% dextrose (100ml/h) were infused into 10 patients with T2DM for 4h. Either 5% dextrose or normal physiological saline was infused on 2 other occasions as controls. Plasma concentrations of NOM were significantly higher in the obese (by 59%) and T2DM patients (by 52%) compared to normal subjects (43±4 vs. 41±3 vs. 27±3 mM, respectively P<0.05). Following insulin infusion, plasma concentrations of NOM fell by 34±15% at 4h (P<0.05). This suppression occurred in parallel with reductions in ROS generation by peripheral blood mononuclear cells (MNC) and plasma MCP-1 concentrations. There was no significant change in NOM concentration or other inflammatory indices following dextrose or saline infusions. iNOS either as mRNA or protein was not detected in MNC. The source of NO is, therefore, probably the macrophages in the reticulo-endothelial system in the liver and the spleen. We conclude that plasma NOM concentrations are significantly elevated in obesity and T2DM and that a low dose insulin infusion suppresses the elevated levels significantly in parallel with a reduction in indices of oxidative stress and inflammation.
Table 1: Change in inflammatory and oxidative stress mediators following 2U/hr insulin/ dextrose infusion in T2DM (n=10) *:P<0.05 One-way ANOVA, #:P<0.05 Two-way ANOVA compared to dextrose control group.

O-0097

Insulin infusion suppresses endotoxin induced oxidative, nitrative and inflammatory stress in normal human subjects

P. Dandona[1], H. Ghanim[1], A. Bandyopadhyah[1], K. Korzeniewski[1], C.L. Sia[1]
[1] State University of New York at Buffalo, Medicine, Buffalo, USA

Our work over the past few years has demonstrated that insulin exerts anti-inflammatory and cardio-protective effects. We have now hypothesized that insulin reduces the magnitude of oxidative, nitrative and inflammatory response induced by endotoxin (LPS). Nine normal subjects were injected with 2ng/Kg of LPS prepared from ***E. coli*** intravenously. Ten others were infused with insulin (2U/h) for 6h in addition to the LPS injection along with 100 ml/hr of 5% dextrose co-infused with insulin to maintain normoglycemia. LPS injection, induced an increase in body temperature, pulse rate, body aches and headache. The subjects also exhibited a rapid increase in plasma concentrations of nitric oxide metabolites (NOM), nitrite and nitrate, TBARS, increase in ROS generation by PMNL and marked increases in plasma FFA, MIF, TNFa and IL-6 concentrations (Table 1). The co-infusion of insulin led to significant reduction in body temperature (100.3 vs. 101.3 F, p< 0.005) and headache, a total elimination of the increase in NOM, FFA, TBARS and a significant reduction in ROS generation by PMNL and plasma MIF concentrations (Table 1). However, insulin did not affect TNFa and IL-6. Thus, insulin reduced clinical symptoms, oxidative, nitrative and inflammatory stress as induced by LPS. Insulin is a potential rational anti-inflammatory therapy for endotoxemia.
Table 1: Changes in oxidative and inflammatory mediators following 2ng/Kg injection of LPS alone (TOP row) or LPS and 2U/hr insulin (BOTTOM row) for 6 hr in normal healthy subjects. *:One-way ANOVA, #:Two-way ANOVA.

Anti-inflammatory effect of the CB1 receptor antagonist SR141716 on human mature adipocytes and its effect on human preadipocytes differentiation

R. Murumalla[1], K. Bencharif[1], L. Hoareau[1], A. Bhattacharya[1], F. Tallet[2], M. Gonthier[1], V. Di Marzo[3], M. Cesari[1], R. Roche[1]
[1] University of La Reunion, Lbgm, Saint Denis, Reunion
[2] Centre Hospitalier Félix Guyon, Service de biochimie, Saint Denis, Reunion
[3] Institute of Biomolecular Chemistry of the National Research Council, Endocannabinoid Research Group, Pozzuoli (NA), Italy

Introduction: Obesity has become a major public health problem and could lead to diabetes type II, atherosclerosis, hypertension, hepatic steatosis, and sometimes cancer. The accumulation of fat in tissues leads to local inflammation characterized by increased proinflammatory cytokines such as TNFalpha. This inflammation is probably one of the most important factors for the development of insulin resistance.
The purpose of this study was to show the effect of CB1 receptor antagonist on human fat cells in primary culture, preadipocytes and mature adipocytes. We have studied the effect of SR141716 (Rimonabant or Acomplia) on the adipocyte differentiation and secretion of TNFalpha and adiponectin by mature adipocytes.
Materials and methods: Subcutaneous (abdominal, buttocks, hips and thighs) tissue samples of human white fat were obtained from normal weight or slightly overweight women undergoing liposuction. Cultures were done as previously described (Gonthier 2007). Moreover, stromal vascular cells were extracted and differentiated into adipocytes. Media samples and cells were collected for secretory and expression analysis. Oil accumulation in adipocytes was observed using oil red-O staining. We measured the change in secretion levels of various molecules secreted by ELISA. Gene expression was measured using RT-PCR.
Results: When mature adipocytes were treated with LPS, SR141716 was able to decrease the expression and secretion of TNF alpha in a significant manner (around 30%) suggesting an anti-inflammatory role of this molecule. Moreover, SR141716 restored adiponectin secretion to normal levels after LPS treatment. When preadipocytes were treated with SR141716, no changes could be observed on differentiation of these cells.
Discussion/conclusion: TNF alpha is known to be an inflammatory cytokine, highly correlated with insulin-resistance. In contrast, adiponectin has benefit effects on metabolic parameters (as glucose uptake, for example). We show for the first time that SR141716 is able to act directly on human adipocytes through an anti-inflammatory effect. In other words, some clinical effects of SR141716 are probably directly related to its effects on mature adipose cells.
CB1 receptors play an important role in adipocyte physiology and thus can contribute to metabolic syndrome. Understanding the interaction between this receptor and TLR4 (LPS pathway) in adipocytes will help us in better understanding of this metabolic syndrome.

Expression and fuction of CD39 and P2X7 receptor in patients with type 2 diabetes mellitus

D. Portales-Pérez[1], M. García-Hernández[1], L. Portales-Cervantes[1], L. Baranda[1], J. Vargas-Morales[1], J. Fritche[1], E. Rivera-López[1], R. González-Amaro[1]
[1] UASLP, Immunology, San Luis Potosi, Mexico

Type 2 Diabetes Mellitus (T2DM) is a polygenic and multifactorial disease with multiple genetic loci associated with the risk of T2DM. Chronic low-level inflammation plays a role in pathogenesis with several pro-inflammatory cytokines (TNFa, IL-6), lipid, reticulum endoplasmic stress and reactive oxygen species involved. In this regard, recent data suggest that the pro-inflammatory receptor P2X7 could be associated with T2DM. It has been reported that the P2X7 receptor modulates release of cytokines (IL-1ß, TNFa, IL-1ra, IL-6) and demonstrates an enhanced P2X7 activity in fibroblast from T2DM patients and also in human fibroblasts from healthy subjects exposed to hyperglycemic conditions. In contrast, CD39/ecto-NTPDase 1 (nucleoside triphosphate diphosphohydrolase 1) is an ecto-nucleotidase expressed primarily on activated lymphoid cells, that is involved in a low release of IL-1ß, and its deletion in mice (CD39/Entpd1-null mice) induces insulin resistance. Because high level of extracellular nucleotides ligand of CD39 and P2X7 receptor are released by several different cells to extracellular milieu upon cell and tissue damage, in this study we propose the activation of P2X7 receptor by its ligand ATP and the function and expression of CD39 in lymphocytes and monocytes from patients with T2DM participate in the pathogenesis of low grade inflammatory process and insulin resistance.
Results: In the present study, we include 12 patients who were subsequently diagnosed with T2DM, without complications (retinopathy, neuropathy, and nephropathy) and 8 healthy subjects (FPG < 100mg/dL). We detected a significant diminished expression of CD39 in mononuclear cells and in particular in CD4+ T lymphocytes in patients with T2DM compared with healthy subjects. However, subpopulations like CD8+CD39+, CD56+CD39+, CD19+CD39+ and CD14+CD39+ showed similar levels of expression in patients and healthy subjects. In contrast, we observed a significant enhanced P2X7 expression in CD14+ cells from patients with T2DM than in healthy subjects. However, peripheral blood mononuclear cells and other subpopulations like CD56+P2X7+, CD8+P2X7+ and CD19+P2X7+ we detected similar level between groups studied. Cell surface receptors were analyzed with flow cytometry and serum inflammation markers with enzyme-linked methods. Finally, we found that one of the functions attributed to P2X7 receptor upon bind to ATP ligand, like diminished levels of CD62L in lymphocytes, were similar in lymphocytes from patients with T2DM and healthy subjects. To determine the ATPase activity of CD39, we measured the amount of orthophosphate released by hydrolysis of ATP in mononuclear cell cultures and did not detect difference between groups.
Conclusion: Based on our data, we hypothesize that the increased expression of P2X7 receptor and diminished CD39 expression could be contributing to pathogenic inflammatory process observed in T2DM.

Pro/anti-inflammation cytokines and acute phase proteins in type 2 diabetics with essential hypertension or its association with cardiovascular disease

V. Poltorak[1], M. Gorshunska[2], N. Krasova[1], I. Karachentsev[2], A. Gladkih[1], E. Jansen[3]
[1] SI "V. Danilevsky Institute of Endocrine Pathology Problems of AMS of Ukraine", Experimental Endocrinology, Kharkiv, Ukraine
[2] SI "V. Danilevsky Institute of Endocrine Pathology Problems of AMS of Ukraine", Clinical Endocrinology, Kharkiv, Ukraine
[3] National Institute for Public Health and the Environment, Toxicology Pathology and Genetics, Bilthoven, The Netherlands

Insulin resistance (IR) is an important component of such chronic pathologies as type 2 diabetes mellitus (T2D), essential hypertension (EH), cardiovascular disease (CVD) and metabolic syndrome (MS). There is a theory putting IR in touch with inflammation within evolutionary development and emphasizing role of tumor necrosis factor-a (TNF-a). The aim of the study was to evaluate the circulating levels of acute phase proteins, pro/anti-inflammation cytokines including TNF-a, and their relationship with metabolic and hormonal parameters of IR in T2D patients with EH alone or combined with CVD.
Methods: 29 middle-age patients with T2D and MS (NCEP ATP III), dysglycemia, dyslipidemia, obesity, EH or its association with CVD were observed. Blood samples were collected repeatedly within 6 mo (n=60). 26 samples belonged to T2Ds+EH, 34 – to T2Ds+EH+CVD. 27 healthy volunteers served as controls (C). Index of IR was calculated using HOMA. Unpaired Student's t test, Wilcoxon-Mann-Whitney test, X^2 test, and Spearman's rank order were used.
Results: It was revealed a significant increase in circulating acute phase proteins (C-reactive protein, $p<0.001$; haptoglobin, $p<0.05$; ferritin, $p<0.001$) without any relation to complication type in T2Ds with chronic hyperglycemia. HOMA-IR was increased as compared to C ($p<0.001$) and had no differences between diabetic groups. Interestingly, that increase in TNF-a levels was more pronounced in T2Ds with EH compared to EH+CVD group (7.62 ± 1.98 vs 4.11 ± 0.35 ng/l, $p=0.045$, 1.73 ± 0.46 ng/l in C, $p<0.001$). It was accompanied also by more pronounced decrease in circulating adiponectin (EH vs EH+CVD: 8.5 ± 0.8 vs 11.6 ± 0.9 mg/l, $p<0.02$, 15.1 ± 1.5 mg/l in C, $p<0.01$). There were many correlations between studied indices and metabolic or hormonal parameters of IR.
Conclusions: We suggest modulating effect of poor glycemic control on low-grade inflammation parameters and their association with IR in T2Ds with EH and CVD. In our opinion it is necessary to elucidate the causes of less pronounced TNF-a level increase in T2D hypertensive patients with CVD compared to diabetics with EH alone against the background of similar diabetes and hypertension duration, IR, glycemic control and extent of obesity.

National plans to optimize diabetes care

O-0101

Assessing the impact of conducting an essential public health services assessment in diabetes prevention and control programs

M. Saunders[1]

[1] *Centers for Disease Control and Prevention, Division of Diabetes Translation, Atlanta, USA*

Aims: To discuss the Essential Public Health Services assessment, the importance of completing in DPCPS and how this can lead to quality improvements in diabetes care.
Background: The goal of the Essential Public Health Services (EPHS) assessment is to promote continuous quality improvements. In 2002, the Division of Diabetes Translation (DDT) recommended that state Diabetes Prevention and Control Programs (DPCPs) complete an EPHS assessment and use the findings of this assessment to develop a state Performance Improvement Plan/s (PIP) and a Diabetes Strategic Plan.
Methods: DPCP data submitted to the DDT's Management Information System (MIS) were reviewed using several evaluation criteria, including the completion of an EPHS assessment; completion of one or more PIPs; completion of a diabetes strategic plan addressing quality improvement issues identified during the assessment; and a review of how current DPCP efforts, as described in their work plans, aligned with the findings of the assessment.
Results: MIS searches revealed that, in 2008, 58 of 59 DPCPs (98%) completed an EPHS assessment. Three DPCPs used the original EPHS assessment; fifty six (56) DPCPs used a modified version. By 2005, 39 of 59 of DPCPs (66%) completed a (PIP), and by 2008, 90% of programs have completed at least one PIP. Additionally, two programs completed more than one PIP during the five year funding period.
An analysis of the top three priorities identified by all DPCPs during the assessment revealed several quality improvement themes such as: health systems improvement, partnerships, surveillance, prevention and wellness, advocacy and policy, professional education and trainings, disparities, evaluation, and communication. Other priorities included community programs, research promotion, assessment and planning, integration, systems approach to diabetes, social marketing and health care reform. In 2005, 61% of all funded programs had a diabetes strategic plan in place and that number rose to 85% in 2008. In 2008, analysis of MIS reports and a review of current work plan templates indicated that more than 85 % of the work of the DPCPs showed direct alignment to the EPHS assessment findings.
Discussion/conclusions: Conducting EPHS assessments and using the data for continued quality improvement activities can have significant impact on DPCPs. This assessment allowed states to identify priority areas and assisted in the development of work plans to address quality improvement concerns. The alignment of the DPCP work plans to the findings of their EPHS is critical in ensuring that DPCPs work to address gaps, and work to strengthen the diabetes public health system. DDT will need to continue to work with DPCPs to ensure that work plans are aligned with the EPHS assessment findings, so that critical gains can be maintained across the diabetes public health system.

Statewide implementation of the Chronic Care Model for Diabetes: a model for improving care across a diverse region

R. Gabbay[1], *L. Siminerio*[2]

[1] *Penn State College of Medicine, Penn State Institute for Diabetes and Obesity, Hershey, USA*

[2] *University of Pittsburgh, Department of Medicine, Pittsburgh, USA*

Aim: The primary care system, where most of diabetes care is provided, is insufficiently oriented toward the management and maintenance of those with chronic illnesses such as diabetes. The Chronic Care Model (CCM) provides the best evidence-based framework to transform this care from an acute and reactive system to a proactive, planned and population-based system of care. To date, however most implementations of the CCM have been in larger practice organizations due in part to unsupported reimbursement for chronic care elements and a mismatch between those who bear the implementation costs and those who potentially receive the financial benefit within the US health care system. The goal of this three year intervention was to align financial resources, health care providers, and patients to implement the CCM across Pennsylvania (PA), a large diverse US state (117,000 sq km) with a population of 12 million including 800,000 with diabetes.
Methods: In 2007, multi-stakeholders from across the State developed a blueprint for how efforts, resources and interests could be combined to strengthen the collective capacity to improve diabetes care. This initiative coincided with the PA Governor's establishment of the Chronic Care Commission, charged with implementing the CCM across the State with a focus on diabetes. Implementation of the CCM is being driven by significant practice incentives supported by insurers aligned with the Patient Centered Medical Home. Regional Learning Collaboratives are supported by a free (state-supported?) diabetes registry, monthly data reporting requirements, regular meetings and trained practice coaches working individually with primary care practices.
Results: Learning Collaboratives have occurred across different regions of the state; each engaging approximately 25 practices of various sizes with diabetes populations of roughly 5000 per collaborative. The first of these collaboratives (Philadelphia region) has completed one year of the intervention with monthly reporting of outcomes. Considerable practice changes have been implemented in Clinical Information Systems, Delivery System Design and Decision Support and have recognized the central role of Self-Management Support and Community partnerships to improve care. Several clinical measures and process measures have already improved.
Conclusion: This unique undertaking, in one of the US's largest states, merging for the first time changes in reimbursement with incentives for CCM implementation, holds significant promise to transform health care in other regions and establishes a potential national model for systematic chronic disease management.

Staged diabetes management ISSSTE: The First National Diabetes Program in Mexico

J. Rodriguez-Saldana[1], *M.A. Morales de Teresa*[1], *C. Tena-Tamayo*[2], *M. Blanco-Cornejo*[2], *I.L. Rivapalacio y Chiang Sam*[2], *I. Sanchez-Diaz*[2], *L.I. Vazquez-Rodriguez*[1], *C.B. Rangel-Leon*[1]

[1] *Resultados Medicos Desarrollo e Investigacion SC, General Direction, Pachuca de Soto, Mexico*

[2] *ISSSTE, Sudirección General Medica, Mexico City, Mexico*

Introduction: Diabetes has become the first cause of mortality in Mexico. Leading contributing factors include lack of coverage/access to care, deficiencies in training of general practitioners and specialists, persistence of the acute model for chronic disease care, a vertical prescriptive approach, abscence or denial of diabetes self care education by practitioners, institutions and medical societies
Objectives: 1) To achieve a 20 percent reduction in mortality due to diabetes by 2011; 2) develop a high quality model of outpatient diabetes care; 3) increase national coverage/access to diabetes care; 4) reduce the rate of acute complications; 5) reduce the rate and the progression of chronic complications; 6) reduce direct costs of diabetes; 7) improve the quality of life of persons with diabetes; 8) introduce self-care diabetes education as an essential component of the program
Diabetes Program at ISSSTE Starting in 2007, implementation of Staged Diabetes Management, a structured program developed by the International Diabetes Center, a WHO Collaborative Center from Minneapolis MN, began at ISSSTE, a social security provider with an affiliation of almost 11 million people with national coverage in Mexico. Multidisciplinary teams were established at each clinic, including general practitioners, nurses, dietitians, psychologists and social workers. Healthcare delivery was improved to reduce waiting times, rotation of staff, and to increase the time for baseline and follow-up visits. Resources were devoted to provide all the clinics with A1c measurements and medications, online continuing education is delivered every month, and an electronic file was created to receive information in real time.
Results: At the first quarter of 2009, 89 diabetes clinics have been established in every state of the country, in which 7,902 patients are currently treated. Acceptance of the program has been universal, and has led to introduction of

additional programs for chronic disease care. Improvements in glycemic control have been documented, with 59.2 percent of the patients achieving A1c levels below 7%.

Conclusions: Less than two years after its creation, the National Diabetes Program at ISSSTE is the largest in Mexico. Milestones include: 1) real, effective national coverage; 2) multidisciplinary approach; 3) a patient centered approach, active participation of patients and their families; 4) the first national program in Mexico to use A1c measurement as marker of glycemic control; 5) the first electronic chart of diabetes in the country; 6) introduction of self-care diabetes education as an essential component of the program. According to UKPDS estimations, the levels of glycemic control achieved in patients treated at ISSSTE, are in concordance with the main objective of the program, a 20 percent reduction in mortality by 2011.

The Australian Diabetes Map

I. White[1], M. O'Brien[1], S. Rempel[1]
[1] Diabetes Australia, Policy, Canberra, Australia

The Australian Diabetes Map is an Australian innovation that provides a virtual picture of the nation's diabetes population. It is a national resource to key decision makers but most importantly to local communities. It can drill down to a defined geopolitical boundary at federal, state and local government level. The map shows prevalence of diabetes together with age, gender and type of diabetes. It also shows the location of health services including hospitals and pharmacies. People accessing the map can make diabetes prevalence comparisons between their local communities and the national average.

It has the potential to better inform politicians, policy makers, health professionals and researchers about the prevalence of all types of diabetes. This will in turn assist health service planning by identifying 'hot spots'; population health interventions by identifying the type of diabetes; post intervention monitoring and surveillance. Understanding how, where and to what extent diabetes affects our community is critical in delivering effective management and prevention strategies.

Using Microsoft's Virtual Earth technology as its platform it is linked to the National Diabetes Service Scheme (NDSS) database which has over 900,000 people registered. The NDSS captures nearly 95% of all Australians diagnosed with diabetes. An Australian Government initiative, the NDSS offers subsidised products, information and support services to people registered under the Scheme.

The NDSS is unique and the only one of its type internationally. It contains information about the registrant including name, age, home address and type of diabetes and if requiring insulin. The types of diabetes registered on the NDSS closely reflect the population statistics for diabetes in Australia.

The map is being developed further to include locations of general practices and primary health care facilities, location of diabetes educators and specialist diabetes centres. The technology underpinning the map has the potential to layer a range of demographic and social indicators to the landscape that will further enhance our understanding of the epidemiology and behavioural science of diabetes. For Diabetes Australia, the map will be a valuable addition to our tool box of strategies to ***turn diabetes around***. It can be accessed at: www.diabetesmap.com.au.

National registry of diabetes mellitus in Uzbekistan

S.I. Ismailov[1], Z.S. Akbarov[2], G.N. Rakhimova[2], Z.M. Shamansurova[2], F.A. Mukhamedova[2], N.M. Alikhanova[2], U.A. Kasimov[2], M. Rakhimdjanova[2], D. Kayumova[2], A. Ryaboshtan[2]
[1] Endocrinology, Endocrinology, Tashkent, Uzbekistan
[2] Endocrinology, Diabetology, Tashkent, Uzbekistan

Aims: Recent epidemiology studies shown that number of Diabetes Mellitus (DM) complications not enough observed and not registered in patient cards, especially in early stages, life expectancy of children after diagnosis of disease was about 8 years in 1998. Creation of National Registry of DM (NRDM) in Uzbekistan should improving registering all patients with DM and help to view all inaccuracy and mistakes and improve the diabetes care. The aim of our investigation was evaluation decisions of the NRDM during the past 8 years.

Methods: Electronic data base with all DM patient data was created and updated every 3 years and all data was undergo to statistical analysis and compare year by year and with epidemiology data.

Results: In start of 2008 104005 patients card with DM were registered, 974 children and 444 adolescents were among them and 17958 patients with type 1 DM. After NRDM, mortality was decreased among children on 60% and among adolescents on 75% and leading cause of death among children and adolescent is end stage of renal disease (ESRD), but 10 years ago - was ketoacidosis and coma. During the NRDM was improved insulin therapy, quantitative – increased adequate doses of insulin and qualitative – more than 75% of patients turn to intensified insulin therapy. According to NRDM, observation and registration of diabetes microvascular complication are increased and vary for nephropathy from 12.3% to 61%, retinopathy - from 12.3% to 64%, after NRDM attention to arterial hypertension increased and variation depended from regions and registered from 12.5% to 25.1% of patients. Analysis NRDM data shown that registration the macrovascular complications among patients was not enough and registering the coronary heart disease vary from 4% to 12.5% and atherosclerosis from 4.2% to 13%, and lipids test was done only by total serum cholesterol in 46.7% patients, which cause for limitation for using antilipidemic drugs – in 8.4-30%.

Conclusion: Creation of NRDM are very helpful for determination of inaccuracy and permit to reduce mistakes and improving the diabetes care and life of people with diabetes both in quantitative and qualitative.

Improving the diabetes management capacities of health care providers in Indonesia

I. Widyahening[1], S. Soegondo[2], P. Soewondo[2]
[1] Faculty of Medicine University of Indonesia, Community Medicine, Jakarta, Indonesia
[2] Faculty of Medicine University of Indonesia, Internal Medicine, Jakarta, Indonesia

Aims: To improve the capacity of preventing, detecting and treating diabetes among health care providers in Indonesia.

Methods: The activities were parts of a project named Improving Diabetes Health Care Delivery in Indonesia which initiated by Indonesian Society of Endocrinology in-cooperation with Ministry of Health with support from World Diabetes Foundation. Between January 2007 until June 2008 several trainings on diabetes management for internist, primary care doctors and diabetes educators were conducted in 8 centers (Jakarta, Medan – North Sumatera, Padang – West Sumatera, Bandung – West Java, Yogyakarta, Surabaya – East Java, Denpasar – Bali, and Makassar – South Sulawesi). Trainings materials including trainings modules, guidelines on diabetes management, and materials for education were developed prior to the trainings. Follow-up meetings among trainings' participants were conducted to assess the implementation of knowledge and skills achieved through the training and its obstacles in their respective health facilities. The meetings also attended by various stakes holders in diabetes management including local health officers.

Results: A total of 1237 health service providers consisted of 125 internists, 539 primary care doctors, 573 diabetes educators were trained. Proportion of hospitals which provide diabetes education for the patients change from 52.8% to 67.7% after the training while for primary health centres change from 46.3% to 67.8%. Addition of three hospitals and 14 primary health centres with special services (clinic) for diabetes were also achieved as a result of the training.

Conclusion: The specific projects' design have some advantages in improving the capacity of preventing, detecting and treating diabetes and reduce the burden of diabetes in the Indonesian society through resolving some of the problem on human resources in Indonesia. Through this project, communication and close interaction between the primary and secondary health practitioners take place and the local health officers realized the burden of diabetes in their area.

A guide for needs assessment and situation analysis in response to diabetes in resource-limited settings

E. Pasquier[1], P. Guimet[1], S. Girois[2], R. Ecochard[3]
[1] Handicap International, Health and Prevention Unit, Lyon, France
[2] Handicap International, Technical Division, Lyon, France
[3] Hospices Civils de Lyon Université de Lyon CNRS, Service de Biostatistique Université Lyon I UMR 5558 Laboratoire de Biométrie et Biologie Evolutive Equipe Biostatistique Santé, Lyon, France

Introduction: IDF and WHO estimated that 80% of the 380 million of diabetic people will live in the developing countries in 2025 and that 20% to 50% of them would be disabled. Handicap International and local partners are currently developing projects in response to this diabetes epidemic in 8 resource-limited countries. The aims of these projects are to prevent the occurrence of disabilities related to diabetes and to mitigate the disabling situation of diabetic people living with complications.
In order to define the most relevant activities to improve the response to diabetes in a given area, before implementing any activity, the first step is to assess the local needs and the available resources. To help local stakeholders in doing this first step, Handicap International has adapted existing guides of situation analysis to diabetes issues.
Aims: To design a methodological guide to assess the needs, demands and resources available and to choose the most relevant intervention strategies in response to diabetes epidemic in a given area of a resource-limited country.
Methods: The process has first defined the necessary characteristics of the guide regarding specific constraints of limited-resource countries. It should be adaptable, flexible and user friendly. It should not be too time consuming, and should lead to affordable activities. All steps should be described from information gathering to data analysis.
Then, we conducted a literature review on the methodologies for situation analysis, needs assessment, rapid appraisal and programming in public health. We analysed them according to their weaknesses and forces regarding the objectives and characteristics of the guide.
Next, we looked for the specificities of diabetes issues in term of public health by conducting another literature review on health structures evaluation, quality of care assessment and diabetes management. According to the objectives of the guide and to the identified specificities of diabetes, we adapted the existing methodologies of needs assessment to diabetes issues. The guide has been tested in 5 different countries of Africa and Asia and improved according to the weaknesses identified during these tests.
Results: A methodological guide of needs assessment and situation analysis in response to diabetes in limited-resource countries has been developed, including 14 steps and 9 tools (interview guides, observation grids, report framework, etc.)
Conclusion: The needs assessment and situation analysis guide in response to diabetes in limited-resource settings is a useful tool to build a relevant project that fits to the needs of local population.

LIVING WITH DIABETES

Awareness and education through skits/song/dance/mime

0108

Awareness and education through skits/song/dance/mime

D. Jones[1]
[1] King Edward VII Memorial Hospital, BHB Diabetes Centre, Paget, Bermuda

A didactic style of teaching has been used and over used to teach diabetes education. There are many other ways of imparting knowledge that are equally if not more effective and, which address the cultural problems educators face in a multicultural society.
Entertainment is a powerful tool and there are many ways of educating through entertainment including, storytelling, puppet shows, song, mime and music.
The aim of this presentation is to show that diabetes education can be delivered through creative avenues and be highly effective. Diabetes education is perceived as the imparting of knowledge and as such connotes a somewhat dry and boring delivery. This presentation aims to prove the opposite and that diabetes education can and should be fun.
The presentation will be given using a variety of educational tools including story telling songs and puppets.

HEALTHCARE AND EPIDEMIOLOGY

Revising the diagnostic criteria for diabetes; the 2009 WHO/IDF initiatives

0109

Revising the diagnostic criteria for diabetes; the 2009 WHO/IDF initiatives

P. Zimmet[1], K.G.M.M. Alberti[2]
[1] Baker IDI Heart & Diabetes, Obesity & Metabolism, Melbourne, Australia
[2] Imperial College, Endocrinology & Metabolism, London, United Kingdom

The diagnostic criteria for diabetes has been a process of evolution and the question now is whether we need a revolution, or at least, a revaluation. The debate as to the appropriate classification and criteria for diabetes mellitus is not a new one. Despite some apparent international consensus in the last decade, it still continues with vigour. Earlier attempts to classify diabetes were considerably enhanced by Himsworth's important observation in 1936 that there appeared to be two categories of diabetes, insulin sensitive and insulin insensitive. These terms preceded those subsequently used, "juvenile-onset" and "maturity-onset" diabetes mellitus. The validation of Himsworth's original observation came with the development of a bioassay for plasma insulin, and the demonstration by Bornstein and Lawrence that the presence or absence of insulin in plasma allowed the differentiation of two discrete entities – true insulin-deficient diabetes and a second form where either low, normal or high insulin levels were found. Subsequently, over the last several decades, the National Diabetes Data Group (NDDG), the World Health Organization (WHO) Expert and Study Groups on Diabetes Mellitus, and the International Diabetes Federation have attempted to come to grips with the classification of diabetes and other states of glucose tolerance. However, if we accept that there are two major forms of diabetes - type 1 and type 2, then we need to decide whether the current classification is both appropriate and satisfactory? In general, it is reasonable to say that there is dissatisfaction, as the classification may not adequately cover or satisfy aetiological, pathogenetic or clinical aspects. In addition, there is considerable debate about the use of the term prediabetes. If we accept that the risk of CVD in relation to plasma glucose is continuous, if there is no threshold, then are the current diagnostic cut-off points which are based on threshholds for retinopathy appropriate? There is a move to introduce HbA1c as a diagnostic test for diabetes. There is mounting evidence that this is appropriate, although there will be many developing nations and disadvantaged communities where it is not affordable or feasible.

Exercise and insulin sensitivity: mechanisms and potential

0110

Exercise and insulin sensitivity: mechanisms and potential

A. Krook[1]
[1] Karolinska Institutet, Physiology and Pharmacology, Stockholm, Sweden

Skeletal muscle is an extremely flexible organ and adapts immediately to changes in usage. In response to exercise and contraction, skeletal muscle also becomes more sensitive to insulin, and thus physical activity is recognised as both a preventative and therapeutic strategy for treatment of insulin resistance

and type 2 diabetes. These changes are reversible, and thus the opposite effects are noted in response to inactivity. A key question is how these changes are initiated and coordinated at the level of gene transcription, and whether there is a "master" exercise-activated signal. The extent of adaptive changes depends both on the nature and quantity of the demand placed on the muscle. While single bouts of exercise merely alter gene expression transiently, repeated bouts of exercise lead to a range of longer lasting adjustments. Several signalling pathways are activated in direct response to muscle contraction. These include the mitogen activated protein kinase cascades, hypoxia, AMP kinase and Calcium activated signalling events.
This lecture will focus on exercise-initiated events in human skeletal muscle. Possible molecular differences in inter-individual response to exercise will also be discussed.

CLINICAL RESEARCH

Is anti-obesity drug treatment appropriate for treatment of obese patients with type 2 diabetes?

0111

For

L. Van Gaal[1]
[1] *Antwerp University, Endocrinology, Diabetology and Metabolism, Edegem, Belgium*

Obesity is considered to be a major health problem and its prevalence is rising worldwide. Obesity is linked to cardiovascular disease through several mechanisms, but the major consequence is the development of type 2 diabetes. In view of the firm link between obesity and type 2 diabetes and the knowledge that diabetic patients have even more difficulties to lose weight, anti obesity management is considered as a starting issue for treatment of patients with type 2 diabetes.
In addition to lifestyle intervention, pharmacotherapy appears to be effective; it gives rise to modest, but significant and meaningful weight loss.
Only a limited number of drugs can be considered as supportive treatment options for patients with type 2 diabetes: sibutramine, as a serotonin and noradrenalin reuptake inhibitor and orlistat, a gastric and pancreatic lipase inhibitor.
Sibutramine has a mainly central mechanism of action and promotes satiety resulting in weight loss; it also shows some moderate peripheral, mainly thermogenic effects. Despite some actions on blood pressure, individuals with type 2 diabetes may benefit with placebo-subtracted weight loss around 4-5 kg; it also shows improvement of A1c ranging from 0.5 to 0.8 % decrease over 1 year period of observation.
The weight results with orlistat are slightly less effective, showing however similar reductions in A1c; lipase inhibition has the extra benefit of a weight independent effect on LDL cholesterol, particularly of interest in patients at risk such as type 2 diabetes.
After the promising and challenging experience with the endocannabinoid receptor CB1 antagonist –rimonabant- a few medications used in the diabetes field may also offer weight loss properties such as exenatide, liraglutide and pramlintide.
The final conclusion on the outcome benefit of weight loss drugs in patients with diabetes can only be given with outcome trials: the SCOUT study (5 year outcome study, n=10.000 patients, 85 % of whom are diabetics) with sibutramine will be the first large trial to shed some light on this important clinical question.

0112

Against

J. Buse[1]
[1] *University of North Carolina School of Medicine, Department of Medicine, Chapel Hill NC, USA*

How can one argue against anti-obesity treatment in obese patients? Theoretically, these agents have demonstrated adequate safety and efficacy for approval by regulatory authorities.
However, all the available agents are associated with adverse effects, some are only approved for short term use and some are somewhat burdensome to take. Furthermore, at least in many countries of the world, they are not covered by health care plans. In general, their efficacy in promoting weight loss is modest on average and their glucose lowering effectiveness is minimal. Therefore, the reason to avoid the use of these agents is that there is no compelling evidence regarding benefits beyond modest weight loss. And they add complexity, cost, risk and sometimes discomfort in patients who already usually have complex, costly, risky and sometimes discomforting treatment programs targeting diabetes, its complications and its other comorbidities.
Anti-obesity treatment is a distraction for most people with diabetes. Furthermore, the GLP-1 agonists and pramlintide provide the opportunity of antihyperglycemic regimens associated with similar weight loss. The evidence regarding the risks and benefits of anti-obesity agents can be summarized as hopeful and unproven; in an evidence-based, resource-constrained world, why would we even consider using anti-obesity drugs?

Intensive glucose control in the critically ill

0113

Intensive glucose control in the critically ill

S.E. Inzucchi[1]
[1] *Yale University School of Medicine, Section of Endocrinology, New Haven CT, USA*

A large body of evidence has associated hyperglycemia with adverse clinical outcomes in critically ill patients. The biological links between acutely elevated blood glucose (BG) levels and derangements in oxidative stress, vascular endothelial function, coagulation, immune function, and wound healing lend support to the theory that this relationship is 'cause-and-effect.' However, it remains highly controversial as to whether hyperglycemia is an actual mediator of increased morbidity and mortality or simply a marker of the sickest patients. Single-center studies in patients during acute myocardial infarction, following cardiothoracic operations, and in the surgical intensive care unit (ICU) have suggested a marked clinical benefit from the use of intensive insulin infusion to reduce BG concentrations. One study in the surgical ICU actually suggested that outcomes were optimized when euglycemia was achieved.
In follow-up studies from some of these groups, results were mixed and the benefits of intensive glucose control in the ICU could not be confirmed. Furthermore, when the question was subsequently addressed within the context of multi-center studies, outcomes proved to be equivalent between the intensive and conventional therapy groups. In each of these investigations, a significantly increased risk of severe hypoglycemia was observed in the more aggressively treated patients - the implications of which remain unclear. In a recent large, international study, a possible mortality risk from intensive glucose management in the ICU was even raised. While our professional organizations consider emerging data in this rapidly evolving field, it appears that achieving improved but not necessarily normalized BG levels is likely the most reasonable approach.

The evidence both for and against intensive glycemic control in the critical care setting will be reviewed. The importance of choosing a safe, effective and validated insulin infusion protocol will be underscored.

HIV therapy and diabetes risk

0114

HIV therapy and diabetes risk

S. Dagogo-Jack[1]
[1] *University of Tennessee, Medicine (Endocrinology), Memphis, USA*

Highly active antiretroviral therapy (HAART) has suppressed viral load, improved CD4 lymphocyte counts, decreased opportunistic infections, and reduced AIDS-related mortality. However HAART has been associated with adverse metabolic effects, including diabetes, insulin resistance, dyslipidemia, and lipodystrophy. The presentation of antiretroviral-associated diabetes is consistent with type 2 diabetes, and evidence of islet autoimmunity is rare in such patients. Early studies focused on HIV-1 protease inhibitors (PIs) as the most likely cause of the adverse metabolic effects–elegant studies have demonstrated the rapid development of insulin resistance and impairment of beta-cell function following exposure to PIs. The mechanism of insulin resistance involves molecular interference with glucose transport. The common peptido-mimetic core of HIV protease inhibitors bind to GLUT4. Risk factors for diabetes in patients with HIV infection treated with protease inhibitors include family history of diabetes, weight gain, lipodystrophy, older age, and coinfection with hepatitis C. Recent reports indicate that the nucleoside analogs (particularly stavudine) are associated with significant risk of incident diabetes during long-term treatment. Emerging data link nucleoside analogs to insulin resistance, lipodystrophy, and mitochondrial dysfunction, thus providing putative mechanisms for the development of diabetes. The management of diabetes in HIV patients follows the same general principles of dietary modification, physical activity, and selective use of medications. Agents that reduce insulin resistance appear to have a primary role. However, lactic acidosis and hepatic dysfunction associated with HAART regimen, and HIV nephropathy may limit choice of antidiabetic medications. Also, the A1c may be misleading in hemolytic states. Clearly, physicians need to be alert to the adverse metabolic effects of the expanding antiretroviral armamentarium. Furthermore, owing to the efficacy of HAART and improved nutritional status, many patients in remission gain significant weight, which increases their risk for insulin resistance, diabetes, and dyslipidemia.

EDUCATION

Complementary medicines: is there a place in diabetes?

0115

Complementary medicines: is there a place in diabetes?

T. Dunning[1]
[1] *Deakin University and Barwon Health, Centre Nursing and Allied Health Research, Geelong, Australia*

Background: The global prevalence of traditional and complementary and alternative medicine (TCAM) use is increasing globally: range 40%-70%. Significantly, TCAM and conventional care are often integrated, which encompasses a different set of risks than using either type of medicine alone. The World Health Organisation Traditional Medicine Strategy 2002–2005 focuses on four main areas: policy and regulation, safety, efficacy and quality, access, and rational use. Many countries have developed guidelines, regulatory, and training process, and pharmacovigilance systems to enhance safety. Safety is a complex issue consisting of several inter-related factors concerning: practitioner-, consumer-, product-, and health system-related factors. However, practitioner and patient perspectives of risk differ.
Aim: To facilitate discussion about TCAM safety factors (practitioners, consumers, products, health system) that need to be considered when providing diabetes care to people using or contemplating using TCAM.
Method: A case study will be used to stimulate discussion about TCAM safety issues. Session attendees will be arbitrarily divided into five groups: four groups will each discuss one of the four safety areas. Group five will discuss the implications of TCAM use for people with diabetes and diabetes practitioners. Each group will record the main discussion points on a pre-prepared data sheet and then prioritise their top three safety issues, which will be presented to the main group.
Outcome: The session speaker will collect all the data sheets after each presentation and summarise the main safety issues and implications and note any significant issues that did not arise in the discussion.

Developing innovative educational materials and programmes for parents and young people with type 1 diabetes

0116

Developing innovative educational materials and programmes for parents and young people with type 1 diabetes

K. Lange[1]
[1] *Hannover Medical School, Dept. Medical Psychology OE 5430, Hannover, Germany*

With the onset of diabetes, families with an affected child face a new demanding task challenging them from now on for 365 days a year. To support all family members coping with the chronic disease, personalized age appropriate ongoing education has to be an integral part of paediatric diabetes care. Specific educational curricula, didactic concepts and materials adapted to each other for parents and children of different developmental stages will be presented. Especially a new modular demand-oriented education programme for adolescents and their parents will be introduced. It focuses on the comprehensive understanding of the intensified insulin therapy (MDI or CSII), practical skills for integrating diabetes into everyday life, helpful parent-adolescent cooperation and supporting a positive sense of self-efficacy. The initial talk explaining the diagnosis is the first important step of education with far reaching consequences for the families' lifelong coping with the disease. The setting, structure and content of this talk as well as the communication skills necessary to build a trustful relationship will be presented together with the printed information for young people at diabetes onset. Authentic stories and pictures of real-life young patients give first hand experiences about the life with diabetes and serve as role models for learning to cope with the disease. The educational materials consist of four "readers", two directed at "beginners", one aimed at "advanced learners" and the fourth at young people with CSII. In addition a collection of worksheets, problem-solving tasks, real life examples and interactive tasks dealing with subjects like exercise, travelling, illness, eating behaviour, weight control, body image, alcohol and other drugs, family planning and contraception, school, working life, legal issues, late complications and developing own future perspectives are provided for diabetes team members to offer lively educational – training – sessions for young people.

WORKSHOP

Initiate a behavioural change in three minutes – break the barriers!

0117

Initiate a behavioural change in three minutes – break the barriers!

J. Bédard[1]
[1] *Sherbrooke University, Medicine, Sherbrooke, Canada*

Behavioural changes (sedentary, diet, smoking, medication compliance..) are fundamental to the overall management of patients with high cardiovascular risks. Health professionals generally use a uniform approach for all patients: identifying problem behaviours, informing patients why and giving instructions on how to change (traditional directive approach).
Patients, however, don't change!
In response to this problem, we present a universal (identical for all professionals and all behaviours) intervention tool, focused on the patient and leading to recognition, reinforcement and the acceleration of the natural path to behavioural change.
Three concepts have been condensed into a coherent whole, creating a single practical tool to use for interventions that span only three minutes.
The first concept (Prochaska stages) orients the clinician toward the stage the patient is at in his journey. It therefore allows individual planning and defines the goal of each intervention: transition from one stage to the next one.
The second concept (Conviction-Confidence scale) defines the TARGET of the intervention.
Transition into Action that leads to change arrives only when Conviction (perception of advantages) and Confidence (perception of ability) are simultaneously very high.
The targeted intervention is intended to first increase Conviction, helping ready a patient (motivated) for change in the Preparation stage, then boost Confidence (identification of barriers and realistic strategies) leading into Action.
The third concept introduces the communication technique: Motivational Interviewing. Through the skilful use of open questions, it provokes, reinforces and accelerates progress along the path to change rather than directing it.
The open questions are intended to increase Conviction, first of all, by spurring the patient to express personal advantages with high emotional resonance (the three first Prochaska stages) and secondly by leading the patient to identify for himself the barriers and solutions (strategies) leading to the transition to action.
There are three levels on which this technique displays its advantages:

1. The use of such a communication technique, is the foundation of an intervention that is individualized, targeted and efficient in identifying the goal (Prochaska stages) and the specific target of each intervention (Conviction, Confidence).
2. The same tool provides an objective evaluation grid, during subsequent visits, to track success or setbacks in interventions when the patient advances or regresses in their progress, leading to subsequent readjustments of intervention strategies.
3. Finally, the use of this same tool (same language, techniques, etc.) by all members of the same therapeutic team (i.e. physicians, nurses, pharmacists, nutritionists, kinesiologists in a diabetes clinic..) creates a synergy that increases the acceleration of patient progress considerably as they move from one professional to the next.

The strength of intervention increases exponentially thanks to the fact that different professionals become links in the same chain – all pulling in the same direction!
Across the spectrum of medical interventions, we have spent more than 30 years focusing on the WHY of changing patient behaviours – the time has now come to promote the HOW!

DEBATE

ASSOCIATION DEVELOPMENT

The relationships between IDF and diabetes associations

0118

What can IDF do to help associations offer better care to their people

A. Ogbera[1]
[1] *Lagos State University Teaching Hospital, Department of Medicine, Lagos, Nigeria*

DM is associated with reduced quantity and quality of life and is unfortunately approaching epidemic proportions. The IDF has a role to play in checking the afore-stated ugly scenario and it can only do this by ensuring effective partnership with member associations. The IDF can help member associations in the following ways

1. Information and experiences sharing – Very little of this obtains right now, both between IDF and member Associations. IDF should regularly release information to member associations, and encourage member associations to share and exchange information on diabetes from their countries.
2. Capacity building -IDF should partner with institutions to train and develop the capacity of members who are involved in health care provision to people living with DM. For the health professionals, areas of focus should include research, treatment and management of diabetes.
3. Insulin provision: There should be an insulin provision programme for children with type 1 DM from developing countries.
4. Reaching out to countries in distress: Glucose lowering drugs, and glucose meters should be made readily available to member countries undergoing natural and man made disasters.
5. Research collaboration among member associations through the provision of research grants. IDF should initiate and sponsor inter-regional research programmes involving member associations from different countries on routine basis. This will assist in building a knowledge base on the issue of diabetes to inform more effective response programmes.
6. Annual/bi-annual competitions among member associations with modest awards to the best three performing associations. Such healthy competitions will enhance the activities of associations in their respective countries as well as bring the associations much closer to themselves and the IDF Secretariat.

Occasonal visits by the leadership of IDF: This would facilitate interaction, encouragement and assessment of the activities of associations, and provide ideas and advice where necessary for the growth of the associations.

0119

Do we have a tendency to blame IDF for our shortcomings: are the associations doing enough by themselves ?

S. Soegondo[1]
[1] *Pengurus Besar Persatuan Diabetes Indonesia, Faculty of Medicine University of Indonesia, Jakarta*

The IDF as an international organization with precedence to health education, aiming guaranteed access to quality care, training, essential drug supply and support to people with diabetes, and take action to eliminate discrimination against them. Member countries join this only organization for people with diabetes with different hopes and aims. Presently, it is mostly known only by committee members/leaders of the associations/member countries. Its existence or direct impact is only felt by a certain group of people with diabetes of member associations. Some countries have active members but most countries have only members on paper. In many countries the IDF is not felt as an internationally strong organization in convincing their respective governments, compared to organizations on HIV- AIDS, Cardiovascular disease, Cancer etc. IDF officials visiting member countries should make courtesy calls to minister of health or even the head of the states if possible. The IDF succeeded initiating the "World Diabetes Day" / " United Nations Day for Diabetes." Success for publicity but,has no direct impact yet on associations and national policies. Associations in some countries are not strong enough, although they manage to organize activities on diabetes education and care in their

country, but often far from IDF expectations. They still needed support from their government, in implementing the IDF guidelines on diabetes education and management. The magnitude of diabetes as a global problem presented by leaders of an organization with an international network would be more convincing for governments. Many associations do not have the capability and the resources to run their organization and had difficulties to fulfill their duties for different reasons. Comments on IDF shortcomings and association's effort to solve them will be discussed further.

MEET-THE-EXPERT

Aspects in industry-association interactions

0120

Association-industry relations: how to make it a win-win situation !

B. Allgot[1]
[1] *Norwegian Diabetes Association, General Secretary, Oslo, Norway*

The background for interactions between the diabetes associations and the industry is based on some common goals within areas of information, awareness, attention, treatment and education in diabetes.
The diabetes associations often seek funding for their activities and projects. The relations to the diabetes related industry should be based on a broader platform. There are different methods used for interactions and different ways to interact: Awareness campaigns, sponsorship, Exhibitions on congresses, advertisements, mission distribution to different target groups, assisting in recruiting members etc. The platform for the interaction should be based on mutual respect, to protect all partners' integrity and credibility, to ensure transparency and to respect the cooperating partner's independence and different roles. One special challenge is the interaction between professionals and volunteers. On a lot of areas the industry has different, but not contradictive goals than the association, for example internal economic goals and goals for the market for their products. The association should always have focus on enhancing the lives of people – to put the interest of people with diabetes first. It is easier for the associations to cooperate on increasing the market than to interact on sharing the market.
The way to a successful interaction is to understand and increase the awareness of the different roles and to reach agreements of common goals for the interactions. By developing ethical and practical guidelines and by acting with integrity, all partners can experience the fruitful cooperation and the power from working together with the industry.

0121

How to enhance the trust in the association-industry relationship

R.J. Heine[1]
[1] *Eli Lilly and Company, Lilly Research laboratories, Indianapolis, USA*

All major stakeholders, health care professionals and their organizations, have a genuine interest in the quality of diabetes care. But also editors of diabetes journals, scientists, health care payers, and the pharmaceutical & device companies are major stakeholders and share this interest. Why is the public perception of the drug industry, doctors and scientists at an historic low? This is a complex question with no easy answers. The perception is that drug companies, and other for profit organizations, are only accountable to their shareholders, which creates an apparent conflict of interest. It is 'apparent', as these interests, also from a business perspective, should be the same. Unfortunately it is in the human nature to be distracted by financial incentives, scientific fame, career opportunities, and other benefits. How can we prevent misconduct? Recently it was recommended that professional medical associations (PMA) should end all relationships with industry to enhance the public's trust. Others rely on full disclosure of existing relationships. Neither offers a real solution. The first proposal eliminates the considerable brain power in industry and their resources; the latter provides meaningless and often misleading information. The solution needs to be found in professionalizing the relationship. An important distinction needs to be made between scientific relationships (research and development) and commercial ties (promotional activities). PMA's, scientists and physicians can contribute considerably in working together with the R&D activities of the drug industry. This professional collaboration can contribute considerably to health care and patient outcome. However, drug companies have to refrain from commercial studies in the guise of science (seeding trials) or promotional meetings in the guise of education. In addition, the PMA's need to teach their membership to identify and to report this kind of misconduct. This mutual responsibility and accountability will enhance the trust and promote the quality of care.

LIVING WITH DIABETES

Diabetes Youth Empowerment Programme: its value and place in the future of IDF

0122

DYEP: its value and place in the future of IDF

M. Hirst[1]
[1] *Stirlingshire Scotland, United Kingdom*

Though dwarfed by millions of people with type 2 diabetes, there is approaching one million young adults between the ages of 18 and 30 with type 1 diabetes. Traditionally, Members Associations - and IDF - have found it difficult to engage with this group. Young people with diabetes often feel marginalised as a result. At the Global Congress in Cape Town, there was an imaginative Youth Ambassador programme whose potential was never fully realised. DYEP, Diabetes Youth Empowerment Programme, would seek to build on that programme, but in some vitally different respects. Much thought has been given to the DYEP concept in the current triennium, with a view to mainstreaming and developing it in the next.
DYEP would be a Member Association led programme. MAs and those interested in diabetes in that country, would identify suitably motivated young people between the ages of 18 and 30. Working with the MA, the young person would plan a project which was suitable to local circumstances - in advocacy, peer support, or community and youth outreach.
The DYEP candidates would then come together at the biennial Global Congress at which they would share experiences and, with appropriate mentoring, would refine their projects with a view to implementing them over the next two years. The buy-in and encouragement of the MA is considered critical to the success of DYEP.
These young people would represent a powerful cadre of champions for type 1 diabetes. They would thrive on the shared experence of coming together with a joint purpose. All would learn from one another and from their mentors.
A stream of talented, trained, committed future leaders would result for MAs and for IDF. The programme would ideally be self-sustaining, with past DYEP 'graduates' coming forward to help lead the programme in future years.

SPEAKERS' CORNER

Diabetes online

0123

Diabetes online

K. Gilbert[1]
[1] *The Type 1 Diabetes Network, President, Melbourne, Australia*

People living with diabetes are using the internet in new and changing ways to learn about their condition, connect with others, document their experiences and build communities. But is it safe and reliable? Should it be recommended and endorsed? Are online services the efficient and economical future for diabetes education and support?

This session will provide a case study of RealityCheck.org.au, a website founded by people with Type 1 Diabetes in Australia more than 10 years ago. The website is now an active online community and has given rise to a national consumer organisation with 4,000 members, The Type 1 Diabetes Network. With the Reality Check online community remaining at the core, many other services and activities have developed, both online and in other forms. The organisation has published educational materials, created advocacy and awareness campaigns and undertaken original research with marginalised groups.
The case study will explore strategies that have been used by Reality Check over many years to manage the real and perceived risks of online discussions about medical conditions whilst maintaining a lively online community that people with Type 1 Diabetes of all ages actively visit, and which has grown into a multi-faceted consumer organisation.

CLINICAL RESEARCH

PPAR-agonists 10 years on

0124

Physiologic lessons

B. Staels[1]
[1] *Institut Pasteur de Lille, Département d'Athérosclérose, Lille, France*

Because of their wide range of actions on glucose homeostasis, lipid metabolism and vascular inflammation, peroxisome proliferator-activated receptors (PPARs) have been identified as ideal targets for the development of drugs for the treatment of diabetes and its vascular complications. In clinical practice, PPARa agonists, such as the fibrates, improve dyslipidemia, while PPARg agonists, such as thiazolidinediones, improve insulin resistance and diabetes. PPARb/d agonists may improve whole body energy homeostasis and thus prove to be useful for the treatment of obesity and diabetes. The complementary action of simultaneous activation of each PPAR in patients suffering from metabolic syndrome and type 2 diabetes has led to the proposal of pharmacological strategies focused on the development of agonists targeting more than one receptor such as the dual PPARa/g agonists. However, despite the benefits of targeting PPARs, safety concerns have recently led to late stage development failures of various PPAR agonists including novel specific PPARg agonists and dual PPARa/g agonists. These safety concerns include potential carcinogenicity in rodents, signs of myopathy and rhabdomyolysis, increase in plasma creatinine and homocysteine, weight gain, fluid retention, peripheral edema and potential increased risk of cardiac failure. Although the discontinued compounds shared common side effects, the reason for discontinuation was always compound specific and the toxicological or adverse effects which have motivated the discontinuation could be either due to the activation of PPARg, PPARa or both (class effect) or due to a PPAR unrelated effect. Thus, when developing novel compounds, the risk evaluation of each adverse effect should be viewed on a case by case basis considering both the PPAR profile of the drug, its absorption/distribution profile, the nature of the side effect and the putative PPAR-related mechanism of action. The selective modulation of PPAR activities is a promising approach to develop new drugs with preserved efficacy but diminished adverse effects.

Results of the RECORD[1] Trial

H. Beck-Nielsen[1]
[1] *Odense University Hospital, Dept. of Endocrinology, Odense C, Denmark*

[1]Rosiglitazone Evaluated for Cardiac Outcomes and Regulation of Glycaemia in Diabetes (RECORD)
Background: Rosiglitazone is an insulin sensitizer used for glucose-lowering in combination with metformin and/or sulfonylurea in people with Type 2 diabetes. Our aim was to assess cardiovascular outcomes in combination with either metformin or sulfonylurea, compared with the combination of the two, over 5-7 years. Additionally we assessed comparative safety.
Methods: In a multicentre, open-label study, we randomized 4447 people with Type 2 diabetes on metformin or sulfonylurea monotherapy with mean HbA1c 7.9 % to add-on rosiglitazone (n=2220), or to a combination of metformin and sulfonylurea (active control group, n=2227). The primary endpoint was cardiovascular hospitalization or cardiovascular death, with a hazard ratio (HR) non-inferiority margin of 1.20.
Findings: In the rosiglitazone and active control groups 321 and 323 people respectively experienced the primary endpoint during a mean 5.5 years follow-up, which met the criterion of non-inferiority (HR 0.99: CI 0.85, 1.16). Hazard ratios for key components of the primary endpoint included CV death 0.84 (0.59, 1.18), myocardial infarction 1.14 (0.80, 1.63), and stroke 0.72 (0.49, 1.06). Heart failure hospitalizations or deaths occurred in 61 and 29 people in the rosiglitazone and active control groups respectively, HR 2.10 (1.35, 3.27), risk difference 2.6 (0.11, 0.41) per 1000 pt-yr. The rosiglitazone group had increased upper and distal lower limb fracture rates, predominantly in women. Mean HbA_{1c} was lower in the rosiglitazone group at 5 years.
Interpretation: Rosiglitazone is confirmed to increase risk of heart failure, and also risk of some fractures (mainly in women). While the data remain inconclusive regarding any possible effect on myocardial infarction, rosiglitazone compared to standard glucose-lowering drugs shows no evidence of increased risk of overall CV morbidity or of mortality.

Long term trials and cardiovascular disease

L. Leiter[1]
[1] *St. Michael's Hospital, Division of Endocrinology and Metabolism, Ontario M5C 2T2 Toronto, Canada*

Thiazolidinediones (TZDs) are effective glucose-lowering agents, and major long-term trials have confirmed the efficacy of both rosiglitazone and pioglitazone in diabetes prevention (DREAM, ACT NOW), and demonstrated the durability of glycemic control associated with rosiglitazone (ADOPT). In addition to directly decreasing insulin resistance, TZDs have favorable effects on a number of cardiac risk factors and markers including some aspects of the lipid profile, coagulation and fibrinolysis, endothelial function, inflammation and fat distribution. This combination of glucose-lowering and possible vasculoprotective effects suggested a promise of cardiovascular risk reduction associated with this class of drugs. Several studies showing benefits on surrogate markers for atherosclerosis (e.g. carotid IMT) reinforced this promise. Although pioglitazone therapy in the PROactive study did not significantly reduce the broad primary cardiovascular composite endpoint, the so-called "principal secondary endpoint" was reduced significantly. A controversial meta-analysis by Nissen and Wolski brought into question the cardiovascular safety of rosiglitazone. This analysis reported a cardiovascular signal of increased ischemic events, derived primarily from 6- to 12-month studies that were not designed to properly capture and adjudicate cardiovascular events. Longer-term cardiovascular studies and meta-analyses, however, have generally not confirmed this finding, although the risk of congestive heart failure has been increased in most studies. On the other hand, despite the initial promise, there is little outcome data demonstrating a CV benefit of TZD use. This has led some to question the role of insulin resistance in promoting atherosclerosis and/or whether the drug(s) may in fact have adverse cardiovascular effects. Alternatively, the lack of demonstrated benefit may simply be a function of the duration of these trials (i.e. a general lack of CV reduction observed in 3- to 5-year glucose-lowering trials).

0127

TZDs and bones

I.R. Reid[1], *A.B. Grey*[1]
[1] *University of Auckland, Medicine, Auckland, New Zealand*

TZDs are now widely used in the management of diabetes, and of some pre-diabetic conditions. They act via the PPARγ nuclear transcription factor, which is expressed in a number of tissues. In stromal cells, activation of PPARγ promotes differentiation along the adipocyte lineage in preference to that of osteoblasts. In addition, by reducing insulin resistance, TZDs are likely to reduce circulating levels of bone anabolic factors, such as insulin, amylin and preptin. Some pre-clinical data suggest that activation of PPARγ stimulates osteoclastogenesis. As a result of these actions, we hypothesized that TZDs might have adverse effects on bone in humans, and conducted a 3-month, randomized, controlled trial in normal postmenopausal women to assess this possibility. Indices of bone formation were decreased by 10-15% within the first month of intervention, without comparable decreases in bone resorption. Associated with this, was a 2% decrease in total hip BMD and a 1.5% decrease in lumbar spine BMD during this short-term study. These data suggested that the detrimental bone effects of these drugs in rodents apply to humans also, and led to an examination of fracture frequency in subjects using TZDs. Adverse events data from controlled clinical trials indicate that TZDs are associated with an increased frequency of limb fractures in women, and observational data suggest an increase in risk of "classical" osteoporotic fractures in both sexes..The rapidity of bone loss and the extent of the increase in fracture incidence suggest that fracture risk assessment should be undertaken in most individuals using TZDs. In most cases this will involve bone density measurement. New agents in this class need to be assessed for their skeletal effects and trials are needed of interventions that may potentially mitigate these adverse changes.

EDUCATION

Diabetes in the young

0128

Insulin therapy in the very young

O. Kordonouri[1]
[1] *Kinderkrankenhaus auf der Bult, Diabetes Center for Children and Adolescents, Hannover, Germany*

The incidence of type 1 diabetes has been increasing rapidly in the last decades, particularly in children younger than 5 years, where a doubling of new cases is predicted between 2005 and 2020 (Patterson et al. Lancet 2009). Optimal treatment aiming not only the achievement of the best possible glycemic control from the beginning of the disease without inducing severe hypoglycaemia, but also normal somatic and psychosocial development of the very young patients is crucial and of great importance.
In the last decade, a paradigm shift has occurred concerning the insulin therapy in pediatric diabetes. While previously it was thought that the best way to overcome barriers of treating children would be to spare them from an insulin regimen consisting of many daily injections, nowadays the majority of pediatric diabetologists feel that the gold standard treatment is intensified insulin therapy. This therapy is based on the basal-bolus principle and aims to mimic the physiological insulin profile seen in non-diabetic individuals as closely as possible. This kind of regimen is believed to allow the flexibility required with the lifestyle needs of young children with diabetes and help their families to better cope with the demands of the therapy. To match these challenges for individually tailored therapy, the choice of short-, intermediate-, long-acting insulins, and insulin analogues, as well as of devices like insulin pumps and glucose sensors have been established as treatment options for young children with diabetes.
Moreover, initial age-appropriate diabetes education as well as subsequent ongoing education during the long-term course of the disease represents an integral part of each therapeutic regimen. Diabetes education is the basis for a self-determined implementation of adequate therapeutic measures by parents and children. Furthermore, support from school and day-care is also important in the very young patients, because good diabetes management has to be maintained even when the children are away from home.

0129

Exercise and the adolescent

M. Riddell[1]
[1] *York University, School of Kinesiology and Health Science Muscle Health Research Centre, Toronto, Canada*

For adolescents with type 1 diabetes, regular physical activity should be a cornerstone of care as it enhances cardiovascular fitness, increases lean mass, improves blood lipid profile, supports psychosocial well-being and health and reduces diabetes-related complications. Compared with sedentary behaviour, being physically active enhances insulin sensitivity and is associated with better haemoglobin A1c (HbA1c) levels in epidemiological studies of youth with type 1 diabetes. Surprisingly, however, clinical trials in which youth with type 1 diabetes undergo aerobic training often fail to demonstrate improvements in HbA1c with regular exercise. This paradox may be explained by the fact that exercise causes increased incidence of hypoglycemia and poor strategies are in place to help youth with diabetes prepare for exercise and competition. Exercise also can cause hyperglycemia, particularly when the event is very vigorous in nature or when there is a high level of competitive stress. This lecture highlights the physiological regulation of blood glucose levels in adolescents with type 1 diabetes during and after sport, and provides recommendations on insulin and carbohydrate intake regimens to help prevent exercise-associated dysglycemia.

Diabetes complications: educating adolescents

J. Cusumano[1], *M. Craig*[1], *M. Silink*[1], *K. Donaghue*[1]
[1] *The Children's Hospital at Westmead, Institute of Endocrinology and Diabetes, Westmead, Australia*

Adolescents appear to consider health the absence of disease rather than the maintenance of wellbeing. Thus educating adolescents with diabetes on future potential problems is challenging.
Since 1989, the Children's Hospital at Westmead has run a dedicated Diabetes Complications Assessment Service (DCAS). Screening for microvascular changes for our adolescents begins 2 years after diagnosis and closely follows ISPAD guidelines. We believe that screening is an essential component in the education of our adolescents. We assess for retinopathy, nephropathy and neuropathy and educate throughout the screening process.
We recently invited a group of young adults to return to our clinic for a follow up study. 101 completed a current health care questionnaire. We included basic questions on the frequency of screening for retinopathy and microalbuminuria. 55% knew the recommended frequency of screening for retinal changes, 18% stated they did not know. 43% knew how often kidney function should be reviewed, 29% stated they did not know. 39% correctly answered the screening frequency for both. Only 6 people stated they did not know if they had diabetes related eye problems but 34 reported they didn't know if they had problems with kidney function. 66% could give a value for their last HbA1c. They were asked how often their HbA1c's should be assessed and 39 answers were correct. Just 18 young adults were correct in their answers regarding the recommended frequency of HbA1c, retinal and renal assessment. 81 people reported they see an adult endocrinologist for diabetes care with the frequency of visits ranging from 3 monthly to 2nd yearly.
This snap shot reinforces our experience that adolescents are more concerned about diabetes affecting their vision. To us they appear most attentive during retinal screening. The message we deliver to adolescents needs to be brief, simple, relevant and positive.

Managing children with diabetes in Bolivia, an underserved country

E. Duarte de Muñoz[1]
[1] *Vivir con Diabetes, Medicina, Cochabamba, Bolivia*

Summary: Bolivia is a developing country with a weak health system. Diabetics do not have assistance, except that provided by the so-called "health insurance".
No child with diabetes in Bolivia has equipment and supplies for self-control and they do not have the economic capacity to acquire them.
The IDF's LIFE FOR A CHILD developed in Bolivia through the work with the Center VIVIR CON DIABETES, has filled an important gap in the care of children with diabetes in Bolivia.
Objectives: Provide children with diabetes in Bolivia, especially the poor, the opportunity to have access to insulin, meters and test strips.
Conduct an educational program, offering this program to parents and families of children with diabetes with distinct content.
Evaluate effectiveness of an educational program when combined with the supply of insulin, glycemic control and the involvement of the family.
Sample:
Group 1: children with diabetes living in Cochabamba, Headquarters of the Center Vivir con Diabetes.
Group 2: children with diabetes receiving insulin and strips but live in other regions of the country where the educational program is not being developed.
Methods:
- Registration of persons, treatment, weight, height, glycated hemoglobin, lipid profile, renal function tests and checks at 6 and 12 months
- Modular implementation of education programs, participatory constructivist method
- Program evaluation and laboratory control.

Expected results: That children with diabetes in Bolivia have the same opportunities for children and young people from other countries.
That children and young people with diabetes and their families in Bolivia have access to diabetes education, through a multidisciplinary team.
That children and young people with diabetes through an optimal treatment and control have an excellent quality of life and do not present complications in the future.

CLINICAL RESEARCH

Genetics of type 2 diabetes - relevance to clinical practice

0132

Understanding the genetic approach to obesity and type 2 diabetes

V. Mohan[1]
[1] *Dr. Mohan's Diabetes Specialities Centre & Madras Diabetes Research Foundation, Department of Diabetology, Chennai, India*

Over the past few decades several approaches have been used to unravel the genetics of type 2 diabetes (T2DM). The first was to focus on forms of type 2 diabetes transmitted with a Mendelian dominant pattern of inheritance and this led to the discovery of genes involved in Maturity Onset Diabetes of the Young (MODY). The second approach looked for variants in candidate genes associated with T2DM. This led to the identification of genes such as PPARg, ***KCNJ11*** and ***ENPP1*** genes to be associated with T2DM. The most powerful approach is the recent high-throughput genome wide analysis studies (GWAS) which have identified several novel genes associated with T2DM and obesity including the TCF7L2 gene.
Large population based (Chennai Urban Rural Epidemiology Study) genetic studies carried out by us have shown some unique genetic findings among Asian Indians who have increased susceptibility to T2DM. The Pro12Ala polymorphism of the PPARg gene, which is known to be protective against diabetes in Europeans, does not offer protection to Indians. We also observed that the Thr394Thr (G®A) polymorphism of PPARGC-1 α gene was strongly associated with T2DM as well as body fat in Indians. Further, the Gly1057Asp polymorphism of IRS-2 gene predisposes Indians to diabetes particularly in the presence of obesity. Subjects with TCF7L2 gene G>T polymorphism at rs12255372 showed a 1.5 fold higher risk of having diabetes confirming similar association in other populations. Some genes like the FTO gene are associated both in obesity and T2DM.

No conflict of interest

0133

Implications of genetics to clinical medicine

S. Del Prato[1]
[1] *University of Pisa, Endocrinology & Metabolism Section of Metabolic Diseases and Diabetes, Pisa, Italy*

Over the past few years there has been an impressive improvement in the ability to identify new genetic risk factors that contribute to the development of type 2 diabetes (T2DM). This advance is largely attributable to surveys of genome-wide association in large samples of the population. Approximately 20 common genetic variants have been recognized to be implicated in the susceptibility to T2DM and almost all of them are related to impairment of insulin secretion. Expectation has been generated that some of these genetic variants may allow better identification of subjects requiring specific prevention measures. This possibility has been tested by assessing the discriminative power of genetic as compared to clinical risk factors to show that common genetic variants associated with risk of diabetes have small effect on the ability to predict the disease. Addition of specific genetic information to the clinical factors, however, slightly improved prediction suggesting that more accurate information on gene – environment interaction should be gathered. An example of such interaction has been highlighted with respect to CV risk. A substantial portion of the T2DM subjects may carry a common allele on chromosome 9p21 associated with risk of coronary artery disease (CAD) in the general population. In diabetic individuals a strong interaction between genotype and glycemic control has been reported. Identification of risk allele carriers may allow better risk stratification although generalization of these observations require confirmation. Genetic factors may also affect response to glucose-lowering medications. For instance, a greater reduction in fasting plasma glucose and HbA1c can be seen in carriers of Pro12Ala PPARγ polymorphism treated with thiazolidinediones. Nonetheless, the pharmacogenetic associations reported so far still have limited impact on the choice of individual treatments. In conclusion, the possibility of translating genotyping into clinical medicine is not yet available and further advances in our capacity to understand disease mechanisms, to gain better interpretation of the impact of genetic variants on risk and drug response, and to effect clinical translation is required.

Genetics of type 2 diabetes

L. Groop[1], *V. Lyssenko*[1]
[1] *Lund University, Clinical Sciences Diabetes & Endocrinology, Malmö, Sweden*

While the genetic causes of monogenic disorders have been successfully identified in the past, the success in dissecting the genetics of complex polygenic diseases has until now been limited. The picture has dramatically changed during the last years with the introduction of whole genome wide association studies (WGAS). In 2007 five WGAS have been published on genetics of type 2 diabetes (T2D) and 10 genes were shown to be consistently associated with T2D (TCF7L2, PPARG, KCJN11, CDKAL1, IGFBP2,CDKN2A/CDKN2B,HHEX, SCL30A8, FTO and WSF1). A recent meta-analysis added 6 more variants to this list and replication efforts of glucose-related traits have shown that variants in G6PC, GCK, GCKR and the melatoninreceptor MTNR1B are associated with glucose and insulin levels. Common to most of these variants is that they seem to result in impaired beta-cell function. Individuals who carry these variants seem to be unable to increase their insulin secretion in response to an increase in BMI and insulin resistance to maintain glucose tolerance normal. It is premature to start to use these genetic variants for prediction of T2D as we have only been able to explain a small proportion of the familial risk of T2D. We shall though not underestimate the importance of dissecting novel biological pathways for the pathogenesis of T2D, some of which might become potential new drug targets. An important step will also be to use the genetic information for prediction of disease progression, development of complications and response to treatment, i.e. a step towards individualized medicine.

Since genetic research has been driven by technical progress, we can anticipate that the possibility to sequence the whole genome within the next years will allow a much more comprehensive genetic map of T2D.
For the first time we can with some confidence anticipate that the genetics of a complex disease like T2D really can be dissected.

Genetics of obesity and height

P. Froguel[1,2]
[1] Imperial College London, Genomic Medicine, London, United Kingdom
[2] Pasteur Institute, CNRS8090-Institute of Biology, Lille, France

Twin and family studies have consistently reported that more than 70% of the human individual variation in adiposity is apparently due to genetic factors. Human height (stature) is even a stronger genetic trait, with up to 90% of the variation in height within a population determined by a combination of multiple inherited factors. Genome Wide Association Studies (GWAS) conducted in dozen of thousands individuals have consistently identified common genetic variations that are associated with stature or with Body Mass Index. So far, up to 300 genetic loci have been reproducibly shown to have an influence on adult height. About 50 loci modulate BMI and increase risk for obesity. Many of these loci also harbor rare mutations responsible for more severe alterations in height/skeletal growth or associated with severe obesity. In this regard, same genes/pathways contribute to both "normal" and pathological phenotypes associated with body corpulence or stature.
The main lesson from genetics studies in obesity is the key causal role of genes involved in appetite/food intake behavior expressed in the CNS. In this regard, the leptin-melanocortin pathway has a central role in human appetite regulation. The newly discovered obesity gene FTO is also likely to modulate food intake. More diverse pathways not well elucidated are involved in stature. Although the predictive value of the common variants thus far discovered remains low, the identification of these loci has led to new insights into the biology of human growth and adiposity, and should help identify genes that underlie previously uncharacterized severe conditions linked to obesity or abnormal skeletal growth, opening new avenues for better treatments.

HEALTHCARE AND EPIDEMIOLOGY

Diabetes and hyperglycaemia: the size of the problem

0136

Cost and projection of the problem

J.A. Johnson[1]
[1] University of Alberta, Public Health Sciences, Edmonton, Canada

Diabetes is a worldwide concern. Globally, the prevalence of diabetes has increased fivefold in the past 30 years, with some considering it an epidemic, driven largely by increasing prevalence of diabetes risk factors, such as aging of the population and obesity. According to World Health Organization (WHO), 171 million people worldwide had diabetes in 2000 and this number will reach 366 million by the year 2030. The clear majority (near 95%) of cases are type 2 diabetes. Despite improved survival overall, mortality rates for people with diabetes remain twice as high compared to those without diabetes, contributing to a 20% reduction in life expectancy, about 11 years of life lost, on average. The accumulation of comorbidities and complications in people with diabetes is also associated with tremendous costs to our health care systems and reductions in functional status and quality of life for individuals living with this disease. Estimates of health care costs have suggested that people with diabetes have 2 to 3 times the health care costs of people without diabetes. Annual health care costs for people with diabetes increase with time following initial diagnosis, and are driven largely by the cost of care for cardiovascular comorbidities. Epidemiologic and economic forecasting models have been developed to predict the future burden and serve as basis for economic evaluations of new treatment strategies.

0137

Changing population shift

P. Aschner[1]
[1] Universidad Javeriana and Asociación Colombiana de Diabetes, Research Center, Bogotá, Colombia

In most populations, the variation of blood glucose forms a continuous unimodal distribution skewed towards the higher values corresponding to people with impaired glucose regulation. The latter are considered at high-risk for developing diabetes and their frequency is increasing (as much or even more than people who already have diabetes and are at the far end of the distribution). What has not been fully recognized is that the glucose distribution of the normal glucose tolerance (NGT) majority also has been shifting to the right, indicating that the whole population is involved. We compared a rural and an urban population where the latter had a prevalence of IGT and diabetes almost double, and the mean blood glucose of the population with NGT was also significantly higher while the coefficient of variation remained roughly constant. Other variables related to diabetes such as weight, blood pressure and triglycerides had a similar trend.
Although the high-risk group has been the target for successful preventive interventions, there is a rationale for changing the population shift by generalizing these interventions, particularly those involving lifestyle changes. It has been hypothesized that moderate and achievable change by the population as a whole might greatly reduce the number of diseased people.
There have been good examples of collective interventions in different parts of the world, but unfortunately they are seldom evaluated at the population level and proving their effectiveness is problematic. They are usually complex and multifaceted, require ingenuity and involve many actors. They may be difficult to implement in other settings due to different priorities, resources, policies and cultural barriers. Nevertheless, they may be the only way to change the population shift in such risk factors as weight and other components of the metabolic syndrome which are driving the diabetes epidemic.

0138

Population - glucose curves

J.K. Cruickshank[1]
[1] University of Manchester, Cardiovascular Sciences & Diabetes, Manchester, United Kingdom

The notion that the basis for T2 diabetes (T2DM) world-wide can be characterised from distributions of glycaemia is out-of-date, now intellectually bereft & possibly dangerous to patients. Evidence that blood glucose, whether 'fasting' or after GTT, is a genuinely independent risk factor for what matters long-term in T2DM, namely cardiovascular, retinal & renal vascular damage / events, is inconsistent and inconclusive. BMI & fat distribution are the major issues, from low starting ranges (eg: $<23 kg/m^2$ in 2 large European-origin, lower in South Asian, populations). Major treatment trials recently published all show that current treatment directed just at glycaemia, tightly or even moderately controlled, have no impact on mortality and may cause death earlier than does standard care, with no impact on stroke, all vascular events nor, contrary to a recent meta-analysis dubiously omitting $\geq$2 important trials to include 1 secondary prevention, useful effect on coronary events. Weight gain in all was substantial - the opposite of physiologically appropriate treatment like metformin. Much-quoted UKPDS, a relatively small but highly complex, multiply sub-randomised trial, showed only very slight impact on eye disease, with effect limited to progression, not prevention, and dubiously significant if events in the intensive blood pressure treatment arm are excluded. These issues have been difficult to debate because they are unpopular, reminiscent of UGDP trial controversies in the 1970s.
In different global populations, blood vessel damage, notably in small resistance vessels & 'stiffening' of larger arteries, is already present ***prior to*** elevation of glycaemia. These and other new data suggest that 'hyper'glycaemia may only be a late development in what precedes such T2DM pathology. While controversial, such data and poor response to expensive, intensive therapy suggest IDF needs to grasp 'non-glycaemic' definitions of T2DM to develop the world's 'diabetes' needs appropriately.

No conflict of interest

0139

Scale of the problem globally

J. Shaw[1]
[1] *Baker IDI Heart and Diabetes Institute, Epidemiology, Caulfield, Australia*

Recent decades have seen a major rise in the number of people with diabetes worldwide, even after accounting for changes in diagnostic criteria and in screening policies. Several factors have been responsible for these changes. Firstly, behavioral and environmental changes mean that the prevalence and risk of type 2 diabetes have risen rapidly. This is best illustrated in countries such as India, in which the prevalence of diabetes in big cities is six times that seen in rural communities. As urbanization rapidly progresses in developing countries, the proportion of the population adopting behaviors that increase their risk of diabetes will continue to grow. Secondly, even if the age-specific risk for diabetes had remained unchanged, we would still have seen the number of people with diabetes rising, simply as a consequence of increases in population size and, in particular, in the numbers of older adults. Thirdly, better care for people with diabetes has improved survival, and so even if the numbers of people developing diabetes remained static, the proportion of the population with diabetes at any one time would have risen.
Although type 2 diabetes has often been seen as a 'Western' disease, and the health problems of developing countries have centred on communicable diseases, the overwhelming majority of people with diabetes now reside in the developing world, and diabetes, along with cardiovascular disease and other non-communicable diseases are beginning to dominate the health problems of the developing world.
Whilst much attention has focused on the rising numbers of people with type 2 diabetes as a result of changes in diet and in physical activity, leading to obesity, there has been an even greater rise in the numbers of children developing type 1 diabetes. This phenomenon has now been described in a number of countries, but has not yet been explained.

Genetic regulation of islet ß-cell function and survival

0140

Novel approaches to understand epigenetic regulation of islet ß-cells

K.H. Kaestner[1], *R. Bhandare*[1], *J. Schug*[1], *N. Brämswig*[1], *M. Penn*[1]
[1] *Institute for Diabetes Obesity and Metabolism, Genetics, Philadelphia, USA*

Aims: The chronic metabolic insults experienced by the pancreatic islet in type 2 diabetes are likely to not only affect the acute gene regulation of beta-cells, but also be reflected in their epigenetic program. We hypothesized that analysis of epigenetic marks of islets from normal or diabetic organ donors can reveal new targets for intervention to improve health and function of beta-cells.
Methods: We employed ChIP-Seq, or the ultra-high throughput sequencing of millions of DNA fragments occupied by a given histone modification to analyze the methylation status of human islets. We focused on the activating marks, histone H3K4me3 and H3K4me1, and the repressive mark, H3K27me3. We also determined the complete microRNA profile of normal and diabetic islets by direct sequencing, and the mRNA profile by microarray analysis.
Results and conclusions: Activating and repressing chromatin marks were remarkably consistent between islets preparations. The same was true for the microRNA profile. Comparison of the chromatin marks between normal and type 2 diabetic islets suggests several pathways that are impaired in the diabetic islet.

Using epistasis to dissect regulatory networks in islet ß-cells

J. Ferrer[1]
[1] *Hospital Clinic/IDIBAPS, Endcrinology, Barcelona, Spain*

Understanding the epigenetic make up of pancreatic insulin producing beta-cells is relevant for efforts to reprogram beta-cells for the treatment of diabetes, to understand how transient environmental cues could lead to long-lasting changes in beta-cells, and to unravel the effects of genetic variation on beta-cell gene regulation. Our current knowledge of the beta-cell epigenome, however, is extremely limited.
We have now used tiling arrays to create a signature of histone modifications in purified mouse pancreatic beta-cells. We determined the unique properties of this signature by comparison to a panel of mouse tissues. We also examined how these modifications are placed during development by examining pluripotent cells, multipotent pancreatic progenitors, and differentiated pancreatic cells. The results revealed that the beta-cell exhibits a program of genes that undergoes selective repression by trimethylated Lysine 27 histone H3. This program is formed by the de novo acquisition of histone modifications during embryonic development, and is consequently shared in part with other cells of common ontogeny. Another major epigenetic program of beta-cells is composed of genes that are selectively derepressed in beta-cells and neural tissues, and thus exhibit lack of trimethylated Lysine 27 histone H3 specifically in these cell types. This program is activated during late stages of beta-cell differentiation concomitantly with the repression of the transcriptional repressor Rest. These results thus identify two major programs that define the epigenetic phenotype of the pancreatic beta-cell.
We have also combined next-generation sequencing technologies with formaldehyde assisted isolation of regulatory elements (FAIRE) to map open chromatin sites in human pancreatic islets. These studies revealed the existence of broad islet-specific regulatory domains linked to known and putative developmental regulator genes. They also provided an opportunity to assess the impact of human sequence variants on chromatin structure in human pancreatic islets, and point to potential epigenetic mechanisms underlying the susceptibility to Type 2 diabetes.

0142

Gene networks regulating islet ß-cell apoptosis

D.L. Eizirik[1]
[1] *Laboratory of Experimental Medicine CP 618, Universite Libre de Bruxelles (ULB), Brussels, Belgium*

Pancreatic beta cells die by apoptosis in early type 1 diabetes mellitus (T1DM). Recent observations by our group suggest that beta cell apoptosis depends on the parallel and/or sequential up- and down-regulation of hundreds of genes. By performing microarray analysis and detailed promoter studies in primary rat beta cells and in human islets exposed for different time points to the cytokines interleukin-1b (IL-1b), tumor necrosis factor-a (TNF-a) and interferon-g (IFN-g) and to diabetogenic viruses, we observed that beta cells respond to damage by triggering several genes involved in defense/repair and endoplasmic reticulum stress, by decreasing their most differentiated functions and their capacity for growth and regeneration, and by inducing expression of diverse cytokines and chemokines. Several of these effects of cytokines are regulated by the transcription factors NF-kB and STAT-1, and by blocking NF-kB or STAT-1 we prevented both cytokine and dsRNA + cytokine-induced beta cell death. Subsequent experiments, combining NF-kB or STAT-1 blocking and microarray analysis, suggested that both transcription factors function as "master switches" of respectively IL-1b and IFN-g effects on beta cells, controlling networks of transcription factors and effector genes that trigger apoptosis and inflammation. Other transcription factors, such as JunB, may function as "protective regulators", decreasing expression of pro-apoptotic genes and modulating endoplasmic reticulum stress. By combining functional studies with microarray and proteomic analysis, performed with or without targeted perturbations of the system, it will be eventually possible to fully map the interacting networks of genes and proteins leading to beta-cell death and amplification of the immune assault. This should allow the search for a cure for T1D to move from an empiric and blind approach to one that is really mechanistically driven.

The role of miRNAs in islet ß-cell function

M. Stoffel[1]
[1] *Institute of Molecular Systems Biology, Zurich, Switzerland*

MicroRNAs (miRNAs) are an abundant class of short non-coding RNAs that have been identified in the genomes of a wide range of organisms. They bind through imperfect base pairing with specific sequences in target mRNAs. This induces either degradation of the target mRNA or translational repression. This mechanism resembles the process of RNA interference triggered by double-stranded RNA and utilizes a similar molecular machinery. To date, dysregulated expression of miRNAs has been implicated in several disease areas. In this lecture the biological function of several miRNAs in the regulation of glucose and lipid metabolism will be discussed. In addition, novel approaches will be illustrated that allow the inhibition of specific miRNA in vivo and might be exploited to effectively regulate therapeutically relevant disease processes.

Prenatal nutrition of mother and child: is it critical?

C. Yajnik[1]
[1] *K. E. M. Hospital, Diabetes Unit, Pune, India*

Conventionally, chronic non-communicable diseases (NCDs) are thought to result from genetic susceptibility, aging and modern lifestyle. Hales and Barker demonstrated that low birth weight was a risk factor for diabetes and cardiovascular disease, which led to the theory of Developmental Origins of Health and Disease (DOHaD). Maternal nutrition is thought important in fetal programming of health and disease.
It is intriguing that the Indian subcontinent is the seat for highest number of low birth weight babies and is also the world's capital of diabetes. Studies in India have shown that low birth weight predicts increased risk of diabetes (Delhi) and cardiovascular disease (Mysore). In Pune we demonstrated that low birth weight was an independent risk factor for childhood adiposity, insulin resistance and other cardiovascular risk factors. Children born small but grown big had the highest risk.
Pune Maternal Nutrition Study was one of the first studies to investigate the effect of maternal nutrition on fetal growth and risk of NCD. We found that maternal consumption of foods rich in micronutrients predicted fetal growth. Maternal vitamin B12 deficiency was associated with intrauterine growth retardation, and childhood adiposity and insulin resistance, especially if maternal folate status was excessive. We have called this as 'nutrient mediated teratogenesis'. Research in Pune and Mysore also showed that vitamin B12 deficiency increase risk of maternal hyperglycemia, which in turn increased the risk of offspring adiposity and glucose intolerance ('fuel-mediated teratogenesis').
It is well known that maternal nutrition influences fetal development (folic acid prevention of nerural tube defects and effect of iodine supplementation on brain development). DOHaD research suggests it may also help reduce the burgeoning epidemic of chronic non-communicable disease.

Postnatal nutrition: the good,bad and ugly

R. Raab[1]
[1] *Insulin for Life Inc, President, Victoria, Australia*

A Past Secretary-General of the International Society for Paediatric and Adolescent Diabetes stated:
'Nutritional management is commonly described as one of the cornerstones of diabetes care; unfortunately, it is the cornerstone which may be least understood, most under-researched, and to which there is the poorest adherence.'
The current recommendation for diabetes of 50% or more of daily calories from carbohydrate (approx 280 gms) is equivalent to 55 teaspoons of sugar or 4 glucose tolerance tests equivalent daily.
Smaller amounts of carbohydrate can result in the following advantages:

1. Greater accuracy in measuring the actual amount of carbohydrate in a meal
2. Smaller amounts of insulin and more predictability in insulin absorption
3. Less serious hypoglycaemia
4. Less delayed stomach emptying, a common, unpleasant and debilitating problem.

These produce more predictability, and less variation in blood glucose levels, and a better quality of life.
The high carbohydrate recommendations grew out of concern with the role of fat in contributing to heart disease. We now know that in fact 'healthy' fats provide protection. The calories from carbohydrate can be replaced with healthy fats such as, for example, avocado, olive oil in cooking and salads, and some types of fish, and many others, making the adoption in daily life of a low, or lower, carbohydrate regime quite easy.
Diabetes is a problem of carbohydrate intolerance and those who are pre-diabetic, susceptible to diabetes or the Metabolic Syndrome will also benefit significantly from a lower carbohydrate regime, and this can have a major role in responding to, and helping prevent, the current diabetes epidemic.

0146

Quality, quantity and timing

M. Wijesuriya[1]
[1] *Colombo, Sri Lanka*

Diabetes is the commonest illness related to nutrition in both its aetiology and its management. Abnormal dietary habits, inadequate physical activity and psychosocial stress often contribute to its development. However, proper nutrition using simple guidelines of quality, quantity and timing are the main stay of non pharmaceutical lifestyle intervention in prevention.
The quality of the meals that we consume throughout life determines good health and protects us from illness. Good quality meals are often natural products, high in nutrition and fibre without any significant refining, polishing and extraction by man. Refined products such sugars, polished starches, oils and fats produce poor satiety resulting in increased consumption, frequent intake which leads to obesity with its high risk of developing T2DM.
Quantity of food intake is determined by the degree of refinement and the timing of meals. The more refined the product, the greater the need for increased quantity to obtain satiety. This will increase the frequency of intake resulting in excess weight gain and obesity.
Proper timing of meals to prevent excessive hunger is essential as it protects the person from frequent high calorie food intake. Modern lifestyle with its attendant pressures of work and study often predisposes to such irregular unhealthy eating habits.
What is good for a person living with diabetes is good for all.

Combating obesity 'spare tyre checks' at motorway services

J. DeVille-Almond[1], *J. Potter*[2]
[1] *Independent Nurse Consultant, National Obesity Forum UK/Men's Health Forum UK, Wolverhampton, United Kingdom*
[2] *University of Chichester UK, Obesity, Chichester, United Kingdom*

This work intended to look at how men perceive their health in relation to obesity.
This paper presents data collected from 266 men (19-84yrs) who visited MOTO service stations on motorway networks during the summer of 2007. Men were offered 'spare tyre checks' at a health check station making the data unusual in that it provides information from the general population and not those visiting clinicians.
The subjects had a number of health indices measured including; body composition by BIA (Tanita BC-420MA), waist circumference. They were also asked a number of questions regarding their perceptions of themselves in matters of health.
The subjects were found to be significantly ($t_{(263)}$= 25.04, p<0.001) overweight (23.01 ± 16.82 kg) and had a mean excess of 4.95 kg of fat. Paired samples t-tests revealed significant differences between their guessed waist and their real waist measurement ($t_{(263)}$=-18.69, p<0.001) with the average estimate being 3.4 ±3.7 inches under. As their waist circumference increased the men regarded their weight to be more important than waist circumference. Subjects were asked to categorise themselves in terms of their body composition. Of those with BMI's 30-35kg/m^2 89% underestimated their size, with 60% of those in the morbidly obese category of >35 kg/m^2 thinking that they were not obese.
The differences between perception and reality that individuals have is likely to have an impact on the effectiveness of any education and intervention programme as they will deem the information or process the information more or less relevant to themselves.

How to make diabetes care affordable, available and accessible

A. Castillo[1]
[1] *Belize Diabetes Association, NGO, Belize City, Belize*

Diabetes, one of the chronic diseases affecting humans, is unfortunately on the rise globally. This increase signifies that worldwide, more persons are in need of education, information, medication, and testing supplies to cope with this condition.
While there may be ethnic groups that show significant susceptibility to Diabetes, on an average, this condition does not discriminate. Diabetes affects persons from diverse ethnic groups and socio economic status.
Although Diabetes has been around for many years, and there have been varied treatments, and various testing equipment, the costs continue to be exorbitant. Undoubtedly, the socio-economic condition of a country impacts the level of healthcare that can be made accessible to its people. Persons in the lower and middle income bracket, often make difficult decisions on whether to spend on food or medication. In many instances the choice is to obtain the food and not the medication.
This presentation seeks to identify ways of making Diabetes Care **Affordable**, **Available** and **Accessible** to persons of all walks of life.
It is evident that no one entity can adequately address the aforementioned issues and derive equitable solutions that would be favorable to all concerned. In this era of global recession it's prudent that all bodies concerned join forces for the good of humankind.
This presentation looks at the role of governments, the pharmaceutical companies, Diabetes Associations and other private entities in making Diabetes Care attainable to all.

0149

Taking diabetes care to the people: change in management paradigm, not the problems of diabetes, but the solutions

S. Bahendeka[1]
[1] *Saint Francis Hospital, Medicine, Kampala, Uganda*

Management approaches of diabetes have traditionally been centred on problems resulting from the effects of diabetes; highlighting known solutions to these problems and health care providers being the most important source of information, with little emphasis on expanding the diabetic care services into the community settings. However, to create a healthy community, the entire community needs to take an active and positive role in changing those community factors that continue to place people at risk. Furthermore there is evidence that interventions are more likely to see successful reduction in rates of onset and progression of diabetes by developing services and resources tailored to the needs of various communities, whether based on income, language or diabetes type, as well as other factors. In the community approach (taking diabetes care to the people), the goal in the management of diabetes is to empower those with diabetes, their families, health professionals, and others at the community level, including families, schools, work sites, local government, and community organizations to work together to prevent and control diabetes. This involves (i) promoting healthy behaviors to prevent type 2 diabetes and other chronic diseases, (ii) implementing education and support programs for people with diabetes, (iii) convening a coalition to address the issues of diabetes in the community, (iv) creating and publicizing a profile of the impact of diabetes in the community, (v) providing diabetes education and training for health professionals, (v) facilitating improvement of diabetes care in clinical settings and (vi) identifying barriers and disparities of access to health care and eliminating them. In order to continue this positive trend there is need to shift the diabetes management paradigm from the traditional health care provider centred approach to solutions derived and generated by the community working together with the health care provider.

Improving wider aspects of the management of type 1 diabetes

0150

Peer to peer program for type 1 diabetes patients and their families

C. Velasco Donoso[1]
[1] *Diabetes Control, Education, Santiago de Chile, Chile*

Thousands of injections and blood monitoring in a year, transform the parents of a diabetic boy and the diabetic himself, into true experts in the subject. In addition they have had to take thousands of decisions, how much to eat, what insulin to vary and with the advantage of being able to state in the act the result of these decisions.
And this is a fact that all the healthcare team respects. For them it is impossible to equal all that for the simple reason that they do not have a diabetic at home. This is an essential fact, since if is wanted that the intervention of the peers is successful, these will have to limit its action to transfer its experience in daily life, leaving, as already we said, the formal education to the experts. This produces a very good relation with the healthcare team in hospitals and clinics, they recognize the complementary thing and valuable that it is this contribution and by the same they accept its intervention inviting them to participate from the diagnosis.
The fact that the peers do not make education formal it does not mean that they cannot collaborate in it. Peer´s organizations can be facilitators of the formal education, providing doctors, dieticians, nurses, physical therapists and others, of classrooms and educative material equipment and compiling of all nature.
The educative activities through their peers must be oriented to fulfill 3 great objectives very precise and that they are: **to accept** diabetes- **to learn the day-to-day practice** of the treatment - **to persist** in the treatment.

Competition in schools "my knowledge about diabetes": raising diabetes awareness for teachers and children

M.T. Pavcic[1], J. Erjavec[1], A. Skvarca[2]
[1] Slovenian Diabetes Association, Ljubljana, Slovenia
[2] University Clinical Centre, Metabolism and Endocrinology, Ljubljana, Slovenia

There are more than 600 diabetics in Slovenian schools. Good treatment and knowledge about diabetes, self management, their peers and all people around them (including teachers) understanding of disease and properly acting are essential so that their life, work and results do not differ from those of their classmates.
One of educative and preventive actions in primary and secondary schools in Slovenia is competition »my knowing about diabetes«. Aims and goals of this competition are raising diabetes awareness, spreading and deepening the knowledge about diabetes and about the lifestyle preventing the onset of type 2 diabetes, comparing school children's knowledge, raising motivation for further knowledge deepening and gathering the youth from different schools and settings.
Competition is one of the most popular school voluntary events in Slovenia. Contestants are children from 13 to 17 years, attending the primary and secondary schools. Slovenian Diabetes Association organises every year the education of mentors - teachers in children's home schools, who prepare them for competition, edits the "Spelling book about diabetes" which explains diabetes, its complications, treatment and life style for children, sets up for mentors papers with more elaborated data about the issues determined for year's competition (the year's IDF theme), settles complementary literature and prepares tests for competition.
The competition takes place on two levels: first, contestants complete tests in children's home schools. The 3 best contestants from each home school attend the republic competition. Participants can gain bronze (in home schools), silver (> 80% points) and gold (>90 % points) awards.
In 11 years the number of participating schools and children is increasing constantly, likewise the winners of bronze, silver and gold awards. Last year 380 schools and 7623 contestants took part in competition. Teachers identify this competition as very useful and children as "learning for life".

Our experience of dealing ethically with industry: lessons for other associations

H. Nedergaard[1]
[1] Diabetesforeningen, Rytterkasernen 1, Odense C, Denmark

Diabetes in Denmark
Denmark 2008: Approximately 240.000 diagnosed with diabetes. Among these 90 – 95 % is type 2-diabetics. Estimation for 2025 is 600.000.
The Danish Diabetes Association has three strategic goals
1. To prevent diabetes and the side effects of the disease
2. To secure the best possible life for people with diabetes
3. Finding a cure for diabetes

Main challenges to reach our goals
At the moment the main challenges for the association is to ensure further means both financially and regarding manpower and to ensure the necessary skills, both in house and externally.
Means to reach the goals
To reach ours and government's goals we involve both the civic society; the public service and business partners. Public- private and NGO must collaborate.
Specifics on collaboration with industry
Ethical base:
- Independence
- Openness and transparency
- Respect for DDA's professional guidelines and recommendations and
- Partners must engage in optimizing DDA's strategies.

Examples
1. The Diabetes Forum – with the support of Novo Nordisk. The seminar was the first of its kind in Denmark with participants from the healthcare sector, the public sector, politicians, industry, unions, NGO's and members from the Danish Diabetes Association. Result: Focus on the gravity of diabetes to society and elaboration of specific recommendations on how to improve the prevention and treatment of diabetes, how to improve the tracing of the many that has diabetes without knowing.
2. Club 20 – a club for businesses and industry with member fee. Result: Fine support from industry, but it's a new initiative and it hasn't been evaluated yet.

Lessons learned
State your reason and ethical base
Ensure clear contracts and clear communication
Don't be afraid to interact

No conflict of interest

Should industry play a role in helping poor and transitional countries?

A. Nientao[1]
[1] Santé Diabète Mali, Ministère de la Santé, Bamako, Mali

It is only by the years 1970 – 1980, that in the poor countries emerged some associations conducted by some doctors totally motivated for the cause of diabetes. They were accompanied by some distinguished personalities from the civil society who are ether diabetics themselves or parents of diabetic persons. Consequently, the relations of the patients' associations with the industries on one hand with the other partners interested in the domain on the other hand are promoting.
The associations must provide the industries partners with a balanced approach which will introduce the action plan containing well specified and relevant objectives. The action plan will be publicized through direct writing, lectures, and through the local newspapers.
One of the numerous problems that the poor countries are facing is that of the high cost of the screening, the early education and early sensitization of the population. In these countries, there are many diabetic people who are not diagnosed. Those who are diagnosed cannot afford the treatment or a good care. The situation should bring the industries to much more responsibility.
They should engage actively not only financially, but also they should support the existing diabetes associations by taking part into the promotion, the development and the achievement of the health national programmes already established by these organisations.
The associations should be a focus point where all the parties involved in the fight against diabetes meet (industries, governments etc…) in order to submit to them the claims and needs of the diabetic people.
Therefore the industries operate in a transparency mode by presupposing a common goal shared with the associations such as: the information about the prevention, the screening, the available treatments, the hopes for new therapies, the accessibility to the most adapted cares.
The industries and the patients associations in the poor and emerging countries must maintain good relation so as to promote the health system in these countries.
The role of the industries is capital to the achievement of a better efficiency.

Association-industry interactions: the do's & dont's

R. Alexis[1], T. Mc Cann[2]
[1] Ministry of Health, Health Surveillance, St Georges, Grenada
[2] St. George's University, Nursing, St Georges, Grenada

Background: Diabetes associations of North America and the Caribbean interact in various degrees with industry to implement public awareness, education, prevention and control of diabetes and its complications throughout the region.
Aims: To obtain information on the nature and scope of interactions between diabetes associations and industry, and to suggest guidelines concerning these relationships.

Methods: A questionnaire was developed and administered to representatives from 14 diabetes associations of the North America and Caribbean region (Jamaica, British Virgin Islands, Anguilla, Canada, USA, St. Lucia, Bahamas, Guyana, Barbados, Grenada, Trinidad& Tobago, Haiti, St. Martin, St Kitts/ Nevis.) Management from pharmaceutical companies, the banking industry and government ministries were interviewed to better understand the range of services and relationships in place.
Results: All but two of the associations interviewed interacted with industry, Relations involved implementation of screening and educational sessions for workers, groups, organization and general public. Training of diabetes educators. Subsidized products for members of diabetes associations, sponsorship of t-shirts, souvenirs, supply of equipment and supplies for screening, trophies, gifts, and refreshments at health promotional events; also interaction in sponsorship of youth camps, workshops, seminars, symposium, Sponsorship of educational materials, for healthy lifestyle promotion.
Strong, positive relationships between associations and industry seem to be based on respect, ethical standards and transparency in practice. Conflicts of interest, self promotion and lack of mutual benefit were viewed as hindering these relationships.
Conclusions: Association and Industry collaboration can bring tremendous benefits to people living with diabetes and those at risk. There must be mutual respect and consideration by all involved. Both association and industry must demonstrate management, financial and ethical responsibility. Working together can enhance the partnership between association and industry at all levels: locally, regionally and internationally.

How should associations deal with the power of industry?

N. Tukayevskaya[1], *Y. Kugayevskaya*[1]
[1] *Diabetic Association of the Republic of Kazakhstan, leading office, Almaty, Kazakhstan*

Diabetic Association of the Republic of Kazakhstan (DARK) - year of foundation is 1995. Number of members (legal entities) in 2009 - 33, 12 of them are representatives of industry.
Years of Association foundation coincided with creating of independent Kazakhstan. Problem – imperfect budget process. Failure in diabetes financing. Fatal cases because of diabetic coma have been recording. Covering necessity in insulin is 25-30%. Association accepted assistance from pharmacompanies to prevent deaths.
Decision to accept assistance entails effort of pressure to Association from pharmacompanies with a purpose of their interests lobbying on market.
Association decided to operate only for patients. Politics - banning of monopoly, interests of patients are priority, Association members equality of rights, not depended on status, joining of new members, including competitors on market. Reasoning of Association decision and collective nature in working out of strategy, openness, clarity and incorruptibility.
Results:

- Creating of definite independent image of Association in all levels of authorities and in all fields of activity, and as a result partners from business not connected with pharm activity appearing.
- Diabetes financing growth (from 300 thousand till 17 000 000 $USA).
- Improving of patients with diabetes mellitus situation in RK.
- Making partner relationships with\between members of Association
- Changing of competitive companies, included in Association to "fair competition" strategy.

Conclusions: for independence of Association, especially for again founded it's necessary the following:
Clear understand and realize the mission of organization.
Financing from sources unconnected with commercial field. Here IDF can play a major role, providing financing assistance and attracting international funds.

Helping a child with diabetes to lead a normal life

G. Parfitt[1]
[1] *Gwent Healthcare NHS Trust, Women Child and Family Division, Newport, United Kingdom*

Aim: This intervention ensures cooperation between schools, healthcare providers and families in caring for children at school who require lunch time insulin injections.
Method: Healthcare professionals provide training to designated school staff to administer insulin to children with diabetes. Interdisciplinary team working is essential for this venture.
A teaching package has been developed specifically for schools to ensure that insulin can be delivered safely by volunteers. This mirrors the teaching given to the families, ensuring consistency in the information given and care provided. Teaching is adapted and an individualised teaching package is offered to suit the needs of the child and school. This ranges from basic injection technique in contrast to dose adjustment of insulin to carbohydrate.
Results and discussion: This initiative is effective and currently 21 junior schools are administering injections, 11 supervise children administering their own injection and 5 have declined to participate in the initiative.
This initiative is successful because the co-ordinated training package provides the appropriate skills to develop confidence, allowing the volunteers to successfully administer insulin.
However in the United Kingdom there is no legislation to ensure that all children have support in schools for diabetes care, allowing some schools to opt out of this initiative.
Conclusion: School involvement ensures children are not discriminated against because of diabetes. It is still not normal practice for young children to be offered this support in schools. Reasons for this are multifactorial and include reluctance from schools, lack of enthusiasm from healthcare professionals and a lack of cohesion between education and healthcare.
This is a practical and effective intervention and in Wales we have developed a working partnership between education and health to try and overcome these obstacles. We hope that this will lead to guidelines for Wales which will allow equity of diabetes care in schools.

Perspective of a parent and siblings

N. Hirst[1]
[1] *Stirlingshire Scotland, United Kingdom*

In her presentation Naomi Hirst will chart her family's diabetes journey over the past twenty five years since her youngest child, Kate, was diagnosed with type 1 diabetes at the age of five.
Her principal focus will be on the role of parent and carer, and the imperative of the person living with diabetes to have someone to provide care and support, whether it be parent, partner, sibling or friend. She will talk of her own experiences in balancing that care with the emotional turmoil which so many carers can feel.
The three issues which she will highlight are:

- The issue of denial both on the part of the person with diabetes, and on the part of the carer, for both can experience denial.
- The issue of transitional care which can be perplexingly inadequate. At a time of adolescence, it is vitally important that when young people move from paediatric care to young adult care, their care arrangements are handled with sensitivity. The needs of both the young person and their carer are important, and nothing should be done which undermines the strength of the 'triangle of care' between the young person, their carer and the clinician.
- The Type 3 diabetes issue. There is an absolute need for the young (and not so young) person with diabetes to have someone close who is their carer - in a supportive and caring, but not controlling and critical, role.

Spouse or partner

B. Brameijer[1]
[1] *Keperra, Australia*

In 1998 I was faced with the possibility of diabetes. I already had some basic knowledge through First Aid training and a relative with diabetes, however I had never thought I would be so directly involved. Information sent by the Diabetesvereniging Nederland was valuable and helpful. Nevertheless, I could not have prepared for what was to come.
Six months later, upon marrying and moving to Australia, it was confirmed: 'Type 3 Diabetes'. Suddenly I was living with daily blood glucose monitoring, insulin injections, counting carbohydrates, reading food labels, dealing with hypos, ensuring there was always hypo food available, and of course, never forgetting the Glucagon Hypokit! On top of that were all the diabetes complications with their resultant additional problems - blindness, renal failure, peripheral and autonomic neuropathy, gastroparesis, a diabetic breast lump, the endless doctor and specialist appointments and the too frequent hospital admissions.
But, I wasn't the one with the elevated blood glucose levels, or the lifetime of Type I Diabetes, it was my wife, Janelle. Living with a person with diabetes, is also living with diabetes - every minute of every day, through every hypo and every complication.
Janelle refers jokingly to my condition as 'Type 3 Diabetes'. Her diagnosis is "the person 'Living with Diabetes' while not clinically being diagnosed with diabetes".

Aetiology of type 2 diabetes - genetics vs environment

0159

Genetics

V. Mohan[1]
[1] *Madras Diabetes Research Foundation & Dr. Mohan's Diabetes Specialities Centre, Department of Diabetology, Chennai, India*

Type 2 diabetes (T2DM) is a multifactorial disease with a strong genetic component. Evidence for the genetic basis for T2DM comes from studies on familial aggregation, twin studies and more recently, genetic studies. The concordance rates for type 2 diabetes among monozygotic genetic twins is 80-90% whereas it is only 40-50% dizygotic twins, thus showing a strong genetic component. The role of genes in T2DM is further exemplified by the fact that not all obese people develop diabetes. It is the ones who have a family history of diabetes (ie., a genetic component) who develop the disorder. The genetics of T2DM has been difficult to dissect out because it is a polygenic disorder with number of genes on multiple chromosomes and the effect of each of these genes is rather modest. Moreover, small sample sizes, case mixes different definitions used and ethnic variations have all being confounding factors. Recently, however there have been rapid advances in the genomics of T2DM, thanks to genomewide association studies (GWAS). Almost a dozen genes have been associated with T2DM through GWAS. However, the TCF7L2 gene has emerged as a strongest genetic marker in T2DM. However, even this gene only has an effect size of 1.2 to 1.6 in different studies. It is thus clear that multiple genes each with a modest effect contribute to the overall genetic risk of developing T2DM. Gene gene and gene environment interaction make the situation even more complex, and complex analytic skills are needed to determine the genetics of T2DM.

0160

Environment

A. Basit[1]
[1] *Baqai Institute of Diabetology & Endocrinology/Baqai Medical University, Department of Medicine, Karachi, Pakistan*

Gene-environment interactions play a major role in the aetio-pathology of Type 2 Diabetes (T2DM). Environmental factors like high calorie diets and reduced physical activity definitely contribute to the increasing prevalence of obesity and T2DM.The thrifty phenotype hypothesis proposed the concept of environmental 'programming' suggesting the existence of developmental windows during which exposures 'set' physiological systems and hence long-term consequences. Extremes of maternal age is also found to be a contributing factor to low birth weight. The protective effect of breastfeeding for childhood obesity and T2DM has also been observed. High prevalence of the disease in the offspring of gestational diabetic mothers or concordance rates of T2DM in identical twins further suggests intrauterine environmental influences. Predictive Adaptive Response hypothesis proposes that the fetus dynamically interacts and reads the environment which it will be born into and adapts to gain a future survival advantage. Environmental pollution and infectivity has also been proposed in certain studies to stimulate the fat cells to secrete molecules that promote insulin resistance, endothelial dysfunction, coagulation disturbances and a proinflammatory state, leading to type 2 diabetes and CHD. Role of stress and depression in the development of T2DM is being implicated. The successes of primary prevention trials in T2DM supports the notion that environmental influences were a cause of their T2DM and encourages further to concentrate on earlier interventions. Better understanding of aetio-pathological environmental factors is suggesting prevention should begin much before the stage of IGT, and interventions in high-risk subjects i.e. families of people living with diabetes alone will not be sufficient. It is necessary to initiate population based programmes for primary prevention of T2DM and must include a range of activities targeted at different age groups from fetal life to old age.

CLINICAL RESEARCH

Diabetes and obesity management: fat distribution, bariatric surgery, obesity drugs as glucose-lowering drugs, appetite control in diabetes

0161

Bypass, hormones and type 2 diabetes

F. Rubino[1]

[1] *Weill Cornell Medical College- New York Presbyterian Hospital, Surgery, New York, USA*

Bariatric surgical procedures have been shown to dramatically improve glucose metabolism in severely obese patients with type 2 diabetes. Consistent reports demonstrate that certain types of surgical procedures reverse metabolic alterations and improve insulin sensitivity and first phase insulin secretion. Experimental studies in animals as well as clinical trials suggest that the clinical and metabolic effects of gastrointestinal bypass procedures are independent of and additive to body weight loss.

Many neural and endocrine gut signals are physiologically important in the regulation of energy homeostasis, body weight, glucose tolerance and insulin secretion, hence, altered gut hormone secretion after gastric bypass procedures offers a plausible explanation of the mechanism by which these procedures achieve diabetes control. Recent research studies suggest that different types of manipulation of gastrointestinal anatomy may activate distinct hormonal mechanisms, which may explain variability of diabetes control across surgical procedures. Operations, characterized by the bypass of proximal small bowel appear to enhance physiologic signals that promote insulin secretion; however, other observations also suggest the possibility that these operations can possibly tackle intestinal dysfunctions that contribute to the pathophysiology of insulin resistance, diabetes and obesity.

In this presentation we discuss the available evidence on mechanisms of diabetes control after gastric bypass surgery and present the hypothesis that dysfunctional intestinal signals may be involved in the underlying pathophysiology of diabetes.

Fat distribution and metabolism

J.P. Després[1]

[1] *Centre de recherche, Institut universitaire de cardiologie et de pneumologie de Québec, Québec, Canada*

Numerous studies have shown that ***in vivo*** insulin resistance is a key feature of an atherogenic, pro-thrombotic and inflammatory profile which has been first described as "syndrome X" by Reaven and then referred to as the insulin resistance syndrome or the "metabolic syndrome" by others. Some investigators have suggested that the most prevalent form of this constellation of metabolic abnormalities linked to insulin resistance was found in patients with abdominal obesity, especially with an excess of intra-abdominal or visceral adipose tissue. We have previously proposed that visceral obesity may represent a clinical intermediate phenotype reflecting the relative inability of subcutaneous adipose tissue to act as a protective metabolic sink for the clearance and storage of the extra energy derived from dietary triglycerides, leading to ectopic fat deposition in visceral adipose depots, skeletal muscle, liver, heart, etc. Thus, visceral obesity may partly be a marker of a dysmetabolic state and partly a cause of the metabolic syndrome. Although waist circumference is a better marker of abdominal fat accumulation than the body mass index, an elevated waistline alone is not sufficient to diagnose visceral obesity. We have proposed that an elevated fasting triglyceride concentration could represent, when waist circumference is increased, a simple clinical marker of excess visceral/ectopic fat. Finally, a clinical diagnosis of visceral obesity, insulin resistance or of the metabolic syndrome is not sufficient to assess global risk of cardiovascular disease. In order to achieve this goal, physicians should first pay attention to the classical risk factors while also considering the additional risk resulting from the presence of abdominal obesity and the metabolic syndrome, such global risk being defined as cardiometabolic risk.

Fat reduction surgery and its metabolic consequences

S. Klein[1]

[1] *Washington University School of Medicine, Center for Human Nutrition, St. Louis, USA*

Medically-significant obesity can be defined as an excessive amount of body fat, which increases the risk of medical illnesses and premature death. Bariatric surgery is the most effective available fat loss therapy for obese patients. Proceedings from a National Institutes of Health Consensus Conference reported in 1991 concluded that eligible patients for bariatric surgery were those who were morbidly obese, defined either as those with a BMI ≥40 kg/m^2 or those with a BMI of 35 to39.9 kg/m^2 plus ≥1 severe obesity-related medical complication. Fat loss induced by bariatric surgery in morbidly obese patients effectively reverses or improves the medical complications associated with obesity, even though most patients remain obese. The metabolic complications of obesity, namely insulin resistance, diabetes, dyslipidemia, and increased blood pressure are improved or completely resolve after bariatic surgery induced weight loss. We have found that bariatric surgery-induced weight loss normalizes insulin sensitivity in liver, adipose tissue and skeletal muscle, decreases hepatic VLDL-triglyceride secretion rate, decreases liver fat content and the hepatic cellular factors involved in inflammation and fibrogenesis. In contrast, surgical fat removal of ~10 kg of subcutaneous abdominal fat by large-volume abdominal liposuction did not improve the metabolic abnormalities associated with obesity. The absence of a therapeutic effect suggests that losing weight by inducing a negative energy balance, not by decreasing adipose tissue mass alone, is critical for achieving the metabolic benefits of weight loss.

Drug therapy

U. Pagotto[1]

[1] *Alma Mater University of Bologna, Dept. Clinical Medicine Endocrinology Unit, Bologna, Italy*

Obesity is closely related to type 2 diabetes and sustained weight reduction is an important issue of the care delivered to obese subjects with diabetes. It is also well known that weight management may be the most important therapeutic task for most obese subjects with type 2 diabetes. On the other hand, the past ten years have been the golden age of obesity research with the enormous and increasing understanding of the mechanisms implicated in the energy balance control. It is now recognized that there are several central and peripheral factors involved in energy homeostasis, and it is expected that the understanding of these mechanisms should lead to effective treatments for the control of obesity and type 2 diabetes. However, nowadays, the approach to the pharmacological treatment of obesity is based upon few traditional and historical drugs. In particular, the drugs currently available are working via the serotoninergic and noradrenergic pathways, whereas those inhibiting nutrient absorption are locally acting as enzyme blockers. Their use in obese diabetic patients has been validated by a series of studies all resulting in modest outcome in both body weight and glycaemic parameters. Great hope has been generated, nevertheless, by the ability of the GLP-1 analogues to reduce body weight in association to the well-defined effect on glycaemia and insulin, and their effect in the context of body weight reduction will be critically discussed in the lecture. Finally, other therapeutics actually under investigation in clinical trials, that would either reduce appetite or enhance energy expenditure actually, will be also discussed in their pros and cons in the presentation.

Medical treatment of diabetic eye disease

0165

Community screening for retinopathy

M. Al Arouj[1]
[1] Dasman Diabetes Center, Clinical Department, Kuwait, Kuwait

Diabetic retinopathy (DR) is the leading cause of blindness in the 20-74 age groups. Regular screening is the most efficient and cost-effective way to detect its early stages. Ideally screening should be done by ophthalmologists, which is not affordable in many countries.
Community based screening is a method through which majority of patients are screened, provided that points of delivery are easily reachable. Methods of community screening include; well trained clinicians in Primary Health Care centers (PHC) with a non-mydriatic digital camera, mobile units, camps, and through optometrists. Kuwait, with its 36 diabetes clinics, within the PHC, distributed all over the country. All clinics are easily accessible and has a call and re-call system. This Kuwaiti set-up can represent a good model for community screening. DR Screening services started since 2001 with 16 digital cameras distributed in these clinics run by trained clinicians, periodically supervised by experienced ophthalmologist, with Referrals to ophthalmology center for severe cases according to a national guideline. In one clinic 7000 patients were examined in the first 3 years. 10.4% had any degree of DR, 50.5% of them were referred.
Another example for community screening is the Kuwait Diabetes Society (KDS) camps where screening for DR is one of its activities. 237diabetics examined in several camps over a 3-years period, 22.8% had DR, 30.2% had their last examination more than 2 years ago, and 32.9% were never examined before. In 2001 the rate of examination was 6.8% increased to 31.6% by 2003. Implementing such programs could increase compliance with guidelines among people with diabetes that had not a recent retinal examination.

0166

Medical treatment of eye disease: can we treat diabetic retinopathy medically?

M. Porta[1]
[1] University of Turin, Medicina Interna, Turin, Italy

Retinopathy is the most frequent complication of diabetes and, although relatively easy to recognize and treat, remains an important cause of blindness in working age and, increasingly, later in life.
Retinopathy is the consequence of 3 types of alterations in retinal capillaries: occlusions, increased permeability and, at later stages, new vessel formation. Occlusions cause areas of non perfusion, associated with microaneurysms, haemorrhages, cotton wool spots and vessel dilation. Leakage from the capillary wall results in edema and hard exudates. Such lesions may evolve towards two sight-threatening, non mutually exclusive presentations: diabetic maculopathy and proliferative retinopathy. In the former, edema and exudates encroach on the macula and cause loss of central vision, especially in type 2 diabetes. In the latter, new vessels arisen in response to ischaemia may bleed and cause fibro-glial proliferation, ultimately leading to retinal detachment.
Our main instrument to prevent blindness is laser photocoagulation. This is most effective when applied before loss of vision. Hence, regular screening for asymptomatic sight-threatening retinopathy is imperative in diabetes care. Recently, intravitreal injection of steroids or anti-VEGF agents has become widespread in the treatment of the most severe cases of retinopathy. Vitreoretinal surgery is applied in selected situations.
There is room for medical intervention, too. Optimised control of blood glucose and pressure, although difficult to achieve, results in effective primary and secondary prevention of retinopathy. More targeted treatments have been subjected to trial. Blockade of the renin-angiotensin system by candesartan resulted in prevention of new retinopathy in type 1 diabetes and regression in type 2. Inhibition of protein kinase C-beta by ruboxistaurin reduced visual loss in patients with macular edema. Finally, fenofibrate slowed progression of retinopathy and need for laser treatment independently of its metabolic effects. Further research is clearly needed to identify pathogenetic mechanisms that can be more effectively targeted.

EDUCATION

IDF global diabetes education activities

0167

Implementing diabetes education in the context of the UN resolution

A. Belton[1]
[1] AB Belton & Associates, Calgary Alberta, Canada

The United Nations resolution on diabetes makes two statements that are directly related to education.

- "Recognizing the urgent need to pursue multilateral efforts to promote and improve human health, and **provide access to treatment and health-care education**."
- "… observe World diabetes day in an appropriate manner, in order to **raise public awareness** of diabetes and related complications, as well as its prevention and care, including through education and the mass media"

This session will explore issues of access to care and education, such as cost, distance and availability of health care providers who are able to provide care and education according to the IDF guidelines. The session will also address issues related to increasing public awareness, how it is done, what difference it makes, who should be targeted and the roles both professionals and non professionals play in raising public awareness through education and mass media. Strategies developed and undertaken within different IDF Regions in an attempt to increase the education and therefore accessibility of those providing care will be discussed. As well public awareness campaigns, on a large scale such as World Diabetes Day, and on a small scale such as training peer educators to work in the community will be highlighted and discussed. Implementing diabetes education must be multi-faceted, it must be done on both the world wide and the local stage and must include both professionals and non-professionals.

National insulin program in Turkey: the snowball effect

S. Ozcan[1]
[1] Istanbul University, Florence Nightingale School of Nursing, Istanbul, Turkey

Introduction: While diabetes is spreading around the world rapidly, improving the knowledge and skills of the insulin therapy among the health care professionals(HCPs) through continued education plays a critical role in diabetes management.
Aim: National Insulin Education Program in Turkey was designed to increase the knowledge of insulin therapy and reduce potential mistakes during implementation among nurses.
Method: An educational kit consisting of the components below was prepared for the HCPs as part of their post-graduate training:

1. Training Slides: Adapted from on the IDF Diabetes Education Module and based on the practical prospective from diabetes educators.
2. Educators' Manual: Provided guidelines for the trainers.
3. Instructions and Letters: Sent to the educators and directors of hospitals to introduce the program, its protocol and evaluation.
4. Handouts: Covered four subjects: insulin injection, lipodystrophy and site rotation, injection devices, and 10 rules of insulin implementations.
5. Pre-test & Post-test: Conducted a pre-test benchmarking and a post-test in 3 months after training.

All hospitals in Turkey were invited to enroll in these two or three hours training programs which were given by diabetes nurses to the nursing staff from various departments such as surgical, oncology, and neurology.

Results: 9,000 nurses were trained by 250 diabetes nurse educators in 54 cities, 125 hospitals. 7,200 participants were evaluated by pre-test, of which 45% completed their post-test. Preliminary results showed positive feedback from participants. They found the program content and educational kit practical, reliable, and useful for their daily practice.
Conclusion: The education program was organized by Turkish Diabetes Nursing Association with collaboration of IDF and Turkish Ministry of Health. It received a great acceptance and participation from nurses. Although the program has ended, there are still many new applications for training. The program was supported by an unrestricted educational grant of Lilly.

Developing a certification program in UAE

H. Saadi[1]
[1] *Faculty of Medicine and Health Sciences-UAE University, Internal Medicine, Al Ain, United Arab Emirates*

Aims: Driven by the high prevalence of diabetes mellitus in the UAE and the scarcity of certified diabetes educators, the Faculty of Medicine and Health Sciences (FMHS), UAE University and the Emirates Diabetes Society (EDS) conducted two diabetes education courses in collaboration with the Diabetes Education Consultative Section (DECS) of IDF. These courses were based on the IDF curriculum for Diabetes Health Professional Education and aimed at educating and certifying health care professionals who work directly in diabetes education or interact with patients suffering from diabetes.
Methods: The first course was a 5-day program held in Al Ain in 2006. The second course was a 3-day program held in Dubai in 2007. Both courses were delivered by DECS members. A third course, organized by the Juvenile Diabetes Education Center, EDS and FMHS, started in April 2009 in Dubai and will run weekly for one year. An application was also submitted to IDF for recognition of this course.
Results: Fifty-six students attended the first course and 60 attended the second course. They mainly consisted of nurses, dietitians, and pharmacists. Their level of diabetes knowledge varied from very good to minimal. Application of the knowledge in teaching the patient and fostering behavior change was new to most. The concept of working with the patient to see what he/she wants to do and is willing to do was new to many of them. Twenty-six of the 31 students who wrote FMHS certifying examination passed. Eighty students are currently enrolled in the third course which consists of didactic teaching, group work and clinical experience. This course will also be followed by FMHS certifying examination.
Conclusion: Diabetes education and certification is highly demanded especially in countries with high prevalence of diabetes. In our experience, courses based on the IDF curriculum are both effective and rewarding.

Education for educators in South Africa – "agents for change"

B. Majikela-Dlangamandla[1], *N.S. Levitt*[1]
[1] *University of Cape Town, Medicine, Cape Town, South Africa*

Non communicable diseases such as diabetes do not head the list of priorities for the health system in South Africa. Few diabetes educators are available to provide this integral part of patient care and self management. The majority work in the private sector (which caters for ~20% of the population) and tertiary institutions; there are none at primary care level where the majority of patients receive their care.
Since the initial diabetes course in 2006 run by Anne Belton and Kavita Kapur, two initiatives followed using the IDF curriculum:

1. Two day workshops run in different provinces, particularly in rural areas, using the services of Government, Diabetes South Africa, University of Cape Town and industry. The theme is "Agents for Change", ie changing from unhealthy to healthy lifestyle, starting with myself - being a role model to my family, my patients and the community. There have been 266 professional nurses, 24 health promotion assistants and 32 community health workers trained using this programme. A sample of measurements taken from 74 professional nurses participating in the courses shows high levels of obesity-only three had a normal BMI and the six with known diabetes had poor glycaemic control (random blood sugars ranged between 12.1-20.1 mmol).
2. The development of a 3 day introduction and 6 months course for professional nurses developed by the Diabetes Education Society of South Africa (DESSA). Although these trained nurses do not become Accredited Diabetes educators, they acquire a sound diabetes knowledge.

Conversation Maps have recently been introduced and 120 professional nurses have been trained to date.
Enormous challenges remain, in particular lack of accreditation for diabetes educators by health authorities.

LIVING WITH DIABETES

Primary prevention of type 2 diabetes: drugs vs lifestyle

0171

DPP

D.M. Nathan[1]
[1] *Massachusetts General Hospital, Medicine, Boston, USA*

The worldwide epidemic of type 2 diabetes continues unabated with a projected prevalence of more than 250 million people in the next decade. The risk factors for diabetes that appear to apply to all populations, in the setting of polygenic risk, include sedentary lifestyle, increasing body fat, and ageing. The current inability to modify genetic risk and the lack of enthusiasm to shorten lifespan as means of confronting the diabetes epidemic have translated into efforts to ameliorate those environmental factors that underlie the epidemic and to determine whether lifestyle interventions or medications can reduce the development of diabetes. Specifically, lifestyle programs to increase activity levels and reduce body mass have been studied to determine whether and to what extent they can prevent or delay diabetes. In addition, metformin, the alpha-glucosidase inhibitor acarbose, and the thiazolidinediones have been studied.
The largest of the diabetes prevention studies, the Diabetes Prevention Program (DPP), randomly assigned participants to a lifestyle intervention program, metformin, troglitazone, or placebo (the troglitazone arm was terminated prematurely owing to concerns over potential liver toxicity). The main study results were published in 2002 demonstrating a 58% and 31% reduction in cumulative incidence of diabetes with lifestyle and metformin, respectively (N Engl J Med 2002;346:393). Subsequent publications have examined the mechanisms of prevention and other study results including: the effects of the interventions on metabolic syndrome and cardiovascular disease risk factors; results in older participants and those with prior GDM; the identification of genetic risk factors and interaction between genetic risk and the interventions; and health economic analyses. Longer-term follow-up results of DPP (DPP Outcome Study) have also been published.
This presentation will review the available clinical trial data that demonstrate the pluripotent effects of lifestyle and medication interventions in the prevention of diabetes.

IDPP

A. Ramachandran[1], *C. Snehalatha*[1]
[1] *India Diabetes Research Foundation, Epidemiology, Chennai, India*

Background Primary prevention of diabetes is of utmost importance in India, where diabetes has reached epidemic proportions.
Objectives: IDPP-1 and IDPP-2 assessed the feasibility and the ideal tool for prevention of diabetes in subjects with Impaired Glucose Tolerance (IGT).
Methods: In IDPP-1, a 3 year community based prospective study, 531 IGT subjects were randomized to receive either life style modification (LSM) or metformin (500mg/d) or combination of both and a standard care control group. Intervention groups received repeated motivation. In IDPP-2, another cohort of 407 IGT subjects were randomized to receive LSM and placebo or

LSM + Pioglitazone (30mg/d). Incidence of diabetes was assessed annually for 3 years. Influence of weight change, intervention regimen, changes in insulin secretion and action on incidence of diabetes were assessed using appropriate statistical analysis. Changes in lipid parameters and blood pressure were also assessed.

Results: Moderate, but consistent LSM and metformin were equally effective in reducing incidence of diabetes (28.5% and 26.4% relative risk reduction in 3 years), but no added benefit occurred with the combination. Intervention strategies caused improvements in insulin secretion and action which occurred without significant weight reduction. Benefits were seen on atherogenic phenotype of lipids, but not on blood pressure. Results of IDPP-2, confirmed the beneficial effect of LSM on incidence of diabetes, but no additional benefit was obtained by adding pioglitazone (LSM- cumulative incidence 31.6%, pioglitazone – 29.8%, p = 0.665)

Conclusions: LSM is the choice of intervention in Asian Indian IGT subjects. Metformin in small doses is also useful. However, no additional benefits are obtained by combining metformin or pioglitazone with LSM. Collateral benefits are seen on the lipid parameters. Significant improvement in secretion and action of insulin occurs with interventions.

Aims: To implement the prevention of type 2 diabetes in primary health care using the Finnish type 2 diabetes risk score (FINDRISC) in identifying high risk individuals for further testing and intensified lifestyle intervention.

Methods: FIN-D2D project was carried out in 2003-2008 as part of the national diabetes prevention programme in the health centers of five hospital districts with the population of 1.5 million. The self-administered FINDRISC was the main screening tool with a score of $\geq$ 15 as cut-off point. High risk individuals were referred for nurse-led intervention programmes based on the experiences from the Finnish DPS-study. Oral glucose tolerance test (OGTT) was performed for detecting undiagnosed diabetes.

Results: Altogether 200 000 persons were screened. A high-risk cohort (n=10 149, 30% men) was collected for evaluation. The number of performed OGTTs increased three-fold on the survey area. Baseline OGTT showed abnormal glucose tolerance in 68.1% of men and 49.4% % of women. 5523 high risk individuals participated in the follow-up. Among them, 45.4% of men and 42.1% of women had at least one intervention visit. 23.7% of men and 28.4% of women had ≥4 intervention visits. During the follow-up of one year the mean weight change was -1.0 kg and waist change was -1.1 cm. If the individual had ≥ 4 intervention visits, weight change was -2.7 kg and waist change was -2.8 cm. After the follow-up of one year, glucose tolerance improved along with lifestyle changes.

Discussion: Screening a large population using FINDRISC is possible in primary health care. Less than half of the individuals at high risk participated in interventions but it was still possible to achieve favourable changes in weight, waist, and glucose tolerance in the whole cohort.

Conclusion: Large-scale screening and effective lifestyle interventions are possible to carry out in a primary health care setting.

Diabrisk SL

T.A. Fernando[1], M.A. Wijesuriya[1], G.C. Viberti[2], J. Karalliedde[2]

[1] *Diabetes Association of Sri Lanka, National Diabetes Centre, Rajagiriya, Sri Lanka*
[2] *Unit for Metabolic Medicine Cardiovascular Division King's College, Department of Diabetes and Endocrinology, London, United Kingdom*

Prevalence of Type 2 Diabetes Mellitus and associated cardio-metabolic disease in young adults is rapidly increasing in Asia. Prevalence of risk factors that predispose young persons has not been identified.

Diabrisk SL is being conducted in an urban young (6-40yrs) Sri Lankan population of 22,577 volunteers (10,612M, 11965F)] to determine the presence of risk factors. It involves selecting persons with two or more risk factors of increased Body Mass Index (BMI), increased waist, physical inactivity and 1st degree family history using a simple questionnaire. Participants receive physical and biochemical assessments and advice on lifestyle modification over 2 years. Participants are randomly divided into intensive or non-intensive groups. Aims are to delay or prevent disease endpoints by simple intensive non-pharmacological lifestyle intervention and assess rate of incidence.

Of 22, 577 subjects, 8814 (46%), 4703 (41%) and 9060 (51%) were males in 6-14yr, 15-19yr and 20-40yr age categories respectively. 34.2% of the study population had two or more risk factors, 33.1% had one and 33.6% none. The prevalence of an increased age appropriate BMI was 19.7% and 15.4% in the 6-14yr and 15-19yr categories with no significant difference between males and females. In the 20-40yr category, 28.1% males and 21.9% females had increased BMI ($p<0.001$ M vs F). There was a higher prevalence of increased waist in females than males: 42.9% vs. 32.0% (6-14yrs); 28.2% vs. 16.0% (15-19yrs); 34.4% vs. 25.9% (20-40yrs) [F vs. M $p<0.05$ for all]. In all groups, prevalence of physically inactive females was higher than males: 39.9% vs. 15.0%; 51.6% vs. 19.5%; 63.0% vs. 41.1%. Physical inactivity increased in both sexes with age [$p<0.05$ for F vs. M and with increasing age].

The study reveals the presence of a significantly high prevalence of modifiable cardio-metabolic risk factors at an early age, and non-pharmacological intervention should be instituted early.

The role of endoplasmic reticulum stress in diabetes

0175

ER stress and the UPR: from yeast to man

D. Ron[1]

[1] *NYU School of Medicine, Skirball Institute, New York, USA*

Eukaryotic cells maintain a balance between the burden of unfolded proteins that enter their endoplasmic reticulum and the capacity of the organelle to cope with this bio-synthetic load. To do so, cells engage signal transduction pathways that respond to deviations from this balance (or ER stress) by altering rates of mRNA translation and gene transcription. These pathways are collectively referred to as the unfolded protein response (UPR) that has features conserved from yeast to mammals.

Evidence accrued in the past 10 years indicates that the UPR is active in beta cells and more so in the overworked beta cells of individuals coping with the consequences of insulin resistance. Furthermore, extreme compromise of UPR components, notably the ER-stress induced kinase PERK and its down stream effector, translation initiation factor 2 alpha, severely compromise beta cell function causing a syndromatic form of diabetes. These findings suggest that beta cells are especially sensitive to the consequences of ER stress and that prolonged ER stress might contribute to a decline in beta cell function in the course of the development of diabetes mellitus.

Here, I will review the workings of the UPR and try to address recent knowledge on the possible role of ER stress and the response to it in the development of diabetes.

No conflict of interest

0176

Lipotoxicity and glucotoxicity as triggers of beta cell ER stress

M. Cnop[1]
[1] *Université Libre de Bruxelles, Laboratory of Experimental Medicine, Brussels, Belgium*

Type 2 diabetes results from a reduced ability of the pancreatic beta cells to secrete enough insulin to stimulate glucose utilization by peripheral tissues. This insulin deficiency is probably associated with a progressive reduction in beta cell mass, secondary to chronic exposure to high free fatty acid (FFA) and/or glucose levels (lipo- and glucotoxicity).
The endoplasmic reticulum (ER) is the cellular organelle where export proteins, such as insulin, are produced and folded. Accumulation of misfolded proteins in the ER causes ER stress and activation of the unfolded protein response. This response aims to alleviate ER stress, restore ER function and prevent cell death, but if these protective steps fail apoptosis is triggered.
The large demand on pancreatic beta cells to synthesize, sort and secrete insulin may render them vulnerable to perturbations in ER function. Accumulating evidence suggests that components of the ER stress response play a dual role in beta cells, acting as regulators under physiological conditions, or as triggers of beta cell dysfunction and death under situations of chronic or severe ER stress. ER stress is present in beta cells in human type 2 diabetes, in rodent models of the disease, and is elicited in conditions of gluco- and lipotoxicity. High glucose induces a mild unfolded protein response, while saturated FFAs trigger more severe ER stress in beta cells by depleting ER calcium. This induces pro-apoptotic pathways and eventually beta cell death. Understanding the molecular mechanisms underlying pancreatic beta cell loss will allow the development of targeted approaches for the prevention and treatment of type 2 diabetes.

The role for the UPR in beta cell adaptation to physiological demand

R.J. Kaufman[1], *S. Back*[2], *D. Scheuner*[1], *B. Song*[2]
[1] *University of Michigan Medical Center, Biological Chemistry and Internal Medicine Howard Hughes Medical Institute, Ann Arbor, USA*
[2] *University of Michigan Medical Center, Howard Hughes Medical Institute, Ann Arbor, USA*

The endoplasmic reticulum (ER) is a cellular compartment specialized for chaperone-assisted folding and post-translational modification of nascent polypeptides. Disruption of ER homeostasis leads to accumulation of unfolded protein and activation of the unfolded protein response (UPR). The UPR emanates from the ER through activation of three transmembrane sensors, IRE1, PERK, and ATF6. IRE1 is a protein kinase / endoribonuclease that, upon activation, initiates a splicing reaction that removes a 26b intron within the ***XBP1*** mRNA. Spliced ***XBP1*** mRNA produces a potent basic leucine zipper (bZiP)-containing transcription factor of the ATF/CREB family that activates UPR gene transcription. Activation of PERK by ER stress leads to inhibition of translation initiation through phosphorylation of eukaryotic initiation factor 2 (eIF2) on the alpha subunit. Paradoxically, there are several mRNAs that require eIF2a phosphorylation for efficient translation, ie. ***ATF4*** mRNA. ATF4 encodes a transcription factor required to activate genes involved in amino acid biosynthesis and transport, anti-oxidative stress responses, and proapoptotic functions, such as CHOP. Finally, ATF6 is an ER transmembrane protein that contains a bZiP domain in the cytosolic domain and a stress-sensing domain in the ER lumen. Upon accumulation of unfolded proteins in the ER lumen, ATF6 transits to the Golgi compartment for cleavage by the proteases S1P and S2P to generate the cytosolic fragment which traffics to the nucleus to activate transcription of a subset of UPR target genes. Recent studies demonstrate that the UPR plays important fundamental roles in the etiology of insulin resistance and type 2 diabetes. Studies will summarize the unique and essential features of the cellular response to ER stress and how ER stress is intimately coupled with oxidative stress and beta cell failure. Glucose-regulated insulin production in pancreatic beta cells requires an intact PERK/eIF2a subpathway to prevent oxidative stress.

No conflict of interest

0178

ER stress and insulin resistance

U. Ozcan[1]
[1] *Children's Hospital Boston/Harvard Medical School, Endocrinology, Boston, USA*

The Endoplasmic reticulum (ER) is a luminal organelle where secretory and membrane-bound proteins are folded into their final three-dimensional structures. Several different pathological conditions, such as deficiency of glucose, increased protein synthesis, aggregation of mutant proteins that are incompatible for folding, virus infections, cholesterol accumulation and free fatty acids exposure interfere with proper functioning of ER, create a state defined as ER stress and lead to activation of a signaling network called the unfolded protein response (UPR).
Sedentary life style in the last several decades severely increased the prevalence of obesity, which led to a severe rise in the incidence of insulin resistance and type 2 diabetes. Molecular mechanisms of insulin resistance are not well understood. In recent years we and others have shown that increased endoplasmic reticulum stress in obesity plays a major role in development of insulin resistance. In this context, X-Box Binding protein (XBP1) was identified as a central regulator of metabolic homeostasis; heterozygous deletion of XBP1 in mice created severe insulin resistance even on a background, which is completely resistant to obesity-induced insulin resistance. Additionally, we recently demonstrated that ER stress and XBP1 has a pivotal role in development of leptin resistance in the brain. Reversal of ER stress with chemical chaperones both sensitized the mice to insulin and to the action of leptin in the brain.
In my talk I will mainly discuss how UPR leads to insulin resistance and discuss the mechanisms that XBP1 utilizes to regulate the insulin sensitivity and metabolic homeostasis.

TEACHING LECTURE

LIVING WITH DIABETES

Future of type 1 diabetes: does technology hold the key?

0179

Future of type 1 diabetes: does technology hold the key?

J.W. Gregory[1]
[1] *Wales School of Medicine Cardiff University, Child Health, Cardiff, United Kingdom*

Recent years have seen dramatic advances in the technology of diabetes management with developments in 'designer insulins', insulin delivery systems and methods for glucose monitoring. Nevertheless, these technical developments still require voluntary input from individuals with diabetes to maximise their potential and achieve optimal glycaemic control. The successful development of a truly automated 'closed-loop' system which will operate independent of patient input remains a long-term goal.
Poor adherence with many practical aspects of diabetes management remains a major obstacle to optimising patient outcomes. Psycho-educational interventions have been shown to have a modest benefit on many outcomes including HbA1c. Techniques designed to facilitate behaviour change such as Motivational Interviewing (MI) have been shown to be beneficial in both teenagers and young adults with diabetes. However, in many clinical services there are shortages of psychologists appropriately trained in techniques such as MI, and the challenge remains to integrate the principles which underlie these methods into routine consultations by all clinical staff. Given the success of MI, the DEPICTED trial has taken some of its key concepts and produced a training package for use by health-care professionals in routine clinic consultations. This intervention is now being tested in the UK across 26 clinics with outcomes to be measured in 697 children and teenagers with diabetes.
Until the arrival of a truly independent, automated 'closed-loop' system, it is likely that optimal outcomes for patients will only be achieved with support from clinicians who have expertise in skilled behaviour change talk. This counselling

style will need to stimulate and support patients to resolve uncertainties in their own minds about making changes to their diabetes management, regardless of the sophistication of the technology involved.

WORKSHOP

Alternative medicine: its role and practice

0180

Alternative medicines and diabetes control: the Jamaican experience

E. Morrison[1]
[1] *University of Technology Jamaica, 237 Old Hope Rd, Kingston 6, Jamaica*

Over the past 3 decades, medico-social studies indicate that a significantly high number of patients come to the evidence-based medical centres only after extensive consultations with their peers and local healers.
A survey in the Diabetes Outpatient clinic at the University Hospital of the West Indies, in Kingston, Jamaica, 1979, revealed that irrespective of the socio-economic strata or level of education attained, some 85% of patients attending the clinic had consulted with the local healers and were taking their alternative medications either instead of, alongside or intermittently with the formal prescriptions.
A Jamaican study by Hugh Jones in 1955, reported that patients were using a variety of 'bush teas' in the treatment of their diabetes. The common outcomes were that glycosuria disappeared as well as the patients seemed to tolerate high levels of glycaemia with less than 2+ ketonuria and little apparent diabetes-related morbidity. It was hypothesised at the time that these 'bush teas' were causing elevated renal thresholds, resulting in aglycosuria and patients believing that they were cured. This clinical picture initially dubbed J-type diabetes, was later called Phasic Insulin Dependence Diabetes mellitus (1981,1995) as a result of further clinical patterns elaborated by Morrison et al.
A detailed study by Morrison et al 1982, of a variety of 'bush teas' on the blood sugar levels in dogs, did reveal reliable and reproducible effects on blood sugar levels. However, in some cases, the sugar levels were elevated with histological damage to liver, pancreas and kidney cortex.
Jamaica is an active participant in the multi-billion dollar trade involving food supplements, natural products and neutraceutics.
There is urgent need for study to be able to offer sound evidence-based advice as to the value of alternative medicines, the use of which is a culturally ingrained behaviour.

Herbal medicine

A.K. Azad Khan[1]
[1] *BIRDEM, Deparment of Gastroenterology, Dhaka, Bangladesh*

Prevention and cure of diseases through natural intervention is, on principle, an attractive method of medical practice. The wide-spread use of plant materials against many diseases throughout human history is an example of such natural intervention. In modern medicine increasing emphasis is given to pure compounds. However, in practice, it also uses combination of drugs or compounds. Plants are store house of compounds and effective therapeutic agent may be developed by isolating, characterizing and manipulating the individual compounds from plants as well as by studying certain extracts or fractions of plants using. In both the cases multidisciplinary research, with application of highly sophisticated technology in certain cases, is a must. Study of cruder plant materials may also relatively be difficult due to variability of potency in respect to age, geographical location and season of collection of the plant. Also no standardized toxicological methods are available for such studies. More and more effort will be necessary in this regard with flexibility for individualized approach keeping scientific transparency. For edible plants human experience, under proper scientific design and monitoring, should be given due importance since many diseases do not have exact animal models. Moreover, ethical aspects of animal research have also to be taken in consideration. The central issue in plant material research is to maintain a scientific outlook. It is important to understand that the great names in this field were highly gifted scientists of their respective ages, but they were, after all, human beings. Thus one should not make them deities and should not turn science into faith.
With the above approach we have been conducting collaborative research on antidiabetic plants with a number institutes. The results indicate that plants may serve as a good source of antidiabetic compounds. Our experience suggests that the effects of various plants materials may be mediated by various mechanism which potentially combat specific pathophysiological events in both type 1 and type 2 DM. Studies with some plant fractions on insulin secretion from isolated rat islets, calcium mobilization in single B-cells, inhibition of carbohydrate absorption through gastrointestinal tract (GI) in rats by inhibiting disaccharidase activities, effects on GI motility and inhibition of platelet aggregation indicate the presence of various principle(s) in hypoglycemic plant extracts.
Our studies have also shown the best time to use the plant materials in relation to meals. This information is of practical importance because plant materials continue to be widely used especially in rural areas of many developing countries.

Meditation

M. Wijesuriya[1]
[1] *Colombo, Sri Lanka*

Mind is the fast track processor of all sensory inputs past and present and the creator of all thoughts, words and deeds. It is a non material functional unit attached to the brain.
Body is the physical component of the human being created by the genetic code and its interaction with its environment. It responds to the thoughts words and deeds produced by the mind.
Stress is a neuro-endocrine response to a threat to physical health, mental well-being and the survival of an individual from conception to death**.** Psychosocial stress is an important aetiological factor in the development of T2DM. Modern lifestyle often increases the level of stress due to failure of achievement. The individual stress response increases hormone levels leading to elevated blood sugar and blood pressure.
Meditation is an art by which the mind can be calmed so that status quo is re established and wide fluctuations of emotion is minimized with the development of happiness and the elimination of sadness by accepting a the knowledge of impermanence.
This is often achieved by concentrating one's mind on single object for a period of time so that calmness of mind would prevail and a state of constant change (impermanence) perceived with acceptance of failure as part of the process. In effect, it detoxifies the human mind using the inner strength which is built into the system to weather the changes of stress without pharmacological intervention. The process of mastering meditation is slow but with persistence, it could be achieved by anyone without religious or ethnic bias.
It would be evident that the mind body interaction is critical for the prevention of T2DM especially in the modern world.

0183

Yoga

J. Woo[1]
[1] *The Chinese University of Hong Kong, Department of Medicine & Therapeutics, Hong Kong, China*

Yoga originated from India around 1900 BC as a tradition to explain or study the human mind and physical conditions, and was disseminated to the West about 150 years ago. The essential components encompass philosophical, psychological and physical elements. Characteristics of the latter consist of breathing techniques and a variety of postures. There are similarities between the yoga state and the practice of mindfulness. The outcomes arising from the practice of yoga include optimism and better health outcomes; effective handling of anger and reduction in sympathetic nervous system arousal. Impact on physical health may be mediated via the hypothalamic-pituitary-adrenal axis. Breathing techniques result in increased oxygen consumption with the

minimum of physical exertion, while the different postures exercise all muscles of the body.
The practice of yoga may be relevant to diabetes through the effective adoption of a healthier lifestyle, positive affect, and reduction in chronic sympathetic nervous system arousal which predisposes to the metabolic syndrome. Currently some evidence support this effect, although the quantity is sparse and studies are largely of short duration, with small sample size and lacking in control groups. Some evidence relating to the beneficial effect of techniques with similarity to the practice of yoga (mindfulness; qigong) and diabetes is also available. The practice of yoga may be beneficial for the diabetic state through promotion of a healthier lifestyle through psychological and physical pathways. However more randomized controlled trials are needed to establish a firm evidence base.

ASSOCIATION DEVELOPMENT

Diabetes care to the people: what is the role of IDF Guidelines?

0184

Clinical guidelines: do they make a real difference?

K. Kadir[1]
[1] *Monash University in Malaysia, Medicine, Petaling Jaya, Malaysia*

The International Diabetes Federation is an international body which represents countries from both developed world as well as third world nations and also the rapidly developing economies of Asia and South America. It represents patients as well as care givers and professionals. It also works closely with the WHO. Thus any guideline from the IDF, especially the Global Guideline For Diabetes Care which seek views and contributions from many countries, and have grades of care depending on resources, are easier to accept locally and are used as a clout to press for improvement in diabetes care. Significant changes and improvements were made in many countries; eg increase in funding for diabetes care, setting up of diabetes centers, more manpower trained in the care of diabetes such as nurse educators and dietitians, and more research funding, eg Singapore and Malaysia have been doing national surveys every 10 years to determine prevalence of diabetes and IGT, obesity, etc.. Governments are more aware of the increasing burden and the need for intervention programs from the guidelines. Thus at national level, these guidelines made a difference. Similarly the Asia Pacific Guidelines made countries in the region change the criteria for overweight and obesity from BMI of 25 to 23, and 30 to 27 respectively. Similar changes were made to waist circumferences. At the practitioner level, there are many guidelines available…national, ADA, EASD, IDF etc. Targets for diabetes care are almost similar. Limitations in terms of financial coverage for care, lack of professional help eg podiatrists, makes it difficult to achieve targets. Several studies clearly showed the difficulty to achieve guideline targets. Our own studies and others published will be presented. The real difference these clinical guidelines make however is that patients and practitioners are more aware of need for and striving to achieve better care.

0185

Clinical guidelines: does one size fit all?

M. de Clerck[1]
[1] *Association Vaincre le Diabète au Congo, Kinshasa, Democratic Republic of Congo*

Yes: the disease is the same all over the world
No: local conditions vary widely, also the way of life for patients. Limited resources
Cost: two options (1) Voluntary work eg IDF (2) Full pay professionals ex Canada; UK ea
Steps in the process of writing guidelines: a long journey
Documentation: finding and evaluating the sources, a long and time consuming task. Collected and evaluated according to strict protocols Best EBM retained as references
In countries with limited budget: Make contact with other countries in same language area and ask permission to use their reference work
Define target and adapt to it
Optimum care: for tertiary university hospitals
Standard: for city hospitals secondary care
Minimal: for health centres primary care
For patients and families
Writing draft: A team with limited number of persons, good internet communication, experience in editorial tasks
Advice fro (1) scientific (2) public health for practical feasibility
Presentation: For the three levels separately
Printed version, electronic (word and PDF) Quick reference sheets
Patient education: usually with many clear illustrations
Printing and distributing Difficult in developing countries
Implementing and keeping up to date
Workshops with the team who wrote the guidelines. A slow process needs repetition to change behaviour. Find and train resource persons "champions" for teaching the teachers sessions

Modifying clinical guidelines based on ground realities

D. Barragan Bauer[1]
[1] *Hospital San Gabriel, Endocrinology and Diabetes Care, La Paz, Bolivia*

Aim of guidelines is to provide useful and accurate information regarding a health topic in order to facilitate the work of the health care provider. Cultural, economical, ethnical factors, among others, make health care reality around the world different. In diabetes care, guidelines should consider many aspects regarding diabetes itself and its complications. Therefore, to make a global guideline which is useful all over the world is not easy. Current IDF guidelines have considered many of these aspects giving general information. But, if you try to use the guideline in your daily practice, the help you get is also very general. How can they be improved considering on ground realities? Three key steps should be taken: First, to know whom the guideline is directed to and what this group expects of it. IDF guidelines intend to provide information mainly to general practitioners in countries and regions that have no guidelines of their own, therefore simple, short and concrete information is essential. Second, to provide concrete information, avoiding referring the reader to other sources to get it. Current guidelines refer the reader to other sources in all clinical topics, this is a barrier to use them and make other guidelines more useful. And third, try to summarize the most important topics with relevant information that can be used all around the world. Differences among health care systems and conditions create an artificial differentiation in Diabetes care, dividing it in minimal, standard and comprehensive care where minimal is the poorest and worst way to treat diabetes and comprehensive the best and more expensive, this is also justifying bad care confusing primary health care with primitive one. It can be possible to implement guidelines that include standard care with alternatives when there is lack of resources.

0187

Matching clinical guidelines; from ivory towers of academia to ground realities?

A. Aguirre Villafán[1]
[1] *Universidad San Francisco Xavier, Head Endocrinology and Nutrition Departement, Sucre Chuquisaca, Bolivia*

The epidemic of cardiometabolic diseases was driven largely by hypercholesterolaemia, hypertension and smoking. Despite important advances in reduction of these risk factors, disturbing increase in the worldwide prevalence of abdominal obesity appears as a new challenge.
While current management of people with Metabolic Syndrome (MS) is appropriated directed towards the correction of the individual abnormalities, however, it may be much more effective to tackle the problem at its source with programs directed towards the prevention and reversal of abdominal obesity.
Strong evidence supports the use of diet and exercise to prevent or delay the onset of T2DM in people with MS/prediabetes. A wide range of initiatives are now underway to move evidence-based diabetes prevention to a community setting, into the public sector.

In middle income countries as in rich countries the burden of MS is growing in direct relation to the pandemic of obesity and T2DM.
Increasingly, within countries diseases follow the social gradient: the lower the status the higher the risk. Worldwide, obesity is seen to be more prevalent in those of lower status than of higher.
International health organizations and governments must address the social determinants of health, translational research into the community setting and make policies to reduce health inequalities within and between countries.

Socratic dialogue: patient empowerment

R. Rubin[1], R. Anderson[2], K. Asimakopoulou[3], J.P. Assal[4], A. Philotheou[5]
[1] John Hopkins University, Medicine and Pediatrics, Monkton, USA
[2] University of Michigan, Medical Education, Ann Arbor, USA
[3] King's College London, Dental Institute, London, UK
[4] Foundation for Research and Training in Patient Education, Geneva, Switzerland
[5] University of Cape Town Private Academic Hospital, Groot Schuur Hospital, Cape Town, South Africa

Socratic dialogue, when used in a small group setting, is a process, guided by a facilitator, designed to address a general question relevant to that group. In this session the question is "What is patient empowerment?" The session faculty will explore this question by examining several practical situations, with the aim of helping the audience understand how to facilitate patient empowerment, and how to monitor whether using the empowerment approach to diabetes care and education leads to improvements in patients' quality of life and/or glycemic control.
Some of the practical situations the group might examine in an effort to explore the meaning of patient empowerment include: 1) first meeting between a new patient and a clinician or diabetes educator, 2) patient in the transition between adolescence and young adulthood, when diabetes care might not be a priority, 3) depressed patient, 4) patient living in a part of the world where many people, particularly women, are anything but empowered, 5) health care provider who wants to facilitate empowerment but is unclear how to do this.
The audience will have an opportunity to explore their own ideas about patient empowerment as the group engages in their Socratic dialogue. The goal of this process is to clarify the meaning of patient empowerment and to help the audience find ways to make their work with patients more effective and more satisfying.

HEALTHCARE AND EPIDEMIOLOGY

Populations at risk: understanding why

0189

Indigenous populations

A. Hanley[1]
[1] University of Toronto, Nutritional Sciences, Toronto, Canada

Indigenous populations around the world are currently undergoing a seismic epidemiological transition, with dramatic increases over the last several decades in a number of chronic health conditions, including overweight, cardiovascular disease and (especially) type 2 diabetes mellitus. While the cultures, histories, local environments and other characteristics of these indigenous populations vary across a wide spectrum, several commonalities are shared among these groups with respect to diabetes. These common features include a prevalence of diabetes that is often several times in excess of the surrounding general (non-indigenous) population of the region; a pronounced leftward shift in age of onset, resulting in a high prevalence of childhood- and youth-onset type 2 diabetes; and a heavy burden of micro- and macrovascular complications, again frequently with an accelerated time course of occurrence. Although it has been demonstrated that Indigenous populations are impacted by many of the well-established risk factors for diabetes (including unhealthy body weight and suboptimal diet and physical activity), a number of distinctive factors may also be at play in these populations, including specific genetic variants and more difficult to quantify factors such as poverty, social and economic marginalization, cultural disruption and loss of traditional lifestyles.
This ominous chronic disease profile among Indigenous populations around the globe highlights an urgent need for effective, culturally appropriate primary and secondary prevention strategies. In this context, a number of successful, long-standing clinical and community-based intervention programs will be discussed.

J.F. Gautier[1]
[1] Saint-Louis Hospital, Diabetes and Endocrinology, Paris, France

An atypical form of type 2 diabetes revealed by ketosis or ketoacidosis (Ketosis-prone type 2 diabetes, KPD) has emerged as one of the most frequent in populations of African descent. It is characterized by an acute onset with severe hyperglycemia and ketosis or ketoacidosis, followed by long-term insulin-free near-normoglycemic remission periods, frequently interrupted by ketotic relapses but without islet-cell autoantibodies. Our studies benefited from the north-east location of Saint-Louis Hospital in Paris, where lives an important community of migrants from sub-Saharan Africa. We observed that 40% of the diabetic subjects of African origin attending our department displayed such a phenotype. At onset, insulin secretion in response to glucose was drastically reduced, but the subsequent remission was associated with a restoration of insulin secretion in most patients. In the context of near-normoglycemic remission, we observed insulin resistance at the level of muscle, adipose tissue and liver as demonstrated in type 2 diabetes. Because of the acute onset of KPD and the high prevalence of this phenotype of diabetes in Africans, we searched for a virus that is commonly found in this population. Human herpes virus type 8 (HHV-8) or Kaposi syndrome associated herpes virus (KSHV) is endemic in sub-Saharan Africa where most individuals get infected during childhood so that around 45% of adults have markers of HHV-8 infection, without necessarily having clinical manifestations. We found a high frequency of HHV-8 seropositivity and viral DNA in the majority of patients with KPD when compared to patients of the same origin but with classical type 2 diabetes or to matched healthy controls. In addition, we showed that the virus is able to infect human islet beta cells ***in vitro,*** therefore providing additional evidence that it could be associated to the acute phase syndrome in these subjects otherwise predisposed to type 2 diabetes.

Lessons learnt from the East Asian population

J.C.N. Chan[1]
[1] Chinese University of Hong Kong, Department of Medicine and Therapeutics, Shatin NT Hong Kong, China

In this pandemic of diabetes affecting 170 million people, 60% will come from Asia with India and China as the 2 most affected countries. Latest figures suggest than 10% of Chinese have diabetes with the most rapid increase in young adults, middle aged men and people with low educational levels. Smoking, family history and obesity are other major risk factors. As in most countries, the majority of diabetic patients are undiagnosed, untreated or managed suboptimally resulting in late presentation and multiple comorbidities. Asians have reduced beta cell function which can be unmasked by small increase in adiposity to cause diabetes. Despite their low BMI, many Asians have increased visceral fat and fatty liver which predict diabetes and cardiovascular disease. Apart from rapid urbanization and lifestyles changes, environmental (e.g. low grade infections and pollutants) and genetic variants are other contributing factors. The high prevalence of low birth weight in some developing areas, gestational diabetes and childhood obesity continue to fuel the epidemic through 'diabetes begetting diabetes'.

Due to the young age of onset and thus long disease duration, Asian diabetic patients are at high risk for cardio-renal complications with cancer emerging as an important cause of death. Despite these health care challenges, there have been exemplary examples of diabetes prevention and care programs in Asia. These include the benefits of lifestyle modification on reducing diabetes risk; use of intensive insulin therapy to cause diabetes remission and use of multifactorial care to reduce risk of cardio-renal complications. The challenge lies in translating this evidence into practice to reduce the burden of these chronic diseases. Here, a population-based strategy and a multidisciplinary care model augmented by government policies and clinical governance are needed to raise awareness, detect disease early and improve quality of care.

Factors giving rise to risk in Africa

E. Sobngwi[1,2], N. Unwin[1], J.C. Mbanya[2]

[1] Newcastle University UK, Epidemiology, Newcastle upon Tyne, United Kingdom

[2] University of Yaoundé 1, Medicine, Yaoundé, Cameroon

Africa is experiencing one of the most rapid demographic and epidemiological transitions of the world's history, with the emergence of diseases of aging, notably non-communicable diseases such as diabetes. The burden of diabetes varies widely in Africa and African diasporas. There is an increase over time that parallels the socio-economic development. Diabetes is still rare in traditional rural communities in Africa (1% to 3%), with a rural-urban gradient in increasing prevalence. In addition to cross sectional urban-rural differences, it was demonstrated that the duration and chronology of exposure to an urban environment influences the risk. Recent rural-urban migration and lifetime migration history are stronger predictors. Changes in diet were incriminated, but available data remain insufficient to fully support this hypothesis. There is increasing measurable evidence on the contribution of physical activity changes to the risk of diabetes. Reduction of commuting physical activity may be the most important predictor. The reduction of walking does not affect only developed countries, but is also a hallmark of urbanization and westernization in Africa. In fact, walking is the main transportation means in rural Africa and is declining with economic development. We observed a large reduction in walking time and pace in an urban community in sub-Saharan Africa, as compared with a rural sub-Saharan African community (a reduction by a factor of 2 to 4 for walking at a slow pace and by a factor of 6 to more than 10 for walking at a brisk pace). This decreased use of daily walking is associated with cardiometabolic risk and deserves similar attention as in developed countries. Intervention studies are still limited in Africa. The authors will discuss available evidence on the risk of diabetes and its determinants, and the implications for prevention of diabetes in Africa.

Diabetes: invest in prevention or early diagnosis ?

0193

Diagnosing unrecognized diabetes is more important than prevention

E. Bell[1]

[1] Diabetes South Africa, East London, South Africa

While the ravages of HIV/Aids grab headlines and the outbreak of swine fever whips people into hysteria, beaming breaking news items on all major television networks, it is diabetes, the silent killer, which is counting the costs of deaths worldwide. Outbreaks, like swine fever, are categorized by their seriousness and the effects it has on humanity worldwide, almost like the onslaught of hurricanes. It is diabetes which is defined by either type 1 or type 2 and not by the fact that it is an epidemic and many succumb to its complications annually. The treatment of diseases like HIV/Aids has a high priority worldwide and many high profile personalities with their red ribbons emblazoned on their attire expose and create awareness to the rest of the world. People who are involved in diabetes campaigns and education are aware of the devastation that this condition brings to people in the world. This raises the question: Is diagnosing unrecognized diabetes more important than prevention? Bearing in mind that prevention is an outcome.

My answer would certainly be yes and in this paper the following points will be interrogated.

- Throughout the world awareness campaigns particularly during world diabetes day highlights the seriousness of diabetes and this should not happen only during this period but all year round.
- Developing partnerships is a prerequisite to ensure the success of these campaigns.
- Early diagnosis reduces/minimizes complications whether it is acute or chronic.
- Involve the health departments and the private institutions in all programs and vice versa.
- Set up support groups at all clinics, hospitals, business, community and the various state departments (business and state institutions have wellness days).
- Complementary medicine has got to be involved.
- Champions need to be identified in families and all the stakeholders to ensure optimum awareness takes place.
- Education is a key component in this setup so that all areas are covered e.g. knowledge of the condition, medication, diet and exercise.
- The challenge today especially in developing countries is poverty which is connected to the price of medication and the cost of living.
- We find that more and more people are being urbanized and this phenomena brings about its own problems e.g. accommodation, running water and sanitation.
- Most of our health care givers are obese and some are unaware that they have hypertension and diabetes and this sets a bad example to their clients.

Should we concentrate on prevention when so many of our preople have undiagnosed diabetes?

K.A. Beecham[1], E. Owusu-Atwi[2]

[1] Korle BU Teaching Hospital, Clinical Biochemistry, Korle Bu Accra, Ghana

[2] Effia-Nkwanta Hospital, Surgery, Sekondi-Takoradi Twin City, Ghana

Persons with diabetes are rising globally in step with the ongoing increase in obesity levels worldwide. There is no cure and has serious and life-threatening complications. By the rule of halves among persons with diabetes 50% are diagnosed, for those diagnosed 50% receive care and 50% reach their targets, 50% achieve desired outcome and only 6% would have a successful outcome. In Ghana, 7 out of 10 cases diagnosed did not know that they had diabetes, the prevalence for impaired glucose tolerance is 12.4% and the trend has

increased 16 fold since independence. Screening of undiagnosed diabetes through primary prevention of diabetes is very important within the population especially the at-risk groups, the vulnerable and in communities. Resources are scarce to handle the ever increasing rise. Access to health care service is a barrier especially for diabetes mellitus in Africa. The reasons are poverty and under-nutrition. Primary prevention is a first step before diagnosis which can be done at the point-of-care in most health facilities in developing countries. However, for the undiagnosed person with diabetes, chronic complications will have already started and or developed for which secondary and tertiary level preventions are the appropriate approaches in managing the condition. The burden of managing undiagnosed diabetes is on person but prevention is at the society. Lack of proper diabetes education, language, poor eating & living a sedentary life are not recognized as a serious problem. The cost-effective means is primary prevention but diagnosis of undiagnosed must be part of program to prevent the onset of chronic complications which is costlier. The at-risk-persons must be targeted through primary prevention. If nothing is done, it will threaten the gains of the economic growth in most countries in Africa. Today we are driving the fight against diabetes in the dark.

SPEAKERS' CORNER

IDF and the associations; but what of the individual with diabetes?

0195

IDF and the associations; but what of the individual with diabetes?

W.H.J.M. Wientjens[1]

Of course, "we all" know that someone diagnosed with diabetes needs medical treatment. In this process of medical treatment, a person with diabetes is just a patient, dependent on his/her own health care system. However, medical treatment is by far not enough for an individual with diabetes. There are also two other very important processes, i.e. the process of education and the process of being a full member of society.

Education does mean that someone with diabetes is learning how to live with his condition of diabetes. As an individual during his journey to good self management. Sometimes alone, sometimes together with others. With family, friends, colleagues. And learn to live with hypo's, hypers, depressions. To live with the threat of complications. Twenty four hours a day. You are not a patient then. You are in this process of education a pupil and hopefully to become a master of your diabetes condition.

And thirdly. Also an individual with diabetes wants to be a full member of society, with all the rights, duties and responsibilities of every human being. Without prejudices, without discrimination. It is so unfair that people are discriminated just because of a label with the text "diabetes" on their forehead. These three above mentioned processes are for me fully equivalent to one another.

By lack of time of the health care professionals, diabetes associations must recognize 'peer support' as a promising approach to diabetes management. People with diabetes and those affected by the condition are able to help other people with diabetes and their family to cope effectively with a range of demands and challenges involved in diabetes management, and in their struggle against discrimination. For the benefit of each individual. So, think globally and act locally.

Healthy lifestyle behaviors and risk of mortality among adults with and without diabetes in the U.S.

S. Saydah[1], *K. Bullard*[2], *G. Imperatore*[2], *E. Gregg*[2]

[1] *Centers for Disease Control and Prevention, Division of Diabetes Translation, Hyattsville, USA*

[2] *Centers for Disease Control and Prevention, Division of Diabetes Translation, Atlanta, USA*

Aim: Few studies have quantified healthy lifestyle behaviors' impact on longevity of the diabetic population. We examined the association between healthy behaviors and all-cause mortality among adults with and without diagnosed diabetes (DM).

Methods: We used data from the Third National Health and Nutrition Examination Survey, a nationally representative survey of non-institutionalized U.S. residents, conducted from 1988-1994 with follow-up for mortality status through 2001 (follow-up mean 8.4 years, maximum 13 years). Diabetes status was self-reported (n with diabetes = 1177, n without diabetes = 15217). We examined 5 self-reported healthy behaviors at baseline: physical activity>= 6 MET per week, not smoking, higher healthy eating index (HEI), moderate alcohol consumption (1-2 drinks/week), and maintaining weight or trying to lose weight in the past 12 months. We used proportional hazards models to determine the impact of a composite estimate of healthy behaviors, as well as each healthy behavior, with all-cause mortality, after adjusting for age, sex, race/ethnicity, education, body mass index (BMI), self-reported health status and heart attack history.

Results: All-cause mortality rate was significantly higher among adults with DM (43.7 per 1000 person years) than adults without DM (9.4 per 1000 person years). A higher summary score of healthy behaviors was associated with lower risk of all-cause mortality among both adults with DM (Relative Hazard (RH) 0.85, 95% Confidence Interval (CI) 0.80, 0.91) and without DM (RH 0.83, 95% CI 0.79, 0.86) after controlling for demographics, BMI, self-reported health status and heart attack history. People in the top 20% of healthy behaviors summary score had an adjusted 58% lower mortality rate than those in the bottom 40%. In models with individual healthy behaviors, persons with and without DM who reported physical activity >= 6 MET per week had a significantly lower mortality rate than those reporting low or sedentary levels [with DM: RH 0.50 (95% CI 0.33, 0.75); without DM: RH 0.65 (95% CI 0.51, 0.82)]. Moderate alcohol consumption was associated with decreased mortality (RH 0.46, 95%CI 0.23, 0.93) among persons with DM but not among those without DM. Among adults without DM, current smoking was associated with increased mortality (RH 1.81,95% CI 1.47, 2.21) compared to not smoking; higher HEI was associated with lower mortality (RH 0.76, 95% CI 0.65, 0.90) compared to lower HEI.

Conclusions: Our findings underscore the central role healthy lifestyle behaviors play in preventing premature mortality among people with and witout diabetes. Promoting and sustaining such behaviors should continue to be a priority for public health interventions.

Rs2383206 and its association with mortality in a cohort of individuals with type 1 diabetes

T. Costacou[1], *R.E. Ferrell*[2], *T.J. Orchard*[1]

[1] *University of Pittsburgh, Department of Epidemiology, Pittsburgh, USA*

[2] *University of Pittsburgh, Department of Human Genetics, Pittsburgh, USA*

Aims: Single nucleotide polymorphism rs2383206 on 9p21 gene has been previously associated with coronary artery disease (CAD) in the general population and individuals with type 2 diabetes. We thus assessed the relationship between this polymorphism and CAD and mortality in the Pittsburgh Epidemiology of Diabetes Complications (EDC) study of childhood onset type 1 diabetes.

Methods: EDC participants with DNA available (baseline mean age 27 and duration 19 years) were studied for the incidence of CAD or mortality (n=482). CAD was defined as EDC-physician diagnosed angina, ischemic changes by electrocardiogram, stenosis ≥50%, revascularization, confirmed myocardial infarction, or CAD death.
Results: The proportions of the cohort with the rs2383206 AA, AG, and GG genotypes were 26.6%, 45.5%, and 27.9% respectively. During 18 years, there were 132 (29.4%) incident cases of CAD and 81 (16.8%) individuals died. Univariately, the proportion of CAD events was lower in those with the GG compared to those with the AA/AG genotypes (21.9 vs. 31.9, p=0.04) although no differences were observed for mortality (p=0.89). This inverse relationship with CAD persisted in multivariable Cox models (HR=0.65, 95% CI=0.42-1.02), whereas a non-significant increased risk was seen for mortality (HR=1.45, 95% CI=0.83-2.53). To eliminate survival bias we repeated analyses by baseline diabetes duration (cutoff 25 years) and diagnosis year (cutoff 1962). Results were not altered for CAD but, surprisingly, a non-significant inverse association for GG vs. AA/AG was now observed for mortality in those with a duration ≥25 years (HR=0.87, 95% CI=0.32-2.36). However, an increased risk was still observed for GG in those with <25 years duration (HR= 1.87, 95% CI=0.94-3.70, p=0.07). Similar trends were observed for analyses by diagnosis year, suggesting that the GG genotype may truly confer susceptibility to early mortality, appearing protective in longer duration individuals. Indeed, the GG genotype was present with a higher frequency in those with <25 years diabetes duration (26.9% vs. 20.9%, p=0.18) or those diagnosed after 1962 (27.7 vs. 20.0, p=0.06).
Conclusion: These findings suggest that the GG genotype of the rs2383206 polymorphism may increase early mortality risk in type 1 diabetes.

Predictive accuracy of the Framingham and UKPDS risk equations in estimating the probability of cardiovascular events in a multi-national contemporary population with diabetes

A.P. Kengne[1], A. Patel[1], S. Colagiuri[1], S. Heller[1], P. Hamet[1], M. Marre[1], C.Y. Pan[1], S. Zoungas[1], J. Chalmers[1], M. Woodward[1]
[1] *The ADVANCE Collaborative Group, The George Institute for International Health, Sydney, Australia*

Aims: The reliability of available general and diabetes-specific equations for predicting the risk of CVD in people with diabetes has been questioned. The aim of this study was to validate the Framingham and United Kingdom Prospective Diabetes Study (UKPDS) risk equations prospectively in a multi-national contemporary population of individuals with type 2 diabetes.
Methods: The 4-year risks of total cardiovascular disease (CVD), and its constituents, were estimated using two published Framingham and the UKPDS risk equations in 7502 individuals with type 2 diabetes without known CVD at baseline who participated in the Action in Diabetes and Vascular disease: preterax and diamicron-MR controlled evaluation (ADVANCE) trial. Risk equations were assessed for their discriminatory capability using the area under the receiver operator characteristic curve (AUC) and calibration within fifths of predicted probability using the Hosmer and Lemeshow statistics (HL).
Results: The risk of major CVD was overestimated by 170% (95% confidence interval: 146-195%) and 202% (176-231%), using the two Framingham equations. The risk of major coronary heart disease was overestimated by 198% (162-238%) with UKPDS and by 146% (117-179%) and 289% (243-341%) with the two different Framingham equations. The AUC ranged from 0.62 to 0.69, being significantly better with UKPDS compared with either Framingham equation (all p ≤0.02 for the differences in discrimination). The risk of major cerebrovascular events was overestimated with the UKPDS and one Framingham equation. For all equations and all outcomes examined, there was a significant lack of fit within categories of predicted probabilities.
Conclusions: Application of the Framingham and UKPDS equations to a contemporary treated population with diabetes is likely to substantially overestimate coronary and total cardiovascular risk. New or adjusted cardiovascular risk prediction tools are needed to provide reliable prognostic information to patients and their care providers, and to guide decisions on the intensity of cardiovascular risk reducing therapies in people with diabetes.

O-0199

Derivation of the ADVANCE models for predicting the risk of major cardiovascular disease in people with diabetes

A.P. Kengne[1], A. Patel[1], S. Colagiuri[1], S. Heller[1], P. Hamet[1], M. Marre[1], C.Y. Pan[1], S. Zoungas[1], S. Chalmers[1], M. Woodward[1]
[1] *The ADVANCE Collaborative Group, The George Institute for International Health, Sydney, Australia*

Aims: There is a continuing need to develop risk prediction tools that will reliably estimate cardiovascular disease risk in various settings. The purpose of this study was to derive new equations for predicting the risk of cardiovascular (CV) events in a contemporary population with type 2 diabetes mellitus.
Methods: Follow-up of the Action in Diabetes and Vascular disease: preterax and diamicron-MR controlled evaluation trial (ADVANCE) cohort was used to estimate coefficients for significant predictors of CV events using Cox models in participants without previous CV event. Similar models were used to fit the 4 years risk of incident CV events. Discrimination and calibration were assessed using the area under the receiver operator characteristic curve (AUC) and Hosmer and Lemeshow statistics respectively. Internal validation used bootstrap methods.
Results: A total of 473 major CV events were recorded during follow-up. Age at diagnosis, known duration of diabetes, sex, pulse pressure, treated hypertension, atrial fibrillation, retinopathy, HbA1c, albumin/creatinine ratio and non-HDL cholesterol at baseline were significant predictors of CV events (multivariable-adjusted p≤0.022). A main risk equation was developed using these predictors, and an alternative model used baseline glucose instead of HbA1c. Models displayed acceptable discrimination (AUC: 0.691 to 0.697) and good calibration (p≥0.13). Based on a cut-off for 4-year predicted risk of 8% and above (equivalent to 10-year predicted risk of 20% and above), the two models reliably identified the 21% of participants in whom 46% of all major CVD were recorded during follow-up.
Conclusions: Many current tools used for estimating cardiovascular risk in patients with diabetes have been demonstrated to be unreliable. We describe a new risk engine, developed in a multi-ethnic cohort of diabetics receiving high levels of contemporary preventative cardiovascular therapies. External validation is needed to demonstrate its potential for widespread clinical use.

O-0200

Framingham and UKPDS risk engines are not universal predictors of coronary heart disease in type 2 diabetes mellitus

A. Kofinis[1], A. Thanopoulou[1], L. Milika[1], E. Dimaki[1], M. Noutsou[1], E. Spanou[1], B. Karamanos[1], A. Archimandritis[1]
[1] *National University of Athens, Diabetes Centre 2nd Department of Internal Medicine, Athens, Greece*

Aim: To assess the incidence of Coronary Heart Disease (CHD) in patients with type 2 diabetes mellitus (T2DM) and its relation to various risk factors, as well as to assess the predictive value of Framingham and UKPDS risk engines in a Greek population of patients with T2DM.
Methods: We followed 941 consecutive patients with T2DM, who were examined for the first time at the outpatient clinic. At the 5th year of follow-up complete data was available for 886 of them (94.2%). At baseline 658 of the patients (47.6% men) did not have macroangiopathy and were included in the present analysis. The mean age was 58.3 years and median diabetes duration 5 years. Hypertension was present in 45.6%, dyslipidemia in 41.0%, while 47.9% of the patients were current or ex-smokers. CHD was diagnosed according to UKPDS criteria, based on ECG findings, myocardial infarction, coronary angioplasty or grafting or CHD mortality. HbA1c was measured at least 15 times during the 5 years of follow-up and lipid levels at least 5 times.
Results: The 5-year incidence of CHD was 6.8%, much lower than the predicted for this population by Framingham (10.01%, p<0.05) and UKPDS (9.99%, p<0.05) risk calculators. The above risk engines did not differ between them in risk prediction. At baseline, patients who later developed CHD did not differ in sex, age, diabetes duration, BMI, blood pressure, lipid levels, HbA1c, hypertension and dyslipidemia prevalences and smoking habits from those who did not develop CHD. During follow-up, patients without CHD showed significant improvement from baseline in HbA1c (7,5vs7,1%), in lipid levels (Cholesterol 225vs214mg%, Triglycerides 161vs149mg%, LDL 149vs138 mg%) and creatinine (1,03vs0,97 mg%), p<0,01 for all. Patients who developed CHD showed improvement only in triglyceride levels (212vs144 mg%).

Conclusions: a) The 5-year incidence of CHD in Greek patients with T2DM is significantly lower than that predicted by Framingham and UKPDS risk engines, meaning that these engines should be used with caution in the Greek and possibly other populations b) These engines provide similar prediction of CHD in T2DM c) In spite of the short duration of follow-up, metabolic control improvement (HbA1c, lipid levels) may possibly decrease CHD incidence.

Changes in all-cause mortality in three Finnish middle-aged population cohorts with and without diabetes

N. Barengo[1], J. Tuomilehto[2]
[1] *Hospital Universitario La Paz, Epidemiology And Clinical Research, Madrid, Spain*
[2] *University Of Helsinki, Public Health, Helsinki, Finland*

Aim: To assess changes in all-cause mortality rates among people with and without diabetes between three large study cohorts with baseline assessment 10 years apart and followed-up for 10 years.
Methods: Six population surveys were carried out in 1972, 1977, 1982, 1987, 1992 and 1997 in randomly selected independent cohorts in North Karelia and Kuopio, Eastern Finland. For the analysis the 1972 and 1977 (cohort 1), the 1982 and 1987 cohorts (cohort 2) and the 1992 and 1997 cohorts (cohort 3) were combined and followed-up for 10 years regarding all-cause mortality. The people developing inident diabetes during the follow-up or having diabetes at baseline were derived from the national drug reimbursement records of the Social Insurance Institution and the hospital admission records of the National Hospital Discharge Register by computer-based record linkage.
Results: A total of 17 361 men and 18 707 women were followed-up for 10 years. The risk of all-cause mortality decreased in cohort 3 compared to the first two cohorts in both men and women who did not develop type 2 diabetes during the follow-up. In men with diabetes all-cause mortality did not significantly change during the follow-up. The Hazard Ratio (HR) for all-cause mortality after adjustment for age, education, smoking, systolic blood pressure, BMI and serum cholesterol was 0.84 in cohort 2 (95% CI 0.51-1.38) and 0.57 in cohort 3 (95% CI 0.28-1.18). NO statistically significant changes regarding all-cause mortality were observed in women in cohort 2 (HR 1.54; 95% CI 0.96-2.49) or cohort 3 (HR 0.59; 95% CI 0.23-1.49) compared to the reference category (cohort 1).
Discussion/conclusion: While all-cause mortality seems to decrease in the non-diabetic segment of the population, no changes have been observed in people with diabetes. Special attention should be given to prevent the onset of diabetes in the population and to intensify the management of patients with diabetes.

No conflict of interest

Serum total adiponectin, cardiovascular disease and all-cause mortality in type 2 diabetes: the Fremantle Diabetes Study

W. Davis[1], K. Peters[1], J. Beilby[2], J. Hung[3], T. Davis[1]
[1] *University of Western Australia, School of Medicine & Pharmacology, Fremantle, Australia*
[2] *PathWest, Department of Clinical Biochemistry, Nedlands, Australia*
[3] *University of Western Australia, School of Medicine and Pharmacology, Nedlands, Australia*

Aim: To assess the relationship between total serum adiponectin concentrations and cardiovascular disease (CVD), CVD death and all-cause death in patients with type 2 diabetes.
Methods: Baseline data (1993-1996) from 1,158 type 2 diabetes patients from the Fremantle Diabetes Study (FDS), a representative community-based, Australian cohort, were analysed. The FDS database was linked with the Western Australian mortality register between 1 January 1993 and 30 June 2007 to identify deaths and causes of death during 11,927 patient-years (mean±SD 10.3±3.9 years) of follow-up. CVD at study entry was defined as a history of coronary heart disease, cerebrovascular disease and/or peripheral arterial disease. CVD death was defined as death from cardiac or cerebrovascular causes, death from peripheral arterial disease, or sudden death. Multiple logistic and Cox regression analyses, stratified by sex, were used to determine the most parsimonious models for prevalent CVD, CVD death and all-cause death. Quintiles of serum total adiponectin were added to each model to determine whether total adiponectin was a significant independent associate.
Results: At baseline, the patients were 63.9±11.4 years of age, 49.3% were male and they had been diagnosed a median [inter-quartile range] of 4.0 [1.0-9.0] years previously. Nearly half (49.1%) had a history of CVD; males had a significantly higher prevalence than females (52.3% vs 44.6%; P=0.006). Both males and females with prevalent CVD had significantly higher levels of total adiponectin than those without (6.0 [2.9-12.7] vs 5.3 [2.8-10.1] mg/L, P=0.036 for males; 9.2 [4.8-17.5] vs 7.8 [4.0-15.1] mg/L, P=0.003 for females). Serum total adiponectin quintile cut-points by sex were 3.2, 4.9, 6.6 and 10.2 mg/L for males and 4.9, 7.0, 9.6 and 14.8 mg/L for females. Serum total adiponectin was not independently associated with prevalent CVD for either sex (P=0.25). During follow-up, 479 deaths occurred (41.4%), 249 (52.0%) from CVD. Serum total adiponectin did not independently predict CVD death in either sex (P=0.24). For all-cause mortality, serum total adiponectin added to the Cox models for each sex (P=0.045) but not linearly. With the second quintile as reference, the highest quintile in males had a 64% increased risk of death (HR (95% CI) 1.64 (1.06-2.55); P=0.028). In females, the lowest, 4th and 5th quintiles had significantly higher risks of death (1.86 (1.04-3.33), 2.09 (1.19-3.68) and 1.96 (1.15-3.36), respectively; P<0.04 in each case).
Conclusions: Serum total adiponectin is not independently associated with prevalent CVD or CVD death in type 2 diabetes, but is an independent predictor of all-cause mortality with a 'U-shaped' relationship.

Background: In this pandemic of diabetes, Asia has the highest number of affected people estimated to exceed 100 million. The Joint Asia Diabetes Evaluation (JADE) Program is the first web-based program to facilitate implementation of comprehensive care recommended by IDF. All enrolled patients underwent comprehensive assessment for risk stratification before triage into various care protocols. We report baseline data of these patients since the program commenced in November 2007.
Methods: The JADE electronic portal (JADE-portal) provides templates to guide data collection during annual comprehensive assessment and follow-up visits. Between Nov 2007 and Feb 2009, clinicians from 7 regions in Asia (HK, IN, KR, PH, SG, TW and TH) used the JADE-portal to manage their patients. Of the 4004 diabetic patients enrolled, 26 had type 1 diabetes, 3687 had type 2 diabetes and 291 had uncertain status. We analyzed the baseline data of the 3687 type 2 diabetic patients.
Results: Of the 3687 patients (PH 1186, HK 832, IN 788, KR 295, TH 275, SG 256, TW 55) [46.1% men, median (range) age: 58 (15-93 years), disease duration: 6.5 (0-71 years)], 10.0% had coronary heart disease, 3.3% had stroke, 3.1% had peripheral vascular disease (0.7% had lower limb amputation), 0.4% had renal failure, 16.2% had at least one of these cardiovascular-renal complications. A further 17.7% had diabetic retinopathy and 7.5% had chronic kidney disease (eGFR <60 ml/min/1.72m^2). Hypertension, dyslipidaemia and obesity affected 84.6%, 76.8% and 30.1% of subjects, respectively. For attainment of treatment targets, 35.3% had HbA_{1c} <7%, 32.3% had BP <130/80 mmHg and 34.0% had LDL-C at or <2.5 mmol/L. Only 5.4% had attained all 3 targets while 38.7% and 23.4% achieved 1 or 2 targets respectively. Using a validated JADE Risk Engine, patients were categorized into 4 risk levels (from low to high): Level 1, n=24 (0.7%); Level 2, n=707 (19.2%); Level 3, n=2358 (64.0%) and Level 4, n=598 (16.2%) which corresponded to a 5-year absolute risk of death or cardiovascular-renal events of 2.5%, 8%,

21.5% and 60%, respectively.
Conclusions: Apart from providing decision support and facilitating data collection for quality improvement purpose, the JADE Program enables clinicians to collect comprehensive data on a regular basis to identify high risk patients for intensified treatment.

Pregnancy and gestational diabetes

O-0204

Pregnancy in adolescents with diabetes

L. Valdes[1], O. Santana[1], B.R. Rodriguez[1], A. Santurio[1], J. Lang[2], A. Marquez-Guillen[2]
[1] *Ramon Gonzalez Coro Hospital, Central Service of Diabetes and Pregnancy, Ciudad de la Habana, Cuba*
[2] *National Institute of Endocrinology, Central Service of Diabetes and Pregnancy, Ciudad de la Habana, Cuba*

Objective: To know the maternal and perinatal outcome in adolescent diabetic.
Patients and method: We retrospectively studied pregnancy outcome in 138 adolescent with diabetes (less than 20 years old), 101 of them were pregestational with diabetes and 37 gestational diabetes. We compared our findings with the pregnancy outcome in 242 nondiabetic adolescents and 482 non adolescent and non diabetic women from the same hospital randomised taking. We used the X2 test of Fisher and Z for the study of proportions.with a significance of $p < 0,05$.
Results: We detected that perinatal mortality of the adolescents with diabetes was similar in all groups, however the cesarean section rate, the frequency of preterm deliveries and the neonatal morbidity was significantly higher in the adolescents with diabetes. The frequency of congenital anomalies in the group of adolescent with diabetes was very high 8,0%(11/138).
Conclusion: All the adverse perinatal findings in the adolescents with pregestational diabetic group could be related with hyperglycaemia of very difficult control in 1 of each 3.

O-0205

Metabolic features and pregnancy outcomes of pregnant women with hyperglycemia

F. Cheng[1], X.H. Guo[1], H.X. Yang[1], G.Z. Lu[1], Y. Hui[1], L. Chen[1], S.K. Li[1]
[1] *The first hospital of Peking University, department of endocrinology, Beijing, China*

Aims: To analyze metabolic features and pregnancy outcomes of pregnant women with hyperglycemia.
Methods: One hundred and thirty pregnant women were enrolled between August 2005 and December 2006 and divided into the normal glucose tolerance group (NGT, n=26), gestational impaired glucose tolerance group (GIGT, n=42), and gestational diabetes mellitus group (GDM, n=62) based on 75 g oral glucose tolerance test (OGTT). Fasting plasma glucose(FPG) and insulin, hemoglobin A1c (HbA1c), lipid spectrum and C-reactive protein(CRP) were measured. Pre-pregnant body mass index(pre-BMI), HOMA-IR, HOMA-B were calculated. Family history of diabetes and adverse pregnancy outcomes were recorded.
Results: Among three groups of GDM, GIGT and NGT, FPG (5.12±0.97mmol/L, 4.71±1.00mmol/L, 3.96±0.47mmol/L, respectively), FIns(9.16±3.98mU/L, 9.28±3.90mU/L, 5.90±3.95mU/L, respectively), HbA1c (5.67±0.76%, 5.62±0.61%, 4.03±0.27%, respectively), total cholesterol (5.54±1.33mmol/L, 5.12±1.23mmol/L, 4.20±1.07mmol/L, respectively), LDL-C(3.06±1.01mmol/L, 2.77±0.84 mmol/L, 2.27±0.77mmol/L, respectively), CRP (2.65 mg/L,3.82 mg/L,1.79 mg/L, respectively), HOMA-IR(1.88,1.82,0.86, respectively), pre-BMI(24.37±3.98kg/m^2, 24.32±2.83 kg/m^2, 22.24±2.79kg/m^2, respectively), the rate of cesarean delivery(71.0%, 52.4%, 19.2%, respectively), infant birth weight(3304.19±607.90g, 3345.48±462.74g, 2987.69±671.63g, respectively), maternal complications(69.4%,54.8%,23.1%, respectively), neonatal complications(29.0%,28.6%,3.8%, respectively) were significantly increased in the GDM and GIGT groups compared with those in the NGT group($P<0.05$). From NGT to GIGT to GDM, HOMA-B(295.75,168.76,126.25,respectively)tended to decrease in turn, there was significant difference between three groups($P<0.05$). Family history of diabetes was more commonly seen in the GDM group(38.7%)vs the NGT group(11.5%)($P<0.05$). Logistic analysis showed that adverse maternal-infant pregnancy outcomes were significantly related with pre-BMI, age and HbA1c.
Conclusions: Severe insulin resistance, ß-cell dysfunction, increased pre-BMI, lipid disorder, and hereditary susceptibility may be the main metabolic features of women with pregnant hyperglycemia. Pre-BMI, maternal age and HbA1c could be the risk factors of adverse maternal-neonatal complications.

O-0206

Inadequate screening for type 2 diabetes following pregnancy complicated by gestational diabetes

B. Shah[1], J. Lowe[1]
[1] *Sunnybrook Health Sciences Centre, Department of Medicine, Toronto, Canada*

Aims: Because of the high risk for the development of type 2 diabetes after gestational diabetes, clinical practice guidelines recommend screening with an OGTT between 6 weeks and 6 months after delivery for women who had gestational diabetes during pregnancy. The aim of this study was to evaluate trends over time in post-partum screening for diabetes after gestational diabetes.
Methods: The study used administrative data sources that provide detailed information on the health care utilisation of all residents of the Canadian province of Ontario (population=12 million). All women aged 17 to 49 without pre-existing diabetes who delivered between April 1994 and March 2008 were identified. Each woman who had gestational diabetes was matched with one who did not on age, region and year/quarter of delivery. For each year/quarter and for each group, the frequency of OGTTs and of any test that might be used to diagnose type 2 diabetes (i.e., OGTT, fasting glucose, random glucose or A1c) was determined up to 6 months post-partum.
Results: Screening with OGTTs after pregnancy with gestational diabetes increased from between 4 and 7% of pregnancies per year/quarter at the beginning of the study to between 13 and 17% of pregnancies at the end. This markedly exceeded the secular trend seen after pregnancies without gestational diabetes, where screening frequency increased from between 0 and 0.3% of pregnancies at the beginning to between 0.3 and 0.6% of pregnancies at the end. The use of any potential test that might diagnose type 2 diabetes after gestational diabetes increased from between 26 and 28% of pregnancies at the beginning of the study period to between 35 and 40% of pregnancies at the end.
Conclusion: Although an increasing number of women with pregnancies complicated by gestational diabetes were receiving OGTTs post-partum, the overwhelming majority of women were not receiving these tests. Even when considering a variety of tests that might have been used to diagnose type 2 diabetes, fewer than 40% of women with gestational diabetes were tested. This finding of inadequate screening in a high-risk population suggests that a large number of women of child-bearing age with type 2 diabetes remain undiagnosed.

O´Sullivan test, A real screening test?

T. De La Cera[1], P. Sotorrío[1], F.V. Álvarez[1], F. Díaz-Cadórniga[2], E. Menéndez Torre[2], M. Riestra Fernandez[2], C. Sánchez Ragnarsson[2]
[1] *Hospital Universitario Central de Asturias, Biochemistry, Oviedo, Spain*
[2] *Hospital Universitario Central de Asturias, Endocrinology, Oviedo, Spain*

Introduction: Glucose metabolism abnormalities during pregnancy are detected by an initial screening test with a 50 gram glucose oral intake, O´Sullivan Test (ST), and further confirmation by oral 100 gram glucose tolerance test (OGTT).
As there are discrepancies regarding whether the ST should be performed in the fasting (F) or in non fasting (NF) state and it is known that previous ingestion influences its results, some authors have questioned its value as a screening test.
Aim: In our hospital and due to lack of consensus criteria, the ST is performed either F or NF. The aim of our work was to study the influence of the F or NF

state in the efficiency of the test.
Subjects: A total number of 568 pregnant women were divided into two groups: 243 were fasting prior to ST and 325 had had breakfast before. Age was similar in both groups: 32 years ± 5SD, range 16-46, and a mean body mass index (BMI) of 23 kg/m2.
Methods: The ST consists of assessing serum glucose (SG) value 60 minutes after a 50 gram oral glucose intake and it is performed between week 24 and 28. A value higher than 140 mg/dl indicates the need for a confirmation test with a 100 g OCTT, performed in the fasting state.
Glucose measurement was done in serum samples in the Modular analytics autoanalyzer (Roche), with a hexokinase glucose enzyme test. The study also included a pre-sugar basal capillary blood glucose test.
Statistics: A SPSS program, version 12.0 was applied and measurements were compared using a "t-student" test for independent samples, assuming significant differences with a p value <0,05.
Results: 57% of subjects did the ST in F state and 43% in NF state.
Out of 568 TS performed, 19% had a positive result: 11% were done F and 8% were done NF.
Women who had eaten breakfast before ST, had higher basal capillary blood glucose test values before the glucose load than SG 60 minutes after it, which is a known fact related to improved insulin sensitivity.
Statistic analysis of SG values shows two different populations with normal distribution and statistically significant different values (p<0,0001), with a shift in the mean value from 122 mg/dl in those who were F to 110 mg/dl in those who were NF. The current 140 mg/dl cut-off value is equivalent to 127 mg/dl in those who are NF with the same typified coordinate.
Conclusion: The study demonstrates that performing ST postprandially can generate false negative results in this population when using the actual cut-off point and it outlines the need to establish a unique protocol for doing the ST, either fasting or non fasting, and to review the cut-off point in accordance with the new ADA criteria.

National Cuban programme of diabetes in pregnancy

A. Marquez Guillen[1], L. Valdes[2], J. Lang[1], B.R. Rodriguez[2], O. Santana[2], J. Cruz[3], E. Guerrero[4], M. Vera[1], L. Ibargollen[5]
[1] *National Institute of Endocrinology, Central Service of Diabetes and Pregnancy, Ciudad de la Habana, Cuba*
[2] *Ramon Gonzalez Coro Hospital, Central Service of Diabetes and Pregnancy, Ciudad de la Habana, Cuba*
[3] *America Arias Hospital, Service of Diabetes and Pregnancy, Ciudad de la Habana, Cuba*
[4] *10 de Octubre Hospital, Service of Diabetes and Pregnancy, Ciudad de la Habana, Cuba*
[5] *Ministry of Public Health, Mother and Child National Programme, Ciudad de la Habana, Cuba*

Aims:
1. Reduce the morbility and mortality of children born to pregestational diabetics mothers.
2. To guarantee the active search and further treatment of gestational diabetes attending to the frequency of risk factors.

Methods: In Cuba, population of known diabetic women in childbearing age comprise aproximately 44,000 patients.
At the same time prevalence of gestational diabetes is 4,6% with an amount of 6,500 deliveries /year.
All the pregestational diabetic women that want to get pregnant are referred to specialized consultations of reproductive risk all over the country.
They receive integral preconceptional attention.
A glucometer is given to each patient in the case that pregnancy is advisable and she is instructed in its use to accomplish an optimal glycemic control. A monthly measurement of glycosilated hemoglobin is done. Criteria for good metabolic control are sustained values of glycosilated hemoglobin below 8% as well as preprandial glycemic values below 5,5 mmol/L and 2 hours postprandial values less than 6,6 mmol/L.
In 2008 the activity was expanded to the 87% of the country.
The patients are care by the same team before, during and after pregnancy.

Acumulative results of first 5 years (2003 - 2008)
Total deliveries in pregestational diabetics 1303
With preconceptional good control 635 (48,7%)
- Congenital malformation 6 (0,9%)
- Perinatal mortality 5 (0,8%)

Without preconceptional good control 664 (51%)
- Congenital malformation 51 (7,7%)
- Perinatal mortality 45 (6,8%)

The active search of gestational diabetes have not been fulfill nationwide and the prevalence in this moment is only 1,48%.
Conclusion: Our experience demonstrates the feasibility of this program to achieve a succesful outcome in pregnant diabetic.

No conflict of interest

O-0209

Women with former gestational diabetes exhibit similar incretin effect on beta cell function as healthy women after normal pregnancy

G. Pacini[1], A. Tura[1], Y. Winhofer[2], A. Kautzky-Willer[2]
[1] *ISIB CNR, Metabolic Unit, Padova, Italy*
[2] *Medical University of Vienna, Internal Medicine 3, Vienna, Austria*

Background and aims: Women with a history of gestational diabetes (fGDM) are at increased risk of developing diabetes and it is known that they present a reduced beta cell function under glucose stimulation. Incretin hormones contribute to augment glucose stimulated insulin production, after oral ingestion of glucose. With this study we aimed to assess the possible role that incretins may play in the altered insulin release of fGDM.
Materials and methods: We studied 105 non-diabetic fGDM women within 6 months after delivery (age=33.5±0.5 years (mean±SE); body mass index, BMI=27.3±0.5 kg/m^2, fasting glucose, G_b=4.68±0.07 mmol/l; fasting insulin, I_b=55±2 pmol/l; fasting C-peptide CP_b=569±31 pmol/l), compared to 38 healthy women after normal pregnancy, CNT (age=32±1, BMI=25±1, G_b=4.32±0.09 (p<0.005), I_b=51±4, CP_b=479±28). Every subject randomly underwent a 75g oral glucose test (OGTT) and a 0.33g/kg frequently sampled intravenous glucose test (IVGTT) with glucose and C-peptide measurements; both lasted 3h. Less than 3 weeks elapsed between the two tests, without any diet or habit changes in between. We calculated the area under the concentration curves (AUC) for glucose (AUC_{GL}) and C-peptide (AUC_{CP}) for 3 h in both tests. The suprabasal, dynamic AUC (dAUC) were computed by subtracting from the AUC the basal area (i.e., fasting value x 180 min). The beta cell function during OGTT (BC_{OG}) and that during IVGTT (BC_{IV}) were calculated according to the respective ratios: $dAUC_{CP}/dAUC_{GL}$. Percent incretin effect was assessed as $100x(BC_{OG} - BC_{IV}) / BC_{OG}$
Results: $dAUC_{GL}$ of fGDM was higher than that of CNT for both tests (338±20 mmol/l 3h vs. 189±21, p=0.0001 for OGTT; 206±13 vs. 119±16, p=0.0002 for IVGTT). $dAUC_{CP}$ were not different between fGDM and CNT and much higher (p<0.00001) during OGTT (285±9 nmol/l 3h vs. 257±15, p=0.13 fGDM vs. CNT for OGTT; 61±3 vs. 55±5, p=0.36 for IVGTT). BC_{OG} was found unchanged (1.82±0.44 nmol/mmol vs. 2.45±0.56, p=0.44 fGDM vs. CNT) while BC_{IV} was lower in fGDM (0.41±0.03 vs. 0.68±0.10, p=0.0006). BC_{OG} was markedly higher than BC_{IV} in both groups (p=0.003). Incretin effect resulted virtually the same (60±3 % in fGDM and 61±4 in CNT, p=0.7).
Conclusion: Women with a history of gestational diabetes, despite higher glucose, exhibit similar C-peptide release in both tests, indicating a reduced beta cell function. However, the elevated beta cell response during OGTT masks possible differences between fGDM and CNT, which instead are highlighted by IVGTT. Therefore, incretins have a potent effect in both groups, which is similar between former GDM and normal women.

Clinical outcomes and nutritional intake

O-0210

Disordered eating behaviours in type 1 diabetes mellitus patients

N. Donmez[1], G. Pekcan[1], M. Kutlu[2]
[1] *Hacettepe University, Nutrition and Dietetics, Ankara, Turkey*
[2] *Gülhane Military School of Medicine Hospital, Department of Endocrinology and Metabolism, Ankara, Turkey*

Objective: Type 1 DM (Diabetes Mellitus) and disordered eating behaviours (DEBs) lead to an increased risk of poor diabetes outcomes. This includes poor metabolic control and increased risk of complications. This study was planned to examine the relationship between type I DM, DEBs and nutritional habits, anthropometric and biochemical parameters in Type 1 DM patients who were recruited to the Gülhane Military School of Medicine (GATA) Hospital, Endocrinology Clinic and healthy controls.
Methods: Total of 40 subjects (22 type I DM and 18 healthy controls) aged 10-30 years (9-13 years preadolescents, 14-18 years adolescents and 19-30 years old adult men and women) are conducted to the study and filled a basic information form (BIF), psychological tests such as Eating Attitudes Test (EAT), Body Image Scale (BIS) and Bulimia Investigatory Test Edinburg (BITE) for the determination of the DEBs. BMI (kg/m^2) is calculated by using weight (kg) and height (m). BEBIS-5 programme is used to evaluate nutritional consumption data and SPSS 13.0 programme is used for the statistical analysis.
Results: According to the EAT scores; DEBs were seen higher in type I DM people than the control group ($p>0.05$). In people who had DEBs were also investigated for the factors such as mother's and father's education, duration of diabetes and HbA_1C levels. But none of these factors was found to be statistically significant ($p<0.005$). Skipping meals was found statistically significant ($p<0.005$) between type I DM and control group. Educational resource for type I DM people are the dietitians (% 48.4), followed by doctors (% 37.9), nurses (% 10.3) and mass media (% 3.4), respectively. It was also found that as the age of diabetes increases, a decrease in HbA_1C levels were observed ($r=-0.524$). Age and HbA_1C levels are positively correlated ($r=0.213$).
Conclusion: DEBs seen in type I diabetes mellitus make the disease difficult to maintain. Metabolic control is important and has to be monitored. Although there are wave of articles on this topic, studies are still limited. This study indicates the importance of multidisciplinary team work and continuous education and testing of the education in specific times. There are limited studies in Turkey so further research is needed.

A high protein diet with resistance exercise improves weight loss and body composition in overweight and obese patients with type 2 diabetes

T.P. Wycherley[1], M. Noakes[2], P.M. Clifton[2], X. Cleanthous[2], J.B. Keogh[2], G.D. Brinkworth[2]
[1] *University of Adelaide, Discipline of Physiology School of Molecular and Biomedical Science, Adelaide, Australia*
[2] *CSIRO, Human Nutrition, Adelaide, Australia*

Aim: To evaluate the effects of two low fat energy restricted diets differing in carbohydrate protein ratio, with and without resistance exercise (Ex), on weight loss, body composition and CVD risk outcomes in overweight and obese patients with T2D.
Methods: In a parallel design, 83 men and women with T2D (age 56.12±7.53 yrs, BMI 35.4±4.6 kg/m^2) were randomly assigned to an isocaloric, energy restricted diet (females: 6 MJ/day, males: 7 MJ/day) of either high carbohydrate (HC; carbohydrate:protein:fat, 55:20:25) or high protein (HP; 40:35:25), with or without Ex (3 d/wk). Body weight and composition, waist circumference (WC) and cardiometabolic markers were assessed pre- and post-intervention.
Results: 59 participants completed the study. There was a significant time x group effect (P=0.04) for body weight, fat mass and WC such that the HP+EX had the greatest reduction for these parameters; weight (HC -8.61±4.61 kg, HP -8.98±4.82 kg, HC+Ex -10.52±5.10, HP+Ex -13.79±5.98), fat mass (HC -6.35±3.44 kg, HP -6.65±4.0 kg, HC+Ex -7.91±3.73 kg, HP+Ex -11.05±3.71 kg) and WC (HC -8.2±4.6 cm, HP -8.9±3.9 cm, HC+Ex -11.3±4.6 cm, HP+Ex -13.7±4.6 cm). Across the groups there was an overall reduction (P<0.001) in lean mass (-2.0•2.3 kg), blood pressure (-15/8•10/6 mmHg), fasting glucose (-2.1•2.2 mmol/L), insulin (-4.7±5.4 uM/L), HbA1c (-1.25•0.94 %), triglycerides (-0.47•0.81 mmol/L) total cholesterol (-0.67±0.69 mmol/L) and LDL-cholesterol (-0.37•0.53 mmol/L) with no significant difference between groups (P•0.17, time x group interaction).
Conclusion: An energy restricted high protein diet combined with resistance exercise resulted in greater weight loss and more favourable changes in body composition. All treatments had similar improvements in glycemic control and CVD risk markers.

O-0212

Effectiveness of shift work on lifestyle intervention in overweight subjects with prediabetes

S. Karamagkiolis[1], E. Georgiadi[1], A. Kanavou[2], T. Simopoulou[1], M. Hamilos[3], V. Lalos[1], P. Philippidis[4]
[1] *General Hospital of Larissa, 1st Department of Internal Medicine, Larissa, Greece*
[2] *General Hospital of Nea Ionia, 2nd Department of Internal Medicine, Athens, Greece*
[3] *University Hospital of Heraklion, Department of Cardiology, Heraklion Crete, Greece*
[4] *General Hospital of Athens "G. Gennimatas", 2nd Department of Internal Medicine, Athens, Greece*

Aims: Prediabetes (PD), meaning impaired fasting glucose or impaired glucose tolerance, is an increasing event over the last years. Moreover, it can accelerate the incidence of Diabetes Mellitus (DM) when it is combined with obesity and disturbances of sleep-wake cycle due to irregular shift work. This study examines if lifestyle intervention (LSI) in overweight subjects with PD has the same results in individuals working fixed or rotational shifts.
Methods: One hundred-four subjects (range 40-56 years old) were joined this study and formed 2 age groups, 40 to 49 and 50 to 56. Inclusion criteria were overweight people (BMI = 25 - 29.9) not receiving any hypoglycaemic medicines and who had at their last blood results Fasting-Glu 100 to 125 mg% and / or 2 hours –postprandial Glu 140 to 199 mg%. Subjects formed 2 groups, 52 of them having fixed working shifts (Group A) and 52 having rotational working shifts with at least one night shift of eight hours every week (Group B). All of them received the same instructions of LSI about diet modification, weight loss, exercise, smoking cessation, etc. After 18 months of follow up, we examined how many of them had normal or near-normal fasting Glu equal or less than 110 mg% and normal or near-normal postprandial Glu equal or less than 154 mg%, as well as how many suffered from DM. For the statistical analysis of the data the Fischer's exact test was used.
Results: Fifteen subjects (28.8%) of Group A and 6 subjects (11.5%) of Group B maintained normal or near normal Glu blood levels ($p= 0.049$, Relative risk = 1.602, 95% Confidence Interval: 1.116 to 2.300). Additionally, 14 subjects (13%) became diabetics by the end of the study, that is five (9.6%) of group A and nine (17.3%) of group B ($p= 0.072$, Relative risk = 0.428, 95% Confidence Interval: 0.156 to 1.178). No statistically significant differences were found between men and women as well as between the pre-mentioned age groups.
Discussion/conclusion: Our study shows that LSI may provide better results in overweight subjects with PD and with fixed working schedule, due mainly to easier adaptation to the changes in their lifestyle from those having rotational working shifts. Both normal sleep loss and misalignment of the circadian rhythm with respect to the sleep-wake cycle may result in bad glycaemic control of prediabetics with irregular working schedule. Although a smaller number of patients in group A, compared to group B, suffered from DM after 18 months of LSI, the result may show a trend but did not prove statistically significant.

Effect of dietary pulses on glycemic control in people with and without diabetes: Meta-analyses and meta-regression models of experimental randomized trials

C.W.C. Kendall[1], J.L. Sievenpiper[2], A.J. Carleton[1], A. Esfahani[1], J.M.W. Wong[1], H.Y. Jiang[3], R.P. Bazinet[1], E. Vidgen[1], D.J.A. Jenkins[1]

[1] University of Toronto, Department of Nutritional Sciences, Toronto, Canada

[2] St. Michael's Hospital, Risk Factor Modification Centre, Toronto, Canada

[3] McMaster University, Michael G. DeGroote School of Medicine, Hamilton, Canada

Background: Dietary non-oil seed pulses (chickpeas, beans, peas, lentils, etc.) are a good source of slowly-digestible carbohydrate, fibre, and vegetable protein and a valuable means for lowering the glycemic-index (GI) of the diet. To assess the evidence that dietary pulses may benefit glycemic control, we conducted meta-analyses and meta-regression models of randomized experimental trials investigating the effect of pulses alone or as part of low-GI or high-fibre diets on markers of glycemic control in people with and without diabetes.

Methods: We searched MEDLINE, EMBASE, CINAHL, and the Cochrane Library for relevant controlled trials of =7d. Two independent reviewers (AE, JMW) extracted information on study design, participants, treatments, and outcomes. Data were pooled using the generic inverse variance method and expressed as standardized mean differences (SMD) with 95% CI, where <0.4, represents a small effect size, 0.4-0.7, a moderate effect size, and >0.7 a large effect size. Heterogeneity was assessed by c^2 and quantified by I^2. Meta-regression models identified independent predictors of effects.

Results: Forty-one trials (39 reports) were included. Pulses alone (11 trials) lowered fasting blood glucose (FBG) (-0.71 [-1.24, -0.17]) and insulin (-0.62 [-1.05, -0.19]). Pulses in low-GI-diets (19 trials) lowered glycosylated blood proteins (GP), measured as HbA1c or fructosamine (-0.28 [-0.42,-0.14]). Finally, pulses in high-fibre diets (11 trials) lowered FBG (-0.32 [-0.49, -0.15]) and GP (-0.27 [-0.45, -0.09]). Inter-study heterogeneity was high and unexplained for most outcomes with benefits modified and predicted by diabetes status, pulse type, dose, physical form, follow-up, macronutrient profile of background diets, design, and study quality.

Conclusions: Pooled analyses demonstrated that pulses alone or in low-GI or high-fibre diets improve markers of longer term glycemic control in humans with significant heterogeneity. There is a need for further large, well designed trials to address the heterogeneity in the data.

[2] St. Michael's Hosptial, Risk Factor Modification Centre, Toronto, Canada

Background and aims: Nuts have been shown to reduce serum cholesterol and the risk of cardiovascular disease and diabetes but few studies have assessed the effect of nuts on glycemic control. Our aim was to assess the effect of two doses of mixed nuts on serum lipids and glycemic control in subjects with type 2 diabetes.

Materials and methods: 117 type 2 subjects with diabetes treated with oral hypoglycemic medications were randomized to one of three treatments for three months: 75 g mixed nuts; 38 g mixed nuts and half portion of muffins; and full portion of muffins. Supplements provided 475 kcal per 2000 kcal diet. The primary outcome was change in HbA1c with serum lipids, CRP, body weight and blood pressure as secondary measures.

Results: Using an intention-to-treat analysis of the data (n=117), only after full dose nuts was a significant reduction from baseline seen in HbA1c of -0.2 ± 0.05 HbA1c % units (P<0.001)) whereas for half nuts plus muffin and muffin alone the respective results were -0.05±0.07, (P>0.05) and -0.05±0.06 HbA1c (P>0.05). Significant differences were also seen between nuts and muffins with greater falls on nuts for LDL-C (-0.19±0.12 mmol/L, P=0.03). Nut intake directly related to change in LDL-C (r= -.24, n=98, P<0.05).

Conclusion: Consumption of mixed nuts daily may improve serum lipids and glycemic control in type 2 diabetes.

Corneal confocal microscopy: a novel surrogate marker for diabetic autonomic neuropathy

M. Tavakoli[1], P. Begum[2], J. McLaughlin[2], R.A. Malik[1]

[1] University of Manchester, Cardiovascular Research Group, Manchester, United Kingdom

[2] University of Manchester, GI Science Hope HospitalSalford, Manchester, United Kingdom

The accurate quantification of the severity of diabetic autonomic neuropathy (DAN) can be time consuming and challenging. At present, most clinicians undertake cardiac autonomic function tests to use as a surrogate of autonomic neuropathy of the GI tract. We undertook a range of tests of small fibre and autonomic neuropathy including the novel technique of corneal confocal microscopy (CCM) to define how they may detect and quantify the severity of DAN in patients with gastroenteropathy.

20 subjects with diabetic gastroenteropathy and 14 control subjects underwent cardiovascular and peripheral autonomic function testing to establish the Composite Autonomic Severity Score (CASS). Quantitative Sensory testing (QST) was performed to assess the severity of somatic neuropathy and corneal sensitivity and CCM were performed to quantify c-fibre dysfunction and damage.

12 patients (60%) had moderate-severe DAN (CASS 4.0 ± 2.2). Corneal Nerve Fibre Density (NFD) 17.8 ± 13.3 (95% CI 11.6-23.9) vs 48.3 ± 12.4 (95% CI 41.1-55.4), Nerve Branch Density (NBD) 8.9 ± 7.9 (95% CI 5.2-12.6) vs 30.1 ± 5.3 (95% CI 27.0-33.2) and Nerve Fibre Length (NFL) 3.6 ± 3.1 (95% CI 2.1-5.2) vs 9.7 ± 2.5 (95% CI 8.3-11.2) were all significantly reduced in DAN vs controls (p<0.0001) and corneal sensation threshold was significantly elevated 1.6 ± 0.9 (95% CI 1.2-2.1) vs 0.7 ± 0.2 (95% CI 0.6-0.8); (p <0.0004). Corneal abnormalities correlated highly significantly with the severity of DAN

(CASS vs NFD [r = -0.713], NBD [r = -0.726], NFL [r = -0.786] and CS [r = 0.659]; p<0.0001).
Patients with DAN had significant corneal nerve abnormalities compared to healthy controls and the severity of nerve damage was very strongly associated with the severity of autonomic neuropathy. Thus CCM may act as a simple non-invasive surrogate marker for DAN in patients with diabetic gastroenteropathy.

Assessment of neuropathy in patients with impaired glucose tolerance and idiopathic neuropathy: novel diagnostic technique

M. Tavakoli[1], A. Marshall[2], M. Roberts[3], R.A. Malik[1]
[1] *University of Manchester, Cardiovascular Research Group, Manchester, United Kingdom*
[2] *Manchester Royal Infirmary, Clinical Neurophysiology, Manchester, United Kingdom*
[3] *Hope Hospital, Neurology, Manchester, United Kingdom*

Patients with idiopathic small fibre neuropathy (ISFN) have been shown to have significant intraepidermal nerve fibre loss in skin biopsies and also an increased prevalence of impaired glucose tolerance (IGT). From these data it has been inferred that IGT contributes significantly to small nerve fibre damage. However, skin biopsy is an invasive procedure therefore we have used corneal confocal microscopy, a novel non-invasive technique to quantify small nerve fibre damage in patients with ISFN.
25 patients with idiopathic painful neuropathy underwent an Oral Glucose Tolerance test (OGTT) and together with 12 aged-matched control subjects detailed evaluation of neuropathy using: Neuropathy Symptom Profile (NSP), Neuropathy Deficit Score (NDS), Nerve Conduction Studies (NCS), Quantitative Sensory Testing (QST) (vibration and thermal thresholds) and corneal confocal microscopy (CCM) to assess neuropathic deficits.
8 (32%) of patients had IGT. Whilst all patients with ISFN had significant neuropathic symptoms, NDS, NCS and QST, except for warm thresholds, were normal. However, CCM demonstrated a highly significant reduction in corneal nerve fibre density (NFD) (P<0.0001), nerve branch density (NBD) (P<0.0001), nerve fibre length (NFL) (P<0.0001) and an increase in nerve fibre tortuosity (NFT) (P<0.0001). These parameters did not differ between patients with and without IGT, nor did they correlate with BMI and blood pressure
Corneal confocal microscopy provides a means to accurately quantify small nerve fibre damage in patients with ISFN. Furthermore, we demonstrate that although IGT is increased compared to the general population in this group it does not influence the severity of nerve damage, challenging the role of IGT in neuropathy.

Evaluation of the relationship between gastric emptying, the current glucose levels and neuropathy in patients with type 1 diabetes mellitus

T. Várkonyi[1], É. Börcsök[1], R. Takács[1], C. Lengyel[1], M. Lázár[2], M. Papós[2], L. Pávics[2], P. Kempler[3], T. Wittmann[1]
[1] *University of Szeged, 1st Department of Internal Medicine, Szeged, Hungary*
[2] *University of Szeged, Department of Nuclear Medicine, Szeged, Hungary*
[3] *Semmelweis University, 1st Department of Internal Medicine, Budapest, Hungary*

The possible correlations between the severity of autonomic neuropathy (AN), the current glucose levels and gastric emptying are still not clearly explored.
Aims: The aims of our study were to evaluate gastric emptying during a continuous glucose monitoring and to assess the severity of AN in patients with type-1 diabetes (DM). Patients and methods: 17 patients with type 1 DM were included into the study (HbA1c: 8.3±0.2%, age: 34.9±2.2 years, duration of DM: 15.7±2.8 years; mean±SE). 9 subjects were healthy controls. Stomach motility was evaluated by a scintigraphic gastric emptying procedure. The subcutaneous glucose levels were measured by a continuous glucose monitoring system (CGMS, Medtronic Sàrl) during the total interval of the gastric emptying. The five standard cardiovascular reflex tests were applied for the assessment of AN. Sensory nerve integrity was studied with a Neurometer (Neurotron Inc., Baltimore, MD).
Results: There was a trend for a longer gastric emptying in diabetic patients compared to healthy subjects ($T_{1/2}$: 80.1±9.8 vs 49.6±5.5 min., p=0.06, diabetic vs control). The ratio of abnormal gastric emptying among diabetic patients was 7/17. No correlations were found between the glucose levels recorded during the gastric emptying (the lowest and highest, the mean, the difference of highest and lowest glucose) and the gastric motility. Gastric emptying in groups of patients created by the different glucose parameters did not differ significantly. There was no correlation between HbA1c values and the gastric motility. Moderate to severe AN was found in diabetic patients (AN: 3.1±0.4 vs 0.3±0.2 p<0.001, heart rate response to beathing: 16.8±1.8 vs 26.3±2.3 beats/min, p<0.01; 30/15 ratio: 1.02±0.02 vs 1.21±0.04, p<0.01; handgrip: 14.6±2.8 vs 28.3±3.5 mm Hg, p<0.05; diabetic vs control). The current perception thresholds (CPT) on the peroneal nerve at 5 Hz of the patients differed from controls (CPT: 2.89±0.9 vs 0.68±0.07 mA, p<0.05 indicating hypaesthesia).
Conclusions: There was no correlation between gastric emptying and actual glucose levels assessed by continuous glucose monitoring. Slower gastric emptying was found in the presence of a moderate to severe autonomic and sensory neuropathy in patients with a 15-year-long duration of type 1 diabetes. These data suggest that severity of autonomic neuropathy rather than the current glucose levels may have importance in the pathogenesis of delayed gastric emptying in diabetic patients.

[11] *Sejong General Hospital, Internal Medicine, Bucheon, Korea*
[12] *Inje University Ilsan Paik Hospital, Internal Medicine, Goyang, Korea*

Objectives: The goal of this study was to compare the efficacy and safety with tramadol/acetaminophen(T/A) and gabapentin(G) in the management of painful diabetic neuropathy.
Methods: This 6-week, multicenter, randomized, open comparative study was conducted at 13 tertiary referral university hospitals in the Republic of Korea. Subjects aged 18 to 75 years with painful symmetric neuropathy in the lower limbs and with a mean pain-intensity score of =4 on numeric rating scale(NRS) (0=no pain to 10=worst pain) during the 48 hours prior to enrollment were eligible. Subjects were randomized to 1 of 2 treatment groups. The primary efficacy measure was the reduction of pain intensity. Secondary measures included scores on the pain relief score, measured on a 6-point scale (complete relief=4, a lot of relief = 3, moderate relief = 2, slight relief = 1, no relief = 0, worse pain = -1), Brief Pain Inventory (BPI), 36 item Short-Form Health Survey (SF-36), subjects' and investigators' mean overall assessments of study drug, measured on a Likert scale (from 2 = very good to -2 = very poor), and average pain intensity (NRS) for the last 24 hours and sleep disturbance due to pain in the lower limbs, based on the record of subject's diary.
Results: One hundred and thirty-nine subjects (T/A, 66, G, 73) were included in the intention to treat population. The 2 groups were similar in terms of baseline pain intensity (mean intensity [SD], T/A, 6.7[1.6] vs G, 6.3[1.6]) and demographic characteristics(mean age, T/A, 58.2 vs G, 56.9 years). The mean pain intensity differences were similar between two groups (mean change score[SD], T/A, -3.1[2.0] vs G, -2.7[2.1]; p=NS). Both groups had similar improvements on the every subcategories of the SF-36 and BPI. Mean pain relief scores were also similar between two groups (mean change score [SD], T/A, 2.1[1.1] vs G, 2.0[1.2]; p=NS). No significant difference appeared between groups in the total number of treatment-associated adverse events (total number (percentage), T/A, 40(50.6) vs G, 31(36.9); p=NS).

Conclusion: The results of this study suggest that tramadol/acetaminophen combination tablets(Ultracet) are as effective as gabapentin for the treatment of painful diabetic neuropathy.

O-0219

Severe symptomatic diabetic gastroparesis and cardiovascular tests exhibit a close relationship

N. Ejskjaer[1], J. Fleischer[1]
[1] Aarhus University Hospital, Department of Endocrinology M, Aarhus C, Denmark

Diabetic gastroparesis is associated with autonomic dysfunction, but the nature of this relationship remains elusive. This study presents detailed clinical data.
Aim: To describe Type 1 diabetes patients suffering severe symptomatic gastroparesis.
Subjects: 19 consecutively recruited type 1 diabetes patients (6 males and 13 females) with delayed gastric emptying and correlating symptom scores. Age 43 years (+/- 14 years). Diabetes duration 21 years (+/- 8 years). Body mass index 26 (+/- 5). All demonstrated autonomic symptoms from more than one organ system.
Method: Cardiovascular autonomic neuropathy (CAN) was assessed by heart rate variability resting, expiration:inspiration and heart rate variability from lying to standing. A ^{13}C-octanoic breath test determined rate of gastric emptying and symptom scores by a validated questionnaire. All patients underwent thorough physical, paraclinical and clinical examinations including endoscopies.
Results: Gastric emptying rates were all significantly increased ($T^1/_2$ = 152 minutes (+/- 33 minutes). All patients but two were diagnosed with CAN. Of the 17 patients exhibiting CAN, 7 were at an early stage of progression whereas 10 were at an endstage of CAN. Blood pressure lying down 140/82 mmHg (systolic +/- 29 mmHg and diastolic +/- 14 mmHg) and blood pressure standing 126/83 mmHg (systolic +/- 32 mmHg and diastolic +/- 15 mmHg) signifies postural hypotension. On validated questionnaires all patients demonstrated symptoms pathognomic for gastroparesis and severely so.
Discussion: Examination for CAN may support a gastroparesis diagnosis in Type 1 diabetes patients suffering upper gastrointestinal symptoms. The finding of CAN in a Type 1 diabetes patient may warrant a need for further investigations regarding gastric motility.
Conclusion: All consecutively recruited patients suffered symptomatic gastroparesis and all but two patients demonstrated cardiovascular autonomic dysfunction. There exists a close relationship between severe gastric motility and cardiovascular autonomic neuropathy.

O-0220

Thalamic microvascular perfusion abnormalities that provide clues to the pathogenesis of pain in diabetic neuropathy.

D. Selvarajah[1], I.D. Wilkinson[2], P.D. Griffiths[2], C.J. Emery[1], R. Gandhi[1], S. Tesfaye[1]
[1] University of Sheffield, Diabetes Research Department, Sheffield, United Kingdom
[2] University of Sheffield, Academic Department of MR Imaging, Sheffield, United Kingdom

Central and peripheral mechanisms have been implicated in the pathogenesis of painful diabetic neuropathy (DN). Within the central nervous system, the thalamus plays a crucial role in modulating and processing somatosensory information that is presented to the cortex. We have demonstrated that thalamic neuronal dysfunction occurs in painless but not painful DN. In this study, we investigate the pathogenesis of thalamic dysfunction by testing the hypothesis that specific thalamic perfusion abnormalities occur in painful and painless DN.
A total of 23 subjects, 18 right-handed, subjects with type-1 diabetes (no-DN=6, painful-DN=5, painless-DN=7) and 5 healthy volunteers (HV), underwent detailed neurophysiological assessments (NIS[LL]+7 tests). Cerebral parenchymal perfusion was assessed by tracking an intravenous bolus of contrast agent using a multi-time point, T2* EPI sequence on a 1.5T magnetic resonance imaging system. Parenchymal perfusion was expressed as relative cerebral blood volume (rCBV), flow (rCBF) and bolus transit time (ttFM). Thalamus and caudate nucleus (control) haemodynamic properties were examined.
Subjects with painful-DN had significantly higher thalamic rCBV (painful DN, mean(SD) 228.7(19.5); No-DN, 202.3(25.8); painless DN, 216.5(65.5); HV, 181.9 (51.7); p=0.04). Subjects with painful DN also had the longest ttFM (Painful DN, 38.4 (3.6); No-DN, 35.3 (13.2); painless DN, 35.9 (13.7); HV, 33.7 (14.9; p = 0.07) and lowest mean thalamic rCBF (painless DN, 6.51 (2.8), No-DN, 6.52 (1.3); Painful DN, 5.93 (0.5); p = 0.08). There were no significant differences in the perfusion properties of the caudate nucleus between subgroups.
These findings imply that painful-DN is accompanied by thalamic vascularity, whereas vascularity is reduced in painless-DN. Similar changes were not demonstrated in the caudate nucleus, which served as a control region. The caudate is a deep brain nucleus not thought to play a major role in somotosensory perception. Therefore, unique pathophysiological thalamic microvascular changes are demonstrated that may provide important clues to the pathogenesis of pain in DN.

Health-related outcomes associated with tapentadol extended release (ER) treatment for the management of painful diabetic peripheral neuropathy (DPN): results of a randomized-withdrawal phase 3 trial

M. Etropolski[1], R. Kleinert[2], D.Y. Shapiro[1], A. Okamoto[1], R. Lange[2], C. Rauschkolb[1]
[1] Johnson & Johnson Pharmaceutical Research & Development L.L.C., Research & Development, Raritan NJ, USA
[2] Grünenthal GmbH, Research and Development, Aachen, Germany

Aims: To evaluate health survey results associated with tapentadol ER treatment for the relief of DPN pain.
Methods: Patients were titrated to an optimally effective and tolerable dose of tapentadol ER (100-250mg bid) during a 3-week open-label (OL) phase. Patients with >=1 point improvement in pain intensity (0-10 NRS) were randomized 1:1 to tapentadol ER or placebo during a 12-week double-blind (DB) phase. Efficacy was evaluated as change in mean pain intensity from start to end of the DB phase using last observation carried forward for missing values. The short form (SF)-36 health survey (evaluates 8 dimensions of physical, social, and mental well-being and 2 summary scores) was completed at pre-specified time points.
Results: In the OL phase, 588 patients received >=1 dose of tapentadol ER and were analyzed for safety; in the DB phase, 389 patients received >=1 dose of study drug and were analyzed for safety and efficacy. On average, patients receiving tapentadol ER in the DB phase maintained the improvement in pain intensity scores observed during the OL phase, but those receiving placebo worsened (least squares mean difference vs placebo, -1.3; P<0.001). Treatment with tapentadol ER was associated with numerical improvements in all SF-36 scores from start to end of the OL phase (Table). On average, patients who received tapentadol ER during the DB phase maintained these improvements, while patients who were switched to placebo worsened with significant between-group differences observed not only for bodily pain, but also for role-physical, social functioning, and physical component summary scores (all P=0.012).

Table1: Mean (SD) Changes in SF-36 Scores (DB, n=389)

Treatment-emergent adverse events reported by >10% of patients treated with tapentadol ER were nausea, dizziness, somnolence, and constipation (OL) and nausea (DB).
Conclusions: Tapentadol ER was effective and well tolerated by patients with moderate to severe DPN pain and was associated with improvements in health status that were maintained over 12 weeks of treatment.

Conflict of interest:

WORKSHOP

HEALTHCARE AND EPIDEMIOLOGY

From theory to practice: a presentation of three translational research projects supported by IDF BRIDGES

0222

Presentation of BRIDGES including result of second round of funding

J.C. Mbanya[1]
[1] *International Diabetes Federation, Yaounde 8, Cameroon*

Rationale and objective of BRIDGES: Despite the recent revolution in scientific knowledge and the introduction of many new diabetes treatments, there remains a major gap between what has been learned through clinical research and what is done in clinical practice to successfully support patient behaviour modification. BRIDGES, an International Diabetes Federation project supported by an educational grant from Eli Lilly and Company was created to identify realistic ways for achieving better outcomes for people with diabetes, to financially support projects testing new hypothesis, and interventions trying to close this gap, and to help halt the progression of this disease.

Setup of BRIDGES: BRIDGES solicits proposals supporting cost-effective and sustainable interventions that can be adopted in real-life settings for the prevention and control of diabetes. To be eligible for support, projects must be based on an initiative that have been proved to be effective in trials to prevent and treat diabetes, improve the care of people with diabetes and delay related complications. Importantly, such interventions must also have the potential to be put in clinical practice in a range of settings and to be widely disseminated to people with diabetes and their communities.

BRIDGES provides funding for two types of initiatives: short and long-term projects. Short term projects should have a maximum duration of 2 years with funding not in excess of US$65,000 and should test hypothesis linked to translational research. Long term projects should have a maximum duration of 3 years with funding not in excess of US$400,000 and should be dedicated to the implementation of the hypothesis.

What has been achieved so far: The first round of funding was concluded in 2007. More than 107 applications were received from all over the world and, following a strict review process, 11 projects were selected and are currently being financially supported. All the projects are ongoing, but the first results received are extremely encouraging. During the morning session, you will have the opportunity to listen to 3 of the supported projects. In the poster area, you will have the possibility to discover the others.

With 147 applications from 56 countries received this year for the second round, BRIDGES demonstrates its global remit, its importance and relevance in today's diabetes community. All the projects received have been thoroughly assessed by the BRIDGES Review Committee and the final selection took place in Montreal just before the beginning of the 20th World Diabetes Congress. The results will be announced at the beginning of 2010.

The third round of BRIDGES will take place during Q2 and Q3 of 2010.

BRIDGES does not only provide grants. In 2008, the International Diabetes Federation organized and financially supported 6 workshops around the world to help potential scientific grant applicants to develop tools, skills and knowledge on study design, methodology and project management as well as to increase their capacity to develop state of the art projects and fundraising. Out of 64 participants at the workshops, 36 have applied to the second round of funding of BRIDGES. 47% developed a letter of intent which was considered of sufficient interest to be asked to complete a full application.

Project title: A Translation Randomized Trial of a Culturally Specific Lifestyle Intervention for Diabetes Prevention in India

Research question(s)/hypothesis: To evaluate the effectiveness, cost-effectiveness, and sustainability of a culturally specific lifestyle intervention in India

Method(s): 700 people with pre-diabetes (Fasting plasma glucose≥100-125 mg/dl and/or 2-hour glucose≥140-199 mg/dl) living in Chennai, India will be randomized to receive either standard lifestyle advice or a culturally specific lifestyle intervention. The 16-week intervention will include: culturally appropriate exercise including walking, strength training, and yoga-based stretching; lifestyle classes focusing on behavior change and modifying the Indian diet for weight loss, portion control, and making healthy food choices; peer support groups; and use of lay educators for teaching and support. The intervention will be followed by a less intensive 8-week maintenance period and 6-12 months of additional follow-up. Program effectiveness will be measured by longitudinal regression models with diabetes incidence and changes in secondary outcomes (including body composition, fasting glucose, plasma lipids, activity, and diet) as outcome measures. Cost-effectiveness of the lifestyle intervention will be determined by assessing the incremental costs and benefits per: case of diabetes prevented and Quality-adjusted Life-year. The acceptability and sustainability of the program will be determined through focus group discussions and interviews with intervention participants.

Public health significance: Data from this study will be used to design and advocate for the implementation of scalable, low-cost, culturally specific lifestyle interventions for the prevention of diabetes in India and other South Asian countries.

Sustainability plan: Plans for sustainability include: (1) lay interventionists will be enabled and empowered to continue teaching lifestyle classes after the study is complete; (2) program materials can be used after the intervention; (3) study results will be presented to health policy makers in India, in the hopes that this program can be implemented on a wider scale.

Effectiveness of a community-based Diabetes Self-Management Education (DSME) program: A pilot study in San Juan, Batangas, Philippines

E. Paz-Pacheco[1], G.J.R. Ardena[1], F.L. Lantion-Ang[1], C. Jimeno[1], N. Juban[2], E. Paterno[2], M.A. Sandoval[1], F. Patal[1]

[1] *Philippines General Hospital, Section of Endocrinology Diabetes and Metabolism, Manila, Philippines*

[2] *Philippines General Hospital, Department of Family and Community Medicine, Manila, Philippines*

Diabetes Self-Management Education (DSME) has been recognized as a fundamental component of diabetes care. To successfully establish a DSME Program in a rural community in the Philippines, the present project consists of 4 phases.

Phase I involved conducting comprehensive community assessment by determining knowledge, attitudes and practices using locally validated questionnaires and conducting focused group discussions. Data from 156 participants showed low overall knowledge score with a mean of 42.71%, lowest in the self-monitoring subscale. Most respondents did not believe in the seriousness of diabetes. Data derived from this preliminary study were incorporated into the program educational materials.

Phase II constitutes prevalence survey of diabetes, impaired glucose tolerance and metabolic syndrome in the rural community. Using a two-stage stratified random sampling method, this phase included 324 residents. Known diabetics constitute 10% of the sample while 19% were newly-diagnosed diabetics. At least 30% satisfied the criteria for metabolic syndrome.

Phase III determines the effectiveness of community-based DSME in improving physiologic measures and health behaviors. Using translated and culturally-modified IDF modules, participants were randomly allocated either to receive DSME program (intervention) or traditional care (control). Peer educators, either ***barangay*** (socio-political unit) health workers or diabetic patients active in the ***barangay***, conducted the DSME program, a 12-week course incorporating strategies to enhance self-management. Data were compared at baseline and after 3 and 6 months after initiation of the program.

Phase IV will tackle diabetes prevention among high-risk community residents identified during Phase II as well as prevention of diabetes complications among known diabetics.

This pilot study is part of a long-term, self-sustaining diabetes program which aims at reducing the burden of diabetes particularly in the rural community. The investigators envision a program that will serve as a "model of community diabetes care" throughout the Philippines by providing culturally-appropriate and comprehensive diabetes care.

Feasibility of developing a training program for peer educators in diabetes

T.S. Tang[1], M.M. Funnell[1], M.M. Heisler[2], R.M. Anderson[1]

[1] *regents of the University of Michigan, Department of Medical Education, Ann Arbor, USA*

[2] *regents of the University of Michigan, Department of Internal Medicine, Ann Arbor, USA*

Background: Professionally-led diabetes self-management education (DSME) interventions are effective in improving diabetes-related health outcomes, but these gains cannot be sustained without continued follow-up and support. Interventions involving peer support have been associated with positive changes in metabolic, cardiovascular, and psychosocial functioning and offer a promising solution to ongoing diabetes self-management support (DSMS). However, existing peer support interventions are time-limited, curriculum-led, and highly structured.

Aims: This study develops a theoretically-driven program for training peer leaders to lead ongoing, empowerment-based, DSMS interventions. The objectives of this pilot study are (1) to determine the feasibility of developing a program training peer leaders to facilitate empowerment-based interventions that support long-term diabetes self-management, and (2) to determine the feasibility (e.g., recruitment, attendance, future intentions) of conducting a peer leader training (PLT) program to facilitate empowerment-based DSMS interventions.

Methods: This study follows a prospective, pre-post design consisting of two phases. Phase 1 involves the development of a PLT program designed to equip peer leaders with the knowledge, skills, and attitudes to facilitate an ongoing empowerment-based DSMS intervention. Phase 2 involves the implementation and evaluation of the PLT program and will recruit adults with type 2 diabetes as peer leaders. Participants will complete measures assessing diabetes knowledge, empowerment-based facilitation skills, motivational interviewing-based communication skills, and self-efficacy.

Discussion: By training peers to support the ongoing self-management efforts in their own community, interventions will have more relevance to the cultural norms, social dynamics, and economic circumstances of the community while promoting long-term maintenance of behavior change. Using peer-led interventions increases the ability to translate effective empowerment-based programs into existing community infrastructures. This approach is designed to be ongoing, patient-driven, and flexible to the evolving conditions of patients' "real-word" environment. If successful, this intervention can be adapted to other at-risk populations in the United States and abroad.

Tackling diabetes as a 'communicable' disease in the Middle East

D.E. Zoughbie[1], K.T. Watson[2], N. Bui[3]

[1] *The Global Micro-Clinic Project, Office of the President, San Francisco, USA*

[2] *The Global Micro-Clinic Project, Office of the Chief Operating Officer, San Francisco, USA*

[3] *The Global Micro-Clinic Project, Research Administration, San Francisco, USA*

The Middle East is currently experiencing a growing diabetes epidemic that threatens to undermine the social, political, and economic stability of the region. In 2004, 15% of Jordanians adults had diabetes and 12% had impaired fasting glucose. Addressing the impact of the diabetes epidemic in Jordan requires a sustainable strategy working at multiple levels: individual, community, and health care system. The Jordan Micro-Clinic Project aims to provide an evidence-based comprehensive national strategy using community-based "micro-clinics," a social network of diabetes patients, to promote healthy behaviors within economically disadvantaged communities in Jordan. The project was piloted in Amman, in which 1) health care professionals and patients were trained and educated in diabetes prevention and management, 2) project participants were recruited into micro-clinic groups (consisting of 2-8 family members or friends of the same social network) and shared technology for glucose monitoring, and 3) micro-clinic groups participated in ongoing social activities and education around diabetes management. Pilot findings revealed a significant drop in BMI and mean glucose levels for all participants after four months, indicating improvements in diabetes management based on program participation. The project is currently undergoing a regional expansion pilot to reduce the impact of diabetes in multiple sites, targeting various geographic areas and demographic groups. Quantitative and qualitative data will be used to assess the effectiveness of the micro-clinic model on improving diabetes management among participants. Demographic and biomedical (HbA1c, BMI, and fasting glucose measurements) will be collected from members of each micro-clinic at several points during the project period. A survey assessment on diabetes-related behaviors and attitudes will be conducted with a sample of the participants at baseline, mid-point, and final. Initial findings suggest that the micro-clinic model has the potential to effectively address the rampant diabetes epidemic in Jordan and potentially throughout other under-served communities globally.

[3] *Wake Forest University School of Medicine, Internal Medicine, Winston-Salem, USA*

Over 3.2 million African Americans have type 2 diabetes (T2DM). This represents approximately 13.3% of the African American population and a significant proportion of the 20.8 million Americans believed to be living with diabetes. On average, an African American is twice as likely to have T2DM as a European American peer.

Aims/methods: In order to gain insights into the genetic contributions to T2DM in African Americans we have carried out both gene-targeted and Genome Wide Association Studies (GWAS) in samples of T2DM-affected cases and non-diabetic controls recruited from the southeastern portion of the United States.

Results: Taking advantage of the LD structure of African-derived chromosomes, we have localized TCF7L2 association with T2DM to a 4kb LD block. With resequencing of 96 African American DNAs in this block we identified 35 novel and 14 known SNPs which were genotyped in 1033 cases and 1106 controls along with the SSTR marker DG10S478. SNP rs7903146 was by far the most strongly associated (admixture adjusted, additive $P=1.59x10^{-6}$; OR 1.39) suggesting this is a functional polymorphism. Admixture in these samples has been evaluated by genotyping 70 Ancestry Informative Markers in all samples. In contrast to TCF7L2, other SNPs associated with T2DM in European-derived samples showed little or no evidence of association with T2DM even in an enlarged sample of 2841 cases and 1964 controls. Only SNPs in CDKAL1 showed even modest evidence of association (P-values 0.06-0.07). Evaluation of these SNPs in the Human Genome Diversity Panel, however, suggests some of these SNPs may be fixed in the African population since Yoruba are monomorphic for the risk allele observed in Europeans.

We have carried out a GWAS analysis on 966 cases and 1033 controls using the Affymetrix 6.0 chip. After extensive quality control 835,042 SNPs were evaluated in admixture-adjusted association analysis focusing on the additive model. Approximately 40 SNPs had P-values $< 10^{-6}$. In addition, SNPs in two previously identified T2DM genes from studies of European-derived populations were among the top hits. SNPs rs17703228 ($P=7.42x10^{-5}$) in "juxtaposed with another zinc finger gene 1" (***JAZF1***) and rs10906180 ($P=6.38x10^{-5}$) in the calcium calmodulin-dependent protein kinase 1D (***CAMK1D***) were associated with T2DM in African Americans. These SNPs are different from SNPs previously observed to be associated with T2DM in Europeans. Replication studies of African American SNPs are underway in a two stage replication analysis totaling over 4,000 cases and 4,000 controls, and evaluation of imputed SNPs and copy number variation is also in progress.

Discussion: While some elements of diabetes risk in African Americans are similar to those in European-derived populations, clear differences are observed that will be of great interest for future investigation.

[2] *Universidad de Antioquia, Genetica Molecular, Medellín, Colombia*

[3] *Universidad de Antioquia, Endocrinologia, Medellín, Colombia*

Aims: Admixture mapping is a recently developed method for identifying genetic risk factors involved in complex traits or diseases showing prevalence differences between major continental groups. Type 2 diabetes (DM2) is at least twice as prevalent in Native American populations as in populations of European ancestry, so admixture mapping is well suited to study the genetic basis of this complex disease.

We assessed the effect of the Amerindian background and its effect on prevalence and risk of DM2, in the population of Antioquia (Colombia) which has a tri ethnic admixture.

Methods: We have characterized the admixture proportions in a sample of an Antioquia population by genotyping 75 autosomal Ancestry Informative Markers, in 582 persons with type 2 diabetes and 267 healthy individual. We assessed the effect of population stratification by comparing the genetic background between cases and controls and analyzed the implications of the results on diabetes type 2.

Results: The test for residual allelic association between unlinked loci yielded posterior predictive check probabilities of 0.0, 0.42, and 0.47 with models based on 1, 2, and 3 subpopulations, respectively. So, There is no evidence for residual stratification. Therefore, in the sample from Antioquia a model with two subpopulations was adequate to account for residual allelic associations. The effective number of generations back to unadmixed ancestors, under a model of admixture occurring at a single pulse was 11 per morgan, with (95% CI) 95% confidence interval (9 - 13.3).

The average proportions of European, African and Native-American admixture were estimated as 0.58, 0.12 and 0.29 for cases and 0.62, 0.11, 0.26 for controls, respectively. The maternal lineages were estimated as 88% Native-American and 6.3% African for cases and 90% and 4.8% for controls respectively. In a logistic model with diabetes as dependent variable, the odds ratio associated with unit increase in Native American admixture proportion (from 0 to 1) was estimated as 5.31 with a 95%CI (1.94 – 14.73), and for African admixture was 3.86, with a 95%CI (1.24 – 12.67). After correcting with income the OR of African ancestry was 2.38 with 95%CI (0.78 - 8.24)

Discussion and conclusion: We observed a significant association of Amerindian ancestry with Diabetes before and after correcting with age, sex and income. Our findings reinforce the importance of admixed populations as a useful resource for mapping traits with different prevalence between two parental populations as well as the assessment of the effects of stratification as a critical factor to appropriately interpret the results of case-control studies in admixed populations

Interaction between PON1 Gln192Arg polymorphism and type 2 diabetes in Indo-Mauritian agricultural workers exposed to herbicides

M. Manraj[1], A. Hebe[2], S. Lee Kwai Yan[2], N. Sem Fa[2], S. Jankee[2], A. Nubheebucus[1], R. Tennant[3]

[1] *University of Mauritius, Department of Medicine, Reduit, Mauritius*

[2] *University of Mauritius, SSR Resource Centre Department of Medicine, Reduit, Mauritius*

[3] *FUEL and MDA sugar estates, Estate Hospital, Vacoas, Mauritius*

Aims: Type 2 diabetes (T2D) is a multifactorial disorder where age, genetic factors and environment play a role. Human serum paraoxonase (PON1) is an enzyme located on HDL-cholesterol that is involved in prevention of LDL-cholesterol peroxidation and in detoxification of organophosphate (OP) pesticides. A previous cross-sectional study on 73 agricultural workers exposed to insecticides had shown a borderline association between the PON1 Gln192Arg polymorphism and T2D, p=0.05. The present study was carried out to confirm association between the polymorphism and T2D in agricultural workers exposed to herbicides.

Methods: After ethical clearance was obtained, and informed consent was provided for genetic studies by 157 male agricultural workers of Indo-Mauritian origin exposed to herbicides, glucose metabolism status and lipid profile were studied in a fasting state, with anthropometric and blood pressure measurements on the same day. PON1Gln192Arg genotyping was performed, blind to phenotype, using PCR-RFLP techniques. Genotype data in present cross-sectional study was compared with data available from 193 male agricultural workers of same ethnic origin, involved in genetic studies on T2D, who were not exposed to herbicides. A p-value = 0.05 was considered to be significant.
Results: Prevalence of T2D (19%) was as expected for Mauritian men of similar age. Allelic frequencies (p=0.017) and genotype proportions (p=0.019) were different between diabetic and non diabetic agricultural workers exposed to herbicides. Diabetic sprayermen were more often homozygous for the Gln192 allele (50%, n=30) than non-diabetic sprayermen (24.4%, n=122), OR=3.10, Cornfield 95% CI: 1.36<OR<7.14, p=0.01. In the non exposed group, no difference was found in allelic or genotypic proportions between diabetic and non diabetic agricultural workers. Genotype proportions were different between hypertensive and normotensive workers, hypertensive workers in the exposed group were more often homozygous for the Arg192 allele (32.2%, n=59) than non hypertensive workers (10.2%, n=98), OR=4.18, Cornfield 95% CI: 1.78<OR<9.80, p=0.001. The same trend was found in the unexposed group: 26.6% of 64 hypertensive v/s 14% of 129 normotensive men, OR=2.23, Cornfield 95% CI: 1.06-4.70, p=0.05.
Discussion/conclusion: We found an interaction between occupational exposure to herbicides and the PON1 Gln192Arg polymorphism on prevalence of type 2 diabetes in Indo-Mauritian men, Gln192 allele being associated with T2D when there was exposure to herbicides. Indo-Mauritian men were also more often hypertensive when they were homozygous for the alternate Arg192 allele, irrespective of occupational exposure to herbicides.

The HNF1A G319S variant is associated with C-reactive protein in an Aboriginal population

S.H. Ley[1], R.A. Hegele[2], P.W. Connelly[3], S.B. Harris[4], M. Mamakeesick[5], J. Gittelsohn[6], R. Retnakaran[7], B. Zinman[7], A.J. Hanley[1]

[6] *Johns Hopkins Bloomberg School of Public Health, Center for Human Nutrition, Baltimore, USA*
[7] *Mount Sinai Hospital, Leadership Sinai Centre for Diabetes, Toronto, Canada*

Aims: Common variants of the hepatocyte nuclear factor 1A (HNF1A) gene encoding HNF-1a have been associated with plasma C-reactive protein (CRP) concentration, which is elevated among individuals with diabetes and metabolic abnormalities. HNF-1 binding to promoter regions of the CRP gene is known to be involved in regulation of CRP synthesis in the liver. A glycine to serine substitution at codon 319 (G319S) of the HNF1A gene has been identified and linked with increased risk for type 2 diabetes - not maturity-onset-diabetes-of-the-young - in a Canadian First Nations population. The aim of this study was to determine the association between the HNF1A G319S variant and plasma CRP among individuals with and without type 2 diabetes.
Methods: Between 1993 and 1995, 728 members of Sandy Lake First Nation participated in a diabetes prevalence and risk factor survey. Fasting glucose and a 75-g oral glucose tolerance test were obtained to determine type 2 diabetes, according to the 1998 World Health Organization criteria. Participants were genotyped for the HNF1A G319S mutation. Fasting blood samples were analyzed for CRP, interleukin (IL)-6, and serum lipids. Interviewers administered questionnaires to obtain demographic and medical history information. Anthropometry and blood pressure were measured.
Results: The prevalence rates of type 2 diabetes were 14.0% (77/550) in homozygous G319, 29.2% (42/144) in heterozygous, and 83.3% (5/6) in homozygous S319 carriers (p<0.001). Under a dominant model, least squares mean CRP levels were higher among the homozygous G319 carriers (1.90 [95% confidence interval 1.55-2.33] mg/l) compared to S319 allele carriers (1.37 [1.12-1.68] mg/l) (p=0.0016), after adjustment for age, sex, hypertension, triglyceride, waist circumference, HDL cholesterol, 2-h postload glucose, and IL-6. When participants were stratified by diabetes status, CRP remained strongly associated with the G319S mutation among people without type 2 diabetes (1.66 [1.33-2.08] mg/l in homozygous G319 vs. 1.18 [0.95-1.48] mg/l in S319 allele carriers, p=0.0030) with similar adjustment. Among participants with diabetes, the CRP levels were elevated in both S319 allele carriers and non-carriers. The association between the G319S variant and CRP was not statistically significant among individuals with diabetes potentially due to the small sample size (4.90 [3.12-7.71] mg/l in homozygous G319 vs. 3.76 [2.39-5.91] mg/l in S319 allele carriers, p=0.25). There was no sex or age interaction with HNF1A G319S variant on plasma CRP levels (p>0.5).
Conclusion: We conclude that the HNF1A G319S variant, which is clearly dysfunctional and a risk marker of type 2 diabetes, is also associated with variation in CRP levels in this population, supporting a mechanistic relationship between HNF1A and plasma CRP.

Novel obesity risk loci do not determine distribution of fat depots: a whole body MRI/MRS study

A. Haupt[1], C. Thamer[1], M. Heni[1], F. Machicao[1], J. Machann[2], F. Schick[2], N. Stefan[1], H. Staiger[1], H.-U. Häring[1], A. Fritsche[1]
[1] *Eberhard-Karls-University Tübingen, Department of Internal Medicine, Tübingen, Germany*
[2] *Eberhard-Karls-University Tübingen, Department of Diagnostic Radiology, Tübingen, Germany*

Background and aim: A recent metaanalysis of the genome-wide association studies (GWAS) have identified six new risk loci for common obesity (TMEM18, KCTD15, GNPDA2, SH2B1, MTCH2 and NEGR1). The effect of these new risk loci on BMI ranged per allele from 0.06-0.26 kg/m2. For most of these gene variants an increase in fat mass is shown, but it is so far unknown if these new risk loci for common obesity have an influence on distribution of fat depots.
Material and methods: We therefore genotyped 1524 non-diabetic subjects for the aforementioned SNPs ((TMEM18 (rs6548238), KCTD15 (rs11084753), GNPDA2 (rs10938397), SH2B1 (rs7498665), MTCH2 (rs10838738) and NEGR1 (rs2815752)). We assessed BMI, waist circumference, total body fat (bioimpedance) and lean body mass (bioimpedance). All subjects underwent an oral glucose tolerance test with determination of insulin sensitivity and insulin secretion. In a subcohort of 343 subjects we measured body composition (total adipose tissue, visceral adipose tissue, non-visceral adipose tissue, liver fat content and intramyocellular lipids) using whole body magnetic resonance imaging (MRI) and spectroscopy (MRS).
Results: After appropriate adjustment for confounding variables and Bonferroni correction for multiple comparisons (corrected alpha-level: p = 0.0085), none of the SNP was significantly associated with BMI, waist circumference, lean body mass (bioimpedance), total adipose tissue, visceral adipose tissue, non-visceral adipose tissue, liver fat content and intramyocellular lipids (all p > or = 0.01, dominant inheritance model).
The risk alleles of TMEM18 rs6548238, NEGR1 rs2815752 and MTCH2 rs10838738 tended to associate in our cohort with higher BMI (all p=0.03) and the risk allele of TMEM18 rs6548238 in addition with higher waist and total body fat (bioimpedance) (p=0.02 and p=0.03). In the MR cohort, we found a nominal association of the risk allele of SH2B1 SNP rs7498665 with higher visceral adipose tissue (p=0.02). In addition, the risk allele of GNPDA2 SNP rs10938397 tended to associate with an increase in total adipose tissue (p=0.05) and non-visceral adipose tissue (p=0.07). The study was sufficiently powered (1-beta = 0.8) to detect effect sizes between 16.9-18.0 % and in the MR cohort between 35.4% and 39.5 %.
Conclusion: In contrast to the risk allele loci in RARRES2 and MC4R, we could not detect significant associations of the novel risk loci on differential distribution of fat depots. Possible weak effects of TMEM18 rs6548238, SH2B1 SNP rs7498665 and GNPDA2 SNP rs10938397 on body composition await further confirmation by larger studies.

O-0232

Effect of Cd36 deficiency on carbohydrate and lipid metabolism is contextually determined by genomic background and reflected in transcriptomic profile

O. Seda[1], L. Sedova[2], F. Liska[2], L. Kazdova[3], J. Tremblay[1], D. Krenova[2], P. Hamet[1], V. Kren[2]

[1] *Research Centre CHUM (CR CHUM), Technopole Angus, Montreal, Canada*
[2] *First Faculty of Medicine Charles University, Institute of Biology and Medical Genetics, Prague, Czech Republic*
[3] *Institute for Clinical and Experimental Medicine, Dept of Metabolism and Diabetes, Prague, Czech Republic*

Aims: Deficiency of fatty acid translocase Cd36 has been shown to play major role in pathogenesis of metabolic syndrome in spontaneously hypertensive rat (SHR). We have tested the hypothesis that its effects on metabolism and genome-wide transcription profile are contextual with genomic background.
Methods: We have derived 4 new congenic strains: 2 BN-Lx.SHR4 and 2 PD.SHR4 by introgression of chromosome (chr.) 4 region of SHR origin including defective Cd36 gene into genetic background of highly inbred models of insulin resistance and dyslipidemia, PD and BN-Lx strains, respectively. We have compared the metabolic profile of BN-Lx.SHR4 congenic strains under standard diet conditions and after 3-day administration of dexamethasone to that of progenitor strains BN-Lx and SHR (n=6 adult males/strain).We have subjected standard diet-fed adult males of PD and PD.SHR4 strains (n=8/strain) to metabolic, morphometric and transcriptomic (Affymetrix Rat 1.0 ST Exon array) profiling.
Results: The BN-Lx.SHR4 strains showed markedly blunted reaction to diabetogenic action of dexamethasone compared both to BN-Lx and SHR. We observed significantly improved glucose tolerance and lower fasting insulin in both PD.SHR4 strains compared to PD. In contrast, one of the PD.SHR4 strains showed highest concentrations of LDL cholesterol compared both to PD and the other PD.SHR4 congenic. Both PD.SHR4 strains had smaller LDL particle sizes and lower HDL cholesterol than PD. The expression profile revealed systematic dysregulation of transcription around insulin gene network node and in number of genes constituting circadian rhythmicity pathway (Arntl, Clock, Nfil3, PER2 and PER3) in PD.SHR4.
Discussion/conclusion: The introduction of chr.4 region of SHR origin including defective Cd36 into BN-Lx and PD genetic backgrounds resulted in disconnected changes in metabolic profile and its reaction to pharmacological challenge. The eventual phenotypic outcome of deleterious mutation is thus a function of complex interactions between environment and genomic background, upon which it operates.

[6] *University of Leeds, School of Biochemistry and Molecular Biology, Leeds, United Kingdom*
[7] *Mellitech, Grenoble, France*

Background and aims: The accumulation of zinc ions into secretory granules is believed to be essential for the formation of hexameric insulin and, ultimately, of insulin crystals and granule dense cores. Correspondingly, a non-synonymous single nucleotide polymorphism rs13266634 in the SLC30A8 gene, encoding the secretory granule zinc transporter ZnT8, has been shown recently to be associated with an increased risk of type 2 diabetes. Here, we describe the effects of deleting ZnT8 gene in mice and a likely molecular mechanism of action of at risk allele.
Methods: Three separate mouse colonies of mice deleted for exon one of the slc30a8 gene were maintained on standard chow on a mixed sv129/C57BL/6 background. Glucose and insulin tolerance were measured by intraperitoneal injection of glucose or euglycemic clamp, respectively. Insulin secretion assay, electrophysiology and imaging techniques, as well as the generation of plasmid vectors and adenoviruses encoding the normal (W325) or elevated-risk (R325) allele of ZnT8, were undertaken using standard protocols.
Results: Abnormal glucose tolerance was apparent in male $ZnT8^{-/-}$ mice from six weeks of age. Whereas in vivo insulin sensitivity was unaltered, islets isolated from knockout mice displayed reduced granule zinc content and abnormal granule morphology with the appearance of atypical, rod-like granules, but normal insulin processing. Glucose or KCl-stimulated insulin secretion were significantly decreased in the absence of the transporter, and the proportion of secretory events leading to complete cargo depletion, as assessed by total internal reflection of fluorescence, was diminished. Molecular modelling based on the bacterial ZnT8 homologue YiiP revealed that the polymorphic residue 325 was located at the interface between ZnT8 monomers in the dimeric transporter and thus likely to impact on the interaction with metallochaperones. Correspondingly, when over-expressed in clonal MIN6 ß-cells, R325 ZnT8 displayed lower apparent Zn^{2+} transport activity than the R325 form of the transporter.
Discussion and conclusions: ZnT8 is required for the normal uptake of zinc ions into insulin granules and normal insulin storage. Reduced zinc accumulation into granules, and defective insulin storage, in carriers of the R allele may contribute to increased risk of type 2 diabetes.

O-0234

Insulin secretion from the INS-1 832/13 ß-cell line is influenced by melatonin receptor signaling

C.L.F. Nagorny[1], H. Mulder[1]

[1] *Lund University, Clinical Sciences Malmö, Malmö, Sweden*

Aims: Several genetic studies have implicated melatonin receptor 1B (MTNR1B) as a new candidate gene associated with the pathogenesis of Type 2 Diabetes Mellitus (T2DM). In mammals, its ligand, the pineal hormone melatonin, binds primarily to its two receptors, MTNR1A and MTNR1B, which are G-protein coupled receptors, and are proposed to exert an inhibitory effect on insulin secretion. It remains uncertain, however, which receptor mediates this effect and to what extent. Therefore, we investigated the effect of MTNR1A/B signaling on glucose-stimulated insulin secretion (GSIS). Also, this study aimed at providing information about whether melatonin is endogenously produced in the pancreatic ß-cell and thus may exert autocrine effects on insulin secretion.
Methods: We knocked down MTNR1A and MTNR1B in the INS-1 832/13 ß-cell line by RNA interference. The transfected cells were then stimulated with glucose alone or in combination with the cAMP raising agent forskolin, given the suggested cAMP-lowering effect of melatonin. Gene expression was measured by Q-PCR for MTNR1A/B and arylalkylamine-N-acetyl transferase (AANAT), the rate limiting enzyme in melatonin biosynthesis.
Results: On the mRNA level both MTNR1A and MTNR1B were successfully knocked down by ~80% (n = 3). Insulin secretion, by stimulation with only glucose, was not affected by knock down of MTNR1B but showed a trend towards an inhibition when MTNR1A was silenced. To induce K_{ATP}-independent insulin secretion, INS-1 832/13 ß-cells were stimulated with 16.7 mM glucose in combination with 35 mM potassium and 250 µM diazoxide. A similar pattern as for stimulation with glucose alone was observed after knock down of either receptor. Stimulation with 16.7 mM glucose in combination with 2.5 µM forskolin evoked a 3-fold increase in GSIS compared to stimulation by 16.7 mM glucose alone. In contrast, knock down of MTNR1A significantly inhibited GSIS under these conditions (90 ± 10 vs 186 ± 51 ng/mg/h; $p = 0.03$, $n = 3$). MTNR1B silencing did not show a significant inhibition of insulin secretion under the same conditions. Furthermore, mRNA of the enzyme AANAT, active in melatonin synthesis, was expressed in INS-1 832/13 ß-cells.
Conclusion: We found that blocking melatonin receptor signaling in INS-1 832/13 ß-cells, particularly that of MTNR1A, decreases the insulin secretory response, foremost that potentiated by cAMP. We demonstrate expression of AANAT, the rate-limiting biosynthetic enzyme, in INS-1 832/13 ß-cells, which suggests that endogenous production of melatonin occurs in these cells. Our data suggest that melatonin receptor signaling is involved in control of insulin secretion and that the involvement of endogenous melatonin may play a role in these processes.

Epidemiology of diabetes in Saskatchewan adults from 1980 - 2005: a comparison of first nations people and other Saskatchewan residents

R. Dyck[1], N. Osgood[2], T.H. Lin[3], A. Gao[2]
[1] *University of Saskatchewan, Medicine, Saskatoon, Canada*
[2] *University of Saskatchewan, Computer Sciences, Saskatoon, Canada*
[3] *National Taipei University, Statistics, Taipei, Taiwan*

The purpose of this research was to investigate the epidemiology of diabetes in Saskatchewan from 1980 to 2005, and compare differences between First Nations people (FN) and other Saskatchewan residents (OSK).
This was a population based study of diabetes (>90% type 2 diabetes) in the total annual Saskatchewan populations of FN and OSK. Using Government of Saskatchewan administrative databases, people with diabetes were identified using an algorithm adapted from the National Diabetes Surveillance System. Diabetes frequency, incidence and prevalence were compared by year, age, sex and ethnicity.
We identified 90,578 incident cases of diabetes in Saskatchewan adults ≥ 20 years from 1980-2005. Of these 82,304 were OSK (55% males) and 8,274 were FN (45% males). Overall, FN women had the highest diabetes incidence and prevalence while OSK females had the lowest rates. Diabetes incidence and prevalence were > 4 times higher in FN compared to OSK women and > 2.5 times higher in FN compared to OSK men. Diabetes incident cases peaked in both FN males and females aged 40-49 while most OSK cases occurred in those aged 70+. There were more diabetes cases in FN females than males particularly during reproductive years, and more diabetes cases in OSK males than females particularly during middle age and older. Over the study period, diabetes prevalence more than doubled in FN females (9.51% to 20.33%) and more than tripled in FN males (4.91% to 16.01%). Diabetes prevalence consistently remained > 4% higher in absolute terms among FN women than FN men. Although diabetes prevalence was lower in OSK, the rates of increase were similar, rising from 2.01% to 5.51% among females and from 2.01% to 6.24% among males. By 2005, almost 50% of FN females and over 40% of FN males aged 60+ had diabetes, while it affected less than 25% of OSK males and less than 20% of OSK females aged 80+.
This study shows marked differences in the demographics of diabetes between FN and non-FN over the longest period reported for a Canadian jurisdiction. Furthermore, within the observed epidemic of diabetes among FN, women were disproportionately affected due to an excessive burden of diabetes particularly during reproductive years. These findings have implications with respect to understanding diabetes risk factors, planning and implementation of prevention and clinical management initiatives, and anticipation of future health care resource needs.

Mobile diabetes telemedicine clinic (mdtc): role in first nations care and treatment

K. Dawson[1], D.A.L. Maberley[2], J.D. Martin[3], W. Hyslop[4], A. Jin[5]
[1] *BC Endocrine Research Foundation, Medicine, Vancouver, Canada*
[2] *University of British Columbia, Ophthalmology, Vancouver, Canada*
[3] *Health Canada, First Nation and Inuit Health, Vancouver, Canada*
[4] *Carriere-Sekani, Family Services Society, Prince George, Canada*
[5] *University of British Columbia, Dept of Health Care and Epidemiology, Vancouver, Canada*

Aims: To describe baseline characteristics and clinical outcomes among clients of a program to improve diabetes care for residents of Aboriginal communities in northern British Columbia, Canada.
Study design: Longitudinal cohort.
Methods: Since 2002, the MDTC serves about 51 communities whose small size and geographic remoteness impede access to specialized diabetes care. A nurse and a visual technician travel to reserves, offering people with diabetes comprehensive annual assessment: history, physical exam, point-of-care lab (A1c, FBG, lipids: TC, HDL, LDL and TG, microalbumin:creatinine ratio (MCR)), and retinal fundus photography. Reports generated from computerized data are transmitted to Endocrinology and Ophthalmology consultants who review and correct and then return reports to community health workers and primary care physicians for action. Physicians get specific recommendations on glycemic, hypertensive, lipid and renal protective therapy. Patients get advice on lifestyle changes and avoidance of complications.
Results: During the 6-year period 2003-2009, the MDTC performed 1,221 assessments on 750 people with T2DM (458 attended once, 173 twice, 80 three times, 23 four times, 11 five times and 5 six times). At first visit: 80% ≥ 50 years old, 24% were 70 or older, 54% female, 50% with duration of DM ≥ 5 years, 74% had BMI ≥30, 64% had BMI ≥35, 65% on oral agents (59% Met, 26% SU, 7% TZD), 15% on insulin. 51% on ACEI/ARB, 34% on other antihypertensive, 26% on a statin, 61% were hypertensive (systolic ≥130 or diastolic ≥80 mmHg), 44% had A1c ≥7.0%, 37% had A1c ≥7.5%, 36% had HDL<1.0 mmol/L, 62% had LDL ≥2.0 mmol/L, 49% had TG≥2.0 mmol/L, 43% had TC:HDL ratio ≥4.0, 29% of women had MCR ≥2.8, 41% of men had MCR=2.0. At subsequent assessments: mean time since previous assessment was 1.7 years, mean decline in body mass was 1.6 kg (95% CI: 0.6 to 2.6 kg), mean decline in LDL was 0.3 mmol/L (95%CI: 0.2 to 0.4 mmol/L). Mean changes in physical activity, blood pressure, FBG, A1c, HDL, TG, TC:HDL ratio and MCR were not statistically significant. However, among clients who returned for second assessment less than 1.5 years later, mean absolute decline in A1c was 0.4% (95%CI: 0.1% to 0.6%). Frequency of hypoglycemic episodes declined with successive visits. Prevalence of ACEI/ARB use increased from 47% at baseline to 73% at fourth or later visits (p<0.0005). Prevalence of statin use increased from 26% at baseline to 48% at fourth or later visits (p=0.002).
Conclusion: The MDTC led to modest improvement in some clinical outcomes. Outcomes were adversely affected by delay in follow-up visits. Effectiveness could be enhanced by increased frequency of contact with clients, and additional supports and education between annual assessments.

O-0237

Burden of type 2 diabetes-associated complications in Canada's First Nations peoples in 2007: the CIRCLE study

S.B. Harris[1], M. Naqshbandi[1], O.K. Bhattacharyya[2], A.J.G. Hanley[3], J.G. Esler[1], B. Zinman[4]
[1] *Centre for Studies in Family Medicine The University of Western Ontario, Family Medicine, London, Canada*
[2] *Li Ka Shing Knowledge Institute St. Michael's Hospital University of Toronto, Family and Community Medicine, Toronto, Canada*
[3] *University of Toronto, Nutritional Sciences, Toronto, Canada*
[4] *University of Toronto, Medicine, Toronto, Canada*

Introduction and aim: First Nations (FN) peoples in Canada suffer from high prevalence rates of type 2 diabetes mellitus (DM). Remarkably little national data are available on DM-associated morbidity in this population. The aim of the Canadian First Nations Diabetes Clinical Management Epidemiologic (CIRCLE) study was to examine the clinical parameters of DM and complications burden.
Methods: Medical charts of consenting DM patients (>=18y) of FN descent from 15 FN communities were randomly audited for DM care in 2007. Metabolic status, prevalence of complications and treatment were documented through a systematic computerized data collection methodology.
Results: Cross-sectional data were analyzed from 733 charts; 63.7% were female, mean age was 54.0y, mean duration of DM was 9.8y, and mean A1C was 8.0%. Of the 672 patients with available data on smoking status, 39.4% currently smoked. The percent of patients with a BMI over 25 was 80.3%. On average, patients were diagnosed with 5.2 comorbidities /complications.
Duration of DM was significantly associated with increasing number of comorbidities/complications (p<.0001) as well as increasing A1C (p<.05) using linear regression analysis. The table provides the overall comorbidity/complication prevalence rates. The most common comorbidities/complications were hypertension (58.3%), dyslipidemia (39.0%) and chronic kidney disease/dialysis (24.3%). Nearly half of the patients (43.9%) had one or more microvascular complication while 18.8% were diagnosed with one or more macrovascular complication. Using multivariate logistic regression analysis controlling for covariates, DM duration was found to be significantly associated with the most number of comorbidities/complications, including: hypertension (odds ratio 1.1[95% CI 1.1-1.2], p<.05), cerebrovascular disease and stroke (1.1[1.0-1.2], p<.05), neuropathy (1.1[1.1-1.2], p<.0001), retinopathy

(1.3[1.2-1.5], p<.0001), and amputation (1.9[1.3-2.8], p<.01).

Comorbidities /Complications	Prevalence %
Hypertension	58.3
Dyslipidemia	39.0
CVD	18.8
CAD, MI & Heart Attack	12.4
Cerebrovascular Disease & Stroke	5.5
Microvascular Complications	43.9
Chronic Kidney Disease & Dialysis	24.3
Neuropathy	11.5
Diabetic Retinopathy	10.5
Amputation	6.3
Depression	10.6

Discussion: FN peoples in Canada have poor glycemic control, high rates of smoking, and high rates of comorbidities/complications, particularly hypertension, dyslipidemia, and kidney disease/dialysis. These rates increase with duration of DM. Microvascular complications pose a large burden. The impact of DM on cardiovascular disease in this population may not have been fully expressed but the high rates of cardiovascular risk factors highlight the imperative need for risk factor intervention and complications surveillance.

Ethnic and province specific prevalence of diabetes mellitus in Sri Lanka – Sri Lanka Diabetes and Cardiovascular Study

P. Katulanda[1], P. Ranasinghe[1], A.V.S. Kulatunga[1], G.R. Constantine[1], M.H.R. Sheriff[1], D.R. Matthews[2]

[1] *University of Colombo, Diabetes Research Unit Department of Clinical Medicine, Colombo, Sri Lanka*

[2] *University of Oxford, Oxford Centre for Diabetes Endocrinology and Metabolism, Oxford, United Kingdom*

Introduction: The prevalence of diabetes among Sri Lankan adults has been recently reported as 10.3%. We aimed to determine the prevalence of diabetes and the underlying risk factors among different ethnic groups and provinces.
Methods: 5000 subjects above 18 years of age were selected by a multi-stage random cluster sampling technique. A structured questionnaire was used to record interview and anthropometric data. Fasting and 2-hour post OGTT plasma glucose were estimated. New cases of diabetes were diagnosed according to the WHO criteria. Data analysed using STATA software.
Results: Altogether 4532 subjects participated (response 91%); males 40%; mean age 46years (SD 15). The crude prevalence of diabetes was 12.6%. The prevalence of diabetes was highest in the Western province (18.8%) followed by Central (12.6%), Southern (12.2%) Sabaragamuwa (11.5%), North-Western (10.0%) and Uva (6.8%) provinces (p<0.0001). Sri Lankan Tamils (22.1%) had the highest prevalence of diabetes followed by the Muslims (21.4%), Sinhalese (11.9%) and Plantation sector Tamils (3.2%) (<0.022). Ethnicity was not significantly associated with diabetes in multivariate regression analysis corrected for obesity and physical inactivity but the province of residence remained significantly associated. In different provinces and ethnic groups, diabetes prevalence positively correlated with obesity indices and income but negatively correlated with level of physical activity.
Conclusion: There is a marked variation in the prevalence of diabetes in different provinces and ethnic groups in Sri Lanka. These patterns underlie the differences in obesity, income and physical activity and can be used for targeted primary preventive strategies.

Type 2 diabetes and growth patterns of offspring of mothers with early-onset type 2 diabetes in indigenous peoples in Manitoba, Canada: the Next Generation Project

J.M. Cloutier[1], H.J. Dean[1], E.A.C. Sellers[1]

[1] *University of Manitoba, Pediatrics and Child Health, Winnipeg, Canada*

Aims: The incidence of type 2 diabetes (T2D) in First Nations children is 20-fold higher in Manitoba compared to other Canadian provinces. Genetic predisposition due to a private polymorphism and maternal pre-pregnancy T2D appear to be non modifiable risk factors for developing T2D in indigenous peoples in Manitoba. The Next Generation Project is a birth cohort of those children born to mothers who had pre-pregnancy T2D diagnosed before 18 years in Manitoba. The Canadian Diabetes Association 2008 guidelines recommend screening for diabetes in at risk children ≥ 10 years of age at least every two years. The objectives are to assess the childhood growth patterns, provide surveillance for T2D in those children ≥ 7 years of age, and to reconsider the validity of screening guidelines for T2D in children of this population.
Methods: Annual heights and weights are recorded and a fasting blood glucose is measured in offspring ≥ 7 years of age.
Results: On December 31, 2008, 40/78 (51%) offspring had completed their 2008 assessment. 100% of the boys, and 68% of the girls ≥2 years of age were overweight or obese. 8/35 (23%) of the offspring ≥7 years of age have T2D. 44% of the offspring ≥ 10 years of age have T2D. 2/8 (25%) of these were diagnosed before the age of 10. All of the 8 children with T2D have one or two copies of the private Oji-Cree HNF1-a G319S polymorphism, associated with a mild insulin secretory defect.
Conclusion: Overweight and obesity are modifiable risk factors for age of onset of diabetes. The high risk genotype and maternal pre-pregnancy T2D in Oji-Cree peoples are non-modifiable risk factors for T2D. The guidelines for diabetes screening need to be customized for this high risk population. Our results inform the design of potential prevention programs.

The emergence of diabetes mellitus as a health problem among Brazilian Xavante Indians

L.J. Franco[1], A.L. Dal Fabbro[1], D.S. Sartorelli[1], A.S. Silva[1], L.F. Franco[2], R.S. Moisés[2], J.P.B. Vieira-Filho[2]

[1] *School of Medicine of Ribeirão Preto USP, Department of Social Medicine, Ribeirão Preto, Brazil*

[2] *Federal University of São Paulo, Department of Medicine, São Paulo, Brazil*

Background: Originally diabetes mellitus was rare among native Americans but change to a high risk group when they adopt life style of Western societies. This situation is now being observed among some Brazilian Indians, particularly the Xavante, who live in the scrubland of Central Brazil.
Objective: To estimate the prevalence of diabetes, obesity and hypertension in the adult Xavante population.
Methods: The Xavante population were brought by catholic priests to the Sangradouro reservation in 1957, located in the North of the State of Mato Grosso, when they were in conflict with farmers. Presently, the population is composed by 1549 individuals (829 men and 720 women), with 612 (38.5%) Indians aged 20 years or more. They have important changes in their traditional life style, with incorporation of industrialized foods, rice, sugar, soft drinks and some alcohol. The survey was based on a 75g glucose tolerance test and capillary glycemia measured by HemoCue. All participants signed an informed consent form.
Results: From the population aged 20 years or more, 351 Indians (57.4 % of the target age-group) underwent anthropometric and clinical examinations. Using WHO criteria, diabetes was diagnosed in 74 (21.1%), and IGT in 108 (30.8%) individuals. The prevalence of hypertension was 9.7% and the rates for obesity (BMI >or = 30 kg/m^2) and overweight (BMI > or = 25 and < 30 kg/m^2) were 44.7% and 37.9%, respectively. A large proportion (50%) of those with previously diagnosed diabetes was on insulin therapy, because of the poor response to oral anti-diabetic drugs.
Conclusion: These results show that diabetes and obesity are now an important health problem for the Xavante population. The increasing prevalence of DM and the perspective of occurrence chronic diabetic complications in an area with lack of health care tend to worsening their health conditions.

O-0241

Serum 25 (OH) D has no effect on insulin resistance among normoglycemic Cree

L. Del Gobbo[1], E. Robinson[2], E. Nieboer[3], E. Dewailly[4], J. Torrie[2], G.M. Egeland[1]
[1] McGill University, Centre for Indigenous Peoples' Nutrition and Environment, Montreal QC, Canada
[2] Cree Board of Health and Social Services, James Bay, Chisasibi QC, Canada
[3] McMaster University, Biochemistry, Hamilton ON, Canada
[4] Laval University Medical Research Center, Social and Preventive Medicine, Laval QC, Canada

Aims: Recent studies have linked vitamin D insufficiency with an increased risk of insulin resistance and diabetes. As vitamin D insufficiency is widespread in North America and a readily modifiable risk factor, we examined the relationship between serum 25 (OH) D concentrations and subclinical insulin resistance in the James Bay Cree, a population in which insulin resistance and type 2 diabetes have reached epidemic proportions.
Methods: A cross-sectional health survey was conducted of randomly selected adults and children from three Northern Québec, James Bay Cree communities surveyed in the summer months of 2005-2007. A total of 328 adult participants (>18 years of age) had serum 25 (OH) D, anthropometric measures and fasting glucose and insulin available for analyses.
Results: A high degree of insulin resistance as measured by homeostatic model assessment (HOMA-IR) was identified with mean HOMA-IR of 4.4 (0.6-23.4) and 10.0 (1.4–79.6) observed for those without and with glucose intolerance based on a fasting plasma glucose cut-off value of 5.6 mmol/L. The majority (91%) of the sampled population was vitamin D insufficient based on serum 25 (OH) D concentrations falling below 75 nmol/L, and nearly half of the population (46%) was deficient or severely deficient (< 50 nmol/L). Serum vitamin D concentrations were negatively and significantly correlated with measures of adiposity such as waist circumference (r = -0.124), BMI (r = -0.201), total fat mass (r= -0.249) and percent body fat (r = -0.264) (all p-values < 0.01). In multivariable linear regression analyses restricted to normoglycemic participants and adjusted for age, sex, BMI, and waist circumference, there was no relationship between serum 25 (OH) D and HOMA-IR (Beta = 0.003, SE= 0.019, p-value=0.86).
Conclusions: The inverse relationship between serum 25 (OH) D and adiposity is consistent with the hypothesis that vitamin D is sequestered by adipose tissue. However, no evidence of a relationship was found between serum vitamin D concentrations and insulin resistance among normoglycemic Cree.

Quality assurance and clinical application of guidelines

O-0242

Healthcare utilization patterns in diabetes mellitus in 1991 and 2007 - A Swedish Population-Based Study

V. Sparring[1], K. Burström[2], L. Nyström[3], J. Östman[4], P.M. Jonsson[1]
[1] Karolinska Institutet, Department of Learning Informatics Management and Ethics/Medical Management Centre, Stockholm, Sweden
[2] Karolinska Institutet, Department of Learning Informatics Management and Ethics and Department of Public Health Sciences, Stockholm, Sweden
[3] Umeå University, Department of Public Health and Clinical Medicine, Umeå, Sweden
[4] Karolinska Institutet, Centre for Endocrinology Metabolism and Diabetes, Stockholm, Sweden

Aims: During the past decade, the general assumption has been that diabetes care has developed towards improved quality and cost-effectiveness. There is, however, little information on changes over time in healthcare utilization patterns and in the excess need and use of services. The aim of this study is to compare healthcare utilization in patients diagnosed 1983 and followed-up 1991 and in patients diagnosed 1999 and followed-up 2008, i.e. with eight years' duration of diabetes, with the general population. The diabetic population was chosen as their diabetes was expected to be in a relatively stable phase, yet long-term complications might start to affect the utilization patterns.
Methods: Since 1983, the Diabetes Incidence Study in Sweden, DISS, prospectively registers all incident cases of diabetes in the age group 15 to 34 years, approximately 400 cases per year. In 1991 and 2007, population-based case-control studies were performed following up incident cases diagnosed eight years earlier, i.e. 1983 and 1999 respectively. For each case, two age- and sex-matched controls were selected from the general population. Retrospective data about utilization patterns in 2007 were collected using a mailed questionnaire, returned by 199 (49%) patients with diabetes and 368 (45%) controls. Comparable data were available from 1991 on the cohort registered in 1983 (n=317, response rate 72%) and corresponding control group (n=586, response rate 68%).
Results: In the group who contracted diabetes in 1999, 87% had insulin treated diabetes compared to 89% in the group diagnosed in 1983. In 2007, at least one visit to a hospital outpatient department, excl. emergency rooms was reported by 69% of the cases and 24% of the controls (p<0.001). Visit at an emergency room was reported by 11% of the cases and 6% of the controls (p<0.05). In 1991, the corresponding figures for outpatient department were 73% and 17% (p<0.001) and for emergency room visits 9% and 7% (n.s.), respectively. Staying at hospital inpatient department during the past year was in 2007 reported by 12% of the cases and 6% of the controls (p<0.05). Corresponding figures in 1991 were 18% and 9% (p<0.05) respectively. Use of services at hospital day care units was in 2007 reported by 43% of the cases and 14% of the controls (p<0.001), while the figures in 1991 were 13% and 5% respectively (p<0.05).
Conclusions: In the diabetic population, there was a higher excess use of day care services in 2007 than 1991. The use of inpatient care had decreased in both the diabetic and control groups. Yet, there was a significant excess use of inpatient care in diabetes also in 2007. The excess use of emergency care in 2007 calls for further investigations.

Root causes of clinical inertia in diabetes care

P.J. O'Connor[1], H.L. Ekstrom[1], J.M. Sperl-Hillen[1], S.E. Asche[1], G.H. Amundson[1], W.A. Rush[1]
[1] HealthPartners, HealthPartners Research Foundation, Minneapolis, USA

Aims: Failure to intensify therapy, which is an error of omission, is a leading cause of failure to reach evidence-based diabetes care goals. In this report we quantify provider, care system, and patient reasons for failure to appropriately intensify glucose medications.
Methods: As part of a larger study, 19 primary care physicians using an EMR-based clinical decision support tool completed a visit action resolution (VAR) form at each visit involving selection from a checklist of possible reasons why diabetes treatment was not intensified at office visits when patients with diabetes were not at recommended clinical goals.
Results: EMR decision support was used and VAR completed at 831 of 1639 (51%) visits with elevated glycated hemoglobin (A1c >= 7%); glucose medications were not intensified at 258 (43%) of the 831 VAR completed visits. Physician-identified reasons for no treatment intensification were: (1) Patient choice or preference, 70 (19.6%), (2) Need for updated A1c, 62 (17.3%), (3) Patient of endocrinology or diabetes nurse, 53 (14.8%), (4) Addressed dietary/lifestyle changes instead, 45 (12.6%) (5) Competing clinical demands, 17 (4.7%), (6) Not my patient, 13 (3.6%) (7) addressed adherence problem, 13 (3.6%). Less frequently cited (< 2.5%) were medication regimen already too complex, hypoglycemia concerns, drug intolerance, cost concerns, advanced age or severe co-morbidities, referred to endocrinology or diabetes educator, close to goal, and other.
Conclusions: We conclude that less than 20%, of clinical inertia is attributable to patient refusal or preference. A majority of instances of clinical inertia could potentially be addressed through provider training or care system changes such as point of care A1c testing and better coordination of care with subspecialty and primary care colleagues.

Decreased wait times at the Diabetes, Hypertension & Cholesterol Centre (DHCC)

D. Dyjur[1], C. Jones[1], L. Antymis[1], K. Erhardt[1], L. Dagenais[1], M. Garnett[1], J. Robertson[1], J. Shaw[1]
[1] Alberta Health Services, Endocrinology & Metabolism, Calgary, Canada

Background: The Diabetes, Hypertension & Cholesterol Centre (DHCC) is a program that serves the Calgary area, which had a total population of 1238799 in 2007. We accept 3700 referrals annually (3746 in 2008), and close to 1700 new clients are seen each year (1677 in 2008). The DHCC participated in a 14 month collaborative to measure and improve access for patients seen at the Centre. Prior to the collaborative, there was no clear measure of what wait times were at DHCC, but there was a feeling that wait times were too long. Two key areas thought to be most problematic: diabetes assessments and 24 h Ambulatory Blood Pressure Monitoring (ABPM) became the focus of this intervention.
Objectives: The AIM team set 2 objectives to improve access at DHCC:
- All new diabetes clients to be seen within 1 week, by October 31st, 2008.
- All 24 h ambulatory plood pressure monitoring (ABPM) clients to be seen within 1 week, by October 31st, 2008.

Methods: The DHCC AIM team attended a series of Learning Sessions to learn about how to measure and improve access. We began to measure the third next available (TNA) appointment, along with a number of other parameters in the Fall of 2007. The AIM team met monthly to discuss principles, and to consider and implement steps to improve access. Measurement continued for the entire period of the AIM collaborative (November 2007 to Oct 31, 2008), and continues today.
Results: In November, 2007, the third next available (TNA) appointment for a diabetes assessment was 96 days, and for a 24 h ABPM appointment was 56 days. By the week of Oct 31, 2008, after implementing several strategies, the TNA for diabetes assessments was 5 days, and for 24 h ABPM remained similar, at 42 days.
Conclusion: Measuring and taking appropriate steps to improve access provides real, measurable improvements for patients. The strategies that had the most impact on TNA for diabetes assessments were cross training of nursing and dietitian staff to increase the supply of clinicians who were able to conduct diabetes assessments, having healthcare professionals work to full scope of practice, and the use of a "short call list" to try and fill assessment spots when patients cancelled with little notice. The TNA for 24 h ABPM appointments was less improved because of lack of space and equipment to work down the backlog.

Development of Quality Assurance for a local education delivery programme

J. Sumner[1], P.A. Dyson[2]
[1] OCDEM, Oxford Centre for Diabetes Endocrinology & Metabolism, Oxford, United Kingdom
[2] University of Oxford, Oxford Centre for Diabetes Endocrinology & Metabolism, Oxford, United Kingdom

Background: Quality assurance (QA) is one of the four key criteria for structured education programmes identified by the Department of Health in the UK. Our local education programme for people with Type 1 diabetes is delivered at 4 different sites by 10 educators and the challenge is to ensure that it is being provided at the required standard.
Aims: To design and implement a QA process for our education programme and to ensure that the programme is delivered at the required standard and that it matches the written philosophy, aims, objectives and curriculum.
Methods: The process of QA began with ensuring baseline competencies and experiences of all educators and the establishment of an educators register. Organisational processes included mentoring, documented self and peer reflection, internal and external evaluation from observed visits and educator study days. All educators delivered at least three courses annually in order to maintain their skills and were subject to the quality assurance process yearly. Any educators who did not meet the required standard agreed further support and review.
At each QA session, educators were observed by another educator from a different site. QA tools were developed and included an assessment form completed by the observer which matched the behaviour of the educators to the written philosophy and curriculum. To assess relative participation and self reflection from group members, a timed session measured the spoken contributions from participants and educators. We aimed for the educators to be talking less than 50% of the timed session.
Peer reflection was based upon observable behaviours and interaction with group participants and included verbatim feedback with reflection. At the end of each QA session, assessors and educators worked in partnership to identify and review any learning needs and to formulate and document a professional development plan to address these. Group participants completed evaluation forms in order to inform the process.
Results: All 10 educators met the standards for competencies and experience and were entered onto the register. During the first year of the QA process, all educators successfully completed the procedure. Benchmarking between the 4 sites has shown that there are no significant differences and that the programme is being delivered as designed. Development plans are in place for all educators.
Analysis of 7 timed sessions showed that the educators met the agreed target, talking for 48% of the session. Participant feedback was used to develop the education programme.
Conclusion: A QA process has been successfully developed and delivered in 4 different sites. It is dynamic, on-going and has supported positive change for both the programme itself and the educators involved.

The effect of predisposing complications on the 5-year incidence of diabetes complications among patients treated in Belgian multidisciplinary diabetes centers

N. Debacker[1], C. Mathieu[2], F. Nobels[3], P. Van Crombrugge[3], A. Scheen[4], V. Van Casteren[1]
[1] Scientific Institute of Public Health, Epidemiology, Brussel, Belgium
[2] UZ Gasthuisberg, Endocrinology, Leuven, Belgium
[3] OLV-Ziekenhuis, Endocrinology, Aalst, Belgium
[4] CHU Sart Tilman, Endocrinology, Liege, Belgium

Aims: Prospective data obtained in real life concerning the development of complications in patients with type 1 (DM1) or type 2 (DM2) diabetes are rather scarce. The aim of the present study was to examine to what extent the presence of complications in 2002 affected the first onset of further complications during a time frame of 5 years.
Methods: Since 2001 a quality assurance project is organized in all Belgian multidisciplinary diabetes centers (n=120). Every 18 months centers collect data (demographics, blood glucose control, cardiovascular risk status, diabetes complications, self-monitoring, and drug treatment) on a cross-sectional random sample of 10% of their adult diabetes patients on >= 2 daily insulin injections and receive a personalized feedback. For the 2007 sample an overlap was induced with the 2002 sample, by using the same alphabetical start letter in the sampling procedure. Patients from both periods were matched using the center code, patient initials, month and date of birth, year of diagnosis, diabetes type, gender and height. Logistic regression was used to adjust for age, gender, diabetes duration and type.
Results: Data of both 2002 and 2007 were available for 1,531 patients. Of these, 43% had DM1 and 57% had DM2. In 2007 the median age and diabetes duration were respectively 47 and 20 years for DM1 and 70 and 17 years for DM2. The 5-year incidence of a first amputation among patients with a foot ulcer history in 2002 was 22.8%. Among patients with peripheral arterial disease (PAD) in 2002 it was 8.9%. In patients without these complications in 2002 it was below 1%. The 5-year incidence of a first foot ulcer among patients with PAD in 2002 was 10.3% and in the group with peripheral neuropathy in 2002 it was 9.1%. In patients without these complications in 2002 it was about 2%. The 5-year incidence of a first myocardial infarction (MI) and CABG/PTCA among patients with PAD in 2002 was resp. 8.7% and 16.4%. In patients without PAD in 2002 it was resp. 4.1% and 8.0%. The 5-year incidence of end stage renal disease among patients with overt nephropathy (ONP) in 2002 was 8.0%, while it was 0.8% among patients without ONP in 2002. Finally the 5-year incidence of blindness was 1.8% among patients with retinopathy (RP) in 2002, while it was 0.3% among patients without RP in 2002. The 5-year incidences of all these complications were significantly higher in patients with preceding complications in 2002, except for MI and PTCA/CABG, where age was an important determining factor.

Conclusion: This quality assurance study provides recent prospective data on the incidence of diabetes complications. The onset of complications is highly related to preceding complications. These results stress once more the importance of rapid and adequate intervention when patients start dealing with diabetes complications.

[7] *University of British Columbia, Medicine, Vancouver, Canada*
[8] *University of Manitoba, Internal Medicine, Winnipeg, Canada*
[9] *Mount Sinai Hospital, Medicine, Toronto, Canada*

Aim: To evaluate the impact of a 12-month glycemic treatment optimization program in 5280 men and women (mean age 60.6±11.9 years) with type 2 diabetes mellitus (T2DM) and glycated haemoglobin (A1C) above the 2003 Canadian Diabetes Association guidelines-recommended target of 6.0-7.0%.
Methods: Subjects in this registry were enrolled between March 2006 and September 2007 from the offices of 331 primary care practitioners across 9 Canadian provinces. Four clinic visits were scheduled over 12 months to monitor A1C and optimize treatment regimens.
Results: Median baseline A1C was 7.8%; IQR, 7.3% to 8.6%. The median 12-month A1C was 7.1%; IQR, 6.6% to 7.9%. Overall A1C target achievement improved between the initial and final visits (P<0.001). Percentage attainment of A1C=7.0% increased with consecutive visits (37.6%, 43.9% and 48.1% at visits 2, 3 and 4 respectively). A1C=6.0% was realized in 4.9%, 6.8% and 8.2% of the group at visits 2, 3 and 4 respectively. Comparisons between baseline A1C and those measured at the last visit (last observation carried forward) indicated 25.9% and 2.2% respectively exhibited worse and pharmacological-resistant A1C. Fasting plasma glucose (FPG) improved concomitantly (medians (25^{th}, 75^{th} quartiles) of 8.6 mmol/L (7.4, 10.3 mmol/L), 7.8 mmol/L (6.6, 9.3 mmol/L), 7.5 mmol/L (6.4, 9.1 mmol/L) and 7.4 mmol/L (6.2, 8.9 mmol/L) at visits 1, 2, 3 and 4 respectively) but only 42.4% reached the target FPG=7 mmol/L at the final visit. Antiglycemic monotherapy decreased with consecutive visits (34%, 29%, 25% and 25% of the subjects at visits 1, 2, 3 and 4 respectively). This paralleled increases in therapy consisting at least three antihyperglycemic agents (23%, 29%, 30% and 29% of the subjects at visits 1, 2, 3 and 4 respectively).
Conclusions: In this prospective epidemiologic cohort of T2DM patients with baseline A1C>7.0%, 48.1% achieved A1C=7.0% and 42.4% FPG=7.0 mmol/L at the final visit following a 12-month aggressive pharmacological treatment program based on current national guidelines. This improvement likely resulted from enhanced clinical awareness and regular feedback coupled with increased application of combination therapy. While these results suggest that an algorithm based on optimized oral hypoglycemic agent regimes is a useful therapeutic option for management of T2DM, T2DM remains difficult to manage and the disparity that persists between clinical outcomes and current Canadian treatment goals remains significant and unsatisfactory. Further measures to bridge this care gap are clearly warranted.

[6] *Wetenschappelijk Instituut Volksgezondheid, Epidemiology, Brussels, Belgium*
[7] *AstraZeneca, Medical, Brussels, Belgium*

Background: Diabetes and micro- and macrovascular complications have an important impact on survival, quality of life and health care costs. Effective treatments and interventions reduce this burden and improve the quality of patient care. However, due to a marked variability in preventive and therapeutic approaches, diabetes care as currently provided may not deliver the optimal expected, health-related gains. Benchmarking, an emerging method, incorporates two-sided feedback of physician's individual performance graded alongside the current mean achievement of a peer group as well as patient's target attainment.
Methods: Belgium conducted the pilot trial for the larger non-interventional OPTIMISE study in which 6 European countries are participating. The aim was to study the effect of benchmarking on quality of care in type 2 diabetes patients throughout a 12-month period. The parameters of interest were percentage of patients achieving pre-set targets according to European guidelines (2007) for HbA1c (<7%), LDL-cholesterol (LDL-C <80mg/dl) and Systolic Blood Pressure (SBP) (< 130 mmHg). Results presented hereafter describe the Belgian baseline data and provide an overview of the current level of target attainment prior to benchmarking randomisation.
Results: 94 General Practitioners (GPs) with 1126 patients were randomized to the intervention group receiving feedback for benchmarking and 93 GPs with 1010 patients to the group receiving no feedback. Both groups were highly superposable for baseline demographic, anthropometric and diabetes-related parameters. In the whole cohort, mean age (1 standard deviation) was 66.9 years (10.6) and 54% were male patients. Mean age at diabetes diagnosis was 59.3 years (11.0), with a mean of 7.6 years (6.6) elapsed since diagnosis. Target HbA1c was reached in 59% of patients. Biguanides and sulfonylureas were most frequently used, with a minority of patients (8%) receiving insulin. 27% of patients achieved LDL-C target, lipid-lowering drugs (LLD) were given to 65%, with statins most frequently used: simvastatin (38%), rosuvastatin (28%) and atorvastatin (24%). 80% of patients were hypertensive (77% treated), with 29% at goal for SBP. Only 4 % of patients reached all 3 three preset targets.
Conclusions: Quality of care in type 2 diabetes patients in Belgium at baseline was suboptimal. Interventions to improve levels of care are necessary. The OPTIMISE study will evaluate the effect of benchmarking on quality of care in general practice.

Impact of adding a pharmacist to primary care teams on blood pressure control in people with type 2 diabetes: a randomized controlled trial (ISRCTN97121854)

S.H. Simpson[1], S.R. Majumdar[2], R.T. Tsuyuki[2], R.Z. Lewanczuk[2], R. Spooner[2], J.A. Johnson[3]

[1] *University of Alberta, Faculty of Pharmacy & Pharmaceutical Sciences, Edmonton, Canada*

[2] *University of Alberta, Faculty of Medicine & Dentistry, Edmonton, Canada*

[3] *University of Alberta, School of Public Health Sciences, Edmonton, Canada*

Aim: The Vascular Intervention Program (VIP) trial was designed to evaluate the effect of adding a pharmacist to primary care teams on medication management for cardiovascular risk in type 2 diabetes. We hypothesized that addition of a pharmacist would improve blood pressure (BP) control.

Methods: This randomized, controlled trial was set in family physician offices affiliated with a primary care network in Edmonton, Canada. Subjects were eligible to participate if they had type 2 diabetes identified from physician rosters. We excluded subjects who qualified for urgent assessment in a regional diabetes program (A1c >8%; BP >220/120 mmHg; triglycerides >15 mmol/L) or were followed by specialists. The VIP intervention began with a pharmacist conducting a complete medication assessment and limited physical examination. The pharmacist made guideline-based recommendations aimed at optimizing medication management of BP, cholesterol and blood glucose. Follow-up visits were conducted as necessary. Controls received usual care from the primary care team. The primary outcome was proportion of subjects with a ≥10% reduction in systolic BP at 1 year, an endpoint which was considered clinically important a priori. Secondary outcomes included systolic BP change, BP therapy changes, and initiation of ACEI or ARB therapy.

Results: 260 subjects were enrolled and allocated to intervention (n=131) or control (n=129). Overall, mean (SD) age was 59.1 (12.1) years, about half (57%) were women, diabetes duration was 6.5 (7.2) years, BMI was 32.5 (6.5) kg/m^2 and A1c was 7.3 (1.3)%. Mean BP was 129 (15) / 74 (10) mmHg and 151 (58%) had elevated BP defined as ≥130/80 mmHg. There were no statistically significant imbalances at baseline. The primary outcome of a ≥10% reduction in systolic BP at 1 year was achieved by 47 (36%) intervention and 30 (23%) control subjects (OR 1.85; 95% CI 1.07-3.18; p=0.027). Systolic BP decreased significantly in both groups, but fell 3.7 mmHg more with intervention than control (p=0.055 for difference). When the analysis was restricted to subjects with an elevated BP at baseline, 40 (49%) of 81 intervention and 20 (29%) of 70 control subjects achieved the primary outcome (OR 2.44; 95% CI 1.24-4.80; p=0.0099). There was a 6.9 mmHg greater reduction in systolic BP with intervention than control (p=0.004 for difference). Intervention group subjects were more likely to have BP therapy changes (OR 2.26; 95% CI 1.33-3.84) and more likely to initiate ACEI or ARB therapy (OR 8.21; 95% CI 1.84-36.68) compared to controls.

Discussion: Addition of a pharmacist to the primary care team produced a significant reduction in BP and more antihypertensive therapy changes. The magnitude of effect was greatest in those not currently at treatment target. Our results suggest that pharmacists may have a major role in helping to optimize BP control in type 2 diabetes.

Implementation of a structured module for insulin therapy self management education for type 2 diabetes in outpatient hospital settings in France

X. Debussche[1], M. Balcou-Debussche[2]

[1] *CHR Reunion - CH Felix Guyon, Chronic and Metabolic Diseases Department, Saint Denis, Reunion*

[2] *Clermont Ferrand University, PAEDI research Laboratory (Process and Actions in Education: Determinants and Impacts), Clermont Ferrand, France*

Aims: Group empowerment courses are a potential approach to help structuring self-management education for insulin treated type 2 diabetes subjects. As a whole, these actions are yet to be better structured in French outpatient hospital settings.The aim of the present work was to assess the feasibility of such courses in 120 outpatient hospital settings in France and their impact on the structuring of the patient education process.

Methods: The initial education module, including 2 outpatient 90-min long group sessions, focuses on stakes and understanding of diabetes and insulin treatment, practical and technical issues, SMBG and insulin dosage. A 3rd session takes place at 2-3 months in order to help the patient in assessing results, evolution of treatment and dosage, difficulties, contextual issues and setbacks. Educational methods (Learning Nests) are based on adult learning principles, socio-constructivism, social learning and empowerment. Group sessions are precisely conceived with knowledge issues, learning outcome indicators, contextual (individual and social) framing for the patients and actions to be discussed. Operating booklets for patients and manuals for educators make the module reproducible. Twenty outpatient hospital self-management education teams in 6 regional areas of France participate in the experimental implementation. One hundred twenty registered nurses, one from each setting, were trained on a one day basis by a social and educational scientist, in order to set up the module and include 20 Type 2 diabetes patients in each structure (insulin naïve with indication of insulin therapy or previously insulin treated). Socio demographical and clinical data (diabetes duration and treatment, BMI, WC, Glyc Hb at 0 and 3 month) are collected by educational teams. Number of inclusions, programmations, attendance at group sessions, quality of data collection and profiles of recruited patients will be analysed as a whole and among the different centres.

Discussion and conclusion: This study will yield important preliminary data on the potential beneficial contribution of the integration of group empowerment modules in self-management education for insulin requiring type 2 patients in France. Differential implementation and impacts will be analysed from the programmation records and from questionnaires completed by educational teams. These preliminary results will constitute the grounds for future multicenter observational and intervention studies on Type 2 diabetes self-management education in French hospital settings.

O-0251

Diabetes peer education and migrant patients: self-help for self-management

C. Guell[1]

[1] *University of Edinburgh, Department of Social Anthropology, Edinburgh, United Kingdom*

Background/aims: This paper is based on doctoral research that explored Turkish migrants' experience with diabetes in Germany, who are said to be almost twice as likely to suffer from type 2 diabetes as Germans or Turks in Turkey. Health statistics frequently identify minority groups as vulnerable to chronic illness, and qualitative studies explore lay beliefs and conflictual medical encounters. My objective was to examine how the Turkish population in Berlin actively engaged in diabetes care, and investigate which social groups are involved in such local experiences. This paper focuses on the role of peer education in diabetes control among Turkish migrants in Berlin, Germany.

Methods: An ethnographic approach was used, including a 12-month period of participant observation and narrative interviews with members of a Turkish self-help group, their families, and health professionals. Assuming active engagement with illness management, I explored relative access to knowledge and social participation in diabetes peer education.
Results: Interviews with healthcare professionals alluded to a migrant patient group disadvantaged and immobilised by high illiteracy rates, lacking language skills and health knowledge. Ethnographic exploration, however, revealed an active engagement with diabetes despite these challenges. Informal diabetes care is communally negotiated. Local Turkish-origin doctors have initiated a patient-led Turkish-speaking diabetes self-help group and community information events to provide native-language diabetes education. Migrant diabetes patients with access to such support manage their self-care confidently, for example negotiate between clinical German dietary recommendations and their Turkish home cooking. They engage in deliberate practices to improve their diabetes control, rather than representing the common image of the disadvantaged migrant patient.
Discussion: The results of the study imply that, despite low socio-economic status and education level, there is an active interest in acquiring illness management knowledge among members of migrant communities and that subsequent communal responses such as the Turkish self-help group in Berlin are strongly related to confident diabetes control. Further research should investigate informal healthcare practices in various settings. This could greatly inform the design of successful approaches to diabetes education for marginalised communities.

Patient Expert: A training program for patients to support and coach other patients with diabetes type 2 developed by the French Organization for Diabetes (AFD)

C. Heritier[1], G. Raymond[1], C. Avril[1]
[1] Association Française des Diabétiques, Executive Desk, Paris Cedex 11, France

Aims: To initiate, develop and implement a training program for peer support, in the field of diabetes, at a national level.
Methods: Patient-to-patient support programs are growing in France, as Ministry of Health officially recognized importance of such programs. However, no certified solid and comprehensive training program is available in France for volunteer patients who would like to assist the 3 million people suffering from, or at risk of, diabetes. Based on its 70-year experience of supporting people with diabetes, and its network of 125 local organizations throughout France, French Organization for Diabetes conceived a specific training program: the Patient Expert Program. French Organization for Diabetes strongly promote that patients should be "actors of their own health"; this program first trains patients to be experts of their own disease, then trains them to provide peer support, coaching and guidance to other patients living with diabetes, to run peer support groups, all on a voluntary basis.
Training program content includes both substantial knowledge and technical aspects.
Phase 1 / Trainee strengthen his knowledge on diabetes, environment and treatments, using a specifically designed CD Rom. **Phase 2 /** Learn communication technique to lead peer groups, to conduct one-on-one meetings, to "listen" carefully to other patient's issues, to accompany them throughout their life project and diabetes related issues.
After completion of this training program, the trainee is considered a Patient Expert.
Supervision: A/ A managing committee at French Organization for Diabetes develops and validates training content and procedures, leads program implementation and assessment. B/ A medical committee certifies training content and contributes to program assessment. C/ "Regional Training Referral Volunteers" (2 per region) have been trained. They recruit trainees, guide them throughout the course of studies, foster groups dynamic, organize trainings, and contribute to training content development and evaluation.
Results: An educational CD Rom developed: 1500 copies available.
20 Regional Training Referral Volunteers trained.
150 persons trained to be Patient Experts in Diabetes
600 days of of training organized.
Conclusions: This training program for patients to support and coach other patients with diabetes type 2 is a relevant program in France, and the French Organization for Diabetes has great hope that it will be certified by French public health institutions soon.

O-0253

Knowledge, attitudes and practices of diabetic patients in a rural community: Phase I of the community-based diabetes self-management education (DSME) program in San Juan, Batangas, Philippines

G.J.R. Ardena[1], E. Paz-Pacheco[1], C. Jimeno[1], F.L. Lantion-Ang[1], N. Juban[1], E. Paterno[1]
[1] University of the Philippines - Philippine General Hospital, Medicine, Manila, The Philippines

Introduction: Diabetes Self-Management Education (DSME) has been recognized as a fundamental component of diabetes care. The present study comprises Phase I of the proposed 5-year community-based DSME Program in San Juan, Batangas, Philippines. To increase relevance, the data derived from this preliminary study will be incorporated to the educational materials of the program.
Objectives
1. To determine the knowledge, attitudes, and practices of diabetic patients in the rural community of San Juan, Batangas
2. To determine if patient factors such as age, sex, duration of diabetes, type of diabetes, attendance in diabetes classes, level of education, family history of diabetes, and use of insulin affect knowledge, attitudes, and practices regarding diabetes

Study design: Cross-sectional analytic study
Setting: San Juan, Batangas, Philippines
Participants: Known diabetics in the community who either have Type 1 or Type 2 diabetes
Methodology: Participants were selected using stratified cluster sampling. Diabetes knowledge and attitudes were assessed using selected items from the American Association of Clinical Endocrinologist (AACE) Knowledge Test and the Diabetes Attitude Scale (DAS-3), respectively. Both questionnaires were previously locally validated and translated into the Filipino language. FGDs were conducted to ascertain myriad practices of diabetic residents in a rural community.
Results: A total of 156 diabetic residents were included in the study. Mean age of the participants was 56.67 years old, with a female predominance (67.31%). The overall percentage score on knowledge ranges from 12.50% to 83.33%, with a mean of 42.71%. The highest and the lowest mean percentage scores among the knowledge subscales were 61.15% and 23.93% for treatment and self-monitoring, respectively. Majority of the respondents strongly believed in the need for patient autonomy (76.4%). However, less than half believed in the value of tight glucose control (48.2%) and the seriousness of diabetes mellitus (45%). A total of 35 respondents were included in the FGDs (average of 12 per strata). Only 4 out of the 35 diabetic respondents owned a glucose meter while only 16 out of the 35 consult their doctors on a regular basis.
Conclusions: The present study highlights the importance of evaluating knowledge, attitudes and practices as crucial means to understand observed behaviors and to guide behavioral change. By offering culturally-appropriate, cost-effective, and comprehensive diabetes care, the present DSME Program aspires to be a "model of community diabetes care" throughout the country, ultimately attenuating disparities in health outcomes for underserved Filipinos in the rural community.

O-0254

Comprehensive care for the prevention and reduction of diabetes: a self-management focused program

S. Burns[1], K. McQueen[1], M. Naruki-van Velzen[1], C. Kam[1], A. Graham[1], S. Chan[1], G. Bondy[1], J. Frohlich[1], A. Ignaszewski[1]
[1] St. Pauls Hospital Providence Health Care, Cardiology, Vancouver, Canada

Aim: Diabetes prevention and risk reduction requires comprehensive, long-term care with self-management support. Standardized diabetes clinics may not include interventions in lifestyle management supporting successful behaviour change. We developed and implemented a new program targeting the reduction of metabolic syndrome risk factors for the prevention and reduction of diabetes and prevention of vascular disease. A combination of intensive interactive lifestyle interventions and self-management strategies are integrated into this effective program design.
Method: Participant referral may be from physicians, allied health professionals or self-referral. This multidisciplinary, nurse-managed physician supported program includes a clinical nurse specialist, patient educator, dietitian, exercise specialist, occupational therapist, physicians and psychology

support. Behaviour change strategies target physical activity, nutrition, weight management, psychosocial risk factors, and self-management. This program is 18 months in duration and includes a minimum of 17 visits. Interactive group sessions are enhanced with prescheduled individual follow-up visits with the multidisciplinary team members. A web-based data management system, PROMIS was utilized and modified for scheduling and data usage. Education includes goal setting, motivation, nutrition principles of healthy eating, physical activity and exercise, cholesterol, negative mood, mindfulness and stress management. Self-management tools include trackers for diet, physical activity and mood, pedometers, participant and group contracting and collaborative goal setting.

Results: FBG at baseline 5.9 (5.5, 6.5), N = 228, at 12 months 5.9 (5.4, 6.4) N = 147, p = 0.10. Weight (kg) at baseline 98.0 (84.3,115.9); at 12 months 92.3 (79.5,106.4) N = 144, p=0.002. Waist circumference (cm) at baseline 112 (102,124,), at 12 months 106.0 (96.0,115.0), N = 133, p <0.0001. TC at baseline 5.5 (4.8, 6.3), at 12 months 5.2 (4.3, 5.8), N = 147, p =<0.001. LDL at baseline 3.3 (2.7, 3.9), at 12 months 3.1 (2.3, 3.6) N = 145, p = 0.008. HDL at baseline 1.2 (1.0, 1.4), at 12 months 3.1 (1.2 (1.1, 1.5), N = 147, p = 0.03. TG at baseline 2.0 (1.5, 2.8), at 12 months 1.7 (1.2, 2.5), N = 147 p =<0.0001. SBP at baseline 130 (0.7), at 12 months 121 (1.1), N = 140, p <0.0001 and DBP at baseline 80.5 (0.4), at 12 months 75.9 (0.7), N = 140, p <0.001.

Conclusion: This new innovative model incorporates key self-management strategies for diabetes prevention and management. We conclude that this comprehensive multidisciplinary program, meets the needs of both participants and communities and is a necessary addition to traditional diabetes clinics.

[4] Baylor College of Medicine, Pediatrics, Houston, USA
[5] Novo Nordisk, Dawn, Copenhagen, Denmark

Aims: This study assessed the psychosocial factors associated with psychological well-being among parents of children and adolescents with diabetes.

Methods: Data are from a cross-sectional internet survey of independent national samples of parents of children and adolescents (aged 0-18) with diabetes (N = 4099) from the Diabetes Attitudes, Wishes and Needs (DAWN) Youth Study. Respondents from Brazil, Japan, the US and 5 European countries provided self-report data for all measures. Psychological well-being was assessed by the WHO-5 with scores ranging from a low of 0 to a high of 100. Multiple regression assessed the independent associations of WHO-5 with country, respondent demographic and disease characteristics, and several sets of modifiable risk factors, including aspects of healthcare provision and participation, perceived social support from friends and work, and diabetes-specific burden (financial, work, everyday diabetes management), worry about complications and parent-child conflict over diabetes care.

Results: Level of WHO-5 (mean ~ 55) was modest. All categories of factors made significant ($p < .001$) independent contributions to explaining variance in both outcomes; together these factors accounted for 24% of the variance in WHO-5 and modifiable risk factors accounted for 19%. Controlling for all factors examined, the following significant ($p < .05$, two-tailed) independent associations were observed with modifiable risk factors. WHO-5 was higher among respondents who reported more integrated diabetes care, greater understanding and support from their health care providers, and who participated more in decisions about their child's diabetes care. Respondents reporting higher satisfaction with friend support or work support had higher WHO-5. Respondents reporting more diabetes-specific burden, worry and conflict had lower WHO-5; the association with burden was stronger than any other factor examined.

Discussion/conclusion: This study shows that many parents of children and adolescents with diabetes in all countries have less than optimal psychological well-being, largely due to modifiable risk factors. Strategies for improving psychological well-being include improving health care professionals' provision of understanding, support, and collaborative decision making, enhancing support from friends and work, and reducing worry about diabetes outcomes, parent-child conflict over diabetes management and the financial burden and everyday demands of dealing with diabetes.

Psychological well-being and quality of life among youth with diabetes in the Diabetes Attitudes, Wishes and Needs Youth Study

B. Anderson[1], M. Peyrot[2], H.J. Aanstoot[3], K. Lange[4], T. Danne[5], L. Deeb[6]
[1] Baylor College of Medicine, Pediatrics, Houston, USA
[2] Loyola College in Maryland, Dept of Sociology, Baltimore, USA
[3] Diabeter, Diabetes Center for Children and Youth, Rotterdam, The Netherlands
[4] Medizinische Hochschule, Medical Psychology, Hannover, Germany
[5] Kinderkrankenhus Auf der Bult, Dept. of General Pediatrics and Endocrinology/Diabetology, Hannover, Germany
[6] Florida State University, Dept of Behavioral and Social Medicine, Tallahassee, USA

Aims: This study assessed the psychosocial factors associated with psychological well-being and quality of life (QOL) among young adults with diabetes.

Methods: Data are from a cross-sectional internet survey of independent national samples of patients with diabetes aged 18-25 (N = 1905) from the Diabetes Attitudes, Wishes and Needs (DAWN) Youth Study. Respondents from Brazil, Japan, the US and 5 European countries provided self-report data for all measures. Psychological well-being was assessed by the WHO-5 (World Health Organization 5) and subjective QOL was assessed by a single-item measure; both measures ranged from a low of 0 to a high of 100. Multiple regression assessed the independent associations of WHO-5 and QOL with country, respondent demographic and disease characteristics, aspects of healthcare provision and participation, perceived social support from family and friends, and diabetes-specific coping.

Results: Levels of QOL (mean ~ 65) and WHO-5 (mean ~ 57) were modest. All categories of factors made significant ($p < .01$) independent contributions to explaining variance in both outcomes; together these factors accounted for 24% of the variance in WHO-5 and 31% of the variance in QOL. Controlling for all factors examined, the following significant ($p < .05$, two-tailed) independent associations were observed. Italian respondents and those living in large cities had higher WHO-5 and QOL. Male respondents had higher WHO-5 and those with type 1 diabetes or using insulin pens had higher QOL. WHO-5 was higher among respondents who reported greater understanding and support from their health care providers, and QOL was higher among those who participated more in decisions about their diabetes care. Respondents reporting higher satisfaction with friend support or family support had higher WHO-5 and QOL. Respondents reporting more successful diabetes-specific coping had higher WHO-5 and QOL; this association was stronger than any other factor examined.

Discussion/conclusion: This study shows that many young adults with diabetes in all countries have less than optimal psychological well-being and quality of life. Most of the identified risk factors for poor well-being and quality of life are modifiable. Strategies for improving psychological well-being include improving health care professionals' provision of understanding, support, and collaborative decision making, enhancing support from parents, and fostering the development of coping skills for dealing with the everyday difficulties of living with diabetes.

Predictors of fear of hypoglycaemia in youth with type 1 diabetes and their parents

M. Nyer[1], L. Campbell[1], S. Mortimer[1], W. Clarke[2], L. Gonder-Frederick[1]
[1] University of Virginia, Psychiatry and Neurobehavioral Sciences, Charlottesville, USA
[2] University of Virginia, Department of Pediatrics, Charlottesville, USA

Aims: Fear of hypoglycemia (FOH) can significantly impact quality of life for people living with diabetes, including both patients and their loved ones. The most commonly used measure of FOH is the Hypoglycemia Fear Survey (HFS), composed of two subscales measuring avoidance behaviors (HFS-B) and worries (HFS-W) related to hypoglycemia. However, FOH as measured by the HFS varies greatly across individuals, so it is important to understand factors contributing to level of fear. Research has shown that, in adults with insulin-treated diabetes, FOH is predicted by hypoglycemia history (e.g. frequency of severe episodes) and trait anxiety. Few studies have looked at predictors of FOH in pediatric type 1 diabetes. This study investigated predictors of FOH in a cohort of 305 youth with type 1 diabetes and their parents.
Research methods: This secondary analysis study merged data sets from studies conducted at the University of Virginia from 1998 - 2008. All data sets contained HFS data from youth with type 1 diabetes and their parents, as well as measures of trait anxiety – the State-Trait Anxiety Inventory for Children (STAIC) and the State-Trait Personality Inventory (STPI) for parents. Data sets also included parent report of frequency of severe hypoglycemia (SH) over the past year. Youth in these studies had been diagnosed with diabetes for at least one year (mean/SD duration = 5.24/3.3 yrs), and ranged in age from six to 18 yrs (mean/SD age = 10.59/3.3 yrs). A total of 47.4% of youth were female, 76.9% of parents were mothers, and 92.5% of families were Caucasian.
Results: Linear regressions controlling for age showed that, for youth, both frequency of SH ($p < .01$) and youth trait anxiety ($p < .001$) predicted total HFS scores, and accounted for 21% of the variance in youth scores ($p < .001$). Parent and youth trait anxiety significantly correlated ($r = .36$ ($p < .0001$), but parent anxiety did not predict youth FOH. For parents, linear regressions showed that age accounted for 15% of variance in HFS-B scores ($p < .001$), parent trait anxiety accounted for 8% in HFS-W scores ($p < .001$). Age and parent anxiety predicted HFS total scores, accounting for 9% of variance ($p < .01$).
Conclusions: In youth with type 1 diabetes, as in adults, both SH history and trait anxiety predict FOH. In parents, the child's age predicted behavioral subscale scores, with parents of younger children reporting more behaviors to avoid hypoglycemia. Trait anxiety predicted worry subscale and total HFS in parents, but frequency of SH in the child did not. The final model for parents accounted for only a small amount of variance suggesting that variables not considered in this study are important predictors of FOH for parents of children with type 1 diabetes.

Innovations in addressing diabetes disparities in homelessness and poverty

S. Davachi[1], I. Ries-Ferrari[2]
[1] Alberta Health Services, Chronic Disease Management, Calgary, Canada
[2] Calgary Drop-In & Rehab Centre, Curriculum Development Research and Best Practices, Calgary, Canada

Homelessness is a growing problem in Canada and worldwide. Despite the significant prevalence of diabetes and other chronic conditions, homeless people frequently encounter many barriers to regular service utilization. The life-long and intense management of diabetes which involves multiple and demanding aspects related to self-monitoring of blood glucose, medical therapy often requiring adjustments, diet, lifestyle modification and continuous education and follow-up, compounds challenges for the homeless population. Effective and appropriate strategies are needed to address complex health needs of this marginalized population.
Project aim: Since 2008, Calgary area, Alberta Health Services, in partnership with the Calgary Drop-In & Rehab Centre has developed an innovative diabetes prevention and management project for people experiencing homelessness and poverty. The specific objectives are: to develop strong partnerships with homeless people and multiple stakeholders; to identify barriers experienced by homeless people and appropriate strategies for delivery of effective diabetes program for homeless population; to increase chances for early detection of diabetes and diabetes prevention and management skills. Further, the project aims to improve the external factors often impacting homeless people's access to effective diabetes care.
Methods: Using the Wagner Chronic Care Model as the guiding principal, the project provides innovative and accessible diabetes screening, prevention and management programs. In order to fully understand the complex needs of the target population, both homeless population and community partners are actively engaged in all stages of the project. All project activities are provided by a multidisciplinary team at the settings where homeless people congregate - Calgary Drop-In & Rehab Centre. The project team is actively involved in improving the availability of diabetes medications and healthy foods to homeless people.
Results: More than 50% of the homeless people are identified at-risk for diabetes, 15-30% has elevated blood glucose and 10% has physician diagnosed diabetes. Access to appropriate primary care, prescription coverage, healthy food and housing are identified as major barriers to effective diabetes care. Innovative diabetes care approaches have resulted in enhanced awareness, access and patient outcomes. Stakeholders have become more responsive to the unique needs of the homeless population.
Conclusions: Active engagement of the homeless people and organizations serving the homeless and dealing with the "whole person" and "their world" are critical in identifying the barriers, needs and best strategies for effective diabetes care. This initiative could serve as a model for delivery of effective diabetes interventions for marginalized populations worldwide.

Organizing a strategic public health approach to addressing diabetes during disasters

A. Albright[1], P. Allweiss[1], K. Ernst[1], B. Rodriguez[1]
[1] Centers for Disease Control & Prevention, Division of Diabetes Translation, Atlanta, USA

Aims: The need to treat chronic conditions is especially magnified when there are catastrophic disruptions of the medical infrastructure, when access to medical care and medications is severely compromised or completely cut-off, and when large-scale evacuations of the population occur. Since diabetes has reached epidemic proportions and has so many related co-morbidities, the need to prepare this vulnerable population at times of disasters has increased. Multiple sectors are involved in responding to emergencies so an integrated approach is necessary for developing preparedness plans. Plans need to address pre, during, and post disaster issues.
Methods/results: The U.S. Centers for Disease Control and Prevention (CDC) has organized a work group in the Division of Diabetes Translation (DDT) to facilitate and provide leadership to enhancing a public health response to diabetes during disasters. The areas of focus are: (1) Educating personnel dedicated to emergency preparedness within CDC about diabetes and other chronic diseases; (2) Forming partnerships with and training first responders, shelter personnel, health care providers, and pharmaceutical/device companies to increase capability for emergency response; (3) Providing diabetes-related educational tools and data to prepare for and respond to emergencies.
Discussion/conclusion: The CDC's mission is collaborating to create the expertise, information, and tools that people and communities need to protect their health – through health promotion, prevention of disease, injury and disability, and preparedness for new health threats. As part of fulfilling this mission, DDT is actively working to improve the emergency response for those with diabetes and other chronic conditions during disasters. Prevalence of diabetes at the county level is being introduced to several groups to aid in preparing for emergencies and is being used in preparedness drills at CDC. Training and educational materials for various audiences have been developed by CDC and several partners and are available for use. Efforts are underway to hold a meeting to discuss medication/supply distribution and stockpile issues to be more effectively prepared for disasters. Strategies used, lessons learned, materials developed and future plans will be discussed.

Screening for depression in type 2 diabetes: should we use the BDI (Beck Depression Inventory), the HADS (Hospital Anxiety and Depression Scale), or a modified measure to correctly identify depression ?

S. Sultan[1], O. Luminet[2], A. Hartemann[3,4,5]
[1] Université Paris Descartes, Institut de Psychologie, Boulogne Billancourt, France
[2] Université Catholique de Louvain, E.C.S.A., Louvain-la-Neuve, Belgium
[3] University Pierre et Marie Curie-Paris 6, School of Medicine, Paris, France
[4] Assistance Publique-Hôpitaux de Paris (AP-HP), Paris, France
[5] Pitié-Salpêtrière Hospital, Diabetes Department, Paris, France

In order to compare the performance of two screening instruments for clinical depression, we administered the Beck Depression Inventory and the Hospital Anxiety and Depression Scale to 298 patients with type 2 diabetes recruited from an outpatient unit at Pitié-Salpêtrière hospital (Paris, France). Clinical depression was assessed with the depression modules of the MINI structured interview. We conducted factor analysis on self-report depression items to determine core components of depressive symptoms. Criteria for evaluating performance of self-reports were derived from logistic regressions and ROC curve analyses. Results showed that the BDI has better properties to correctly identify depression than the HADS (in its original version). The ability to correctly identify clinical depression is different according to current patients' regimen (oral versus insulin). Results are discussed in light of the recent literature.

Living sexuality in the context of Diabetes: body and gender constructions of Cuban and Peruvian people

L. Ledon-Llanes[1], B. Fabre[1], J. Chirinos[2], M. Mendoza[1], A. Agramonte[1], C. Garcia[1], A. Hernandez[3], J. Hernandez[3]
[1] National Institute of Endocrinology, Psychology, Ciudad de La Habana, Cuba
[2] Peruvian University Cayetano Heredia, Public Health and Administration Faculty, Lima, Peru
[3] National Institute of Endocrinology, Diabetes Care Center, Ciudad de La Habana, Cuba

Aims: Gender constructions and meanings related to the own body and health care process are fundamentals in the identity conformation and sexual expression. Considering the limited literature about representations and social meanings that support sexual experiences of people living with Diabetes Mellitus, the study explored meanings of sexual experiences of people living with Diabetes Mellitus from Cuba and Peru.
Methods: There were carried out two segments of the qualitative study: the first one with 10 Peruvians and the second one with 10 Cubans (both groups, women and men). For some people, Diabetes Mellitus was associated to other endocrine diseases (acromegaly, Cushing's syndrome), and all of them were living with body changes as a result of endocrine diseases. There were used an in-depth interview guide and two projective tests. Interviews were recorded and all the information was qualitatively processed, validating it through technical and theoretical triangulation. Ethical aspects were considered.
Results: Sexuality was constructed from a normative sense that demands a strict coherence between biological sex, gender experiences and ways of body representing. Endocrine diseases experienced, body changes resulting and difficulties to accomplish with traditional gender roles, were experienced as a "break" of this "coherence", having a deep impact over their sexualities and identities, especially in men. Even when some differences appeared related to cultural context and particularities of endocrine disease, almost all men referred having changed their life because of their sexual dysfunction and difficulties to sustain their traditional roles as economic providers, while women expressed the deep impact of body changes over their sense of attractiveness and desirability.
Discussion/conclusions: An important dimension of the deep impact that sexuality changes had for these people was related to the sustaining of traditional gender constructions. Cultural context, endocrine illness processes and gender identities defined some particularities in the way they lived their sexualities. It was a general experience living a complex process of "broken identity".

Medical center for Intendedly Displaced People from Abkhazia

D. Khorava[1], S.H. Sharia[1], E. Patsatsia[1], R. Kurashvili[2], E. Shelestova[2], L. Tsutskiridze[2]
[1] Ministry of Labor Health and Social Affairs, Abkhazia, Tbilisi, Georgia
[2] Georgian Union of Diabetes and Endocrine Associations, Endocrinology dept., Tbilisi, Georgia

The Medical Center for Intendedly Displaced People (IDPs) from Abkhazia was rehabilitating in the framework of the American-Georgian Military Education Humanitarian Aid Program and under the financial support of the Government of Abkhazia. The Joint Medical Center for IDPs was officially opened in July 2008. The Center will carry out the program for IDPs with diabetes mellitus (DM) "Multifactorial Intervention in patients with DM and Metabolic Syndrome". The Program at its initial stage plans to provide complete laboratory investigations and various counseling for 50 IDPs with the pathologies. In 10 selected participants continuous glucose monitoring will be carried out; 200 participants will undergo diabetes education course; 22 people with diabetes will receive glucose-monitoring means and test strips. The Program will be carried out under the initiative of the Ministry of Labor, Health and Social Defense (MLHSD) of Abkhazia, financial support of the Government of Abkhazia, in close partnership with the Georgian Diabetes Center/Georgian Union of Diabetes and Endocrine Associations (GUDEAS) and participation of the "Caucasus Medical Group". The Program was supported by the IDF-Europe. Official opening of the Center was attended by the Ambassador of the USA in Georgia; Chairman of the Medical Committee of the Georgian Parliament, Minister of Refugees, Minister of LHSD, Chairman of the Government of Abkhazia, members of Abkhazia Government, President of GUDEAS and representatives of local NGOs. IDPs need serious attention and support from the Government and the society in whole. Each program is a step forward aimed at establishing diabetes services for IDPs.

TIDES: being prepared for an emergency

0263

TIDES: being prepared for an emergency

D. Jones[1]
[1] King Edward VII Memorial Hospital, BHB Diabetes Centre, Paget, Bermuda

Recent disasters such as Hurricane Katrina and the Tsunami have highlighted the need for relief agencies and diabetes associations to focus on emergency preparedness. Hurricane Katrina was one of the most powerful storms to ever hit the United States. It left in its wake, the loss of medical records and closure of health care facilities which adversely affected the health of many with diabetes.
Many of those in shelters had no medical records and this made it very difficult for the health care providers to replace their medication. Many arrived for help and the only information provided was that they had been on a "blue pill" or "yellow pill".
The purpose of this talk is to identify the many problems patients with diabetes face in the time of a disaster including low literacy rates, generic versus brand names and not understanding the importance of taking their medications.
Education is key. I hope that this talk will not only identify the importance of patient education in respect to medication adherence but will assist in providing some insight into why medication compliance has been poor and how it can be addressed. A summary of a survey on medication compliance in Bermuda will be part of this presentation.

Food and diabetes: what's the fuss?

0264

Home cooked vs fast food

A. Gibor[1], S. Rattray[1]
[1] Fresh Ideas, Catering, Plettenberg Bay, South Africa

A brief introduction to Scott and Andy. Who we are, what we do and why we were invited to speak at the seminar, including our experiences with friends, family and guests who also have diabetes.
Outline our topics and define the difference between natural and refined food products as well as slow food compared with fast food. Detailed advantages of home cooked meals and the ease of cooking them.
List the natural ingredients that can be used to assist with diabetes, stressing the point that in no way are any natural remedies a replacement for medicine that has been prescribed by a doctor.
Describe ways to ensure a balanced diet that assists in balancing blood sugar levels, what foods help and what foods hinder. Discuss meal guidelines emphasising that managing your diabetes with food does not mean that you have to lead an un-natural lifestyle. Breakdown the various food groups and suggest alternatives for a balanced diet focusing on the more natural and slow methods of growth and cooking. We will cover aspects such as what happens to various foods during the cooking and storage processes and what the implications to glucose and blood sugar levels there may be. We will also link our session to other sessions in particular food labelling.
A cooking demonstration will be done in conjunction with our talk and will include various cooking suggestions, hints and tips in general and will demonstrate how to cook a delicious meal.

Children with diabetes: teams, targets, technology and therapeutic education

T. Danne[1]
[1] International Society for Pediatric and Adolescent Diabetes, Kinderkrankenhaus auf der Bult, Hannover, Germany

Half a million children in the world are affected by diabetes with approximately 70,000 new cases every year. Ever-increasing efforts are necessary to accomplish the mission statement of the International Society for Pediatric and Adolescent Diabetes "A better world for children and adolescents with diabetes" under the diverse challenges to pediatric health worldwide. Recent developments indicate that approaches focussed on age-appropriate education of patient, family and other caregivers in intensified insulin treatment are successful in many places. These efforts have been shown to lead to an improved long-term prognosis.
Ideally, the child with diabetes should have access to a specialised multidisciplinary team of diabetes healthcare professionals. The therapeutic goal of a normal somatic and psychosocial development combined with a glycemic target of an HbA1c of below 7.5% for children of all ages has been adopted by many paediatric diabetes centres. On the other hand, recent findings put less emphasis on the long-term risks of severe hypoglycaemia. Thus, there has been a paradigm shift in the treatment of pediatric diabetes. The majority of pediatric diabetologists now believe that the gold standard treatment is intensified insulin therapy. It should mimic the physiological insulin profile as closely as possible thereby allowing the flexibility required with the lifestyle needs of children with diabetes. The choice of rapid-acting, short-acting, intermediate acting, long-acting insulins and insulin analogues as well as devices like insulin pumps and glucose sensors have led to many new pediatric treatment options.
The European SWEET-project (www.sweet-project.eu) is developing a largescale international IT-based benchmarking. This allows to monitor outcome quality as a basis for exchanging best practice models in pediatric diabetology. It is likely that with better understanding of the molecular, medical and psychosocial mechanisms involved, the next advances in the treatment of children of all forms of diabetes are just around the corner.

Physical activity and diabetes: what to prescribe, why and how?

0267

Physical activity and diabetes: what to prescribe, why and how?

R. Sigal[1]
[1] University of Calgary, Medicine, Calgary, Canada

There is increasingly strong evidence for the value of physical activity/exercise in people with diabetes. However, implementation of this evidence is often a challenge. Health care practitioners often have little or no training in exercise prescription, patients may lack motivation to become more active, and there are competing demands on the time of both patients and health care practitioners. In this session we will briefly review current physical activity recommendations and the evidence behind them, but will focus primarily on practical strategies to translate the evidence on physical activity into action.

MEET-THE-EXPERT

First line combination therapy for type 2 diabetes

0268

First line combination therapy for type 2 diabetes

B. Zinman[1]
[1] *University of Toronto, Mount Sinai Hospital, Toronto, Canada*

Type 2 diabetes mellitus (Type 2 DM) is a progressive disease and for most patients, glycemic control will deteriorate over time. Insulin resistance and beta-cell dysfunction are the two most important pathophysiologic mechanisms responsible for the progression from normoglycemia to impaired fasting glucose (IFG), impaired glucose tolerance (IGT) and ultimately to Type 2 DM. In the United Kingdom Prospective Diabetes Study (UKPDS), the early and initial drop in A1c as seen with monotherapy was followed by a progressive deterioration over time whether the patients were treated with insulin, sulfonylureas, or metformin. In another analysis of the UKPDS data, the investigators demonstrated that only a small portion of patients were able to achieve an A1c of less than 7% on monotherapy and that this portion consistently decreased for all therapies over the 3, 6 and 9 year period of follow up.
The current strategy for managing Type 2 DM involves the use of pharmacology that targets pathophysiology. Since most therapeutic agents for the management of Type 2 DM achieve an approximate 1% decrease in A1c, it is not surprising that combination therapy will be required. The need for combination therapy should be recognized early, and in many patients it is entirely appropriate to initiate combination therapy shortly after diagnosis. It is also important to appreciate that Clinical Practice Guidelines are evolving and that currently the Canadian Diabetes Association and the American Diabetes Association Clinical Practice Guidelines recommend an A1c target of less than 7%.
In summary, there is clear consensus that the current management of diabetes is less than optimal and a more targeted approach to glycemic control using multiple agents will be required in order to achieve the desired outcome of reducing complication risk.

HEALTHCARE AND EPIDEMIOLOGY

Primary prevention programmes for diabetes: lifestyle vs drugs

0269

Lifestyle

D.M. Nathan[1]
[1] *Massachusetts General Hospital, Medicine, Boston, USA*

The worldwide epidemic of type 2 diabetes continues unabated with a projected prevalence of more than 250 million people in the next decade. The risk factors for diabetes that appear to apply to all populations, in the setting of polygenic risk, include sedentary lifestyle, increasing body fat, and ageing. The current inability to modify genetic risk and the lack of enthusiasm to shorten lifespan as means of confronting the diabetes epidemic have translated into efforts to ameliorate those environmental factors that underlie the epidemic. Specifically, lifestyle programs to increase activity levels and reduce body mass have been studied to determine whether and to what extent they can prevent or delay diabetes. Several studies, conducted in far spread parts of the world, have demonstrated a powerful effect of lifestyle interventions to decrease and delay the development of diabetes. The relatively uniform results of lifestyle intervention, decreasing the development of diabetes by ~40-60%, translate into an average four or more year delay of diabetes in many populations. Contrary to expectations, older persons have had a particularly robust benefit with lifestyle programs. Longer-term follow-up results of several of the largest studies have been carried out and demonstrate a durable effect of lifestyle interventions. Relatively few studies have included a medication arm, but the largest of the prevention studies, the Diabetes Prevention Program (DPP) compared metformin and a lifestyle intervention program. The DPP demonstrated in its initial clinical trial period that lifestyle intervention was approximately twice as effective as metformin in preventing the development of diabetes in a high-risk population.
This presentation will review the available clinical trial data that demonstrate the pluripotent effect of lifestyle intervention programs on diabetes prevention as well as their effect on reducing cardiovascular disease risk. These data will be compared and contrasted with the available data with medications.

0270

Drugs

J. Chiasson[1]
[1] *CRCHUM, Université de Montréal, Montréal Quebec, Canada*

The prevalence of pre-diabetes and type 2 diabetes is growing at an epidemic rate worldwide. We now know that we can prevent or at least delay the progression of pre-diabetes to diabetes. This raises the question, which prevention strategies should be adopted: a pharmacological or a non-pharmacological strategy? I would like to make a case in support of the pharmacological approach.
All the trials that assessed the efficacy of lifestyle modification on the progression of IGT to diabetes are consistent; if sustained, diet and exercise reduce the conversion of IGT to diabetes by 29 to 67%. The problem, however, is that lifestyle modification, particularly weight reduction, is difficult to achieve and even more difficult to maintain on the long term. Fortunately, a number of drugs are now available for the prevention of diabetes.
The Chinese Prevention Trial, the Diabetes Prevention Program and the Indian Diabetes Prevention Program showed that metformin could reduce the risk of diabetes in subjects with IGT by an average of 34%. The Chinese Prevention Trial and the STOP-NIDDM Trial demonstrated in subjects with IGT that acarbose reduces the risk of diabetes by 43%. In the latter study, acarbose treatment was also associated with a 49% risk reduction in cardiovascular events and a 50% reduction in the progression of the IMT of the carotids. The DREAM Study showed in pre-diabetics that rosiglitazone could reduce the risk of diabetes by 60%. And finally, in the ACT-NOW Study, pioglitazone reduced the incidence of diabetes by 82% in IGT subjects.
Diabetes can be prevented. A healthy lifestyle should always be encouraged at all stages of life. Drug should not replace lifestyle modification but should be used judiciously in conjunction to lifestyle modification in a well structured program.

Grant-writing for translational research

K.M. Venkat Narayan[1], *M.B. Weber*[2]
[1] *Emory University, Global Health, Atlanta, USA*
[2] *Emory University, Nutrition and Health Sciences, Atlanta, USA*

Translational Research seeks to bridge the gap between scientific research and the community by translating available knowledge so that it is practical and usable to everyday public health and clinical practice. This workshop will address key components of translational research projects and tips for writing translational research grants, with a focus on phase-two translational research, which promotes the adoption of the fruits of promising clinical research by the community-based health care system under uncontrolled and (often) uncontrollable conditions. The workshop will cover the following: (1) necessary project components, including study aims and objectives, background, research plan, and sustainability; (2) tips for grant writing; and (3) avoiding common pitfalls.

Genome-wide association scans for obesity and diabetes

0272

Genome-wide association scans for obesity and diabetes

N.J. Wareham[1]
[1] Institute of Metabolic Science, MRC Epidemiology Unit, Cambridge, United Kingdom

The field of the genetics of diabetes and obesity has been rapidly advanced by the availability of new technology and by its application in large co-ordinated studies. Previously progress in identifying the genetic basis of type 2 diabetes from either linkage studies or candidate gene association studies had been limited, with only PPARγ and KCNJ11 being proven to be associated with diabetes. The technological advance of genomewide association studies has led, at the time of submission of this abstract, to the identification of 20 genetic loci that are convincingly associated with disease. Analyses in large consortia will identify further loci. The implications of these discoveries for increasing understanding of the aetiology of diabetes will be discussed, as will the role of these loci in disease prediction. Progress in understanding the genetic basis of obesity had been even slower than for type 2 diabetes, but the availability of GWAS has resulted in the discovery of FTO and a series of other loci convincingly associated with obesity. This talk will discuss prospects for uncovering gene-lifestyle interaction of risk of obesity. Although progress following the introduction of GWA studies has been remarkable, most of the genetic variation underlying diabetes and obesity remains to be discovered. A series of alternative explanations beyond common variants may explain this missing heritability.

EDUCATION

Health literacy: what is its implication for education?

0273

Health literacy: what is its implication for education?

J. Piette[1]
[1] University of Michigan, Internal Medicine, Ann Arbor, USA

Patients' health literacy level determines their abilities to manage a host of different skills related to diabetes self-care, including: understanding medication regimens, identifying and reaching behavior change goals, communicating effectively with their clinical team, and negotiating the bureaucracy associated with healthcare use. Limitations in health literacy are a potent risk factor for difficulties in self-management and poor outcomes. However unlike other barriers to successful diabetes management for patients around the globe, health literacy deficits can be addressable via a number of approaches to self-care support during and between outpatient encounters. In this session, we will discuss recent research on the epidemiology of health literacy in diabetes, including recent efforts to understand the specific mechanisms linking literacy problems to patient outcomes. We then will review practical methods for identifying patients who have health literacy deficits in real-world clinical environments. Finally, we will discuss ways in which clinicians can improve self-management support for diabetes patients who have health literacy problems by increasing the quality and frequency of interactions. In particular, we will discuss projects in Latin America designed to give clinicians and limited literacy patients the tools they need to be successful.

ASSOCIATION DEVELOPMENT

Traditional medicines in diabetes care

0274

Traditional medicines may be a cost-effective option in treating diabetes

G. Nindorera[1]
[1] Burundi Diabetes Association, Civil Society, Bujumbura, Burundi

Is the traditional medicine cost effective in healing diabetes?
Case of Burundi.
In spite of its small area, Burundi has a population of 8 million people whom 90% live in rural area with not enough infrastructure (schools, hospitals, transport, etc.)
Throughout the country, there are both true and false traditional healers who, according to their saying are able to heal any disease. Both say also that they have been inspired by spirits or inherited from their parents.
Some of those healers are organised in associations but each keeps his knowledge as a secret as it is a source of revenue. There is no study done in healing diabetes but those healers keep on saying they are able to heal it. Unfortunately all those who ran to consult them, go back to modern physicians at the end of the day.
The opinions of the administration and of the modern physicians diverge for there is no public presentation of the traditional products. That is why one product can be administered to many patients suffering from different diseases.
Conclusion: People will always run to those traditional healers by belief but whenever they can afford it they go to the public health centers or hospital.
At the beginning, one could say it doesn't cost a lot but at the end you find that you lost the wealth and the health.

Traditional medicines must be validated by associations before being accepted as cost-effective diabetes care

K. Tossou[1], S. Adziah[1], A. Davon[2]
[1] Association Togolaise du Diabete, diabetes association, Lomé, Togo
[2] Association Togolaise du Diabete, diabetes center, Lomé, Togo

Aim: This study tries to determine the contribution of diabetes associations for the validation of traditional medicine as cost-effective diabetes care
Method: 469 diabetics, representing 30% of diabetic attendees followed by diabetes educators and physician at the Association Togolaise du Diabete (ATD) centre in Lome, who resort to traditional medicine, have been dispatched into the following 3 groups: the first one (Group1) representing 30% of the total is characterized by the use of usual medicinal plants known for their hypoglycaemic activities, such as Momordica charentia, Cathrantus roseus, used under different forms (decoction, infusion, maceration); the second group (Group2:15%) has used different remedies sold by traditional healers; the last group(Group3:55%) combine medicinal plants with usual antidiabetic drugs The main parameters observed are: Fasting glycaemia, BMI, Blood pressure, type of side effects, monthly costs of treatments. Interviews, contacts with traditional healers, health personals, and researchers of consultation of data records, done.
Results: the average glycaemia was 1, 89+- 1,2g/l for Group1, 2,39+ 0,99g/l for Group2 and 1, 21+ -0,28 g/l for Group3. Some side effects such as nausea, vomiting, itches, diarrhoea and palpitations were observed in less than 5% of cases. 2 cases of death were reported for the group2. The average monthly costs were respectively 1,50 Euros for Group1, 15 Euros for Group2, and 10 Euros for Group3. In these last 6 months, the percentage of traditional medicine users (Group1+Group3) has increased from 30% to 70%, while that of traditional healers remedies (Group3) decreased to less than 5%.
Conclusion: Evidently, this diabetes association knows how to appreciate the cost-effectiveness of traditional medicine, identify and dismiss quacks, easer money and dreams sellers among traditional healers, and so, has the ability to validate successfully traditional medicine before being used as cost effective diabetes care

CLINICAL RESEARCH

Statistical interpretation of clinical trials in diabetes

0276

Statistical interpretation of clinical trials in diabetes

J. Lachin[1]
[1] George Washington University, The Biostatistics Center, Maryland, USA

This presentation begins with a description of the principles of statistical inference that include the concepts of the type I (false positive) and type II (false negative) error probabilities, power and sample size. Factors that affect the type I error probability are described that include various types of biases, as are factors that affect power. These include the influence of multiple tests and missing data. The intention-to-treat principle, both for the design and analysis of trials is described and contrasted with so-called efficacy or per-protocol analyses in which various exclusions are applied. The potential bias introduced by missing data, and its inflation of the type I error probability, is described. The limitations of statistical methods are reviewed and the intention-to-treat design described so as to minimize the potential for bias. The Diabetes Control and Complications Trial as an intent-to-treat trial is contrasted with other trials in which there was substantial missing data. The preservation of power with an intent-to-treat design is also described. Multiple tests of significance, subgroup analyses, and primary plus secondary analyses and their potential weaknesses are described.

DEBATE

ASSOCIATION DEVELOPMENT

The associations should take the lead in offering diabetes care

0277

Let us not blame only IDF, what are we ourselves doing for diabetes care?

W. Lee[1]
[1] Diabetic Society of Singapore, advisor, Singapore, Singapore

Let us not blame IDF, what are the associations themselves doing for diabetes care? The IDF has been criticised for being irrelevant to and far removed from the needs of member associations. Often this arises from a misunderstanding of the complementary roles and responsibilities of the IDF and its member associations. The IDF leads globally, national associations serve locally.
The IDF is Global flag bearer and advocate, establishes standards and best practices, promotes sharing and exchange of ideas. The IDF is an ideal executive partner for charitable foundations to fund pilot projects for proof of concept and widespread rollout such as the Unite for Diabetes campaign and the the Western Pacific Declaration on Diabetes, and the Task Forces on Insulin, Diabetes Education.
The national diabetes associations should perform the same role within a local context. The national associations will have the local expertise to decide and act on national priorities.
The national association can liaise with IDF and other external bodies such as ISPAD, WHO and aid agencies to identify local needs, serve as points of contact and also to vet and sponsor deserving individuals for exchange programmes. Examples include the Tanzanian Diabetes Association collaboration with the World Diabetes Foundation, Diabetes Australia's role in distributing diabetes supplies, and the Insulin for Life programmes.
Well resourced national associations, like the Finnish Diabetes Association, and the American Diabetes Association, are able to help establish national standards. All national associations should be promoting diabetes awareness and help persuade people to access appropriate care
Local associations also need to make a case for IDF funding and support for their projects. IDF's resources are to be shared with all its members, based on need and the capacity to benefit
National associations must do their part and not just wait for IDF to act.

No conflict of interest

0278

Has IDF forgotten us ?

L. Ipai[1]
[1] Port Moresby General Hospital, Internal Medicine, Port Moresby, Papua New Guinea

Papua New Guinea (PNG) is part of the Western Pacific Region (WPR). It comprises a large volcanic and 600 smaller scattered islands. Topographically it is among the most rugged in the world. Population is around 6 million. Diabetes first emerged in 1970's as a disease of major Public Health concern in various South Pacific communities, previously regarded as "paradise". Attention was first drawn when a prevalence study in Nauru revealed that about 30% of population had diabetes, an exceptionally high rate second only to Pima Indians. Later studies showed high rates also in some PNG populations, particularly Wanigela and some other coastal tribal groups.
WPR region has 25% of global population and 30% of world's diabetic population. There is great diversity of culture, lifestyle, and affluence. Onset of diabetes is increasingly being diagnosed in younger age groups, e.g. 40-59 years. There is a strong association with obesity brought about by urbanization and Westernization, probably due to deleterious environmental and behavioral changes of acculturation which unmask genetic susceptibility.
There are many challenges facing island nations. Barriers such as great distances, rugged terrains, low literacy levels, low socio-economic status plus poor infrastructure are obstacles to proper management of diabetes. Drugs are expensive and supply inconsistent. Routine tests to monitor diabetes status are often not done due to costs.
In 2000 the Western Pacific Declaration on Diabetes was made by the WHO-WPRO, IDF-WPR and SPC. IDF's contribution to the island nations in the region appears to be not visible. We need IDF's expertise as a partner in achieving common goals. In this age of globalization poor nations seem to be getting poorer, while rich nations get richer, and health is no exception. I believe IDF can do more in technical input, assisting with access to drugs and treatment, strengthening national associations etc.

DEBATE

LIVING WITH DIABETES

Healthy lifestyle - diet vs exercise

0279

Exercise

A. Farquhar[1]
[1] Family Practice, Family Practice, Kelowna, Canada

To debate the relative merits of exercise and diet in the context of diabetes is indeed a very weighty matter and perhaps in fact rather artificial since it is well accepted that both diet and physical activity are key components in achieving good diabetes control.
In the management of diabetes lifestyle factors are critical. For most people achieving weight loss can be frustratingly difficult. There is no question that calorie reduction through alteration of diet is the most effective way to lose weight. Unfortunately there are so many different diets, all of which have some expert from somewhere (Oprah to Atkins) propounding their diet's particular benefits. The whole issue of dietary advice can be confusing and challenging for not only the layperson, but also for professionals.
A "diabetic diet" is a term that is still frequently used and in my opinion is not only misleading and useless, but has significant negative connotations.
My presentation will emphasize the multiple benefits of regular exercise that go far beyond easily measured physical/physiological indices. Living well with diabetes is about much more than diet and A1C and Blood pressure and Cholesterol. It's about living a full and active life uncluttered by the myths and misconceptions (often diet based) that still, sadly, shroud diabetes.

0280

Diet

D. Cairns[1]
[1] London, United Kingdom

Diet can evoke a range of advice and guidance over what is the optimum eating habits for people with diabetes.
After losing my boyhood dreams to fly jets in the British Royal Air Force in 1989 to diabetes, I quickly realized the importance of diet in helping to control diabetes. However, everybody's experience of diabetes, and diet within one's diabetes management, is different. And guidance can vary around the world.
My own experience has been to adopt a "moderate diet", effectively "lower carbohydrate" which in turn I believe has helped me achieve a normal life and career. In addition it has helped allow me to return to my flying dreams, including two flying projects, www.diabetesworldflight.com and www.diabetesflight48.com.
The first flying project resulted in meeting many communities and people with diabetes while passing through 22 countries, with fascinating insights into diabetes management in different parts of the world. It ranged from Samoa where diet seemed naturally "carbohydrate rich", to meeting Ron Raab in Australia, who was, and still is, a proponent of low carbohydrate diets.
My talk in October will include observations, recommendations and guidance from different parts of the world, and anecdotes of people's experience of "what can work" with respect to diet and diabetes.

CLINICAL RESEARCH

Prediabetes: which organ is the culprit?

0281

Beta cell

S.E. Kahn[1]
[1] VA Puget Sound Health Care System and University of Washington, Division of Metabolism Endocrinology and Nutrition Department of Medicine, Seattle, USA

For many years it has been clear that the beta cell is defective in individuals with established type 2 diabetes. This abnormality can be demonstrated following stimulation of insulin release both intravenously and orally. Recognition that insulin sensitivity is an important determinant of the beta-cell's response to stimulation has advanced our understanding of the critical role played by the beta cell in glucose metabolism. Thus, examining insulin responses simultaneously with insulin sensitivity has made it clear that prediabetes is also characterized by beta-cell dysfunction and that diminished insulin release is a characteristic of the pathogenesis of type 2 diabetes around the globe.
Reducing the progression from prediabetes to type 2 diabetes has involved two broad approaches, intensive lifestyle intervention and medications, both of which have been aimed at decreasing insulin resistance and enhancing beta-cell function. These interventions have proven effective and the beneficial changes in glucose tolerance have been shown to occur in part as a result of improvements in beta-cell function. Thus, future endeavors to either prevent or slow the progression from prediabetes to diabetes have to be cognizant of the critical role the beta cell plays in determining abnormalities of glucose tolerance.

0282

Muscle

G. Shulman[1]
[1] Yale University School of Medicine, Howard Hughes Medical Institute, New Haven, USA

Despite much work, the cellular mechanisms responsible for insulin resistance in type 2 diabetes and the metabolic syndrome remain unknown. Recent NMR studies have demonstrated increases in intramyocellular lipid content in young lean insulin resistant offspring of parents with type 2 diabetes, suggesting that dysregulation of fatty acid metabolism may be responsible for mediating the insulin resistance in these individuals. In this lecture I will present data that supports a unifying hypothesis for insulin resistance in muscle and liver where imbalances between fatty acid delivery vs. mitochondrial oxidation leads to net accumulation of intracellular diacylglycerol, which in turn activates novel PKCs leading to decreased insulin signaling and insulin action. I will also discuss recent NMR studies demonstrating that insulin resistance in skeletal muscle can promote the development of atherogenic dyslipidemia (increased triglycerides and decreased HDL concentrations) and NAFLD by promoting increased hepatic lipogenesis following carbohydrate consumption.

No conflict of interest

0283

Liver

M. Roden[1]
[1] German Diabetes Center, Dept. Metabolic Diseases Heinrich-Heine University, Duesseldorf, Germany

The liver is the primary organ to control gluconeogenesis and the temporary storage of glucose as glycogen. Moreover, prediabetic states, e.g. obesity, inherited insulin resistance in relatives of humans with type 2 diabetes (T2D) and women with previous gestational diabetes, are frequently associated with increased content of hepatocellular lipids, also termed steatosis or nonalcoholic fatty liver (NAFL). Steatosis not only correlates with components of the metabolic syndrome and insulin resistance, but also predicts the development of T2D and its cardiovascular complications. Elevated liver fat may be due to partitioning of free fatty acids to the liver (fat overflow) and to imbalanced release of adipocytokines thereby stimulating inflammatory pathways, e.g. protein kinase C, the transcription factor nuclear factor kB, and c-Jun N-terminal kinase 1. This will lead to typical features of the metabolic syndrome: production of triglyceride-enriched lipoproteins with increased circulating triglycerides and decreased HDL-cholesterol, and systemic low grade inflammation giving rise to C-reactive protein. However, the hepatic abnormalities underlying the development of NAFL per se remained unclear. Using magnetic resonance spectroscopy we recently reported that decreased hepatocellular inorganic phosphate and ATP levels could serve as markers of altered mitochondrial function leading to steatosis in human liver. Furthermore, short-term dietary intervention studies provided evidence for rapid regulation of liver fat and insulin sensitivity preceding any changes in muscle fat content. In conclusion, the liver is critical for metabolic fluxes and inflammatory processes which underlie insulin resistance and the metabolic syndrome.

0284

Adipocyte

T. Kadowaki[1], T. Yamauchi[1]
[1] Graduate School of Medicine, Department of Metabolic Disease, Tokyo, Japan

Adiponectin is a fat-specific hormone which is the most abundantly expressed adipokine in white adipose tissue (WAT). Adiponectin sensitizes the body to insulin and obesity is accompanied by decreased plasma adiponectin levels, which plays a pivotal role in metabolic syndrome and type 2 diabetes - linked to obesity. Adiponectin also directly suppresses atherosclerosis via multiple pathways such as anti-inflammatory action. Adiponectin mediates its biological effects via its plasma membrane receptors, AdipoR1 and AdipoR2. In fact, adiponectin KO mice as well as AdipoR1/AdipoR2 double KO mice show insulin resistance and impaired glucose tolerance. In liver, adiponectin activates AMPK and PPARα via AdipoR1 and AdipoR2,respectively, causing suppression of gluconeogenesis and lipogenesis and stimulation of fatty acid oxidation. In muscle, adiponectin activates AMPK via AdipoR1, causing stimulation of glucose uptake and mitochondrial biogenesis.In endothelial cells, adiponectin protects from increased neointimal formation in response to cuff-injury via AdipoR2. Obesity is also accompanied by decreased expressions of adiponectin receptors in liver, muscle and WAT, which is also causally involved in obesity-linked insulin resistance. Upregulation of plasma adiponectin and adiponectin receptors as well as development of adiponectin receptor agonists may serve as fundamental and versatile therapeutic strategy for obesity-linked morbidities such as metabolic syndrome, type 2 diabetes and atherosclerosis.

Brain

S. Obici[1]
[1] *University of Cincinnati, Medicine, Cincinnati, USA*

There is a large body of evidence indicating that the brain plays a crucial role in orchestrating the regulation of peripheral glucose and lipid metabolism. Moreover, evidence shows that abnormalities in CNS circuits contribute to the failure of normal glucoregulatory mechanisms. Neural pathways that regulate energy balance are often overlapping with those that regulate glucose metabolism. Hence, the common link between obesity and type 2 diabetes might involve these common CNS circuits. We will review the current evidence supporting a role for the CNS in the control of glucose homeostasis and in the pathogenesis of type 2 diabetes.

0286

Integrated Approach

L. Ji[1], *X. Zhang*[1]
[1] *Peking University People's Hospital, department of endocrinology, Beijing, China*

Recent advances in genomics, transcriptomics, proteomics and metabonomics technologies offered a great opportunity for more comprehensive understanding of pathophysiology and etiology of complex diseases such as diabetes and obesity. Metabonomics, a novel methodology arising from the post-genomics era, provided an approach which bridges the gap between other "omics" measurements and metabolic end product, since metabolites can be identified and quantified, which reflect the general status of humans more precisely. With its integrated characteristics, this strategy has begun to be employed in pre-clinical and clinical researches, which provide potentially important clues to disease etiology and healthy management. A number of investigations have also been reported to understand the diabetes related metabolic alterations.
We analyzed the serum metabonomic characteristics of Chinese population with normal glucose tolerance (NGT), impaired glucose regulation (IGR) and type 2 diabetes (T2DM) using the metabonomics approach based on the combination of NMR spectroscopy and multivariate data analysis. This study showed a clear metabonomic trajectory from NGT to IGR and further to T2DM, probably indicating the presence of a continuous progressive development axis for the glucose intolerance severity. Furthermore, we found that compared with NGT subjects, the IGR and T2DM participants showed clear serum metabonomic changes highlighted with the dysfunctions of choline metabolism, glucose metabolism, lipid and amino acid metabolisms, and disruptions for lactate and TCA cycle. We can postulate that the abnormal metabolism of nutrient substance by liver, muscle, adipose tissue, and gut microbiota, form a network of inter-regulation in the development of diabetes.

SYMPOSIUM

The diabetic foot updated

0287

Community based foot programmes

H.C. Pedrosa[1], *S.G. Mello*[1], *P. Teixeira Filho*[1], *M.S.O. Dias*[2], *M.B. Gomes*[3], *D.G. Armstrong*[4], *R. Frykberg*[5], *A.J.M. Boulton*[6]
[1] *Health Secretary, Programme of Diabetes, Brasilia, Brazil*
[2] *Associação de Diabéticos, Conselho Científico, Brasilia, Brazil*
[3] *State University of Rio de Janeiro, Endocrinology and Diabetes, Rio de Janeiro, Brazil*
[4] *University of Arizona, Southern Arizona Limb Salvage Alliance, Tucson, USA*
[5] *Veterans Affairs Hospital, Podiatry, Phoenix, USA*
[6] *University of Manchester, Diabetes Centre, Manchester, United Kingdom*

Despite the rise of Diabetes and a dramatic poor control (A1C > 7.0% among 75%) there is not a proper policy to prevent complication: a report verified registration exam for eye, foot and microalbuminuria 47%, 58% and 39%, respectively. There are no amputation official data but a few hospital based studies show a prevalence of 45-75%. To circumvent the unawareness among health professionals the Brazilian Save the Diabetic Foot Project started to be implemented in 1992 in Brasilia, where a 77% trend towards major amputation reduction was reached (2000-2004) after the Foot Centre had been set up. Primary care surveys found 7-10% high risk patients (ulcer/amputation) not followed by specialists. Workshops have been delivered for doctors and nurses: over 60 out-patient centres have been implemented. The foot care status has not been followed properly due to a lack of support and ongoing education (firstly addressed by the Project). To urgently reevaluate the Project a Rescue Plan (RP) has focused community care by: 1) diagnosing loss of protective sensation, 2) developing a basic podiatry course, 3) providing education (patients / families), 4) reinforcing the referral-counter referral. The pilot RP shall involve a mobile unit to deliver care in deprived areas comprising 67 health centres (a 559.671 > 40 yr population, 11% DM = 57.163). A 70% screening target by 402 professionals encompasses 40.012 and will be inserted in the Health Secretary institutional framework, supported by the Associação de Diabéticos de Brasília and spread to other Brazilian states in the future.

0288

The acute Charcot foot of diabetes

W. Jeffcoate[1], *F. Game*[1]
[1] *City Hospital, Foot Ulcer Trials Unit, Nottingham, United Kingdom*

The acute Charcot foot remains a fascinating enigma. Despite the major morbidity which may result from it, little is known of its causes or its best treatment. Research is made very difficult by the rarity of the condition, and by the absence both of an agreed definition and of reliable diagnostic markers. This means that ever since Charcot's day, understanding has been based largely on uncontrolled observations made on selected series of patients with established disease, and on speculation. Current thought centres on the possibility that the key process in the development of the condition is local inflammation, and that this triggers osteolysis and predisposes to fracture and fracture-dislocation of the bones and joints of susceptible individuals. It has further been suggested that the process may be potentiated by the loss of neuropeptides such as calcitonin-gene related peptide, CGRP, resulting from the underlying neuropathy, and that it may be mediated through the RANKL/OPG signalling pathway. If correct, this hypothesis opens the door to a number of new therapeutic options. The hypothesis has also sparked further work into the processes linking bone breakdown and arterial calcification in diabetes, both of which are linked to neuropathy. This, in turn, has led to increasing awareness of the adverse effect of arterial calcification on left ventricular strain, and the realisation that distal somatic neuropathy, with or without Charcot's disease, is itself an independent risk factor for cardiovascular mortality.

No conflict of interest

0289

Advances in diabetic foot ulcer care

R. Sibbald[1], *K. Woo*[2]
[1] *Women's College Hospital, Dermatology, Toronto, Canada*

Persons with Diabetes are prone to develop foot ulcers. Based on VIPS (Adequate vascular supply, infection and critical colonization control, plantar pressure redistribution and sharp surgical debridement), clinicians can determine if ulcers are healable, non-healable or maintenance wounds.
Local Wound Care includes **DIM** before **DIM*E*** (**D**ebridement**, I**nfection **& I**ncreased bacterial burden control along with **M**oisture Balance) before the **E**dge effect representing Advanced Therapies becomes a reasonable option for healable wounds.
There is some evidence that sharp surgical debridement creates an acute wound within a chronic wound and this method of debridement may facilitate healing in healable wounds compared to more conservative measures.
Surface increased bacterial burden as determined by any three signs from the mnemonic NERDS (**N**on-healing, ↑**E**xudate, **R**ed friable granulation tissue, **D**ebris on the surface and **S**mell) is reliable and sensitive for surface bacterial damage responsive to topical antimicrobial dressings. Deep and surrounding skin infection as defined by any three signs of the mnemonic STONEES (↑Size, ↑Temperature Os: probing/ exposed bone, ↑New areas of breakdown, ↑exudate, Erythema or Edema, and Smell) determines the need for a systemic antibiotic. Both clusters of signs are both sensitive and specific.
Moisture balance can be achieved with the correct matching of exudate to moist interactive dressings. If a wound bed is adequately prepared and a wound fails to heal, Advanced therapies including growth factors, skin substitutes and negative pressure wound therapy may have a role to accelerate healing. (Table 1)

Table 1: Advanced Therapies for Diabetic Neurotropic Foot Ulcers

Advanced Therapy	RCT or Meta-analysis	Results
Oasis	Yes	Complete healing equal to PDGF
Growth Factors (PDGF)	Yes	Complete healing
Apligraf	Yes	Complete healing
Dermagraft	Yes	Complete healing
Hyperbaric Oxygen Therapy (HBO)	Yes	Prevention of Amputations
Therapeutic Ultrasound	Yes	Complete healing
Negative Pressure Wound Therapy (NPWT): post surgical complete healing	Yes	Decreased Wound Size

Revascularization approach

A. Piaggesi[1]
[1] *University of Pisa, department of Endocrinology and Metabolism - Diabetic Foot Section, Pisa, Italy*

Peripheral Arterial Disease (PAD) represents the most important risk factor for lower extremity amputations (LEA) in diabetic patients, and it affects 49% of diabetic foot (DF) patients. Beside the high risk of LEAs, PAD is associated to a high cardiovascular co-morbidity, such that it is considered as a marker of mortality in these patients.
The possibility of a peripheral revascularization, both endovascular and surgical, particularly in below knee (BK) arteries, changed the prognosis of a large number of patients, in the same way that coronary angioplasty and by-passes changed the prognosis of ischemic heart disease.
Endovascular techniques, have been demonstrated to be at least as safe and effective in the management of PAD as traditional surgical approach, but their repeatability, the lower impact on the general conditions of the patients and the wider indications make them the first-choice strategy for the multi-complicated DF patients.
Unluckily even today, there's some confusion about indications and results evaluation of the endovascular treatment; DF patients have specific clinical aspects which make difficult their classification following the usual criteria.
A multidisciplinary approach in highly specialized centers is the key for achieving a positive and durable clinical success, which should address all the components – local and systemic – that contribute to determine the complexity of these cases.
The management of the local aspects of the DF, as well as the treatment of the systemic pathologies that are most frequently present in these patients have the same importance than the technical success of the revascularization procedures, to heal the patients.
Follow-up and surveillance programs of DF patients submitted to revascularization procedures are mandatory to delay as much as possible recurrences, frequent and severe, worsening an already critical scenario; new promising drugs and technologies, including regenerative medicine options, are now available to cope with this task.

Can we treat diabetic neuropathy?

S. Tesfaye[1]
[1] *Sheffield Teaching Hospitals, Sheffield, United Kingdom*

There is now little doubt that poor blood glucose control is an important risk factor for the development of diabetic peripheral neuropathy (DPN). Furthermore, recent research has shown traditional cardiovascular risk factors for macrovascular disease to be associated with an increased risk of DPN.
There is now strong evidence implicating nerve ischaemia as the cause of DPN. Studies in man and animal models have revealed reduced nerve perfusion and endoneurial hypoxia. These vascular changes strongly correlate with clinical defects and nerve pathology. Clear differences in epineurial blood flow and thalamic magnetic resonance spectroscopy have been demonstrated between subjects with painful and painless neuropathy. Overall, the evidence emphasises the importance of vascular dysfunction, driven by metabolic change, in the aetiology of DPN, and highlights potential therapeutic approaches.
Unfortunately, apart from glycaemic control, there is as yet no treatment that can stop/delay the progression of diabetic neuropathy. However, new compounds have emerged in the symptomatic management of painful and autonomic neuropathies.
Epidemiological data on Diabetic Painful Neuropathic Pain (DPNP) are limited. In one population-based study the prevalence of DPNP, as assessed by structured questionnaire and examination, was estimated at 16%. It was notable that, of these patients, 12.5% had never reported symptoms to their doctor and 39% had never received treatment for their pain. Thus, despite being common, DPNP continues to be underdiagnosed and undertreated. Pharmacological treatment of DPNP includes Tricyclic compounds, SNRIs, SSRIs, anticonvulsants, opiates, membrane stabilisers, the antioxidant alpha lipoic acid, topical capsaicin etc. Over the past 5 years new agents with less side effect profiles have emerged. Management of the patient with DPNP must be tailored to individual requirements and will depend on the presence of other co morbidities.
Finally, there have been recent developments in the treatment of troublesome postural hypotension, and the management of diabetic gasroparesis with pyloric Botulinum toxin injection and gastric pacing.

Screening for diabetes: moving to reality?

0292

Rationale for screening

S.J. Griffin[1]
[1] Medical Research Council, Epidemiology Unit, Cambridge, United Kingdom

Type 2 diabetes (T2DM) is frequently asymptomatic, the true onset occurring several years before diagnosis. Around 30-50% of people with T2DM remain undiagnosed, and around 20-30% already have complications at diagnosis. T2DM therefore meets many of the criteria for suitability for screening, however important uncertainties remain.

Justification for screening programmes requires that the overall benefit of testing, resulting mainly from earlier intervention, is greater than any possible harms of testing the population. Whether this criterion is met for T2DM screening remains uncertain. There are no trials and few data on the effects on mortality and morbidity of population-based screening, but modelling studies report reductions in diabetes-related mortality of up to 40%. Studies on the potential harms of screening have mainly focused on those screening positive, showing limited evidence of adverse psychological effects. However, the effect of screening on health behaviours such as physical activity, diet and health service use is uncertain. As the majority of those screened test negative, even a small adverse effect may outweigh a large benefit to the few testing positive.

Intensive treatment of multiple risk factors in patients with established T2DM halves mortality. However, recent trials raise doubts about the effects of intensive treatment of glycaemia in this group, but highlight the benefits of glucose-lowering early in the course of the disease. Earlier onset of intensive glycaemic control may reduce cardiovascular risk. However, there is no trial evidence that detection by screening followed by intensive multi-factorial treatment improves cardiovascular outcomes, or that treatment effective for clinically diagnosed patients produces greater benefit when commenced earlier. This is a critical but unknown parameter in assessing the balance between the costs and benefits of screening.

The arguments for and against screening for T2DM will be reviewed and new data that address many of the outstanding uncertainties will be presented.

Cost-effectiveness of screening

S. Colagiuri[1]
[1] Institute of Obesity Nutrition and Exercise, University of Sydney, Sydney, Australia

Screening and early detection is one strategy for minimising the individual and societal impact of type 2 diabetes. While a logical theoretical approach, as yet there are no outcomes studies which demonstrate the effectiveness of this strategy, although the ADDITION study is currently underway.

A number of screening protocols are in use with the most common involving screening for high risk individuals based on clinical information, followed by a laboratory test. In general, the cost of detecting a case of undiagnosed diabetes is low but varies according to the screening protocol. Screening procedures which use routinely available information to identify people at high risk of diabetes or are linked to other screening programs are usually about US$500 for each case detected. Overall these costs are considered reasonable and generally affordable in the context of opportunistic screening programs in countries with well developed health systems.

Since there are no definitive outcome studies on the effectiveness of early intervention in people with screen-detected diabetes, there can be no definitive statement of its cost-effectiveness. However, a number of models have been developed to address this issue. It should be noted that the outcomes of these modelling exercises are dependent on the model structure and assumptions, particularly the estimated clinical benefits of the modelled scenario. Using the US CDC model, the cost per QALY gained by a one time opportunistic population screening of all people over age 25 was estimated at US$57,000.

Screening programs are more likely to be cost-effective if combined with prevention interventions for people found to be at high risk of the future development of diabetes as well as treating people with newly diagnosed diabetes as illustrated in modelling studies from the UK and Australia.

Non-invasive: FINDRISC and others

J. Tuomilehto[1]
[1] University of Helsinki, Public Health, Helsinki, Finland

The risk of type 2 diabetes (T2DM) may be approximated by certain characteristics, so-called risk factors that are associated with the development of the disease. Ideally, risk factors are causal; many of them are relatively easy to determine and some of them may favorably be altered by interventions in order to prevent the progression of hyperglycaemia. Such scores can be used for the identification of undiagnosed T2DM or to predict the future T2DM. Models to develop scores have included various demographic, anthropometric, behavioral and biochemical parameters. The predictors, and in particular their classification varies among different populations and ethnic groups. Only a few T2DM risk scores have been developed to predict the development of the disease. The current ADA website has a simple diabetes risk-prediction test based on non-laboratory data from six questions, relating to height, weight, age, exercise, family history of diabetes and for women, the birth weight of a baby.

There are several other risk scores to detect either undiagnosed diabetes or the future risk of diabetes that have been recently developed in several populations. The FINnish Diabetes RIsk SCore (FINDRISC) was developed as a self-administered questionnaire specifically designed to identify individuals according to their future risk of developing T2DM without the need for laboratory tests. Multivariate analyses and validation were performed using data from the 1987 and 1992 FINRISK studies, respectively. Individuals who completed a questionnaire received a clinical examination including an FPG and an OGTT at the start of the study and the endpoint during follow-up was drug-treated diabetes. The final FINDRISC uses eight questions related to age, BMI, waist circumference, use of antihypertensive agents, history of hyperglycaemia, physical activity, and consumption of fruit, berries and vegetables (www.diabetes.fi). Its sensitivity, specificity and prediction based on AUR-ROC are robust. Individuals with low scores are very unlikely to develop T2DM and can be excluded from further investigation and allow resources to be focussed on those in the higher-risk groups. The FINDRISC is playing a central role in the current Finnish Type 2 Diabetes Prevention Programme. Individuals with higher scores are advised on lifestyle changes within the primary health care and are also given an OGTT to identify undiagnosed T2DM. The FINDRISC was the main tool in pan-European screening and prevention program, the **D**iabetes in **E**urope: **P**revention using **L**ifestyle, Physical **A**ctivity and **N**utrition Intervention (DE-PLAN) project, and it is now widely used in Europid populations.

Several risk scores for the identification of asymptomatic T2DM have been developed in a number of populations. Whether a score was developed for the identification of undiagnosed T2DM or to predict the future T2DM, it seems that most parameters the models have are more or less the same, and also across populations. The differences seem to relate the relative weight of each parameter and cut-points to be used. Diabetes risk scores are useful tools and offer the solution for screening for T2DM and T2DM risk in primary care and by lay people.

0295

Invasive: FPG and OGTT

E. Ur[1]
[1] University of British Columbia, Endocrinology and Metabolism, Vancouver, Canada

Diabetes mellitus (DM) is a serious worldwide health problem, associated with significant, preventable complications. Screening has been advocated in order to facilitate early intervention. Whilst the glucose cut off for the disease has been defined based on risk for microvascular complications, glucose as a risk for cardiovascular disease (CVD) has a continuous relationship. Debate has surrounded the concept of pre-diabetes – lower levels of dysglycemia associated with enhanced risk of progression to diabetes and CVD.

The diagnostic gold standard was the OGTT, a test that assessed both fasting glucose and the response to a standardized glycemic challenge. Its practical challenges meant that the fasting plasma glucose (FPG) has been added as an alternative. However, problems with the FPG include logistic difficulties and that 20% of individuals with glucose below 6.9 mmol/l will have DM on an OGTT as they have a deficiency that is only manifest with a glucose challenge. In addition, FPG cannot identify Impaired Glucose Tolerance (IGT).
Alternatives to screening with FPG or OGTT include A1C (glycosylated hemoglobin) testing and risk calculation using questionnaires.
The A1C test is not standardized in many parts of the world and though it provides a simple index of glucose exposure, it is also sensitive to hemoglobinopathies and anemias. The recently proposed addition of A1C to the diagnostic maze would be an unhelpful contribution to the existing confusion.
Questionnaires have been validated in specific ethnicities, but widespread use may be limited in diverse populations.
In conclusion, screening for diabetes should be done by FPG in high risk populations, with a OGTT in individuals with risk factors and elevated (but non-diabetic) FPG. Pre-screening tools (eg A1C, questionnaires) can potentially be used to identify high risk individuals in overall low risk populations; these individuals should then undergo glucose testing (FPG, and OGTT if necessary).

LIVING WITH DIABETES

Stress: the critical factor in type 2 diabetes?

0296

Stress in utero

P. Wadhwa[1]
[1] *University of California Irvine, Psychiatry OB/GYN and Pediatrics, Irvine CA, USA*

Epidemiologic studies suggest that birth phenotypes such as birth weight are associated with subsequent health and disease risk. It is unlikely that this association is causal, because birth weight is, at best, a crude marker of conditions during fetal life that also may directly influence the physiology of the developing individual to produce long-term consequences. We and others have suggested that exposure to prenatal stress may represent one such condition in intrauterine life that has the potential to significantly impact long-term health and disease risk (Wadhwa, 2005). To test this hypothesis, we conducted a study in a sample of healthy young adults with normal birth outcomes born to healthy women with healthy uneventful pregnancies. One half of the study population was born to mothers who had experienced a major stressful life event during the index pregnancy (prenatal stress group; PS), whereas the other half was a sociodemographically-matched population with no history of maternal exposure to prenatal stress (comparison group; CG). Assessments were performed to examine (i) body composition and glucose-insulin metabolism (BMI; basal and post-OGTT levels of glucose, insulin, leptin, adiponectin; fasting lipid profile), (ii) immune function (immune cell trafficking and LPS-stimulated production of pro- and anti-inflammatory and Th1/Th2 cytokines), (iii) endocrine function (basal and post behavioral/pharmacological stress levels of pituitary-adrenal stress hormones, chronobiological regulation of adrenal function, and assessment of HPA-axis feedback sensitivity), and (iv) cognitive function (working memory under basal and hydrocortisone conditions). Our results indicated that the young adults exposed during intrauterine life to maternal psychosocial stress consistently exhibited a significant dysregulation of all these key physiological parameters, thereby placing them at increased risk for developing clinical disorders. Specifically, individuals in the PS group exhibited primary insulin resistance and a lipid profile consistent with the metabolic syndrome (Entringer et al, 2008a), altered immune function with a Th2 shift in the Th1/Th2 balance (consistent with increased risk of asthma and autoimmune disorders; Entringer et al, 2008b), altered endocrine function, with an increased ACTH and reduced cortisol response to stress (consistent with the high-risk endocrine profile exhibited by individuals exposed to early life neglect/abuse; Entringer et al, 2009), and reduced cognitive function (impairments in working memory performance after hydrocortisone administration; Entringer et al, 2009, in press). These findings thereby suggest (a) that ***in utero*** exposure to maternal psychosocial stress may confer negative long-term physiological consequences, and (b) the effects of prenatal stress may directly influence adult health without necessarily being mediated by adverse birth phenotypes such as low birth weight.

Chronic stress, visceral obesity and type 2 diabetes

C. Tsigos[1]
[1] *YGEIA Hospital, Department of Endocrinology, Athens, Greece*

Chronic stress represents a prolonged threat to homeostasis that can progressively lead to a deleterious overload and complications caused by both the persistent stressor and the detrimental prolongation of the adaptive response. Stress and emotional status have long been suspected as having major effects on glucose homeostasis. These effects are mediated by glucocorticoids and catecholamines, the principal effectors of the stress response. Epidemiological data provide evidence for a significant positive association between cortisol levels, and hence of the activity of the hypothalamic-pituitary-adrenal (HPA) axis, and the salient features of the metabolic syndrome, particularly visceral obesity and insulin resistance, and the risk for developing type 2 diabetes and atherosclerosis. Moreover, visceral obesity, an unconventional low grade inflammatory state, is characterized by the capacity of adipocytes to express and secrete proinflammatory hormones and cytokines that activate the acute phase reaction and may act as additional chronic stimulus to the activation of the HPA axis. Thus, a vicious cycle may develop, whereby stress-induced chronic mild hypercortisolemia contributes to insulin resistance and adipocyte growth and accumulation, particularly in the visceral depots, and ***vice versa***. Understanding better the underlying mechanisms of these complex interactions will hopefully provide novel insights into the pathophysiology of visceral obesity, type 2 diabetes and their cardiometabolic complications and will help introduce appropriate therapeutic interventions.

Inflammatory stress

J. Pickup[1]
[1] *King's College London School of Medicine, Guy's Hospital, London, United Kingdom*

Although type 2 diabetes (unlike type 1 diabetes) has not been traditionally regarded as a disease of the immune system, there is increasing evidence that activation of the innate immune system and chronic low grade inflammatory stress play a major role in the pathogenesis of type 2 diabetes and the metabolic syndrome, and associated clinical and biochemical features. The evidence for this includes abnormal blood levels of acute-phase reactants in type 2 diabetes (e.g. triglyceride, C reactive protein [CRP], fibrinogen, sialic acid, low levels of albumin, testosterone, zinc etc). Epidemiological clues that inflammatory stress is related to type 2 diabetes include the graded increase in inflammatory markers with increasing features of the metabolic syndrome and the many studies which show that elevated inflammatory markers and proinflammatory cytokines predict the onset of type 2 diabetes. Indicators of inflammation (e.g. elevated serum sialic acid) are amongst the strongest independent predictors of cardiovascular mortality in type 2 diabetes and it is likely that activated innate immunity is the common antecedent of both type 2 diabetes and atherosclerosis. Anti-inflammatory drugs such as aspirin reduce CRP and triglyceride and at the same time lower glycaemia and insulin resistance. The IL-1 receptor antagonist anakinra has recently been shown to reduce glucose levels and improve insulin secretion.
Stressors that produce inflammation in type 2 diabetes include increasing age, inactivity, obesity, diet, smoking and psychological stress. These are modified by individual susceptibility caused by racial and genetic factors and low birth weight. Adipose tissue is an important inflammatory source in type 2 diabetes, not only because of cytokines produced from adipocytes (e.g. TNFalpha, IL-6, reduced adiponectin etc), but also because of infiltration of fat by proinflammatory macrophages. Macrophage infiltration and inflammation of the islets also seems to be a key part of the pathogenesis of type 2 diabetes.

0299

Oxidative stress

A. Ceriello[1]
[1] Warwick Medical School, Department of Diabetes, Coventry, United Kingdom

The different forms of diabetes share high level of glucose in the blood and the tendency to develop a series of complications highly costly in terms of longevity and quality of life. Recent findings connect diabetic complications to high glucose generated oxidative stress. High glucose determines superoxide production at mitochondrial electron transport chain level. Superoxide reacts with nitric oxide producing peroxynitrite that determines DNA single strand breaks and PARP activation. GAPH modification operated by PARP enzyme determines the activation of the four major pathways known to be linked to diabetic complications: the augmented flux of polyol pathway, the increased formation of advanced glycated end products, the activation of protein kinase C and the increase of the hexosamine pathway flux. Different ***in vivo*** and ***in vitro*** studies support this unifying theory that is opening new perspectives in the development of strategies to control diabetes complications, but is also casting a different light on the molecules already in use.

Monoclonal antibody-based approaches in type 1 diabetes

K. Herold[1], V. Ablamunits[1], B. Bisikirska[2]
[1] Yale University, Immunobiology, New Haven, USA
[2] Columbia University, Medicine, New York, USA

Clinical studies have shown that the loss of insulin production in the first years of Type 1 diabetes can be attenuated by treatment with FcR non-binding anti-CD3 monoclonal antibody (mAb). These studies have also shown improvement in insulin requirements. The mechanism of the anti-CD3 mAb in humans is not clear however. MAb treatment causes a transient reduction in the number of circulating CD3+ T cells but the kinetics of the changes in cell counts and the expression of T cell receptor excision circles (TRECs) suggests that the recovering cells are not new thymic emigrants. We had found that clinical responders to anti-CD3 mAb treatment could be identified by an increase in the relative number of circulating CD8+ T cells. When CD8+ T cells are isolated from patients treated with anti-CD3 mAb they show regulatory function ex vivo. In vitro, we have found that CD8+ T cells cultured with FcR non-binding anti-CD3 mAbs acquire regulatory function and inhibit proliferation of CD4+ T cells. The cultured cells express Foxp3, CD25, GITR, and CTLA-4. TNF-α is required for their induction. The effects of TNF-α for induction of the cells involves signaling through the TNFRII that is expressed on the most potent CD8+ Tregs. We conclude that anti-CD3 mAb can induce long term attenuation of progression of Type 1 diabetes. Our studies suggest that anti-CD3 mAbs induce CD8+ Tregs in vivo. The expression of TNFRII identifies the most potent adaptive CD8+ Tregs.

Autoreactive CD8+ T cell specificities in human type 1 diabetes

B.O. Roep[1]
[1] Leiden University Medical Center, Leiden Diabetes Center & Dept. Immunohaematology, Leiden, The Netherlands

Type 1 diabetes is a T cell-mediated autoimmune disease with β cells being the target of the autoimmune destruction process. The mechanism of destruction is still unknown, but recent evidence points to CD8 T cell autoreactivity associated with autoimmunity and loss of β cell function in new onset type 1 patients as well as recurrent autoimmune islet destruction in type 1 diabetic islet transplant recipients. Indeed, circulating CTLs can kill β cells via recognition of a glucose-regulated epitope. These results also identify a mechanism of self-antigen presentation that is under pathophysiological regulation and could expose insulin-producing β cells to increasing cytotoxicity at the later stages of the development of clinical diabetes.
To allow fast detection of low frequency circulating islet autoreactive CD8 T cells, we developed a fast and high-throughput assay determining T cell responses in stored blood of T1D patients using quantum dots (Qdots) as fluorochromes to generate peptide-HLA multimers instead of conventional tetramers. This allowed the simultaneous screening of eight different epitopes derived from Insulin, Pre-pro-insulin, IA2, GAD65, IGRP and pplAPP, with high specificity and sensitivity. Increased frequencies of circulating islet autoreactive T-cells were detected in T1D patients at disease onset compared to non-diabetic controls. Changes in their absolute numbers were detected after clinical islet transplantation and during clinical immunotherapy.
Our studies imply that CD8+ autoreactive T cells are involved in the final pathway of β cell destruction leading to insulin deficiency, hyperglycemia, and clinical type 1 diabetes. Our findings further suggest that autoreactive CTLs are important targets for immune-based interventions in type 1 diabetes and argue for early, aggressive insulin therapy to preserve remaining β cells.

Antigen-driven pancreas-specific immunosuppression by autoreactive CD8+ T cells

P. Santamaria[1], S. Tsai[1], A. Shameli[1], J. Yamanouchi[1], P. Serra[1], Z. Medarova[2], A. Moore[2]
[1] Julia McFarlane Diabetes Research Centre (JMDRC) University of Calgary, Department of Microbiology and Infectious Diseases Institute of Infection Inflammation and Immunity, Calgary, Canada
[2] Harvard Medical School and MGH, Department of Radiology, Charlestown MA, USA

Blunting autoreactivity without compromising systemic immunity remains an elusive goal in the treatment of autoimmunity, including type 1 diabetes (T1D). Traditionally, vaccines have been used to expand T- or B-lymphocytes capable of affording protection against pathogens or cancer, or to delete T- or B-lymphocytes capable of causing autoimmunity. Here, we propose to cure T1D by using a 'vaccine' that induces the expansion (rather than the deletion) of autoreactive CD8+ cells. This new type of 'vaccine' consists of nanoparticles that are coated with autoantigenic peptide/MHC class I complexes. Such particles selectively induce the expansion, in an antigen-specific manner, of small pre-existing pools (generated spontaneously during disease) of memory low avidity autoreactive CD8+ T-cells having exquisite, non-antigen-specific, anti-diabetogenic properties. High-avidity (pathogenic) autoreactive CD8+ clonotypes are not expanded by this treatment because, unlike their low avidity counterparts, they do not spontaneously differentiate into memory cells during diabetogenesis, presumably because they die in response to chronic stimulation with self-antigen. Most importantly, these peptide/MHC-coated nanoparticles can not only blunt the progression of insulitis to overt diabetes in pre-diabetic animals, but also restore normoglycemia in acutely diabetic NOD mice. Therapy was inconsequential in 'autoantigen-inexperienced' mice; and diabetic mice engineered to bear an immune system blind to a therapeutic epitope, hence lacking epitope-experienced T-cells, were specifically refractory to the cognate pMHC-nanovaccine. The observation that pMHC-nanovaccines blunt autoimmunity by boosting autoregulatory T-cell memory exposes a novel paradigm in the pathogenesis and treatment of autoimmunity.

No conflict of interest

0303

Antigen-specific versus non-antigen specific antidiabetogenic strategies

A. Lernmark[1]
[1] Lund University/CRC, Clinical Sciences, Malmö, Sweden

The pathogenesis of type 1 diabetes (T1D) is proposed to progress over several stages. Subjects are born with genetic susceptibility largely conferred by HLA. Islet autoimmunity is triggered in these genetically predisposed individuals and ß-cell killing by cellular immunity is activated leading to insulin deficiency. The autoimmune insult of progressive and selective killing of β cells, may take months to years. Throughout this autoimmune prodrome several genetic, autoimmune and biochemical markers may predict the disease prior to clinical

onset. Once the clinical disease is established, the patient will be dependent on exogenous insulin and will require strict control to sustain euglycemia and minimize complications. Primary prevention trials, for example using nasal insulin in Pre-POINT are considered. Gluten-free diet was given to islet autoantibody-positive children in the PREVFIN trial without any significant preventive effect. The TRIGR trial is an international effort to test if hydrolyzed casein milk formula can reduce T1D risk among high-risk infants. Vitamin D (cholecalciferol) is tested in an ongoing randomized, feasibility pilot study in Manitoba, Canada. The Nutritional Intervention to Prevent Diabetes (NIP-Diabetes) is testing a proposed preventive effect of oral docosahexanoic acid (DHA) against islet autoimmunity. Secondary prevention trials with parenteral insulin in islet autoantibody positive first-degree relatives did not prevent T1D. Non-antigen-specific agents without effects were cyclosporine, BCG vaccine, ketotifen, and nicotinamide, as in ENDIT and DENIS. Tertiary prevention trials have been antigen-specific or non-antigen specific. Immune modulation with alum-formulated GAD65 shows promise to reduce the loss of ß cells. Numerous intervention trials with immune suppression have at best had transient effects in preserving residual β-cell function. CD3 monoclonal antibodies had some effects in postponing autoimmune ß-cell destruction with preservation of endogenous insulin production. Novel prevention and intervention trials are needed to prevent the triggering of autoimmune insult and to halt the autoimmune ß-cell killing.

EDUCATION

Establishing diabetes education in emerging countries

0304

Diabetes education development in China: a two decade story

Q. Lou[1]
[1] *Sir Run Run Shaw Hospital Zhejiang University Medical College, Nursing Education, Zhejiang, China*

Aims: To give an overall view of diabetes education in China, and assess and summarize evidence and gaps in the literature regarding diabetes education in China.
Methods: History review of diabetes education in China and systematic literature review.
Results and discussion: Diabetes education had a great impact on glycemic control in China, but China has a long way to go to improve the way they deliver diabetes education, for diabetes education in China is rather didactic, lack of structure or standards, behavior change is not emphasized, and most importantly, China does not have enough qualified diabetes educators. The literature review supports the conclusion that diabetes education can improve glycemic control in short duration and it also has some positive effect on lifestyle behavior. However, several limitations were noted in the literature reviewed. First, the design was not very reasonable. Frequently selected convenience samples and assigned to different groups according to patients' willingness could create bias. The second concern pertained to study methods. Many studies failed to report demographic information about sample groups; for example, source, education level, income, occupation, type and duration and complications of diabetes were not always adequately described. The third consideration was the variety of different outcomes measurements. Not a study mentioned blinding assessors. The reliability and validity of the instruments used to measure knowledge and behavior change were deficient. Last but not least, the duration of observation was rather short. The durations of most studies were 3-6 months, thus, the impact of diabetes education on chronic complications and medical cost could not be evaluated.
Conclusion: China should reform the way they deliver diabetes education, for example, set up standards for diabetes education, evolve diabetes education from didactic teaching to more theoretically based empowerment models, and long-term impact of diabetes education should be evaluated.

Diabetes education in Georgia

E. Shelestova[1], *R.B. Kurashvili*[1], *N.G. Asatiani*[1], *L.R. Tsutskiridze*[1], *M.G. Gordeladze*[2]
[1] *Georgian Union of Diabetes and Endocrine Associations, Clinical endocrinology, Tbilisi, Georgia*
[2] *Pediatric Hospital of Tbilisi State Medical University, Pediatric Dept, Tbilisi, Georgia*

Education of people with diabetes has become an integral part of diabetes care worldwide. Effect of education on treatment outcomes first was demonstrated in 1972. Unfortunately in 1970s we lived in society, where many ideas, common for international diabetes/scientific society were unacceptable. Though progress was "penetrating our everyday life". In the second half of 1980s leading centers started to implement patient education. In Georgia first "5-day in-patient education course" was initiated at the end of 1980s. It was carried out at the Dept. of Metabolic Disorders (now Georgian Diabetes Center/GUDEAS). The Course was based on M. Berger/V. Jorgens first books were translated into Georgian. Past 20-yrs were the hard period for our country – economic, energy, political crises, healthcare system (HCS) reorganization/lack of insurance system international processes. Still patient education was implemented at the Diabetes Center, Pediatric Hospital where most new cases of type 1 diabetes (T1DM) are supervised; later education was initiated in other places. Due to objective reasons, regular, obligatory group education courses for T2DM, could not be carried out though individual training was performed. Since 2000 we realized that only TPE could not improve the treatment outcomes, diabetes health professional education (DHPE) needs attention. Today education carried out by the GUDEAS includes: TPE, DHPE, Medical students, Society. Lately various institutions show interest in TPE; pharmcompanies start its sponsorship. Diabetes education is a complex system, where all elements are equally important. If only TPE is addressed – we will face reality where "Educated patient is too expensive". Thus, main goal is – change mentality of the whole society. This needs time and effort.

Diabetes education in Brazil: the successful experiences of FENAD, ANAD and ANBED

F. Fraige Filho[1]
[1] *FENAD, Medical Education, Sao Paulo, Brazil*

FENAD, **"National Federation of Diabetes Associations and Entities"**, joint of Brazilian Diabetes associations, acting in the advocacy of the people with diabetes offering guidance in the creation of new associations. It organizes an annual campaign involving more than 1000 Brazilian cities, disseminating information, guiding, and educating people on diabetes and its complications, preventions (~1 million glycemia tests). This action involves the Municipal Health Secretaries with their diabetes' professional team. The media also plays an important role disseminating education and awareness to every population levels.
ANBED, **"National Brazilian Association of Educators in Diabetes"** was conceived within the format of the American Association of Diabetes Educators, and IDF's guidelines. It created the first Post Graduate Course for the Formation of Diabetes Educators. The first presencial course started February 2008 and finished December 2009 with 360 hours, graduating 20 educators in diabetes. In 2009 it starts with Distance Learning Courses available to all States of Brazil.
ANAD, "National Association of Assistance to the Diabetes" with the mission of improving the lives of the people with diabetes has two lines of action: with the patients and with professionals through a continuous education in Diabetes.
Patients have an educational program with great success in captation, permanence and results, through educational techniques applied in interventions to specific groups.
The mass media education is done through periodicals, magazines, TV and radio programs with web site available, and printed educational material such as comics, cartoons, folders and books as well as glycemia tests campaign and diabetes complications prevention. An Annual Multidisciplinary Multiprofessional Congress is organized with courses in different areas: medical specialties, nutrition, nursing, psychology, physical activities, odontology, podology, an opportunity to recycle and update knowledge.

0307

Distance education for educators in India

S. Kakar[1]
[1] Lady Irwin college, Foods & Nutrition, New Delhi, India

Background: In India's urban areas, approximately 12 percent of adults live with diabetes, compared to only seven percent in the United States (CDC data, 2005) and the United Kingdom. With 40.9 million diabetics, India has the highest incidence of diabetes in the world. Additionally, research has identified a genetic factor that predisposes Indians to the development of diabetes.
There is a great need for trained health care professionals in India, including nurses, dieticians and nutritionists, to educate patients about proper diabetes care. Besides teaching basic aspects certain skills need to be imparted so as to make patients self-reliant in daily chores.
In India, specialized training for nurses is available for intensive care, coronary care, maternal and child health, dialysis and neurosciences. In a few isolated cases, nurses working in close liaison with specialists have been motivated to learn "care skills" and teach them to patients with diabetes. A couple of pharmaceutical firms have trained on short term basis, a few nurses in this field who are assisting physicians in few clinics in metropolitan cities.
There is no formally recognized diabetes management curriculum for allied health professionals in India. In 2007, Project HOPE launched the "India Diabetes Educator Project." A six-month distance learning program at training centers with onsite workshops will empower the allied health cadre of professionals. The curriculum includes patient empowerment to deal with daily self-care and prevention and management of complications. Forty Master Trainers (MTs) will be trained from 10 Diabetes Centers to ensure sustainability.
Methodology: International experts conducted screening of various medical centres throughout India and realized a strong need of imparting the knowledge and skills to effectively manage diabetes and empower patients living with diabetes. Further step was taken towards training professionals with some standardized skill based information regarding diabetes. Indian experts were roped in to ensure cultural adaptation and regional specific practices. Forty MTs will train 3000 allied health professions.
Outcomes: Training Centers were identified based on interest in strengthening diabetes management, good turnover of patients with diabetes, and adequate training infrastructure. Twenty-two MTs have been trained up till now. Distance learning mode was identified as the most cost effective to impart quality diabetes management. Onsite workshops were identified as contact points and standardization of training materials was done in order to attain uniformity. Workshop details, student assignments and other supplementary materials are provided in trainer manual. Training content, PPTs and methods for implementing interactive sessions are included on a CD - ROM.
Conclusion: By using distance learning technology reaching the maximum number of health professionals and imparting diabetes education will be rapid and effective.

ASSOCIATION DEVELOPMENT

Association and governments: interaction and co-operation

0308

Government-association interactions: how to go about this in the right manner

V. Basant Rai[1]
[1] Mauritius Diabetes Association, Rose Hill, Mauritius

The State has a governing responsibility to ensure that there is the required delivery of services within legislative and policy frameworks. The Government therefore accepts primary responsibility for the development of policies and legislation to facilitate and direct the design and implementation of service programmes in a given field.
It is the role of associations to deliver services efficiently and effectively within the framework of Government policies and strategies consulted and negotiated between associations and Government.
Associations must work in partnership with Government to achieve common aims and objectives. Associations are accountable to Government for their policies and service programmes. They must also be open, transparent and accountable to the public.
The right way for an association to interact and to go about conceptualising the partnership with Government is firstly to accept that both parties have a shared vision and responsibility for the delivery of appropriate services within set frameworks according to the needs and problems. Diabetes being an upsurging problem it is the shared vision of both to overpower this silent epidemic. As associations reflect the diversity of society, **firstly** they must promote local initiatives and problem solving. Through their work in a broad array of fields including the health sector, they must create **awareness** of the problem at the "grass root" level using the numerous volunteers associated with them. By empowering citizens to promote change in the community, they become the tool for change and Government recognises them as an advocacy group.
Secondly: private enterprises become aware of the local problem and tend to financially help the associations to carry out the set activities. Associations hence become a space between the profit making sector and the Government. Enterprises can negotiate with Government for other interests as they are also contributing in the shared vision of Government, creating a partnership across and among the 3 sectors.
Thirdly: associations take up challenges and enable social change, that the public and private sector simply cannot do. Government is then drawn to the associations to take risks that are economically unacceptable to business and politically unacceptable to Government.
In addition, non-governmental association advocacy campaigns induce a reluctant Government to adopt policy reforms and force improvements in business practices. Governments can force businesses to allocate a certain % of their profit annual for corporate social responsibility.

Harmonising interactions between governments and associations

M. Al-Lamki[1]
[1] WHO Collaborating Centre for Research &, Endocrinology, Seeb, Sultanate of Oman

Harmonizing means: to bring or come into agreement. Both Government and Association bodies have programs to follow. When one looks closely, the program may not complement each other, but rather compete in a contrary manner, or compete without resolve.
Both bodies should realize their limitations.
Each country has placed by-laws under which Associations are governed, so much so as to avoid misuse of funds and influence. Despite the by-laws, the manner, which the Government and Association address issues are contrary to the spirit of harmony.
Associations have to define their status on annual basis; "who are we",the organization, the programs in place, identify the partners and supporting roles. On the other hand – the Government bodies should do likewise and know "who are they".
One of the best examples on the issue of harmonizing between two or more bodies is the document, "International Harmonization of the Regulations on New Pharmaceutical Drugs". This has created precedence into safety of new drugs and other related issues.
Therefore, it would be valid for the International Diabetes Federation to lay ground rules to achieve harmonization and effectively gain the confidence from the various Governmental bodies, eg Department of Non-Communicable Diseases-hence oversee very important issues like availability of insulin, foot care programs etc.

Co-operation between associations, governments and international organizations

M.M. Omarova[1]
[1] Azerbaijan Diabetes Society, Republican association, Baku, Azerbaijan

Diabetes is a global problem having devastating human, social and economic impact. Today over 250 million people live with diabetes in the world. It is also estimated that 50% of people living with diabetes are unaware of their condition associated with diabetes. The low level of awareness is often due to inadequate national healthcare policies.
Social and economic costs of diabetes rise with the increasing prevalence of disease and its complications, which often lead to the premature disability and

death. Diabetes is the third cause of death from diseases following cardio-vascular disease and cancer.
Considering the number of people with diabetes (one in every five people in the world) all states suffer huge economic costs mainly due to social welfare benefits. On the other hand saving on diabetes and ignoring the disease leads to irrecoverable losses.
Governments are committed to the implementation of international instruments. The St. Vincent Declaration calls national governments for prompt and effective actions to improve life and health of people with diabetes. The UN Resolution on diabetes encourages governments to work out national policies for prevention, care and treatment of diabetes in line with the sustainable development of their health care systems taking into account the internationally agreed development goals. The pandemic of diabetes in the whole world requires urgent actions but governments and healthcare providers cannot bear the whole burden of diabetes. It is of crucial importance "to unite for diabetes" involving all stakeholders and combine their efforts. In this regard the triangle comprised of governmental institutions, associations and international organizations constitutes the core of the bridging gaps between normative acts and the reality. The participatory relations on both the vertical and the horizontal levels is the pre-requisite of making change.
In the presentation the roles and functions of these partners and the successful model of cooperation will be defined.

Interacting with the government to get the most for the cause of diabetes care

C. Phillip[1]
[1] *Diabetes Association of Trinidad and Tobago, Chaguanas, Trinidad and Tobago*

The epidemic of diabetes continues to threaten the economic and social development and the lives and health of millions of people. By the year 2025 it is estimated that there would be three hundred million (300) persons living with diabetes.
In the region of the Caribbean thirty five million (35) are currently affected and the World Heath Organization (WHO) forecasts an increase to sixty four million by 2025. In 2003 it was estimated that diabetes was related to some three hundred thousand (300,000) deaths in Latin America and the Caribbean, although official statistics link only seventy thousand (70,000) deaths to disease annually. Additionally the societal costs of diabetes were estimated at sixty five billion dollars in 2002.
Countries are now at a critical juncture and the time has now come for governments to implement comprehensive and integrated policies and programme and actions to reverse this deadly epidemic.
The Diabetes Association of Trinidad and Tobago's objective is to continue to partner with the government in promoting the health of persons with diabetes and to prevent or delay the onset of diabetes through Education, Advocacy and Research. The association has come a long way since 1988 Incorporated by an Act of Parliament of the T&T Government, Act No. 15 of 1988-89 as a charitable voluntary community service organization for diabetes.

Transitional care - adolescence to adulthood

0312

Transitional care - adolescence to adulthood

D. Hawkes[1]
[1] *Royal Gwent Hospital Newport, Paediatrics, Newport, United Kingdom*

Adolescents are now widely recognized as a distinct group of individuals with specific health needs. Transferring patients has been around as long as paediatricians. Simple transfer has been challenged in the last decade by 'transition', emphasizing the need for the change to adult care to be a guided educational and therapeutic process rather than an administrative event. The American Society for Adolescent Medicine define good transition as 'the purposeful, planned movement of adolescents and young adults with chronic physical and medical conditions from child-centred to adult-oriented health care systems'
Transition from paediatric to adult care is a major milestone and commonly poorly done. It coincides with other transitions occurring at this time of life:
From parental supervision to independence, from school to post school options. Anecdotal evidence suggests this is the period when young people with diabetes 'drop out' of the system, often having no specialist follow-up only picking up insulin prescriptions.
Evidence from our service suggests that failure to attend transition results in poor engagement with the adult clinic and a poor uptake of annual review appointments, thus increasing the likelihood of developing microvascular complications and increased mortality. Well planned transition programmes however, have measurable benefits for young people and their parents including improvements in clinical, educational and social outcomes. For these reasons transitional care should be a multidimensional, multidisciplinary process which addresses the medical, psychosocial and educational needs of the young person.
In this open forum I aim to discuss the specific needs of the adolescent, explore models of care and obstacles to good transition, review the literature, and share the views of young people and their families from a local clinic.

SPEAKERS' CORNER

Celebrating diabetes

0313

Celebrating diabetes

S. Sasseville[1]
[1] *Montreal, Canada*

An inspirational speech about a thrilling journey to the summit of Mt Everest. Sébastien Sasseville was the first Canadian living with type one diabetes to reach the highest point on earth, the third in history. In this session, Sébastien will be sharing precious lessons learned not only during the climb, but over the years spent preparing for Mt Everest. Diagnosed in 2002, he quickly decided to make diabetes the best thing that had ever happened to him. Sébastien will be talking about the process that leads to the acceptance of the disease, how to be empowered by obstacles and how diabetes can be gift. From base camp to summit via the Khumbu ice fall and the death zone, the audience will be taken on this iconic ascent through breathtaking pictures and the exciting stories. Climbing Everest is no small task, climbing it with diabetes is even riskier. This speech will address the different strategies and innovative solutions that were used on Sasseville's 2008 expedition. Most importantly, he will reinforce and share his vision that diabetes should not be a limitation and that people with diabetes can do anything they want.

Kathmandu Declaration: UNR implemention of prevention strategies

0314

Primary prevention

M. Wijesuriya[1], *R. Williams*[2], *C. Yajnik*[3]
[1] *National Diabetes Cetre, N/A, Colombo, Sri Lanka*
[2] *Swansea University, Clinical Epideminology, Swansea, United Kingdom*
[3] *King Edward Memorial Hospital, Diabetes Unit, Pune, India*

Kathmandu Declaration: UNR implementation
The Kathmandu Declaration was developed as an action plan of the IDF UNR on Diabetes 61/225 of 2006. This was formulated at the inaugural meeting of the Diabetes In Asia Study Group in Nepal October 2008. The main aim of

this declaration was to formulate and accept preventive strategies and their interactions in order to combat the pandemic of T2DM
A unique "Life circle" approach which encompassed the contribution of preconception, pregnancy, infancy and childhood and adult life was conceived taking into consideration the interactive nature of all aetiological factors in the different stages in life. The declaration included both primary and secondary prevention with greater emphasis placed on the former as the modality of reducing incidence or prevalence in the future.
It is hoped that most member associations of the IDF will accept the principles laid down in this declaration to enhance and institute quality care taking into consideration the Stepwise approach in their national health programmes in their respective countries.

0315

Secondary prevention

A.S. Bhoraskar[1,2]
[1] *Raheja Hospital, Diabetology, Mumbai, India*
[2] *Asian Heart Institute, Diabetes and Endocrinology, Mumbai, India*

Complications of diabetes are devastating both in terms of economics and individual suffering.The cost of managing complications is 3-4 times higher than the cost of treatment.There is adequate clinical data supporting merits of 'lifestyle' intervention programs.This along with drug treatment has shown significant reduction in complications of diabetes.
The UKPDS & DCCT studies have also shown that tight control helps to prevent microvascular complications. It is a well recognised fact that macrovascular disease and diabetes are 2 faces of the same coin, have a 'common soil', which predisposes an individual to both these conditions and the main culprit is faulty nutrition. Hence its correction appears to be the most logical step towards prevention of complications.
Statagies of secondary prevention: In keeping with the philosophy of the UN resolution,the Khatmandu Declaration has given clear cut guidelines which support a multifactorial, multisectorial & multidiciplinary approach to diabetes care.The multisectorial approach advocates the concept of total care in every aspect of the patients health, education, agriculture,sports mental & spiritual environment. Multidiciplinary approach involves participaton of healthcare professionals,patients, relatives, Government organisations, NGO's, religious leaders,celebrities and the industry.
Lifestyle modification: The role of nutrition cannot be underestimated. There is a strong evidence supporting this method of intervention in lifestyle modification.The present epidemic of type 2 DM and the macrovascular complications are due to faulty diets containing high amount of refined carbohydrates and omega-6 fatty acids.Diets rich in omega-6(n6) fats derived from so called 'heart friendly' 'cholesterol reducing' vegetable seed oils which have high n6 content and high n6/n3 ratio, along with depletion of anti-oxidants and absence of n3 fatty acids are the major risk factors which can be easily corrected by switching over to cooking media which have low n6/n3 ratio such as ghee, coconut or olive oil.Avoiding fried, processed, preserved, refined food and energy dense drinks can certainly help managing type 2 DM.

Why hasn't islet transplantation worked?

R.L. Hull[1], J. Udayasankar[1], S.E. Kahn[1]
[1] VA Puget Sound Health Care System and University of Washington, Medicine, Seattle, USA

Islet transplantation is a potential cure for type 1 diabetes. However, the rate of graft failure remains high, despite use of non-glucocorticoid based immune suppression. Thus, understanding mechanism(s) by which transplanted islets fail remains a critical question. While immune-mediated islet destruction is still possible, it is less common than before and has highlighted the importance in islet transplant failure of non-immune mechanisms.
Since aggregation of the beta cell peptide islet amyloid polypeptide (IAPP or amylin) as amyloid is associated with the loss of beta cells in type 2 diabetes, we have focused on islet amyloid deposition as another potential non-immune mediator of islet transplant failure. The importance of this mechanism has been highlighted by the recent description of amyloid in human islets following transplantation.
To determine the effects of amyloid deposition on islet transplantation outcomes, we utilized transgenic mice expressing amyloidogenic human IAPP as a model of amyloid-prone islets. Islets from human IAPP transgenic or non-transgenic mice (the latter as a non-amyloidogenic control) were transplanted into streptozocin-diabetic syngeneic recipients. Mice were followed for one or six weeks after transplantation during which time hyperglycemia recurred in recipients of human IAPP transgenic grafts but not those that received non-transgenic islets. Amyloid formed in 100% (8/8) of transgenic grafts at one week and 92% (11/12) of transgenic grafts at six weeks after transplantation; as expected amyloid was not observed in non-transgenic islet grafts. Amyloid formation was associated with a significant reduction in beta cell volume, increased beta cell apoptosis and decreased beta cell replication.
In summary, amyloid deposition is a potential non-immune mechanism underlying the failure of transplanted human islets. Since all human islets have the propensity to form amyloid, developing approaches to reduce amyloid deposition following transplantation may have beneficial consequences for beta cell preservation thereby improving glucose control.

Fundamentals of stem cell therapy

J. Dominguez-Bendala[1], C. Ricordi[1]
[1] University of Miami, Diabetes Research Institute, Miami, USA

The last decade has witnessed the consolidation of "regenerative medicine" as a recognized scientific field, encompassing disciplines as diverse as cell biology, immunology, and developmental biology. Conditions thus far considered incurable suddenly appear within the reach of an ever-growing therapeutic arsenal that includes both adult and embryonic stem cells. By any measure, human embryonic stem cells (hESCs) remain the gold standard against which other stem cells are judged. The fact that adult stem cells (ASCs) are the subject of many more clinical trials than hESCs is by no means a reflection of their relative merits, as the latter were described just 10 years ago while the former have been around for more than four decades. Another misconception is that ASCs are invariably safer than hESCs, whose tumorigenic potential is well known. Recent evidence suggests that fetal stem cells (which could be considered "adult" inasmuch as they are committed to specific tissues) and mesenchymal stem cells may also develop into tumors. Here we review the advances and challenges of the prospective use of stem cells in the context of type I diabetes, an autoimmune disorder in which the insulin-producing β cells are ablated. The identification of this disease as an ideal target of regenerative therapies is based on several criteria: (a) there is only one cell type destroyed (unlike other conditions in which replacement would require complex tissue engineering involving several cell types); (b) replacement can be ectopic, as long as the transplanted cells are vascularized; and, most importantly, (c) there is already a cell-based therapy (islet transplantation) successfully used in humans. Thus, proof of principle exists that diabetes can be ameliorated by transplanting insulin-producing cells. If stem cells could be efficiently coaxed to differentiate into beta cells, their inexhaustible supply would bridge the gap between islet availability and clinical demand.

Inducing antigen-specific tolerance to prevent type 1 diabetes

P. Pozzilli[1]
[1] University Campus Bio-Medico, Endocrinology and Diabetes, Rome, Italy

Immune intervention at diagnosis of type 1 diabetes (T1D) aims to prevent or reverse the disease by blocking autoimmunity, thereby preserving/restoring β-cell mass and function. Recent clinical trials of antigen specific and non antigen specific immune therapies have demonstrated the feasibility of modulation of islet-specific autoimmunity in patients with partial prevention of loss of insulin secretion. The goal of any therapeutic intervention in T1D is the preservation of insulin secreting cells that can be achieved by the abrogation of pathogenic reactivity to beta cell autoantigens while preserving full capacity to generate a normal immune response against foreign antigens.
Two antigen specific therapies (Diape277 and GAD) will be discussed. These approaches are currently being tested in large international multicenter trials and all of them use similar outcome in terms of beneficial effect on C-peptide secretion as evidence of a therapeutic effect on restoration of β-cell function.
Immunomodulatory humanized peptide from HSP60 (p277 peptide), modified to increase its stability in vivo (DiaPep277), has shown evidence of preserving C-peptide secretion in patients with recent T1D. Interestingly, drug treatment affected the phenotype of the response to DiaPep277 in the immunized subjects with enhancement of Th2 type cytokine production. It should be underlined that C-peptide levels decreased later in time even in the treated group although less pronounced than in placebo group whereas a similar study carried out in children with T1D had no beneficial effect in preserving β-cell function or improving metabolic control. Additional trials in adult onset T1D patients seem to confirm these preliminary promising results.
Glutamic acid is transformed by glutamic acid decarboxylase (GAD) into GABA (gamma-aminobutyric acid), an important neurotransmitter. GAD exists in different isoforms including GAD65 which can be detected in pancreatic islets where it may regulate, in part, insulin release.
GAD65 is a major auto-antigen in T1D and autoantibodies appear before the onset of the disease. Recent phase II studies in man suggest that it might be beneficial in limiting the disease process in T1D. Therapy using GAD65 in an alum formulation is well tolerated without adverse side-effects. In clinical trials there was an attenuation of decline in stimulated C-peptide in the GAD65-treated group compared with controls. The mechanism of action of GAD65 is unclear but an impact on immunoregulation has been suggested. Further, in one phase II study a range of cytokines, including IL-5, IL-6, IL-10, IL-13, IL-17, IFN-ϒ and TNF-α, were higher in samples from GAD65-treated patients than in controls.
In conclusion, data obtained so far using antigen specific immunotherapy are encouraging because they showed an effect in preserving the function of beta cells without significant adverse effects.

Prevention

K. Herold[1], E.M. Akirav[1], L. Opare-Addo[1], J. Sherr[2]
[1] Yale University, Immunobiology, New Haven, USA
[2] Yale University, Pediatrics, New Haven, USA

Immunologic, metabolic, and genetic tools are now available to identify individuals at high risk for development of Type 1 diabetes. Data from the Diabetes Prevention Trial-1 showed that first degree relatives of patients with the disease who have more than 3 positive autoantibodies or who have islet cell autoantibodies and impaired or indeterminant glucose tolerance have an extraordinarily high rate of progression to overt diabetes over a 7 year observation period. New immune therapies such as anti-CD3 or anti-CD20 antibodies, or GAD65 immunization, that have been successful in attenuating the progression of disease, may be equally or even more effective in preventing progression to overt disease since beta cell reserve is even greater in prediabetes than after diagnosis. Understanding the changes in

beta cell mass and function during the progression from prediabetes to overt disease may help design prevention strategies. We have studied changes in beta cell mass and proliferation in NOD mice during progression from insulitis to frank hyperglycemia and after immune therapy with anti-CD3 antibody. In prediabetic NOD mice there is a significant increase in beta cell proliferation, prior to a decline in glucose tolerance. Glucose is an important driver of beta cell replication because treatment of NOD mice with phlorizin decreases the rate of replication. The mechanisms controlling beta cell replication involve glucose stimulated production of VEGF by beta cells. Following treatment with anti-CD3 mAb there is striking increase in beta cell area compared diagnosis. However, the majority of "new" beta cells are those that have recovered insulin granules after anti-CD3 mAb treatment rather than proliferating cells. We conclude that during progression of diabetes, the islet inflammatory milieu and glucose can stimulate beta cell replication. The factors that control beta cell mass may suggest potential treatment strategies that, when combined with immune therapy, can prevent the disease.

The lipocentric pathway to hyperglycaemia and type 2 diabetes

R. Unger[1]

[1] *University of Texas Southwestern Medical Center, Internal Medicine, Dallas, USA*

The lipotoxic consequences of diet-driven endogenous hyperinsulinemia are well-recognized as the cause of metabolic syndrome. Not appreciated is the fact that insulin monotherapy in type 1 diabetic patients (T1DM) may cause a variant form of metabolic syndrome dominated by high prevalence of atherogenic complications. Recent studies in our lab suggest that hyperleptinemia can restore insulin-deficient rodents to a perfectly normal life without insulin treatment. Delivery of leptin, either by adenovirus gene therapy or by infusion of the recombinant protein, maintains normoglycemia indefinitely and restores wellbeing to insulin deficient mice and rats without the need for the hyperinsulimia otherwise required. Abnormal metabolomic patterns in liver, which demonstrate marked elevations of all species of short- and long-chained acyl carnitines, are restored to normal by insulin and by leptin. However, whereas insulin simply re-esterifies the ectopically deposited fatty acids entering the adipocytes, from which they may re-emerge whenever insulin levels fall, leptin treatment, by contrast, results in ectopic fatty acid oxidation and elimination as CO_2 and H_2O. The result is a dramatic lowering of plasma and tissue triglycerides and fatty acids, with more stable reduction in short and long chain acyl carnitine species and TCA cycle intermediates as measured by metabolomic array than is achieved by insulin monotherapy. The studies strongly suggest that peripherally injected insulin can suppress glucagon and inhibit hepatic glucose production only at concentrations that greatly exceed the insulin requirements of peripheral tissues. Leptin supplementation, by suppressing both glucagon and hepatic glucose production, permits stabilization of glycemia using a markedly reduced dose of exogenous insulin; the elimination of chronic hyperinsulinemia is expected to reduce the late atherogenic and lipotoxic consequences of lifelong exogenous hyperinsulinemia and thus prevent metabolic syndrome at the end of life.

Liver fat as a feature of ectopic fat and the atherogenic dyslipidemia of type 2 diabetes

M. Taskinen[1]

[1] *Helsinki University Central Hospital, Division of Cardiology Biomedicum, Helsinki, Finland*

Ectopic fat is defined as the deposition of triglycerides in organs that usually contain minor amounts of fat like liver, skeletal muscle, myocardiocytes, and pancreas. Non-alcoholic fatty liver disease (NAFLD) associates with obesity, insulin resistance and Type 2 diabetes. The hallmark is excessive accumulation of triglycerides in hepatocytes. Fatty liver secretes in excess several established cardiovascular risk factors including VLDL particles, CRP, PAI-1, fibrinogen, F VII and glucose. Importantly increase of intra-abdominal fat mass is an independent predictor of the liver fat content and associates tightly with the hepatic insulin resistance. Thus fatty liver seems to be the hallmark of hepatic insulin resistance. The dynamics of fatty acid (FA) metabolism and FA sources (fluxes from adipose tissue, diet and de novo lipogenesis) play a critical role in the pathogenesis of both liver fat accumulation and hepatic insulin resistance. FAs entering the liver may be directed to VLDL triglycerides, β-oxidation or storage. The imbalance between FFA flux, β-oxidation, DNL and VLDL secretion results in fatty liver. Therefore it is not unexpected that liver fat content correlates with different component of diabetic dyslipidemia.

We have reported that large VLDL 1 particles are the principal component of VLDL species that accumulates in plasma as triglyceride level rises. Available data indicate that overproduction of VLDL 1 TG and apo B is the dominant feature of diabetic dyslipidemia. The key question is what forces drive the overproduction of VLDL 1 particles in type 2 diabetes and insulin resistance. Both intra-abdominal fat content and liver fat volume correlate with VLDL1 TG and apo B production rates in univariate analyses but only liver fat volume remains significant in multiple regression models. Thus hepatic steatosis is the proximate cause of VLDL overproduction. We also explored the relationship between liver fat and the suppression of VLDL 1 production by insulin in subjects with a wide range of liver fat volume. Insulin down regulated VLDL 1 secretion in subjects with low liver fat but failed to suppress VLDL 1 secretion in subjects with high liver fat resulting in overproduction of large VLDL 1 particles. We also reported that VLDL 1 production rate correlated inversely with LDL size and HDL cholesterol. Thus the overproduction of large VLDL1 particles initiates a sequence of events leading to the atherogenic lipid triad.

Visceral fat as a feature of ectopic fat; implications for CVD risk in diabetes

T. Mazzone[1]

[1] *University of Illinois, Section of Endocrinology Diabetes and Metabolism Department of Medicine, Chicago, USA*

Patients with Type 2 diabetes have a marked increase in cardiovascular disease (CVD) risk associated with dyslipidemia and increased markers of systemic inflammation. These subjects are usually obese and commonly manifest increased visceral adiposity. We evaluated the relationship between visceral adipose tissue (VAT) and lipoprotein and inflammatory markers of CVD risk in 375 subjects with Type 2 diabetes. In multivariable regression models, VAT was positively related to VLDL particle number, LDL particle number, and VLDL size; and negatively related to LDL and HDL particle size. These relationships were unchanged after addition to BMI or subcutaneous adipose tissue (SAT) to the model. Neither BMI or SAT were independently associated with lipoprotein parameters. Similar analyses showed that VAT was positively associated with MCP-1, PAI-1, ICAM-1 and VCAM-1. BMI was most closely associated with CRP. SAT was not related to the level of any inflammatory marker. In this diabetic cohort, a waist circumference of greater than 90cm for males or 85cm for females, in combination with a serum triglyceride level of greater than 177mg/dl, identified a group of diabetic patients with a significant increase in visceral fat compared to subjects matched for waist circumference. Subjects with high triglyceride and elevated waist were also more likely to have increased levels of apoB, non-HDL cholesterol, VLDL cholesterol, and lower levels of HDL cholesterol compared to subjects matched for waist alone. These results demonstrate that VAT is associated with important lipoprotein and inflammatory markers of CVD risk in subjects with Type 2 diabetes, independent of BMI, SAT, and waist circumference. They confirm that adipose tissue distribution remains an important determinant of CVD risk in Type 2 diabetes.

Visceral/ectopic fat: important therapeutic targets in type 2 diabetes

J.P. Després[1]
[1] *Centre de recherche, Institut universitaire de cardiologie et de pneumologie de Québec, Québec, Canada*

The prevalence of type 2 diabetes is showing a spectacular progression worldwide, a phenomenon largely resulting from the epidemic proportions reached by obesity. However, physicians have been puzzled by the heterogeneity of obesity as not every obese patient is characterized by chronic complications such as type 2 diabetes, hypertension and CHD. In this regard, body fat distribution, especially visceral adipose tissue accumulation, has been found to be a key correlate of a cluster of diabetogenic, atherogenic, prothrombotic and inflammatory metabolic abnormalities now often referred to as the metabolic syndrome. Such excess visceral adiposity is also associated with increased lipid accumulation at undesired sites such as the liver, the heart and the skeletal muscle, a phenomenon referred to as ectopic fat deposition. This dysmetabolic profile is predictive of a substantially increased risk of CHD even in the absence of hyperglycemia, elevated LDL-cholesterol or hypertension. For instance, some features of the metabolic syndrome (hyperinsulinemia, elevated apolipoprotein B, and small LDL particles; the so-called atherogenic metabolic triad) have been associated with more than a 20-fold increase in the risk of CHD in middle-aged men of the Québec Cardiovascular Study. Excess visceral adiposity/ectopic fat has also been shown to be a highly prevalent feature of type 2 diabetes. It is therefore suggested that the hyperglycemic state of type 2 diabetic patients may only represent the tip of a huge dysmetabolic iceberg largely explained by the high prevalence of visceral obesity/excess ectopic fat in this population of patients. Whereas glucose lowering trials in patients with type 2 diabetes have failed to report substantial effects on cardiovascular outcomes, it is proposed that the loss of visceral/ectopic fat could represent a useful therapeutic objective to reduce cardiovascular morbidity/mortality in patients with type 2 diabetes. This hypothesis should be experimentally tested in randomized trials with hard cardiovascular outcomes.

SYMPOSIUM

Intervention for prevention of type 2 diabetes: periodical or lifetime?

0324

What have we learned from long term follow-up of diabetes prevention?

N.J. Wareham[1]
[1] *Institute of Metabolic Science, MRC Epidemiology Unit, Cambridge, United Kingdom*

A series of diabetes prevention trials have convincingly demonstrated that lifestyle intervention and glucose-lowering therapy in people with impaired glucose tolerance can reduce progression to diabetes. An analysis of the Finnish Prevention Study has demonstrated that the effect of lifestyle intervention on risk of diabetes persists well beyond the period in which the intervention was administered. Conversely, the risk of progression to diabetes seen in people on glucose-lowering treatments reverts to that of the placebo group when the treatment is stopped. However, trials such as DREAM have shown that the effect of pharmacological treatment on the likelihood of progression to diabetes is no more than one would predict given the glucose-lowering effect of the agents involved. Thus a critical question is the long term impact of these interventions on the complications of diabetes. In the Da Qing study the long term follow up showed prolonged beneficial impact on the risk of progression to diabetes but was underpowered to demonstrate an impact on cardiovascular outcomes. This remains an important but unanswered question.

No conflict of interest

0325

Is there a role for drug treatment?

M. Hanefeld[1]
[1] *GWT-TUD GmbH, Center for Clinical Studies, Dresden, Germany*

Prediabetes defines a risk category for diabetes and represents an established risk factor of cardiovascular disease (CVD). Dysglycemia is indissolubly connected with the diseases of the metabolic syndrome. However, the risk for CVD associated with dysglycemia develops along a continuum within and below the range of cut-off limits for categories of prediabetes. Moreover relative and absolute risk for cardiovascular complications in people with prediabetes depends not only on level of dysglycemia but also on comorbitidies such as metabolic syndrome and background with presence or absence of CVD as major determinants. Therefore with a tsunami of newly diagnosed people with prediabetes a risk-adjusted decision for medical treatment is mandatory. So far data from prospective controlled intervention trials with drugs suggest that we only treat dysglycemia but do not achieve a permanent remission after withdrawal of drug treatment. Therefore safety and convenience are essential for long-term treatment.
Data from high standard intervention trials are only available for metformin, acarbose and two glitazones: rosiglitazone and pioglitazone with an average follow-up time < 5 years.
In the DPP study with metformin a relative risk reduction of 31 % was achieved whereas in the STOP-NIDDM trial using acarbose with the same criteria as for DPP the incidence of newly diagnosed diabetes was reduced by 36 %. The DREAM study with rosiglitazone reached a risk reduction of 60 % and ACT-NOW with pioglitazone of 81 % resp.
Metformin is recommended for treatment of prediabetes in the US particularly for younger obese male subjects with IFG and combined IFG/IGT.
Acarbose is the only drug with approval for treatment of IGT in 26 countries. Glitazones bear the burden of increased risk of heart failure, bone fractures in women and weight gain. The only drug with documented reduction of hypertension and cardiovascular events is acarbose in the STOP-NIDDM trial. Thus with respect to efficacy and safety, only acarbose and metformin may be considered for treatment of IGT.
Then the question is who should be treated?
There is consistent evidence from epidemiological studies that people with the combined hyperglycemia (IFG/IGT) are at very high risk for both type 2 diabetes and CVD. The same applies for people with prediabetes and the metabolic syndrome. In a secondary analysis of the STOP-NIDDM trial the number needed to treat to prevent development of new diabetes in the presence of metabolic syndrome with acarbose was 5.8.
Furthermore in the GAMI study and other prospective observational studies of patients with acute coronary syndrome, IGT was a serious independent risk factor for recurrent myocardial infarction and mortality. Therefore it seems to be reasonable that patients with background CVD and dysglycemia should be treated with acarbose or metformin to glycemic targets recommended by the IDF guidelines on management of postprandial hyperglycemia.
In conclusion people on very high risk for diabetes and cardiovascular disease e.g. those with combined dysglycemia, metabolic syndrome and/or documented CVD represent a subgroup for which medical treatment should be considered together with best efforts of life style intervention.

How to identify high risk individuals for type 2 diabetes?

Q. Qiao[1]
[1] *University of Helsinki PL41, Department of Public Health, Helsinki, Finland*

In spite of the fact that uncertainty exists on whether a screening program for type 2 diabetes will benefit individuals screen positive and is cost-effective, screening programs have been carried out for different purposes worldwide. Given that a screening program is under developing what should be taken into account. In this presentation the issues which need to be taken into account when developing a screening policy are discussed including six aspects: 1) a brief review of how diabetes is defined, and its progress from pre-diabetes to undiagnosed diabetes, its latent course and complications occurring during the period. 2) Why to initiate a screening program: to detect undiagnosed diabetes in order to provide treatment early or to provide with intervention

to prevent the development of diabetes in individuals with pre-diabetes? 3) Risk factors associated with diabetes, which may be used to characterise and classify individuals into different phenotypic groups, and thus may help to identify the groups with high-risk for asymptomatic diabetes and pre-diabetes. 4) To provide with a detailed review on screening instruments and their performance. The instruments include blood glucose tests, blood HbA1c test, blood fructosamine, urine glucose test, and risk assessment questionnaires (scores) based on either phenotypic risk factors or genetic determinants. The performance of these screening instruments will be discussed. 5) Who should be screened and how? Does the screening target at general population or at high-risk sub-population? This will determine how to implement the screening program. 6) Take home message: how to identify high-risk individuals for type 2 diabetes depends on the aim of the screening, the place and the targeted population, the capacity to carry out the screening and the capacity to treat individuals screen positive.

How do we apply these results to the real world?

R.F. Hamman[1]
[1] *Colorado School of Public Health, Epidemiology, Denver, USA*

Long term follow-up of lifestyle interventions among high risk persons shows persistence of delay in the development of diabetes over 10-20 years. Strategies to move these efficacy results into the real world can be divided into high risk and general population strategies – sometimes called primary vs. primordial prevention.
Several elements of individual primary prevention lifestyle strategies are important – multiple risk factor intervention on diet, physical activity, and especially weight loss. These are usually best accomplished through targeted programs that involve multiple encounters and reinforcement, with attention to barriers and individual goals. The more participation there is in a program, the better the goal achievement. This argues that limited and short term interventions will have less positive results, and some evidence bears this out.
Some 'real world' primordial translations have focused on individual behaviors, such as increasing physical activity, reduced soft drink consumption, reductions in TV watching, or modification of school lunch programs. Whether such targeted individual behavioral approaches will succeed in overall diabetes reduction is not yet clear. Several programs using existing community resources have shown promise. The pilot studies using the YMCA facilities and staff have shown significant weight loss among high risk adults. Community-based interventions in American Indian communities also show promise by linking native traditions with programs to slow weight gain in youth and promote weight loss in adults.
Governmental recognition of the importance of diabetes prevention has come largely from the European countries, most notably Finland and the EU countries through several initiatives (FIN-D2D, DE-PLAN, IMAGE). In the US, less coordinated action has occurred, due in part to lack of incentives in the health insurance industry.
Moving from efficacy trials to real world translation has been active and multifocal. Whether policy makers can prioritize diabetes prevention remains to be seen in many developed and developing countries.

LIVING WITH DIABETES

New technologies in the management of diabetes

0328

New technologies and aids in management

P. Madden[1]
[1] *PEPSICO, Advocacy + Education for Diabetes and Obesity in Research and Development, Purchase, USA*

With every advance in clinical interventions our primary responsibility is to ensure **SAFETY**. To maximize safety and success we need to work closely with our patients and their vital family members/friends that are key to the patient's diabetes management. Important people in the lives of our patients must have a basic understanding of the patient's diabetes and the products/medicines that sustain and enhance their lives.
Every new technology/aid (glucose meters/strips, insulin pumps, CGMS, diabetes management/support software…) must be determined as being "right" for each patient. Challenges with education/understanding, availability of products, cultural differences, costs, patient desire to use technology all need to be assessed before a decision is made to move forward with new technology. We must strive for the best overall balance of blood sugars with minimum glucose excursions while at the same time keeping in mind how the patient emotionally "works" with the multiple, daily diabetes challenges. Coupled with superb education there are ways to enhance a patient's success with these technologies for example: learning from great role models who use these products, having slower introductions to new technology, being part of a support group in your practice, a diabetes association or the newer electronic diabetes support groups…
For many patients, introducing technology into their diabetes management program will actually require them to focus more attention on their diabetes management than they have in the past. Patients must be willing to make the necessary changes to effectively use the technology and they must understand that it takes focused time to benefit from technology.
Successful use of technology/aids has an incredible payoff that includes significantly enhanced daily balance of diabetes realizing the fullest and most productive lives (school, careers, relationships/friendships, sports, play) while helping to ensure enhanced health throughout life.
You Are outstanding!

Emerging new treatments in diabetes

L. Gnudi[1]
[1] *King's College London, Unit for Metabolic Medicine Cardiovascular Division, London, United Kingdom*

Emerging new treatments are under study for both the treatment of type 1 and type 2 diabetes.
Type 1 diabetes is characterised by autoimmune destruction of insulin producing beta cells. Promising studies are currently ongoing to modulate autoimmunity in early diagnosed type 1 diabetic patients. Blocking autoimmunity would result in preservation of beta cell function and endogenous insulin secretion. New technologies have focussed on the modulation of autoimmunity with antigen-specific and non-antigen-specific approaches. Studies on antigen-specific modulation, using islet specific auto-antigens such as GAD 65, peptide ligand for insulin B23, or smaller epitopes of pro-insulin are currently ongoing. Non antigen-specific approaches with Anti CD3 antiserum have clearly shown that suppression of T-cell immunity halts beta cell damage. Both approaches are promising tools to induce tolerance and reduced beta cell destruction. Trials are ongoing looking also at the long term effects of these treatments on preservation of beta cell function and immune tolerance.
In type 2 diabetes new emerging treatments are represented by new hypoglycaemic agents. Analogues of the incretin glucagon-like peptide-1 (GLP-1) and compounds devoted at increasing GLP-1 half life when secreted in the circulation have been found to improve endogenous insulin secretion and to favour weight loss, key objective in the management of type 2 diabetes, with important improvement in glycaemic control.
Other new hypoglycaemic agents are represented by inhibitors of glucose reabsorbtion in the proximal renal tubule (SGLT2 inhibitors). The use of these compounds will results in glycosuria with calories lost in the urine, consequent weight loss, and improved glycaemic control.
All these new treatments are not free from potential side effects. Side effects will have to be carefully assessed for a critical development and use of these new drugs in diabetes.

Transplantation

A. Misra[1]
[1] *Fortis Hospital, Diabetes and Metabolic Diseases, New Delhi, India*

Diabetes mellitus causes many debilitating and life threatening microvascular and macrovascular complications. Many trials show that tight glycemic control by intensive management including insulin treatment effectively delays onset and slows the progression of diabetic microvascular complications, and also benefits macrovascular complications. However, effective medical treatment which could 'cure' diabetes is not available. Recent studies with stem cell treatment have shown promise.
A number of advances have occurred in the field of islet cell transplantation and clinical results have shown promise. The most successful mode of transplantation in patients with type 1 diabetes mellitus is transplantation of pancreas. In patients with end-stage renal disease and type 1 diabetes mellitus, simultaneous pancreas-kidney transplantation has become the therapy of choice. Clinical outcomes of this type of transplantation have improved significantly, showing long-term survival and protection from progression of complications.

0331

Regeneration of beta cells: stem cell therapy

W. Macfarlane[1]
[1] *School of Pharmacy & Biomolecular Sciences, University of Brighton, Brighton, United Kingdom*

Improvements in islet transplantation therapy for the treatment of Type 1 diabetes have provided critical proof of principle that cell replacement therapy can allow liberation from insulin injections and freedom from hypoglycaemia in those with Type 1 diabetes. However, limitations in donor material have restricted the availability of this therapy, and patients receiving islet transplants currently require lifelong immunosuppression. There is an overwhelming demand for new sources of insulin-producing cells and a world-wide research effort is underway, focussing on the extraordinary potential of stem cells. This includes work with immature starting cell populations such as embryonic stem (ESC) cells and stem cells from bone marrow or umbilical cord blood. Continually improving protocols are being developed to drive these cells towards the formation of insulin-producing cells. However, progress is not limited to cells of embryonic or developmental origin. Recent progress has also come from studies on more mature adult stem cells (ASC), from organs including the pancreas. Driving the formation of insulin-producing cells from adult stem cells may offer a number of advantages and this is an area of world-wide research interest at present.
To generate cells which can be safely utilised in the treatment of Type 1 diabetes, the highest standards of efficacy and safety must be met. On a functional level, cell populations must have the capacity to accurately sense changes in blood glucose concentrations and respond by secreting insulin. Optimised cell populations would also ideally be able to avoid immune destruction when transplanted. These demands represent a significant challenge to researchers in the field. However, these challenges must be met if we are to utilise the extraordinary opportunity that stem cells represent. Here, we will assess progress over the last five years and critically evaluate the potential of stem cell therapy for the treatment of Type 1 diabetes.

Novel approaches in diabetes education

0332

Shaping diabetes care from a patient's view

M. Weiss[1]
[1] *Patient Centered Solutions LLC, Patient Advocacy, Pittsburgh, USA*

The past two decades have been marked by many therapeutic advances in the treatment of diabetes, as well as an almost unanimous recognition of the professionals' need to employ modern theories of patient-centered care. Nevertheless, an alarmingly low number of diabetes patients actually follow healthcare professionals' recommendations, resulting in continually disappointing outcomes for them and their providers. A major contributor to this irony is the absence of a uniform definition of "patient-centeredness" which has enabled some professionals who truly care about their patients to believe that they are patient-centered, without having introduced any significant modifications into the way they have always approached these patients.
Health care has always contained an inescapable element of patient-centeredness as professionals have necessarily focused upon treating their perceived needs of the patient. But this simplification often overlooks the patient's own perception of his or her needs. Without that additional perspective, the efficacy of empowerment methodologies is greatly jeopardized. To correct this phenomenon, traditional diabetes education curricula must be supplemented to incorporate patients' questions and concerns, particularly at the time of diagnosis when they often have many fears, anxieties and misconceived expectations of their professionals' abilities to cure their condition. Optimally, diabetes education must address these concerns before and during the course of providing information about the clinical components of diabetes. Essential lessons include:

1. Diabetes is inherently self-managed and cannot be cured by medications or procedures.
2. Self-management's effectiveness is dramatically enhanced by a lifelong process of ongoing support and education.
3. Treatments will likely change over time.
4. Negative emotions are common and should be addressed.
5. Desired behavioral changes are best accomplished in single steps.
6. Complications are not inevitabilities.
7. Self-management is hard work.

Understanding these basic principles should better prepare patients to accept and implement their self-management responsibilities.

The narrative-autobiographical approach in diabetes care and education

A. Maldonato[1], *N. Piana*[2], *D. Bloise*[3]
[1] *La Sapienza University, Diabetes Unit, Rome, Italy*
[2] *CURIAMO, Internal Medicine, Perugia, Italy*
[3] *Diabetes Unit, St. Giuseppe Hospital, Marino (RM), Italy*

The narrative approach, introduced as an educational tool firstly in the humanities, and then in medicine as a component of "Narrative-Medicine", is a method that helps understand and explain reality, considered as a complex text that can only be described starting from each person's subjective interpretations. Adding quality to the quantity-based research, the narrative approach is an effective instrument to improve our ability to describe and understand complex situations: the narration of a personal story becomes a primary source of knowledge. In this perspective, education is not only a way to transfer knowledge, but also an opportunity for individuals to reveal themselves as unique beings and to understand the real meanings they give to themselves, to others, and to the external world.
This is particularly important when illness strikes, demanding individuals to attach a meaning to their condition, re-interpreting their story, their world and their life. In this context, the autobiographical approach represents an effective way in helping patients to reveal needs and feelings related with their condition. If implemented in a group, the sharing of each one's stories adds a value to the power of self-writing.

We have used the narrative-autobiographical approach, along with self-management education, with adolescents with type-1 diabetes during summer camps. To facilitate self-writing, we adopted a step-by-step approach, and associated/integrated other communication tools. We then performed a qualitative analysis by the grounded-theory method, which has shown that the autobiographic approach had been highly appreciated by adolescents with diabetes, helping some of them to develop self-awareness, self-training and the continued discovery of each one's innermost feelings. For many it represented a safety valve to get rid of the distress and sorrow accompanying the disease. Many of the resulting changes reported after the camp reflected an increase in self-efficacy, maturity, acceptance of the disease and responsibility in self-management.

Using story, writing, music and drama in patient education

M. Frank[1]
[1] *The Hospital For Sick Children, Diabetes Team, Toronto, Canada*

The purpose of diabetes education is to provide people with the knowledge and the skills that they need to manage diabetes well, day by day. For all learners, education is enhanced by a multidimensional approach. Story telling, drama, music and writing for example, can bring education to life and encourage reflection, personal application and insight. Education through the arts has the potential to bridge experience and understanding, to foster imagination and creativity and promote effective coping and problem solving. It is empowering. Furthermore, use of the arts provides a means for everyone to learn, cutting through differences in culture, educational background and ability, and reducing the distance between teacher and learner. It adds a more holistic and humanistic quality to our standard approach to diabetes education. Diabetes education through the arts can be used successfully with children and with adults, with individuals and with groups, in health care settings and in the community.
The aim of this session is to examine the rationale for using music, story, writing and drama in diabetes education, to provide practical examples of how various art forms have been incorporated into diabetes education in a variety of settings and to explore the feasibility of using the arts more routinely in practice. The importance of, and challenges in, evaluating the impact of the use of arts in diabetes education will be addressed.

Novel approaches in diabetes education: group education, bilingual health advocates and the elderly

T. Greenhalgh[1], *Multidisciplinary Diabetes Clinical Team*[2], *F. Macfarlane*[3]
[1] *University College London, Division of Medical Education, London, United Kingdom*
[2] *Newham University Hospital Trust, Department of Diabetes, London, United Kingdom*
[3] *University of Surrey, School of Management, Guildford, United Kingdom*

Introduction: The expert patient model of lay-led peer support is widely used in diabetes but is less popular with minority ethnic groups and those with low health literacy. We tested an alternative model of peer support for limited English speakers – informal groups facilitated by bilingual health advocates, in which participants shared stories in their own language about living with diabetes. We drew on a rich literature from medical humanities on the role of the illness narrative in healing and coping.
Study design: Randomised controlled trial with in-depth process evaluation.
Methods: 158 people referred for diabetes education were randomised to attend a story-sharing group in their own language or receive structured, nurse-led diabetes education, through an interpreter if necessary. Groups were held in six languages and ran fortnightly for six months.
Outcomes: Primary outcome was UKPDS risk score. Secondary measures included attendance, HbA1c, well-being, and Patient Enablement Score. These were measured immediately after the intervention and six months later. Process measures included ethnographic observation of groups and qualitative interviews with staff and patients.
Results: There was no difference between groups in UKPDS risk score or overall well-being. Attendance and patient enablement scores were significantly better in the story-sharing groups ($p < 0.001$). Embedding the story-sharing groups into a busy public-sector diabetes service posed many challenges but since the model was very popular with clinicians, managers and patients, these were successfully overcome.
Conclusion: Sharing unstructured personal stories amongst peers produces comparable clinical outcomes to structured nurse-led diabetes education in socio-economically deprived minority ethnic groups with diabetes. Further research is needed to link this service model more closely with personalised clinical care plans with a view to impacting further on diabetes outcomes.

Prevention of type 2 diabetes and CVD: diabesity

0336

Prevention of type 2 diabetes and CVD: diabesity

N. Unwin[1]
[1] *Newcastle University, Institute of Health and Society, Newcastle, United Kingdom*

The twin epidemics of diabetes and obesity represent one of the biggest public health challenges of the 21st century. All over the world levels of obesity and diabetes are increasing. Even in the countries of sub Saharan Africa it is estimated that in adults aged 35 to 64 years diabetes is responsible for at least 1 in 20 deaths, and in countries with a high prevalence of diabetes, such as those of the Middle East, this figure rises to between a quarter and a third of deaths. In most populations studied 60 to 80% of all deaths in people with diabetes are due to cardiovascular disease (CVD). The relationship between the risk of CVD and blood glucose is continuous, rising well below the diagnostic threshold for diabetes. This means that the deaths associated with raised blood glucose are much greater than those associated with diabetes alone. This talk will provide an up to date overview of the following:

- The nature of the relationship between measures of obesity and the risk of type 2 diabetes and whether this differs across ethnic groups;
- Evidence that obesity in pregnancy, now a major problem in many parts of the world, leads to an increased risk of diabetes in the offspring and the implications of this for prevention;
- The long-term follow up of diabetes prevention trials in those at high risk and what is known of the feasibility and cost effectiveness of implementing the interventions from these trials in different parts of the world;
- Interventions that are effective in the prevention of cardiovascular disease in people with diabetes;
- The need for population wide measures, that include addressing diet, physical activity and smoking, to reduce the risk of obesity, diabetes and cardiovascular disease, and evidence on what works.

Insulin resistance, islet ß-cells and mitochondrial dysfunction

0337

Insulin resistance, islet ß-cells and mitochondrial dysfunction

M. Roden[1]
[1] *German Diabetes Center, Dept. Metabolic Diseases Heinrich-Heine University, Duesseldorf, Germany*

Insulin resistance of muscle and liver and impaired insulin secretion by ß cells are typical for humans at risk of or suffering from overt type 2 diabetes. Alterations of the density and/or function of mitochondria have been described in ß-cells, skeletal muscle cells and hepatocytes. Mitochondrial function is critical for the regulation of insulin secretion and is impaired by gluco/lipotoxicity during the

development of secretion defects. On the other hand, the role of mitochondrial function in other tissues is still unclear. Human mitochondria can be studied either in biopsies or in vivo using magnetic resonance spectroscopy. Similar to findings in mitochondriopathies, fasting mitochondrial function as assessed from flux through ATP synthase can be unchanged or up to 40% lower in insulin resistant states. During insulin stimulation, ATP production nearly doubles in metabolically healthy humans but remains unchanged in type 2 diabetic humans and their insulin resistant relatives. These cohorts frequently exhibit reduced mitochondrial density in skeletal muscle. In the liver, overt type 2 diabetic humans have lower ATP production than young metabolically healthy humans which might also result from lower mitochondrial density or structural abnormalities. Age, fat mass, physical activity, plasma free fatty acids and glucose correlate negatively with mitochondrial function. However, methodological differences between studies make it difficult to decide whether reduced mitochondrial content or function accounts for reduced ATP production in insulin resistance. Inherited abnormalities seem to be related to lower mitochondrial density, whereas in overt type 2 diabetes chronic hyperglycemia and dyslipidemia could first diminish the function and subsequently density of mitochondria via oxidative stress and apoptosis.

HEALTHCARE AND EPIDEMIOLOGY

Models of diabetes care from around the world

0338

Model from Canada

S. Harris[1]
[1] *The University of Western Ontario, Family Medicine, London Ontario, Canada*

Canada's universal healthcare system is funded federally, but delivered provincially. Models of delivery of diabetes care therefore vary from province to province depending on the population base, the rural, urban and ethnic mix of the population, and the amount of funding dedicated to diabetes. Researchers and policy makers are increasingly able to make better-informed decisions based on the National Diabetes Surveillance System data. According to NDSS data the national prevalence of diabetes increased 24% from 2000/01 to 2004/05. In 2004/05 5.5% (~1.8 million Canadians) had diabetes, with provincial prevalence rates ranging from 4.2 to 5.7%. In Canada, 74% of people with diabetes are cared for exclusively by family physicians, yet in recent years fewer than one-third of medical students chose family medicine residencies. In addition, physicians are aging, reducing their working hours, and limiting the number of new patients. Projected dramatic increases in diabetes will therefore coincide with a dramatic decrease in physician supply, New models of care will be essential to meet the growing burden that diabetes will place on the healthcare system. Delivery systems based on or adapted from the Chronic Care Model and other quality improvement initiatives have been successfully implemented in several provinces and are associated with improvements in patient outcomes and other measures. Care provided within these models is often offered by multidisciplinary teams and is structured to improve access to information and communication between and amongst patients and their healthcare providers. An example of national model is the Aboriginal Diabetes Initiative that involves aboriginal peoples (who have 3 to 5 times the rates of diabetes than the general population) in development and implementation of holistic and culturally appropriate programs. This session will examine a selection of successful Canadian models.

0339

Model from India

A. Ramachandran[1], *A. Nanditha*[1], *A. Samith Shetty*[1], *C. Snehalatha*[1]
[1] *India Diabetes Research Foundation, Epidemiology, Chennai, India*

India which has the largest number of diabetic persons in the world, faces multiple obstacles in providing a comprehensive diabetes care model for the whole country. The National Health Policy in India is implemented through a three-tier system of primary, secondary and tertiary levels of health care.

Health systems in India include conventional public and private health sectors, indigenous health systems sector including Ayurveda, Sidda and similar alternative and complementary health care systems. A small segment of the working population has access to health care provided by military, railway, police and employees state insurance hospitals.

Private sector hospitals play a major role in the prevailing health care delivery systems. This sector has several Centres of Clinical Excellence meeting rigorous international standards to treat non-communicable diseases including diabetes. Rich and middle class segments of the population depend on private sector hospitals for treatment of their illnesses. Even the poor prefer the private hospitals and private practitioners unless the treatment costs are beyond their capacity to pay forcing them to get into a "debt trap".

Launch of a National Programme for Prevention and Control of Diabetes, Cardiovascular diseases and Stroke by the government has produced nation-wide interest for better management and prevention of diabetes and its complications. Health promotion through an effective communication and community mobilization through interventions at workplace and at community levels are planned. Stress is being laid on improving awareness among the public regarding diabetes and its complications. The model system has the goals of assessing the prevalence of risk factors, risk reduction for prevention and also for early diagnosis and appropriate management of diabetes. Capacity building at state levels and health promotion through effective communication and community networking are planned.

0340

Model from Africa

M. Abdullah[1]
[1] *University of Khartoum, Faculty of Medicine, Khartoum, Sudan*

Sudan is the largest country in Africa with population of 37 millions. Inspite of its good agricultural, animal and petrol resources it is still considered poor, with suboptimal health services including care for diabetic children. The incidence and prevalence of type 1 diabetes are rising and type 2 cases are increasing. Previously almost 80% were admitted with DKA with 1-2%mortality.Lack of medications, staff, monitoring and investigative facilities in addition to ignorance, poverty and difficult accessibility to health centers were all compounding factors. The Sudanese Childhood Diabetes Association (SCDA) is an NGO that was established in 2003 to help in overcoming these problems in collaboration with the government and other similar local and international bodies such as IDF and WDF. The government was convinced to provide insulin free and recently it was approved to provide free health insurance for the diabetic children and their families. The IDF has helped in securing insulin and investigations cost to some children. The WDF is funding two projects; The Sudan Childhood Diabetes Program and Integrated Management of Childhood Diabetes. Both aim at training multidisciplinary teams, improving laboratory facilities, health education including school health in establishing clinics in various states and making treatment accessible at primary care level and peripheries by mobile clinics and others. National management guidelines have also been produced. The Association also provides socioeconomic help to poor families including meters, strips, food, clothes, school fees self supportive productive projects in addition to free investigations including HbA1c.Many multidisciplinary clinics are being set in the country. A national childhood diabetes center is being built by SCDA as a referral center in addition to provision of excellent laboratory facilities, training and research. In conclusion childhood diabetes is becoming an important health problem even in developing countries and our experience has shown that cooperation between the NGOs and the government can lead to fruitful results.

0341

Model from Europe

E. Standl[1]
[1] *Munich Diabetes Research Institute at the Munich Helmholtz Center, Research Department, Munich, Germany*

Despite the growing diabetes prevalence rates of some 10 percent of the adult population and the increasing cost burden of the disease, as well as the repeated calls for action from European and international health communities, the progress made by European governments in introducing national diabetes plans and improving the quality of care of the 53 million people with known

diabetes remains low and depressingly slow. The models of care – if they exist at all – are characterized by diversity. Only 13 (less than half) of the European Union (EU)'s 27 Member States have a national diabetes plan or policy framework for diabetes. Outside the EU, especially in the ex-Soviet Union countries, centralized structured care persists in many coutries. A key question is that of access to adequate care and treatment. In general, there is good access to essential diabetes treatments in countries across Europe, however access to more advanced treatments and technologies is more restrictive in a number of EU Member States, and very limited in a number of countries outside the EU. Government budget reforms are beginning to affect the availability of prescribed treatments offered free of charge to diabetes patients. There is also a growing debate in some countries around the use of health technology assessment and its potential negative impact on patient access. Structured team approach involving a diabetologist, a dietician and a diabetes educator or nurse is the gold standard of care on the level of specialised, secondary care. However, the majority of patients is primarily seen by primary care doctors. Still some countries are even missing the profession of certified diabetes educators or nurses. Disease management programmes for type 1 and type 2 diabetes have been developed in many countries to improve the quality of care at the primary care level and to bridge the gap between primary and secondary care. 20 years after the St. Vincent Declaration has set out diabetes recommendations for Europe it is high time that finally the widely recognized best practice in the prevention, care and management of diabetes are finally implemented.

Regeneration of ß-cell mass via endogenous progenitor activation

H. Heimberg[1], X. Xu[1], N. De Leu[1], J. D'Hoker[1], X. Xiao[1], G. Grouwels[1], N. Swales[1], S. Bonné[1], M. Van De Casteele[1]
[1] Vrije Universiteit Brussel, Diabetes Research Center, Brussels, Belgium

Novel strategies in diabetes therapy would benefit from the use of stem/progenitor cells but whether or not adult beta cell progenitors exist is one of the most controversial issues in today's diabetes research.
From robustly injured pancreas of adult mice, we isolated a cell type with high similarity to the islet cell progenitor in embryonic pancreas. This adult multipotent progenitor cell does not divide but is able to differentiate into functional beta cells that proliferate.
We will update on new models that involve stem/progenitor cells for beta cell generation and speculate on the signals needed for their recruitment to feed into perspectives for the generation of new beta cells for transplantation and regeneration in diabetes.

Differentiation potential of islet precursor cells

P.L. Herrera[1], R. Desgraz[1]
[1] University of Geneva Faculty of Medicine, Genetic Medicine & Development, Geneva, Switzerland

Aim: During pancreatic development, islet endocrine cells originate from progenitors defined by the expression of the transcription factor Neurogenin3 (Ngn3). As a population, Ngn3+ cells are multipotent, i.e. generating different islet cell types. However, whether a single Ngn3-expressing cell is a multipotent stem / progenitor cell or on the contrary a unipotent precursor is not known.
Method: To explore this, we generated mosaic mice by labeling very few Ngn3+ cells with Cre recombinase in MADM mice. The clonal descendents of labeled cells were analyzed at birth, in young adults and in aged mice, and determined whether clusters of Ngn3+ progeny were homogeneous or not.
Result & discussion: Our observations lead us to propose a new paradigm to refocus ideas on how cell number and type must be regulated in building complete islets of Langerhans.

Co-opting molecular control of cell cycle progression in the human pancreatic ß-cell for diabetes therapy

A. Stewart[1]
[1] University of Pittsburgh School of Medicine, Division of Endocrinology, Pittsburgh, USA

Adult human and in rodent pancreatic beta cell replication is an unusual event. For many years, this was interpreted to mean that adult beta cell replication cannot occur. Efforts to enhance pancreatic beta cell mass by enhancing beta cell replication were viewed as unlikely to lead to therapeutic advances. However, it is now clear that adult rodent beta cells can and normally do replicate, and that this process can be manipulated and enhanced using growth factors and intracellular signaling molecules. In contrast, it is equally clear that human beta cells are different: maneuvers and mitogens that enhance rat and mouse beta cell replication have only limited effects on adult human beta cells. Ultimately, approaches to enhance beta cell replication must activate the fundamental machinery that controls cell cycle progression in any cell type, the G1/S transition step in cell cycle progression, also called "retinoblastoma pathway" or "pRb pathway". Our laboratory has focused on defining the members of the pRb pathway in rodent and human beta cells, and using these molecules to define strategies to expand human beta cell replication. Using this approach, we have comprehensively characterized the critical regulatory molecules in the rodent and human beta cell. One example is cyclin-dependent kinase-6 (cdk-6), and its partner, cyclin D_1. Whereas adult human beta cell replication rates are normally very low (~0.3% in 8 hours), addition of cdk-6 and cyclin D_1 to human islets produces an immediate and robust (13%, or 40-fold) increase in human beta cell replication, and this is accompanied by markedly enhanced pancreatic islet transplant outcomes. In this symposium, these studies will be discussed.

Tracing the duct cells and reaching ß-cells

S. Bonner-Weir[1]
[1] Joslin Diabetes Center/Harvard Medical School, Islet Transplantation and Cell Biology Section, Boston, USA

While there has been progress in deriving insulin-producing cells from embryonic stem cells and potentially from induced pluripotent stem (IPS) cells, there is increased interest in using endogenous sources for beta cell replenishment. Experimental rodent models provide evidence that replication of pre-existing beta cells as well as differentiation of new beta cells from progenitors contribute to the normal, compensatory, and regenerative growth. Our data from the regeneration rat model of partial pancreatectomy led us to hypothesize that differentiated pancreatic ductal cells function as progenitors for new islets after birth, that with stimulus they replicate and regress to a less differentiated phenotype that is equivalent to that of embryonic pancreatic progenitors and these then redifferentiate to form new acini and islets. We have used three approaches to test this hypothesis. First, both mouse and human duct-enriched (and islet-depleted) cells have been shown to give rise to islet hormone-positive cells ***in vitro*** or when transplanted. Second, examination of the molecular changes in isolated duct cells after partial pancreatectomy showed that in the process of regeneration mature pancreatic duct cells do regress and sequentially recapitulate embryonic differentiation, in fact newly formed beta cells express duct markers. Third, we took a direct approach of genetically marking ductal cells using carbonic anhydrase II (CAII) as a duct cell-specific promoter in Cre-lox lineage tracing experiments. In these experiments CAII-expressing pancreatic duct cells act as progenitors that give rise to both new islets and acini after birth and after injury. This identification of at least some pancreatic ducts as ***in vivo*** progenitors for all differentiated pancreatic cell types has implications for a potential replenishment therapy for diabetes.

Camping experience in Eastern Europe

I. Vlasenko[1]
[1] *Ukrainian Diabetic Federation, Regional development, Kiev, Ukraine*

Analysis of the advantages and disadvantages of camps for people with diabetes, based on 17 years of working experience in the eastern European region

Aims:

- Organising recreational activities and training under real-life conditions.
- Psychological adaptation.
- Involving new volunteers to the organisation.
- Working with the mass media.

Methods: To promote a healthy lifestyle (healthy diet, physical activity and self monitoring).

- Promoting social activity (involving young people in the public diabetic movement, leadership and team-building; motivating the elders to clubs and supporting groups).
- Promoting a positive image of NGO.

To conduct a survey of the Diabetic Associations of 12 countries, with the aim of learning from their accumulated experience.

Results: Carrying out analysis of the information, to identify:

- Principles of forming and preparing teams (methods and ways of working with participants, developing a day-by-day and hour-by-hour plan and an algorithm for carrying out events).
- Optimal places and duration of events.
- Medical care.
- Economic aspects.
- Impact on quality of life.
- Mistakes and lessons.

Conclusions: The analysis provided the best possible guidance on how to establish camps for people with diabetes, taking into account social factors and the age of the participants. To obtain more detailed information about the problems of setting up camps, a questionnaire was sent to the organisations of countries in other regions.

Camps in SACA Region

C. Solari[1], *M.T.U. Mark Thomaz Ugliara Barone*[2]
[1] *Asociación de Diabéticos del Uruguay, Montevideo, Montevideo, Uruguay*
[2] *ADJ San Pablo, San Pablo, San Pablo, Brazil*

As we all know, diabetes camps are one of the best experiences a person with diabetes can have.

It gives you the tools to learn self confidence, independence, to have fun, to notice that you are not the only one in the world with that problem.

It has shown metabolic improvements delaying its complications during development. This seems even more evident when the experience is repeated.

Uruguay was the first country in the SACA Region to do camps for kids with diabetes, dating back to 1954. At the time it was a 20 day camp with over 35 kids, an appointed doctor, a nurse and her studying group, and a nutritionist.

Nowadays we still have camps in our country getting into account the pros and cons of the times.

An investigation led by Mark Thomaz Barone and myself held last year leads to this conclusion.

The total number of camps in SACA Region is 56 and the total number of campers is 2188. According to the IDF Diabetes Atlas 2003, the prevalence of type 1 diabetes among children (0-14 years) in SACA region plus Mexico is of 43,000

Knowing the long and short term benefits of educative camps for children with diabetes, and also knowing the benefits to the community as a whole; is that we recommend this information to be known by private as well as public institutions, so that we can all give support to camps initiatives in the region and go beyond the numbers we found.

Camping in the Caribbean

B. Cooper[1]
[1] *Bahamas Diabetic Association, The College of the Bahamas, Nassau, The Bahamas*

Over the past twenty years, the formation of diabetic camps for children has become popular throughout the Caribbean. The establishment of diabetic camps in the Caribbean became necessary because many simply could not afford to travel every summer to the United States or other countries for the event. The diabetes camp for children gives kids the basic training on how to monitor the disease, as well as the medication in a controlled environment. Additionally, the camp keeps a record of all participants so that data can be recorded for quality control of the programme.

Although the formation of diabetic camps for children in the Caribbean has resulted in positive feedback, there has been some negative connotation as well. Some of the challenges incurred include getting healthcare professionals committed to one week of service during the programme, getting parents to relinquish their children to this new concept, as well as locating adequate facilities to host the event. In addition, sponsorship for the camps has been a challenge, as well as locating experienced dietitians for meal planning relative to diabetics.

The camp is hosted on a daily basis for one week during the summer, where participants come in during the morning hours and leave at 4:30 pm. The structure of the camp includes a series of lectures and events that are done throughout the course of the day. During a typical day at the camp, participants have their glucose levels assessed upon arrival, followed by group discussions, physical activities, lunch, and a lecture by a guest speaker, craft and the final test at the end of the day before going home. Data is collected on glucose levels, weight, height, and also how participants feel after physical activities.

Designated sites are chosen for the testing and administering of insulin during the sessions. Moreover, participants are made aware of the difference between hypoglycemia and hyperglycemia, so that they can become aware of foods that tend to have a high glycemic index level, and how to associate this with other persons relative to social issues.

Based on findings relative to the children's diabetes camp, it was discovered that participants tend to experience high and lows after lunch either from too much activities or foods too high on the glycemic index chart. Participants were coming into the camp the following morning with either high or too low levels. This occurred because they did not consume a snack before bed time or the snack was high in sugar. It was also discovered that swimming tends to help a lot with the glucose level and it was something the children enjoyed doing much more than the other activities.

In the future, better background checks must be carried out on participants because data relative to participants are not sent in by the parents, or proper medical chart on participants. There needs to be a better balance with regards to the lectures, the physical activities, and the way we utilize our time. More training needs to be done in food preparation, monitoring and the use of physical activities in maintaining proper control of their diabetes.

Supporting and empowering diabetes camping initiatives

N. Cuttriss[1]
[1] *AYUDA, Arlington VA, USA*

Aims/learning objectives:

1. Understand the elements of the AYUDA Volunteer Program that empower youth to serve as agents of change in diabetes communities abroad
2. Acknowledge diabetes camps can serve as vehicle to motivate youth to live happier and healthier lives
3. Appreciate the diversity of diabetes camps throughout the world

Methods: AYUDA is a nonprofit organization that empowers youth to serve as agents of change in diabetes communities abroad. AYUDA's innovative peer learning model trains teams of international volunteers to work with local diabetes youth leaders and motivate them to live happier and healthier lives with diabetes. For over a decade, AYUDA has collaborated with local counterparts to build off of the traditional diabetes camp model and developed an innovative and proven methodology to use peer support in youth-to-youth settings. The AYUDA volunteer experience consists of: (1) cultural exchange program, (2) diabetes outreach and education activities, (3) youth empowerment and leadership training activities, (4) supporting local projects

such as diabetes camps. In 2009, AYUDA offered volunteer programs in Boliva, Dominican Republic, and Ecuador.

Results: In the past decade, AYUDA has expanded its support to diabetes communities throughout the world by creating the AYUDA Volunteer Program that has sent 200 volunteers abroad and by creating the Campo Amigo Internacional (CAI) Youth Leadership Program that has led to an international network of over 400 dedicated young diabetes leaders from 20 different countries who learn from each other to apply the experiences and knowledge gained from CAI to enhance local diabetes camps, associations and communities.

Discussion/conclusion: AYUDA's model has seen increasing demand from both international diabetes communities and interested international youth volunteers. Customized versions of AYUDA's youth to youth model have been launched in Belize, Bolivia, and the Dominican Republic as pilots to study the possibility of replicating AYUDA's model.

Support group success at grass roots level and the link with the regional department of health in South Africa

J. Bayly Brown[1]
[1] *Diabetes South Africa, National Office, Cape Town, South Africa*

Diabetes South Africa would have been in existence for 40 years in 2009. In 1991 the first support group was started at the Red Cross Memorial Hospital for Children in Cape Town. The second group followed in 1992 in Somerset West just outside Cape Town. More groups followed over the years, there are now 35 such groups in the Western Cape, one of the 9 provinces of South Africa.

The support groups meet at various times and some meet weekly others monthly. The activities at these groups range from various speakers on diabetes problems and diets to basic first aid principle. About 4 years ago with funding from the European Union, the Regional Department of Health approached DSA with the idea to put these groups to better use. Four groups were highlighted and their leaders were put through a training course by the local university on basic diabetes management. (for lay persons)

At the meetings, the members are weighed, have their blood pressure measured as well as their blood glucose. This is recorded on sheet for each member. Basic eye testing is also carried out and those that require further intervention are then referred to the eye clinic.

There have been a number of successes for the members, with weight loss, improved blood pressure readings and Hb1AC. Those with extremely high blood glucose readings are referred back to the local clinic and doctor with the records of their readings.

Long term it is hoped that these patients will be able to collect their medication (dispensed from a central pharmacy) at the venue where they meet.

Diabetes in the SACA region: current status and possible solutions

P. Orellana Pontaza[1]
[1] *APRECOR, Guatemala, Guatemala, Guatemala*

It is intended to display information on the status of diabetes in the region that corresponds to SACA, where it has worked continuously with the various countries of the region. There have been workshops bringing together almost all countries and have reached consensus on priorities, as it has worked in each of them individually, some are more advanced than others, but all working with the same vision.

To publicize the situation of the region, the base of data from the Diabetes Atlas of IDF, which is a reliable document, and that was updated with data until 2007.

The area of the IDF SACA Region is a little over 20 million Km^2, with a population of 252 million habitants (2003). Only 5.4% of the world population lives in South America. It is the continental territory with the smallest density after Oceania.

Estimated prevalence of diabetes in the Americas, where in 2000 an estimated 35 million people suffering from the disease and increase of 64 million people who will suffer it, with prevalence from 3.1 to 8.2% in different countries in 2000, by 2025 will be a prevalence of 4.1 to the lowest 12.2%.

In the SACA region in 2007 the diabetes prevalence ranging from 14 to 6% in different countries, with higher prevalence in Central America and the countries of northern and southern South America the lowest prevalence. Some data were derived from prevalence surveys in different cities of countries.

But by 2025 the prevalence increases to 20% of the population of Central America, Hispanic Caribbean, Brazil and other South American countries were between 6 and 8%, with the exception of Paraguay are expected to maintain its current prevalence among 4 and 6% of its population.

Taking into account the number of people affected by diabetes are under the age group 20 to 79 years, we see that in the SACA region doubles by 2025 from what was in 2007. These people are still many of them economically active.

In most countries of this Region

- Prevalence data are old or they are not available.
- Some of the studies do not follow international standards.
- Data on the prevalence of diabetes complications are not available.
- Cost studies are scarce.

This data should make the work and support each other on common issues which have been detected to be strengthened, such as:

- Education and prevention at all levels
- Training of health professionals
- Working with governments
- Work with patients themselves, who are unaware of much information of interest
- That people have access to drugs and equipment
- Raise public awareness in relation to diabetes

For this, the region has begun to work, developing a strategic plan carried out through different projects according to the needs of each country. This also agrees and is working on the need to influence governments to obtain:

- Human and financial resources to effectively manage diabetes.
- The prevention and education at all levels.
- Access to early diagnosis.
- Access to supplies for the treatment and control.
- No discrimination.
- Laws for people with diabetes and at risk of it.
- National Diabetes functional, because in some countries but not have the resources.
- Diabetes is not a health priority in some countries, remain the maternal and childhood diseases.

0352

The role of the association in improving care in Russia

E. Gustova[1]
[1] *Moscow Diabetes Association, President, Moscow, Russia*

Public diabetic movement goes back to 1988 in the Soviet Union (USSR).

Moscow Diabetic Society (MDS) became a pioneer and leader. Next year diabetic organizations were created in Kharkov, Novgorod, Tula and a number of other cities. It was the time when in reality people with diabetes were completely helpless under the existing public health system.

Russian Diabetic Federation (RDF), which became a fully legitimate member of IDF, was founded in 2000. More than 100 regional and interregional public diabetic organizations are currently registered in Russia. According to experts, they are the most public and active non-commercial organizations in RF.

Our goals:

- To influence the state policy related to diabetic care in order to improve life standards of each person irrespective of place of his residence and welfare.
- Lobbying rights and freedoms of people with diabetes in the Russian state and legislative bodies and RF regions; participation in activities of social councils at all levels of RF government agencies. (The model law project "Principles of socio-medical protection of people suffering diabetes", CIS inter-Parliamentary Assembly; Heads of the Governments signed

"Agreement on CIS states cooperation in the issues of controlling diabetes incidence rate"; International forum "Let's unite to fight diabetes!" in Moscow)

These documents allow us to conduct more effective dialog with government structures regarding development and improvement of medical care to people suffering diabetes.

Consequently we see:

- Not only political parties, but dynamically developing public organizations can be the basis of civil society in Russia.
- Integrated and system approach to resolving the living standard issues of people with diabetes, as well as cooperation of all government departments and medical professionals with diabetics and their family members and close ones.

The main driving powers for implementation of national diabetic issues are diabetic public unions and each patient with diabetes can and must contribute. We must concentrate on what is uniting us, as the famous saying goes "Nothing will change until you change it".

Diabetes care in Anguilla: where do we go from here?

D. Ruan[1], *C. Goddard*[2]
[1] *Anguilla Diabetes Association, Anguilla, The Valley, Anguilla*
[2] *Anguilla Diabetes Association, Endocrinology, St.Michaels, Barbados*

Anguilla is the most northerly of the Leeward Islands and represents a mere 35 square miles of land. Our 15 000 citizens utilize the services of a government owned hospital and five community health centres which are all managed by the Health Authority of Anguilla.

For the past five years, services rendered to persons affected by diabetes have been guided by the Framework of the Diabetes Care Team of Anguilla.

The expanded diabetes team includes a certified diabetes educator, dietitian, physician, internist, nephrologist, endocrinologist, ophthalmologist, foot care specialist and a social worker.

At the primary level, the community health services include weekly physician clinics, diabetes education, foot care, home visits and nutritional counseling whilst at the secondary level, total patient care is coordinated.

The Diabetes Care Team of Anguilla plans to sensitize and lobby to the Government on the impact of Chronic Non Communicable Diseases (CNCDs). Implementation and monitoring of comprehensive programmes advocating preventative measures for CNCDs is the way forward. This will include additional play fields and parks designed with walking and biking trails; exercise and nutritional programmes in the workplace and other parts of the wider community.

Additionally, programmes to promote more cultivation and sale of local produce and encourage the use of local indigenous fruits will be piloted. Measures to decrease importation tax on fruits, vegetables and juices, increase importation tax on alcohol, tobacco products and sodas (high calorie beverages). Also discounted cost of medications for persons with chronic non communicable diseases will be included in the comprehensive programme.

OPEN FORUM

IDF and the UN Resolution

0354

Will the UN recognition of diabetes make a difference to the lives of our people with diabetes

T. Milenkovic[1]
[1] *Medical Faculty, Clinic of Endocrinology Diabetes and Metabolic Disorders, Skopje, Macedonia*

On 20 December 2006, the United Nations General Assembly passed Resolution 61/225. This landmark Resolution recognizes diabetes as a chronic, debilitating and costly disease associated with major complications that pose severe risks for families, countries and the entire world. Governments have acknowledged that diabetes is increasing at epidemic rates and is affecting all countries. It was established that if a situation with diabetes is to be managed, we need to be able to measure it, and we need to know how well it is working. Out of this came different measures and campaigns in countries worldwide in order to improve diabetes treatment and to make positive difference to the lives of people with diabetes.

In the Eastern European region, including Macedonia, there is huge room for improvement of diabetes treatment and related outcomes. What could we do and what are we doing? Firstly, we could improve the awareness about diabetes, its risk factors and complications, and do more in identifying high-risk individuals. We could take simple steps to prevent diabetes and facilitate patient-physician communication. What are we doing? Group and individual patient education is performed since 1995; numerous lectures were held to raise diabetes awareness among general population; brochures were published covering specific diabetes issues such as nutrition, foot care, sick day rules, pregnancy, acute complications. Finally, a web-based national diabetes register is implemented to learn about the current diabetes treatment and outcomes, and to help us plan the future necessary action. Together with the UN recognition of diabetes we could make a difference.

Diabetes in Uzbekistan: new horizons and collaboration ways

S.I. Ismailov[1], *G.N. Rakhimova*[1], *N.U. Alimova*[1]
[1] *Association of Endocrinologists of the Republic of Uzbekistan, Scientific-Research Institute of Endocrinology Tashkent, Mirzo-Ulugbek District, Uzbekistan*

Aim: to assess efficacy of the National Register (NR) in children and adolescents with type 1 DM and LIFE FOR A CHILD (LFC) grant in Uzbekistan.

Materials and methods: the NR among children and adolescents with type 1 DM has been conducted since 2000. Starting from 2007 the LFC program under the IDF auspices with participation of 42 patients from Tashkent, 15 patients from Samarkand region and from 2009 with the participation of 40 patients from Andijan region has been conducted.

Results: within the period from 2000 to 2007 type I DM mortality among children and adolescents was found to decrease from the time of the NR by 99% and 84%, respectively, due to higher frequency of basic-bolus therapy by 86.4% and 83.6%, respectively, to improvement in supply with insulin in children up to 94.2% and to 94% in adolescents as well as to higher frequency of the out-patient self-control.

Within the period of the LFC program due to permanent supply with the self-control devices, pens and insulins from IFL as well as to self-education HbA1c in children in Tashkent decreased from 9.8% to 8.3%, in adolescents from 9.4% to 8.7%. Diabetic retinopathy (DR) incidence in children with type 1 DM in Tashkent was decreased by 34.7%, diabetic polyneuropathy (DPN) being reduced by 35.9%. No cases of diabetic nephropathy (DN) and physical development retardation were registered. In Samarkand region HbA1c reached 8.7% in children and 7.4% in adolescents. DPN incidence in children with type 1 diabetes mellitus was reduced by 12.5%. DR was registered in 30.7%, IV degree DN in 23%.

Conclusions: reduction of mortality among children and adolescents with type 1 DM is the evidence for properly selected strategy and tactics for conduction of the NR. Long-term carbohydrate metabolism compensation in the participants to the LFC program contributes to the reduction in microangiopathies.

SPEAKERS' CORNER

Association-goverment interaction: how to go about it!

0356

Association-goverment interaction: how to go about it!

S. Langlois[1]
[1] Diabète Québec, Montreal Québec, Canada

Government and non-profit organizations have a lot in common: they are dedicated to fulfill the need of people that share a specific preoccupation and therefore support the implementation of policies, programs, strategies and action plans to achieve collective goals and improve the well-being of a population.
Government leaders are elected by the Citizens and the association board members by their General Assembly. Both groups are mandated to manage in the best common interest and take the required decisions to do so. They shall respect the law and assume responsibilities with integrity toward those who gave them such mandate. They have a duty to report about the activities and the realization of their organization on a determined basis.
They have a lot in common but the interesting aspect of their mutual relationship is the interaction that such organizations have between each other. One will try to influence the other and the other may react positively or negatively.
Diabetes associations have a duty to advocate for the crucial needs of people living with the disease. It is in the mandate of such groups to raise the issue of the need for diabetes prevention, education, and access to the right treatment and medication. They are therefore a group of influence, and they assume the responsibility of being the voice of quality toward the political leaders to increase their understanding of the tremendous impact of diabetes for the society. The costs are extremely high but if no-one put forward those concerns, nothing will ever be undertaken by any government. Governments react to the heat. They will move if there is a push to do so. One shall never forget the old saying: ***The squeaking wheel get the oil!*** A diabetes association shall invest lots of efforts in being such a wheel to succeed in such a domain. Lobbying is educating the ones that can make a difference. Lobbying is a lengthy process to achieve long-term results.

ORAL PRESENTATION

CLINICAL RESEARCH

Clinical care improving outcomes

O-0357

Relationship between HbA1c target range and mortality in a population based study in type 2 diabetes: The Diabetes In Germany (DIG) Study

M. Hanefeld[1], C. Koehler[1], I. Benke[1], J. Stelzer[1], P. Ott[1]
[1] GWT-TUD GmbH, Center for Clinical Studies, Dresden, Germany

Aims: One of the major questions surrounding HbA1c targets is the overall benefit and eventually its effect on mortality.
We aimed to answer this by evaluating the relationship between different target ranges used by IDF and ADA and mortality in a population based study in patients with type 2 diabetes in Germany.
Patients and methods: 4020 unselected patients with type 2 diabetes aged 35-80 years from 238 sites, median follow-up time 3.7 years, 2959 completed the study or died (n=175, 5.98%), 397 dropped out. Determinants of death were calculated by stepwise regression analysis.
Results: At baseline 7.6% reported previous MI, 4.3% a stroke and 6.7% coronary revascularisation summarized as major cardiovascular event (MACE). The average HbA1c was 7.0±1.2%. Out of 1033 patients with HbA1c <6.5% 6% died, the corresponding figures for HbA1c =6.5% <7% were 574 and 5.3%, for >=7% <8% 685 and 5.1%, and for >=8% 462 and 7.6% (n. s. for tendency). Stepwise regression analysis with a predictive power of 95.1% and all major risk factors revealed MACE at baseline (p<0.0001), age (p<0.0001), smoking (p=0.016), systolic blood pressure (p=0.003) and male sex (p=0.002) as independent risk factors for mortality.
Conclusions: We found no difference in mortality in relation to cut-off levels for HbA1c control in a population rather well controlled for HbA1c at average. Only those with HbA1c >=8% show a tendency for increased risk. In our study only the classical risk factors age, male sex, blood pressure, smoking and previous MACE are independent risk factors for premature death.

No conflict of interest

O-0358

Relationship between HbA1c- target value of the ADA, glycemic variability and risk of silent hypoglycemia in patients with type 2 diabetes mellitus

B. Engler[1], C. Koehler[1], C. Hoffmann[1], W. Landgraf[2], S. Bilz[1], C. Schoner[1], M. Hanefeld[1]
[1] GWT-TUD GmbH, Centre for clinical studies, Dresden, Germany
[2] Sanofi-Aventis Germany, Medical Affairs, Berlin, Germany

According to the findings of the ACCORD study, decrease of HbA1c<7.0% was suspected to be associated with an increased risk of hypoglycemia and mortality. To avoid possible harmful effects of aggressive HbA1c control a moderate reduction to target level of 7.0 – 7.9% was recommended.
To prove the clinical relevance of this recommendation we performed an observational study with CGMS (continuous glucose monitoring system) to analyze glycemic variability and time spent at low glucose level (silent hypoglycemia, glucose< 3.1 mmol/l).
In 110 consecutive type 2 diabetics the interstitial glucose concentration was measured with CGMS over 72 h. The patients took a standardized test meal (TM) on day 2. We divided the patients in group 1 with an HbA1c<7.0% (N=65) and group 2 with an HbA1c>=7.0% (N=45). The groups were characterized as follows:

sub- group (HbA1c)	1 (<7,0%)	2 (>=7,0%)	significance
age (years)	65±7	62±10	n.s.
BMI (kg/m*)	29±4.1	33±5.5	p=0,001
duration of diabetes (years)	4.5±3.5	12.7±7.9	p<0,001
HbA1c (%)	5.8±0.5	8.3±1.2	p<0,001

The anti-diabetic therapy differed not significantly in regard to the application of insulin (55% vs. 58%) and DPP-4 inhibitors (2% vs. 7%). However, the patients in group 2 were treated more frequently with sulfonylureas (none vs. 22%, p<0.001) or metformin (43% vs. 77%; p=0.012).
We analyzed the following parameters: average glucose on day 2 (avGTM), fasting glucose on day 2 (fG), maximal glucose after the test meal (Gmax), glucose 2h after test meal (G2h), MAGE (mean amplitude of glycemic excursions) on day 2 (MAGETM), standard deviation of average glucose on day 2 (SDTM), and duration of silent hypoglycemia over 48h (Hypo48h).

sub- group (HbA1c)	1 (<7,0%)	2 (>=7,0%)	significance
avGTM (mmol/l)	6.3±1.0	9.3±2.2	p<0.001
fG (mmol/l)	5.8±1.2	8.8±2.5	p<0.001
Gmax (mmol/l)	9.3±1.9	14.4±3.1	p< 0.001
G2h (mmol/l)	7.4±1.9	12.7±3.5	p<0.001
MAGETM	2.6±1.1	4.8±2.1	p<0.001
SDTM	1.3±0.6	2.3±0.8	p<0.001
Hypo48h (min)	53.6±139.9	14.1±70.9	p=0.055

Patients with HbA1c>7% had a distinctly higher glycemic variability which may have harmful effects on the vascular wall. However, CGM revealed no significant higher risk of silent hypoglycemia in patients with HbA1c<7%. Obviously HbA1c- level is not a reliable indicator of risk of hypoglycemia.

No conflict of interest

O-0359

The strict control of hyperglycaemia in the early stage of diabetes is important in maintaining long-term glycaemic control - from a longitudinal analysis for 8 years

H. Hirukawa[1], F. Kawasaki[1], Y. Kanda[1], F. Tatsumi[1], S. Hamamoto[1], M. Shimoda[1], K. Tawaramoto[1], T. Anno[1], M. Hashiramoto[1], M. Matsuki[1], T. Mune[1], K. Kaku[1]
[1] Kawasaki Medical School, Internal Medicine, Kurashiki, Japan

Aims: Physiological condition of type 2 diabetes mellitus (T2DM), especially pancreatic b cell dysfunction, is known to be progressive, if not well controlled. In order to answer the question how and when we should start to treat the

disease intensively in maintaining long-term glycemic control, we analyzed the longitudinal clinical data for patients with T2DM and assessed clinical parameters responsible for the long-term glycemic control.

Method: Physical and laboratory examination data, and glucose lowering medications for patients with T2DM visiting our hospital have consecutively been recorded once a year for 8 years from 2001. We analyzed the changes in HbA1c and treatment for each subjects. Treatment was adjusted to achieve HbA1c <6.5%.

Results: Total 637 patients (M/F =375/262) were included in this study. The average observation period was 7.5±0.5 years. At the baseline, average age was 61.3±10.0 years, duration of diabetes 11.2±8.5 years, BMI 23.8±3.6kg/m^2, HbA1c 6.7±1.1%. BMI was not changed through the observation period. The yearly change of HbA1c was 0.03%, and the final HbA1c level (6.9±1.1%) was significantly elevated from the baseline (p =0.0002). Patients with nutrition therapy decreased in number from 192 (30. 1%) to 70 (11.0%). Patients with OAD therapy increased in number from 301 (48.7%) to 465 (73.5%). Almost half of patients received SU drug (56.5 %) at baseline. At the final, the frequency of OAD used was SUs 40.2%, glinides 22.4%, metformin 47.7%, pioglitazone 59.6%, and aGIs 35.2% for each. The frequency of patients with OAD monotherapy was significantly decreased from 49.5% to 18.3%. Patients who required insulin therapy increased in number from 186 (29.7%) to 236 (37.0%). The change of HbA1c in each period after the onset of diabetes was 6.3±1.0 to 6.7±1.3% in 5 years or less (n=164, p <0.0001), 6.8±1.2 to 6.8±1.0% in 5-10 years (n=136, NS), 7.0±1.1 to 7.1±1.0% in 10-20 years (n=183, NS) and 7.0±1.0 to 7.1±1.1% more than 20 years (n=95, NS).

Conclusion: Our results demonstrate that glycemic control deteriorates with the progress of diabetes duration, and strongly suggest that a strict control of hyperglycemia in the early stage is required to maintain the long-term glycemic control.

[4] *St. Michael's Hospital, Division of Endocrinology and Metabolism, Toronto, Canada*
[5] *Vernon Jubilee Hospital, Diabetes Education, Vernon, Canada*

Background: The Canadian Diabetes Association developed the 2008 Clinical Practice Guidelines for the Prevention and Management of Diabetes in Canada, an internationally recognized evidence-based set of clinical recommendations for the prevention of type 2 diabetes and management of type 1 and type 2 diabetes. An expert committee of 99 volunteers from various healthcare professions across Canada developed the Guidelines. The Dissemination and Implementation Committee, a volunteer group of various healthcare professionals and people living with diabetes developed the dissemination strategy.

Aims: The Association's goal in developing the Guidelines is to improve the quality of care for people with or at risk of diabetes by translating evidence-based knowledge into recommendations of care for healthcare professionals and encouraging the incorporation into practice.

Methods: The dissemination strategy included a media release, with the launch of the Guideline to raise the profile and communicate key recommendations. The strategy also includes rolling out key themes from the Guidelines, every 6 months for the next three years. Each theme consists of clinically orientated, practical information and accompanying tools to help integrate diabetes prevention and management strategies from the Guidelines into practice.

Results: The first theme, cardiovascular disease (CV) resulted in the creation of several innovative 'tools' distributed to over 100,000 healthcare providers including physicians, diabetes educators, and allied health care professionals.

The first is a branded portfolio designed as an information repository for health professionals to store essential content of the ***Guidelines***.

The second is a synopsis of key information on CV disease and diabetes.

The third is a clinical assessment tool providing an algorithm for cardiovascular risk assessment.

The fourth is self-assessment tool for lay individuals to keep and perform a self-analysis of their CV risk and to inform them of the key measures to lower this risk. This tool is expected to reach over one million Canadians with diabetes.

Lastly, the 'What's up?' document is a conversational newsletter apprising health care providers of the key elements of the 2008 ***Guidelines*** and important changes from the previous Guidelines.

Conclusion: The development of the 2008 Clinical Practice Guidelines, along with these dissemination and implementation strategies will effectively contribute to knowledge translation for health professionals to improve their care of people with diabetes. The Association intends to evaluate the effectiveness of the Guidelines and the dissemination and implementation strategies on behavior change, patient care and empowerment as these strategies unfold over the next 3 years.

Diabetes control and management in Senegal: results of the Diabcare project

M. Ndour-Mbaye[1], A. Sarr[1], A. Lèye[2], M.S. Ka-Cissé[3], S.N. Diop[3]

[1] *Centre de Lutte contre le diabète Marc Sankalé, Médecine Interne, Dakar, Senegal*
[2] *Hôpital Aristide Le Dantec, Medicine Interne, Dakar, Senegal*
[3] *Centre de Lutte contre le diabète Marc Sankalé, Médecine Interne, Dakar, Senegal*

In Senegal, as in other parts of Africa, diabetes epidemiology is poorly documented and a reliable baseline status is fundamental to allow proper management as well as the implementation of a prevention programme. For this reason the DIABCARE-Africa project has been implemented aiming to provide simple yet standardised information from thousands of patients recruited from numerous centres all over Africa (Kenya, Tanzania, Ghana, Nigeria, Cameroun, Senegal). This project is designed similar to the Europe and Asian Diabcare and is a collaboration between Novo Nordisk Regional Office Africa and Gulf, the IDF and the participating African countries. It supports the aims of the Diabetes Declaration Africa through which the IDF, WHO and the African Union call on governments of African countries to prevent diabetes and related non communicable diseases.

The present reports results of the Diabcare-Senegal project. The main objective was to describe diabetes control and management, as well as the stage of late complications observed in diabetic patients who are under follow up and treatment. A descriptive study has been conducted in 5 centres specialised in diabetes management over a period of three months. All patients being followed up in the so called centres for more than 12 months have been included. There were 387 patients with a mean age of 52.2 +/- 12.4. Diabetes was type 2 mainly [92.5%] with a mean duration of 7.1 +/- 5.6 years. Main complications were neuropathy [26.3%], eye complications [20.5%], and diabetic foot [5.1%].

Almost half of type 2 diabetic patients [46.3%] were free of any antidiabetic pharmacological agents. For patients under treatment, most [44.3%] were treated with OAD monotherapy while 10.1% were under insulin monotherapy and 5.2% under combination of OAD and insulin. Despite the frequent association of central obesity, HBP, dyslipidemia very few patients were treated for those comorbidities.

Glycaemic targets with HbA1c < 7% and <6.5% were achieved in 47.4% and 40.2% of patients respectively. Mean levels of HbA1c, FPG and PPPG showed moderate control (7.6 ± 2.4 %, 8.4 ± 4 mmol/L and 10.5 ± 5.5 mmol/L respectively) but the majority of patients failed to achieve glycaemic targets as defined by ADA or IDF.

Only 36.9% of patients treated for high blood pressure achieved the goal and 49.1% untreated patients presented nevertheless blood pressure values beyond recommended targets. Similarly, only 8.4% received treatment for dyslipidemia while 60.4% of patients presented HDLc below 1 mmol/L.

Pharmacological management of diabetes in Senegal should be implemented earlier and be more aggressive including treatment of both hyperglycaemia and associated cardiovascular risk factors. Prevention should aim for reduction of complications through a better glycaemic control.

Comparison of the clinical management of type 2 diabetes in Canada's First Nations peoples to national guidelines: the CIRCLE study

S.B. Harris[1], M. Naqshbandi[1], A.J.G. Hanley[2], O.K. Bhattacharyya[3], J.G. Esler[1], B. Zinman[4]

[1] Centre for Studies in Family Medicine The University of Western Ontario, Family Medicine, London, Canada
[2] University of Toronto, Nutritional Sciences, Toronto, Canada
[3] Li Ka Shing Knowledge Institute St. Michael's Hospital University of Toronto, Family and Community Medicine, Toronto, Canada
[4] University of Toronto, Medicine, Toronto, Canada

Introduction: Diabetes mellitus (T2DM) is one of the most common causes of morbidity and mortality in developed nations, with much of the burden due to complications of T2DM. In Canada, approximately 7% of the population has T2DM with rates up to 5 times higher in Aboriginal peoples. Despite the "epidemic" status of T2DM in Canada's First Nations (FN) peoples, there is no national data about diabetes care delivery and adherence to published national clinical practice guidelines (CPGs) for T2DM.
Aim: The aim of the Canadian First Nations Diabetes Clinical Management Epidemiologic (CIRCLE) study was to examine the degree to which the clinical status of T2DM in FN peoples across Canada was in accordance with the Canadian Diabetes Association 2003 CPGs.
Methods: A random chart audit for T2DM care during the 2007 calendar year was completed for 733 consenting patients (>= 18 years) from 15 FN communities using systematic computerized data collection. Metabolic status, prevalence of complications and treatment were documented.
Results: Results are compared to the key CPG recommendations for the treatment and management of T2DM and the degree to which patients surveyed met these CPGs. Results indicate that 33.2% [95% CI 29.0-37.4] had an A1C of 7.0-8.9% and 27.1% [19.1-35.1] had an A1C of 9.0% or greater. Of the 27.1% of patients with an A1C of 9.0% or greater, 87.6% [83.6-91.5] were not receiving insulin. Blood pressure was above the target 130/80 mmHg in 51.3% [44.7-57.9] of patients, with 13.4% [10.3-16.4] of those not on an ACE or ARB at the time of audit. LDL cholesterol was above the 2.0 mmol/L target for 65.8% [58.9-72.7] of patients, with 37.7% [28.9-46.4] not on a statin. Overweight, defined as a BMI of 25-29.9 was prevalent in 24.3% [18.6-30.0] of patients, 25.7% [19.4-31.9] were obese with a BMI of 30-34.9 and 30.3% [19.6-40.9] were morbidly obese with a BMI of 35 or greater. The prevalence of current smokers was 39.4% [19.0-49.9].
Conclusion and discussion: The CIRCLE study demonstrates that a considerable proportion of T2DM FN patients in Canada are not well controlled and that disease burden is high. The percentage of patients not at A1C target is higher than in a similar study carried out with the non-Aboriginal population in Canada. Major care gaps exist in the management and treatment of T2DM patients in FN communities. Further research into alternate models of diabetes health care delivery in FN communities are urgently required.

ADVANCE-ON: A Post-Trial Observational Study

S. Zoungas[1], A. Patel[1], B. Neal[1], S. Harrap[2], D. Grobbee[3], M. Marre[4], B. Williams[5], P. Hamet[6], N. Poulter[7], L. Lisheng[8], S. MacMahon[1], J. Chalmers[1]

[4] Universite Paris 7, Diabetes Endocrinology and Metabolism, Paris, France
[5] University of Leicester, Medicine and Biological Sciences, Leicester, United Kingdom
[6] University of Montreal, Medicine, Montreal, Canada
[7] Imperial College, Preventive Cardiovascular Medicine, London, United Kingdom
[8] Cardiovascular Institute and Fu Wai Hospital, Cardiovascular, Beijing, China

Background: Globally, the prevalence of diabetes continues to rise sharply. Three recently completed large-scale clinical trials failed to confirm anticipated beneficial effects of intensive blood glucose lowering on cardiovascular events in patients with diabetes. Even more recent data suggest that the benefits of intensive glucose control strategies may accrue late and that follow-up of these trials may have been insufficient to address this crucial clinical question.
Objective: The primary aim of this study (ADVANCE-ON) is to define the long-term, post-trial effects of intensive glucose control with a gliclazide MR-based regimen (targeting an HbA1c =6.5%) compared to standard glucose control, on death and major macrovascular events in 11,140 high-risk patients with type 2 diabetes who took part in ADVANCE. Secondary aims are to determine the long-term, post-trial effects of routine blood pressure lowering with a fixed combination of perindopril-indapamide on the same 2 outcomes.
Methods: All consenting surviving patients randomised in the ADVANCE trial (from 213 active clinical centres in Australasia, Asia, Europe and North America) will be observed for five years after their final ADVANCE study visit, in the setting of their usual care. It is anticipated that the patterns of glucose control in the randomised groups will converge early after completion of the trial and cessation of the randomised interventions. Vital status and major clinical events will be documented at annual follow-up. The two primary outcomes will be death from any cause and major macrovascular events (non-fatal myocardial infarction, non-fatal stroke and cardiovascular death). Assuming a conservative annual event rate of 2.3% the study will have more than 80% power (with a=0.05) to detect a 13% or greater difference in relative risk for the primary outcomes. The effects of the interventions will be explored jointly and separately for events recorded during ADVANCE and ADVANCE-ON and tested using Cox models and log rank tests using the intention to treat principle.
Conclusion: The evidence provided by the ADVANCE-ON study, representing a contemporary cohort of patients with long standing diabetes from around the world will either confirm or refute the UKPDS post-trial findings in patients with new onset diabetes, and play a pivotal role in defining future clinical management for tens of millions of individuals with type 2 diabetes worldwide.

Cardiovascular (CV) risk evaluation in people with type 2 diabetes (T2D) on insulin therapy (CREDIT) study – CV disease and CV risk at baseline: the Italian subgroup analysis

G. Vespasiani[1], G. Garrapa[2], S. Leotta[3], V. Borzi[4]

[1] Ospedale di San Benedetto del Tronto, Diabetologia, San Benedetto del Tronto (AP), Italy
[2] Ospedale S. Croce, Diabetologia, Fano (PU), Italy
[3] Ospedale Sandro Pertini, Diabetologia, Roma, Italy
[4] A.O. Universitaria V. Emanuele - Ferrarotto e S. Bambino, Diabetologia, Catania, Italy

Insulin treatment improves long-term glycemic control, which can reduce the risk of CV events associated with T2D. The Cardiovascular Risk Evaluation in people with T2D on Insulin Therapy (CREDIT) study is a long-term (4-yr), 314 center, non-interventional trial in North America, Europe and Asia with 22 Italian participating centers. People with T2D (n=417) who had recently started insulin (basal, short-acting or premix insulin at the physician's discretion) were eligible for evaluation (60/40% male/female; age (mean±SD) 63.5±9.5 yr; BMI 29.3±5.4 kg/m2; diabetes duration 12.9±8.4 yr). Most (64.3%) had =1 diabetes-related complication; macrovascular disease was present in 32.9 %. At the time of starting insulin, A1C and plasma glucose (PG) levels were high (A1C 9.1±1.8 %, fasting BG 207.1±69.7 mg/dL, postprandial BG 229.9±68.5 mg/dL). 39.5% of T2D patients in this study were obese (BMI >30.0 kg/m2), while 9.6% had low-density lipoprotein cholesterol = or >160 mg/dL and 41.1% had triglycerides = or >150 mg/dL. While the lipid profile and obesity varied with increasing A1C category, other risk factors including hypertension and smoking were comparable between categories. Thus, in this Italian population with T2D, despite a high prevalence of macrovascular disease, the delay in starting insulin therapy and the high A1C level were associated with poor management of other CV risk factors, suggesting a common problem in managing metabolic risk.

Prevalence and outcomes of unrecognized diabetes mellitus and prediabetes among acute stroke patients with admission hyperglycaemia at the Philippine General Hospital: DASH Study

M. Cardino[1], C. Josol[1], C. Jimeno[1], G. Manalo[1]
[1] Philippine General Hospital, Endocrinology, Manila, The Philippines

Retrospective study by Gacutan showed 21% admission hyperglycaemia at Philippine General Hospital. Screening for glucose disorders among hyperglycaemic stroke patients is a venue for secondary prevention. Stroke Society of the Philippines has no screening guidelines for post-stroke hyperglycaemia.
Objectives: To determine prevalence and outcomes of unrecognized diabetes and prediabetes among stroke patients; determine predictors for unrecognized diabetes.
Methodology: Cross-sectional prospective.
Population: Stroke patients from January-December 2008 with admission hyperglycaemia. RBS, HbA1c &NIHSS taken on admission. All were followed up 6-weeks post-discharge for screening (using FBS &75-grams OGTT) except those discharged with anti-diabetes medications.
Outcomes: Mortality at 6 & 12 weeks. Functional outcomes (Modified Rankin & Barthel's Index) done at OPD follow-up.
Results: There were 504 stroke patients, 178(35%) with admission hyperglycaemia. Nineteen were unclassified (10 patients with unkown DM history expired and 9 lost to follow-up). Majority were newly-diagnosed diabetes 32.7%(52 of 159), stress hyperglycaemia(29.56%), IGT(13.8%), IFG(8.8%), IGT+IFG(3.7%), previous diabetes(11.32%). By Kruskal-Wallis, diabetic stroke patients were older(67.78±13.15years), higher BMI(25.44±4kg/m2), higher waist/hip ratio (0.97±0.18), higher admission NIHSS(21±7) compared to other groups. Alcohol, smoking, hypertension, nosocomial infections were associated with diabetes($p<0.01$) using Fischer Exact's test. No association for sex and atrial fibrillation. By Kruskal-Wallis, admission RBS was higher among diabetics compared to prediabetics and stress hyperglycaemics(180±6 vs. 147±46 vs. 133±27, p0.001); HbA1c was higher among diabetics versus other groups respectively(8.4±2.4 vs. 5.43±0.6 vs. 4.8±0.5, p0.001). Higher triglyceride and lower HDL seen among diabetics versus stress hyperglycaemia. No trends for cholesterol and LDL across groups. On multiple logistic regression, age(OR:1.06,p0.07), smoking(OR:9.81,p0.05) & HbA1c(OR:11.39,$p<0.01$) were predictors for unrecognized diabetes. Higher Modified Rankin score and lower Barthel's index (indicative of poor motor function) were seen among diabetics compared to other groups measured on follow-up. Mortality at 6 weeks was higher among diabetics(OR: 2.34,$p<0.01$) and trend towards higher mortality at 12 weeks(OR:1.81,p0.063) compared to other groups.
Conclusion: Thirty-five percent of stroke patients had hyperglycemia; majority were unrecognized diabetes. Using FBS and 75-grams OGTT 6-weeks post-discharge, we identified 32.7% new diabetics and 26.4% prediabetics eligible for treatment and secondary prevention. Mortality was higher with diabetes. Age, smoking, HbA1c were predictors of newly-diagnosed diabetes.

O-0366

Trends in cardiovascular risk factors in patients with type 2 diabetes

K. Chikkaveerappa[1], K. Jones[1], D.B. Jones[1]
[1] Arrowe Park University Teaching Hospital, Diabetes and Endocrine, Wirral, United Kingdom

Aims: To study the trends in cardiovascular risk factors in a clinic population of patients with type 2 diabetes over seven years period.
To evaluate the impact of introduction of National institute of clinical excellence (NICE) United Kingdom (UK) guidelines in the treatment of type 2 diabetes.
Methods: Design: Sequential analysis of the patients data was undertaken from the Wirral diabetes register database with comparison against national United Kingdom guidelines targets.
Setting: Outpatient diabetes clinic in a university teaching hospital foundation trust UK.
Participants: All patients with non-insulin dependent diabetes entered into Wirral diabetes register between 2000 and 2006 (seven years).
Main outcome measures: The following parameters were analysed; systolic and diastolic blood pressure, glycosylated haemoglobin (HbA1c), total cholesterol, triglycerides, high density lipoprotein cholesterol and low density lipoprotein cholesterol.
Results: Between 2000 and 2006 a progressive decline can be observed in mean total cholesterol from 5.1mmol/l to 4.3 mmol/l ($p<0.001$) and mean low density lipoprotein cholesterol from 3.6 mmol/l to 2.2 mmol/l ($p<0.001$).
There is a marked drop in mean population blood pressure readings from 147/86 mmHg in 2000 to 137/75 mmHg in 2006. The mean blood pressure of the sample has been lower than 140/80 mmHg since 2003, reflecting National Institute of Health and Clinical Excellence (NICE) UK guideline targets.
In 2006 41% of patients have HbA1c value of <7% compared 42% in 2000. There is also an overall fall in the percentage of patients with HbA1c >9% from 19% in 2005 to 15% in 2006. However improvement in HbA1c over seven years period in all the percentage group were not significant compared to the improvements seen in lipid and blood pressure control.
Conclusions: This study demonstrates a clear downward trend in blood pressure and lipid values. This trend is not seen to the same extent in HbA1c values in the clinic population studied, reflecting changes in treatment targets. Although NICE UK guidelines and targets for the treatment of type 2 diabetes appear to have had a significant effect on blood pressure and lipid parameters in this population, there is no evidence of significant improvement in glycaemic control. It is likely that more intensive intervention or more potent therapies will be needed to improve glycaemia in patients with type 2 diabetes mellitus. Importantly we would expect the lowered lipid levels and blood pressure to reduce future risk of cardiovascular disease in this population.

No conflict of interest

O-0367

SIMETRIC project (metabolic syndrome as cardiovascular risk factor): correlation of diabetes and metabolic syndrome with cardiovascular disease in a ten-years follow-up

J. Cabre[1], B. Costa[1], J.L. Piñol[1], J. Basora[1], J. Saumell[1], G. Reus Metabolic Syndrome[1]
[1] Catalan Health Institute, Primary Care, Reus, Spain

Aims: To analyze prevalence of metabolic syndrome (MS) in assisted population >15 y. in primary care (according WHO/NCEP-ATPIII criteria) and its correlation with cardiovascular disease (CVD), a multicentric cohort study was performed (2 basic health areas (n=43,000), ten-years follow-up).
Methods: 1489 participants, that gave their informed consent, were questioned on anamnesis, risk factors, anthropometrical parameters, blood pressure, analytic profile and oral glucose tolerance test (OGTT) (except in diabetics), current treatments, presence of CVD and CVD risk scores.
Results: Mean age 52,3±17,6 y., 860 women (57,8%). 558 had hypertension (37,5%), 234 type 2 diabetes (15,7%), 359 prediabetes (24,1%), 483 obesity (32,4%), 342 dyslipidaemia (23%) and 279 smokers (18,7%). Mean BMI 27,8±5,5 kg/m^2. CVD risk score according Framingham's function was 11,2±9,8%, and according Spanish tables (REGICOR) 10,0±13,9%.
259 subjects (17,4%,[CI95%: 20,0-26,3]) fulfilled MS criteria (WHO), and 303 (20,3%,[CI95%: 26,9-32,6]) according NCEP-ATPIII criteria.
CVD was observed in 212 individuals (14,2%): 88 nephropathy (5,9%), 76 coronary events (5,1%), 68 stroke (4,6%), 53 peripheral arteriopathy (3,6%), 32 retinopathy (2,1%) and 8 neuropathy (0,5%). The relative risk of complications between patients with/without MS (NCEP) was 2,67.
Logistic regression of MS components on all-type CVD shows an odds ratio(OR)=2,52 (CI95%:1,7-3,6) for hypertension, OR=1,58 (CI95%:1,1-2,3) for dyslipidaemia and OR=1,23 (CI95%:0,99-1,59) for type 2 diabetes. The analysis the MS criteria by WHO-set shows OR=2,2 (CI95%:1,4-3,6) and by NCEP criteria OR=1,5 (CI95%:0,9-2,5).
Conclusions: Prevalence of MS is high in general assisted population. MS supposes a greater risk of CVD, specially by WHO-criteria (high prediction of CVD). Therefore, this confirms that detection of MS is a cornerstone in primary care.

Impact of diabetes and hypertension on the incidence of acute stroke for the DECODE study group

M. Hyvärinen[1], Q. Qiao[1], J. Tuomilehto[1]
[1] University of Helsinki, Department of Public Health, Helsinki, Finland

Aim: We examined the impact of diabetes and hypertension on acute stroke incidence in women and men.
Methods: Data from 9 northern European cohorts were collaboratively analyzed. The study included 9985 men and 8375 women aged 25 to 90 years. The median length of follow-up was 12.9 years. A multivariable adjusted Cox proportional Hazards model was used to estimate the hazard ratios (HRs) for stroke incidence.
Results: A total of 356 (3.6%) women and 642 (7.7%) men had acute stroke event. In both genders diabetes and hypertension were independent risk factors for stroke incidence. When people without both diabetes and hypertension were used as a reference group (women and men separately), the multivariable adjusted HRs were 1.99 (1.51-2.63) in women and 1.37 (1.12-1.68) in men with hypertension but without diabetes, 1.78 (0.99-3.21) in women and 1.79 (1.08-2.98) in men without hypertension but with diabetes and 3.29 (2.28-4.76) in women and 2.54 (1.92-3.34) in men with both hypertension and diabetes. No interaction between diabetes and hypertension was found in either gender.
Conclusions: Diabetes increased the risk of stroke incidence in both genders independent of hypertension.

No conflict of interest

O-0369

Cardiovascular Function in type 1 diabetes: the DCCT/EDIC Research Group

S.M. Genuth[2], P.A. Cleary[1], J.C. Backlund[1], J.A.C. Lima[3], D.A. Bluemke[4]
[1] The George Washington University, The Biostatistics Center, Rockville, USA
[2] Case Western Reserve University, Biomedical Research, Cleveland, USA
[3] Johns Hopkins Medical Institutions, Russel H. Morgan Dept of Radiology, Baltimore, USA
[4] Johns Hopkins Medical Institutions, Radiology and Imaging Sciences, Bethesda, USA

Background: The EDIC observational follow-up of the Diabetes Control and Complications Trial (DCCT) has reported benefit of prior intensive therapy on retinopathy, nephropathy, neuropathy and cardiovascular disease events (CVD). Using Cardiac MRI (CMRI), we evaluated cardiac function in former DCCT intensive (INT) and conventional (CON) therapy subjects 14 to 15 years after DCCT closeout.
Methods: CMRI was performed in 28 clinics and read centrally using MASS software. Six functional outcomes were evaluated: end diastolic volume (EDV) and systolic volume (ESV), stroke volume (SV), cardiac output (CAROUT) and left ventricular end diastolic mass (LVDM), adjusting for body surface area, and ejection fraction (EF).
Results: Of 1211 active EDIC subjects asked to participate, 90% agreed. A total of 850 scans (~75% of the consented participants) have been performed. Fifty-one patients with CVD were excluded from this analysis. On a quality control scale of 0,1,2, the mean score was 1.77 with only 2% unacceptable (0 score) examinations. Reproducibility was high for all measures (intra-class correlations > 0.91). Normal EF (50-70%) was prevalent (>85%) in both INT and CON treatment group.

Least Square Means by Gender (adjusting for basic covariates (BC) - reader, machine type and attained age) and by Group (adjusting for BC and gender)

Outcome	Females	Males	INT	CON
EDV (ml/m²)	66.4	74.0	70.3	70.1
ESV (ml/m²)	24.2	28.8	26.4	26.6
SV (ml/m²)	42.2	45.2	43.9	43.5
EF (%)	63.7	61.4	62.7	62.4
CAROUT (L/min/m²)	3.1	3.2	3.1	3.1
LVDM (g/m²)	66.5	80.2	73.4	73.2

*All p-values < 0.01 between genders. No significant differences between INT and CON

Conclusion: A large multicenter study of CVD in type 1 diabetes is feasible, attractive to participants and yields new information. After excluding patients with clinical CVD events, 89% of the subjects had normal EF; least square mean differences between men and women were statistically significant on all the functional outcomes; no differences were detected between the INT and CON treatment groups.

No conflict of interest

O-0370

Prevalence of cardiovascular disease in people with diabetes with and without schizophrenia: a population-based cohort study

L.C. Bresee[1], S.R. Majumdar[2], S.B. Patten[3], J.A. Johnson[1]
[1] University of Alberta, School of Public Health, Edmonton, Canada
[2] University of Alberta, Department of Medicine, Edmonton, Canada
[3] University of Calgary, Departments of Community Health Sciences and Psychiatry, Calgary, Canada

Aims: Individuals with diabetes have a high prevalence of cardiovascular (CV) risk factors and cardiovascular disease (CVD), as do individuals with schizophrenia. It is unclear, however, whether the prevalence of CVD is further increased in people with diabetes and schizophrenia. The aim of this study was to evaluate prevalence of CV risk, CVD, and revascularization procedures in people with diabetes and schizophrenia compared to people with diabetes only.
Methods: A population-based cohort study was used to evaluate the study aim. Information from the databases of Alberta Health and Wellness was used to create the cohort, and included all individuals aged 20 years and older in the Canadian province of Alberta with diabetes from 1995 to 2006. Individuals with diabetes were identified using criteria from the Canadian National Diabetes Surveillance System. Schizophrenia, CV risk (hypertension, dyslipidemia), CVD (congestive heart failure [CHF], stroke, acute coronary syndrome, ischemic heart disease, arrhythmia, old myocardial infarction), and revascularization procedures (coronary artery bypass grafting, percutaneous transluminal coronary angioplasty) were identified using physician claims data, ambulatory care data, and hospitalization data. Prevalence of CV risk, CVD, and revascularization was compared using multivariable logistic regression while adjusting for differences in age, sex, healthcare subsidy, and number of physician visits (to control for surveillance bias).
Results: We identified 129,438 people with diabetes, and 2,261 (2.0%) of these individuals had schizophrenia. Individuals with diabetes only were older (mean age 60.3 years vs. 57.6 years), more likely to be male (51% vs. 42.9%), and less likely to have subsidized health care (39.6% vs. 73.3%) compared to individuals with schizophrenia and diabetes. After multivariable adjustment, prevalence of dyslipidemia was not significantly different between groups (OR: 0.97; 95% CI: 0.89 - 1.05), and hypertension was less prevalent in people with diabetes and schizophrenia (OR: 0.60; 95% CI: 0.55 - 0.65). Individuals with schizophrenia and diabetes were more likely to have CHF (OR: 1.31; 95% CI: 1.18 - 1.46), stroke (OR: 1.27; 95% CI: 1.14 - 1.42), and CVD (OR: 1.19; 95% CI: 1.10 - 1.30), but were less likely to undergo revascularization (OR: 0.51; 95% CI: 0.41 - 0.63).
Conclusion: Despite having a higher prevalence of CVD, individuals with schizophrenia and diabetes were significantly less likely to undergo revascularization compared to people with diabetes only. Also, prevalence of CV risk factors was lower (hypertension) in people with diabetes and schizophrenia, or no different (dyslipidemia) between groups. This may be due to a lack of screening, or other lifestyle risk factors increasing the risk of CVD in those with schizophrenia and diabetes.

[7] *West German Heart Center Essen, University Hospital University of Duisburg-Essen, Essen, Germany*

Aims: Diabetes mellitus type 2 (DM) is known to be associated with atherosclerosis and increases the risk for cardiovascular disease (CVD). Coronary artery calcification (CAC), a specific marker of coronary atherosclerosis, predicts CVD. Here we examined the gender distribution and impact of CAC by diabetes status on incident CVD in a population-based cohort.
Methods: Out of 4,814 study participants of the Heinz Nixdorf Recall Study (aged 45-75 years), we included 4,301 participants without overt CVD at baseline and with data for CAC, diabetes and with information for myocardial infarction/coronary death (primary endpoint). Baseline examination included detailed standardized medical history, blood analyses and electron-beam tomography. Prevalent DM is based on selfreport and/or intake of diabetes medication. CAC, measured as Agatston score, is presented as median and interquartile range (Q1-Q3) and transformed to log(CAC+1) in regression models. We calculated hazard ratios (HR) and 95%-confidence intervals (95%-CI) for primary endpoints with Cox proportional hazards models adjusting for covariates age, CAC, BMI, blood pressure and anti-hypertensives.
Results: The mean observation time was 5.02 (±0.77) years, with 94 (65 men) events, including 17 participants (11 men) with DM. Highest CAC was documented in men with events, with a median CAC in men with DM of 663 (Q1-Q3:1,721), without DM 210 (918). In men without events these figures were 108 (420), resp. 47 (202). In women without myocardial infarction/coronary death and no DM the known distinctive lower CAC burden compared to men is reflected in a median CAC of only 1.3 (32). Even in women with events and DM the CAC is still lower compared to men (28;1,228). Nevertheless, the high CVD risk for women with DM is also apparent in our study with an age-adjusted HR of 3.65 (95% CI: 1.42-10.72) compared to women without DM (men 2.03 (1.02-4.01)). Adjusting for covariates did not change the HR in women (3.90;1.42-10.72), but in men the HR decreased considerably (1.49;0.72-3.08). Stratifying for DM revealed that in men with DM, an increasing CAC is associated with an increasing risk for myocardial infarction/coronary death (age-adjusted HR log(CAC+1): 2.01;1.18-7.71), different to women with DM (1.24;0.8-1.8). However, in both men and women without DM the risk according to CAC burden did not differ (1.46;1.25-1.71, resp. 1.41;1.17-1.70).
Conclusions: Coronary artery calcification plays an important role for CVD risk in men with DM, while CAC seems to be of less importance to explain the increased CVD risk in women with DM. However, these results have to be confirmed in studies with more events, especially with regard to women with DM.

Treatment of obesity and diabetes by a Canadian aboriginal medicinal plant in a mouse model of diet-induced type 2 diabetes

D. Harbilas[1], A. Brault[1], D. Vallerand[1], A. Saleem[2], L. Martineau[1], J.T. Arnason[2], P.S. Haddad[1]

[1] *Université de Montréal, pharmacologie, Montréal QC, Canada*
[2] *Université de Ottawa, Biologie, Ottawa ON, Canada*

The prevalence of the metabolic syndrome is increasing among the Cree of Eeyou Istchee (CEI - Northern Quebec) as a result of increases in obesity and insulin resistance. Non-traditional diet and sedentary lifestyle along with cultural disconnect of modern type 2 diabetes (T2D) therapies are involved. Exploring treatments from within CEI traditional pharmacopeia represents a valuable alternative. W7, a CEI plant extract from the Canadian Boreal Forest, demonstrated anti-obesity and anti-diabetic properties in a recent in-vivo prevention study. We thus evaluated the potential effects of two preparations (aqueous (AE) and ethanolic (EE) extracts) of this plant in a mouse model of diet-induced obesity and T2D. C57/BL6 mice were subjected to high fat (HF) diet for sixteen weeks resulting in obesity, hyperinsulinemia and mild steady-state hyperglycemia. Plant extracts were introduced in the HF diet for the last eight weeks and tested at doses of 125 and 250 mg/Kg as the in-vivo prevention study. Treatment with EE 125 was found to have the most significant effects. It significantly decreased body weight by 13% and retroperitoneal fat pad weight by 16% as compared to HF control mice. No statistical difference was observed in water or food intake. In EE 125 animals, plasma insulin was significantly diminished by 87 % compared to HF controls. Area under the curve of glycemia versus time was also reduced in treated animals and statistical significance was reached in the EE 250 group (15% reduction) as was the ratio of insulinemia to glycemia (64 % by EE 250 and 85% by EE 125). The effectiveness of EE 125 was also related to a decrease in the lipid content of the liver, as confirmed by histological analysis revealing a significant reduction in the proportion of steatotic livers and a shift toward more moderate grades of steatosis as compared to HF controls. The relative liver weight was significantly reduced by 20 % by EE compared to HF controls. Moreover, treatment of animals by EE 125 significantly diminished plasma leptin by 41 % and leptin/adiponectin ratio by 42 % compared to controls. Plasma TNF-a increased by 800 % in HF controls and was returned to normal values by treatment with each plant extract (AE and EE). The treatment of animals with AE 125 demonstrated a profile of effects similar to EE125 but lower effectiveness. These plant extracts thus exhibit promising anti-obesity and consequently anti-diabetic effects. Mechanisms remain to be elucidated but current results point towards a stimulation of metabolic rate.

[3] *Faculty of Medicine, Pharmacology, Montreal, Canada*
[4] *Faculty of Science, Animal Biology and Physiology, Yaounde 1, Cameroon*

Background: Anacardium occidentale L. (Cashew tree) of the family Anacardiaceae have been documented as traditional plant treatment for diabetes and hypertension.
Aims: To investigate vasorelaxant effect of the cyclohexane-soluble of Anacardium occidentale leaf (AOL1), the dichloromethane-soluble (AOL2), the Ethyle-Acetate soluble (AOL3) and the methanol-soluble (AOL4) in resistance mesenteric arteries isolated in normal Wistar rats. We also hypothesized that reducing the prooxidant parameters in high glucose-induced endothelial

dysfunction in human endothelial cell line (EAhy) by these fractions could improve endothelial function.

Methods: Total antioxidant activity of cashew leaf was determined using DPPH free radical scavenging assay and results were expressed in gram trolox equivalent (TE)/gram of extract. Assessment of vascular function was carried out on second-order mesenteric arteries isolated and incubated in 5 ml organ bath containing physiological saline. EAhy cells were cultured under normal (5.5 mmol/l) or high glucose (20 mmol/l) concentrations for 4 and 7 days with or without extracts of AOL (7 µg/ml, 12.5 µg/ml and 25 µg/ml).The activity and expression of protein kinase C, NO synthase and antioxidant enzymes, namely, superoxide dismutase, catalase and glutathione peroxidase were investigated.

Result and discussion: The most potent antiradical reactivity was observed in AOL4 extract, a methanol-soluble fraction with 2023 TE/g of extract compared to chlorogenic acid (2976 TE/g of extract) as standard. In isolated mesenteric artery rings precontracted with phenylephrine, AOL1, AOL2, AOL3, and AOL4 induced a concentration-dependant relaxation with IC50 values of 120 µg/ml, 100 µg/ml, 70 µg/ml and 70 µg/ml, respectively. Exposure of Eahy cells with high glucose for 7 days significantly ($p<0.05$) decreased cell viability (22%), the level of antioxidant gluthatione and expression of protein kinase C. Incubation with low concentrations (7 µg/ml, 12.5 µg/ml) of AOL3 and AOL4 for 7 days significantly ($p<0.05$) attenuated high glucose-induced dysfunction of EAhy cells. HPLC-DAD profile recorded for AOL3 and AOL4 indicates the presence of for major peaks with close retention times.

Conclusion: ***Anacardium occidentale*** leaf extract induces a NO- and endothelium vasodilatation in mesenteric arteries precontracted with phenylephrine. Particularly, AOL3 and AOL4 improved high glucose-mediated endothelial dysfunction and thus may be potential new therapeutic agents for diabetic cardiovascular complications.

O-0374

Effects of Mongolian traditional medicinal plant extract on in vivo insulin action in streptozotocin-induced diabetic rats

O. Khookhor[1], Y. Sato[1], M. Nagasaki[1]
[1] Aichi Gakuin University, Health Science Faculty Psychological and Physical Science., Nagoya, Japan

Aims: In the present study, we firstly performed a preliminary investigation on the acute effect of Mongolian medicinal plant extract Myricaria alopecuroides on the blood glucose tolerance in rats, evaluated by an oral glucose tolerance test (OGTT). Then, investigated the effects of the same extract on in vivo insulin action in streptozotocin (50mg.kg^{-1}BW,i.v.) -induced diabetic rats by means of the euglycemic clamp.

Methods:

Oral glucose tolerance test (OGTT).
Rats were randomly divided into control and plant extract (PE) groups (6-13 rats per group).Time-course blood glucose concentrations were determined 30, 60, and 120 min after glucose load.

Whole blood and plasma assays
Blood glucose concentration was determined using an automated analyzer model 2300 STAT Plus. Plasma insulin concentration was measured by the Special Reference Laboratories Inc. using a chemiluminescence enzyme immunoassay method.

Statistical analysis
Data were analyzed by one-way analysis of variance. When a significant difference was found ($P < 0.05$), values were further compared with Student's t test. The StatView was used for statistical analyses. Data are expressed as means ± SE.

Results:

1. Effect of plant extract on blood glucose concentrations
   Blood glucose concentrations and net incremental area under the curve (net AUC) for control and plant extract before and after oral load of glucose are summarized in Table1, ($P<0.05$).
2. Acute effect of plant extract on MCR
   Rats divided into acute and 7-days oral administration groups. At low–dose insulin infusion, the decreased metabolic clearance rates of glucose (MCR) in diabetic rats were improved by a single and 7 days administration of plant extract (500mg.kg.BW, p.o.; acute effects: control: 8.6± 0.7ml kg^{-1}min^{-1}. versus plant extract: 15.4 ± 1.4 ml kg^{-1}min^{-1}, and 7-days effects: control: 8.2 ± 0.6 ml kg^{-1}min^{-1} versus plants extract: 16.5 ± 1.2 ml kg^{-1}min^{-1}, $P<0.001$, respectively).
3. Effect of 7-day administration of plant extracts on MCR
   During high-dose insulin infusion, the MCR was increased in 7-days ***Myricaria*** extract treated diabetes compared with saline diabetes, but, these changes were not observed after a single ***Myricaria*** extract treatment.

Discussion: Outcomes from the euglycemic clamp studies indicated that (1) impaired insulin sensitivity induced by STZ was improved by single and 7 days administration of plant extract Myricaria alopecuroides (impaired MCRs of diabetic rats were ameliorated by 80% and 95% as a result of single and 7-day treatment, respectively) and (2) 7-day treatment with plant extract improved insulin responsiveness in diabetic rats.

Conclusion: These results suggest that a single administration of the Mongolian plant extract can improve glucose utilization and insulin resistance in diabetic rats.

The CIHR Team in aboriginal antidiabetic medicines: a community-based collaborative approach uniting healers and biomedical scientists to validate Cree traditional medicine

P. Haddad[1]
[1] Université de Montréal, Pharmacology, Montreal QC, Canada

Obesity and Type 2 diabetes are considered global epidemics by WHO. Aboriginal people such as the Cree of Eeyou Istchee (James Bay area of northern Quebec) are particularly affected and suffer greater complications. This may be due in part to low compliance with modern medicines because of a cultural disconnect. A multidisciplinary team was therefore put together to explore the antidiabetic potential of Cree Traditional Medicine (TM) involving Boreal forest plants. The team is composed equally of scientists with expertise in botany, phytochemistry, nutrition, pharmacology, biochemistry, toxicology and clinical endocrinology, as well as Cree Elders and members of various Cree health institutions, notably including the Cree Board of Health and Social Services of James Bay (CBHSSJB). A novel ethnobotanical approach based on diabetes symptoms was used to identify potential antidiabetic plants, and a total of 17 species were characterized phytochemically. Each species was screened for primary antidiabetic activity using 1) a pancreatic beta cell line to assess effects on glucose-dependent insulin secretion; 2) muscle and adipocyte cell lines to assess effects on insulin-dependent and -independent glucose transport; 3) an adipocyte cell line to assess glitazone-like activity; 4) an intestinal cell line to assess effects on glucose transport. Secondary antidiabetic activity screening included 1) protection against hyper- or hypoglycaemia in a pre-neuronal cell line; 2) pro- or anti-inflammatory activity in a macrophage cell line; 3) anti-oxidant and anti-glycation activity using cell free bioassays. Toxicological potential was also assessed by using an array of recombinant cytochrome P450 isoforms (CYPs) and other flavin-containing oxygenases. No species affected insulin secretion but several plant extracts increased basal and/or insulin-dependent glucose transport in muscle cells, adipocytes or both, while inhibiting intestinal glucose transport and exhibiting weak to moderate inhibition of CYPs. For such promising species, detailed studies uncovered a predominant mode of action related to inhibition of mitochondrial respiration and activation of AMPK, similar to metformin. For several of these species, active principles have been identified using bioassay-guided fractionation. Bioavailibility, antihyperglycemic and/or anti-obesity efficacy has been confirmed for 4 plants using in vivo animal models of obesity, insulin resistance or diabetes. Clinical studies are also underway to document the safety and efficacy of Cree TM using a culturally-adapted, all-inclusive, observational protocol. Finally, our project represents a pilot study for the integration of Cree TM into diabetes care for the CBHSSJB.

A Gymnema sylvestre extract stimulates insulin secretion from isolated human islets of Langerhans in vitro: role of extracellular Ca2+ and protein kinase activation

A. Alromaiyan[1], B. Liu[1], G.C. Huang[2], S.A. Amiel[2], P.M. Jones[1], S.J. Persaud[1]
[1] *King's College London, Diabetes Research group, London, United Kingdom*
[2] *King's College London, Division of Gene & Cell Based Therapy, London, United Kingdom*

Background: Folk remedies such as Gymnema sylvestre (GS) plant extracts have been used to treat diabetes mellitus for many centuries, but their direct effects on insulin secretion and mode of action have not been studied in detail.
Methods: We have used isolated human islets to examine the effects of a novel GS extract, termed OSA (U.S. Patents 6949261 and 6946151), on insulin secretion and to investigate whether the stimulatory effect of OSA in human islets is dependent on the presence of extracellular calcium and protein kinase activation.
Results: Basal insulin secretion from human islets at 2mM glucose was stimulated by 0.25mg/ml OSA (347±16% basal, P<0.0001, n=3), and OSA also potentiated insulin secretion at 20mM glucose (20mM glucose: 352±44% basal, 20mM glucose + 0.25 mg/ml OSA: 863±77% basal, P<0.0001, n=3). OSA-induced insulin secretion was significantly inhibited by nifedipine, a voltage-operated Ca^{2+} channel (VOCC) blocker (2mM glucose + 0.25mg/ml OSA: 665±32% basal; + 10mM nifedipine: 370±9%, P<0.001, n=4). The insulin secretagogue effect of OSA was dependent, in part, on protein kinase activation since incubating human islets with staurosporine, a general protein kinase inhibitor, resulted in partial inhibition of OSA-induced insulin secretion (2mM glucose + 0.25mg/ml OSA: 673±27% basal; + 200nM staurosporine: 485±19%, P<0.0001, n=4).
Conclusions: These data indicate that the GS isolate OSA stimulates insulin secretion from human islets in vitro, at least in part as a consequence of Ca^{2+} influx and protein kinase activation.

Antidiabetic activity of cycloart-23-ene-3ß, 25 diol in streptozotocin-nicotinamide induced diabetic mice

S. Badole[1], S. Bodhankar[1]
[1] *Poona College of Pharmacy Bharati Vidyapeeth University, Pharmacology, Pune, India*

Aims: Cycloart-23-ene-3β, 25-diol was isolated from stem bark of Pongamia pinnata. The aim of the study was to evaluate the antidiabetic activity of cycloart-23-ene-3β, 25-diol in streptozotocin-nicotinamide induced diabetic mice.
Methods: Overnight fasted mice were treated with nicotinamide (110 mg/kg, i.p.). After 15 min, streptozotocin (200 mg/kg, i.p.) was injected. Increase in blood sugar after 3 days confirmed diabetes. After one week, diabetic mice were divided into following groups (n=6) viz; Group II- vehicle (tween 80, 2%; 10 ml/kg, p.o.), Group III- glibenclamide (10 mg/kg, p.o.), Group IV- cycloart-23-ene-3β, 25-diol (1 mg/kg, p.o.). Group I was separate non diabetic. Acute study involved determination of serum glucose at 0, 2, 4, 6 and 24h. Chronic study include daily administration for 28 days of cycloart-23-ene-3β, 25-diol and glibenclamide. Serum glucose, body weight, food intake and water intake were determined on 7th, 14th, 21st and 28th day. On day 28th the following parameters were determined; haemogram, lipid profile, liver function, renal function in serum. Oral glucose tolerance test (OGTT) was performed in cycloart-23-ene-3β, 25-diol pretreated mice on day 29. On 30th day, all animal were sacrificed by cervical dislocation. Organs were removed from animals for histopathology.
Results: Cycloart-23-ene-3β, 25-diol (1 mg/kg) and glibenclamide (10 mg/kg) showed significant reduction in serum glucose level in acute and subacute studies. The antihyperglycaemic effect was onset at 2h and peak effect at 6h. In chronic study, maximum reduction in serum glucose level was observed on 28th day. Levels of WBC, cholesterol, triglycerides, urea level, uric acid, albumin, globulin, ALT, AST and LDH were higher in the vehicle treated diabetic mice, but were controlled by cycloart-23-ene-3β, 25-diol and glybenclamide. Drug treated groups showed no significant elevation of HDL. Other parameters were not significantly different in all groups. Body weight, food intake and water intake was not affected in treated groups. Increased glucose utilization was observed after 28 day treatment in OGTT. Microscopic examination of liver, kidney, heart and spleen revealed alterations in vehicle treated group, which were less pronounced in cycloart-23-ene-3β, 25-diol and glibenclamide treated groups.
Conclusion: These findings indicated the antidiabetic activity of cycloart-23-ene-3β, 25-diol.

Qei-Fu-Di-Huang-Wan on metabolic control in type 2 diabetic subjects - double-blind placebo-controlled study

C.J. Chang[1], Y.C. Yang[1], J.S. Wu[1], F.H. Lu[1]
[1] *College of Medicine National Cheng Kung University, Department of Family Medicine, Tainan, Taiwan*

Aims: In STZ-diabetic rats, acute oral administration of Qei-Fu-Di-Huang-Wan (QFDHW) decreased the plasma glucose level and very similar to that of metformin treatment. Oral administration of Fu-Zei, the individual constituents of QFDHW, reversed the elevated mRNA and protein levels of PEPCK in the liver of STZ-diabetic rats. The aim of this study is to investigate the efficacy and safety of QFDHW on metabolic control in Type 2 diabetic patients.
Methods: In this randomized, double-blind, placebo-controlled trial, 23 patients were assigned to receive oral QFDHW 4gm thrice daily for 3 months, and 27 patients were assigned to receive placebo. At entry and at 1, 2 and 3 months, glycemic control (fasting plasma glucose and HbA1c), blood pressure, BMI and lipid profiles were measured.
Results: At study entry, patients in the two groups well matched for age, gender, BMI and glycemic control. After 3 months, there was a 8.2% difference (p<0.05) in fasting plasma glucose and a 5.8% difference (p<0.05) in HbA1c between this two groups. The most frequent adverse events in patients receiving QFDHW were upper respiratory infection, musculoskeletal pain and epigastric discomforts. No treatement-related side effects were noted.
Discussion/conclusions: QFDHW had significant effect on metabolic control in Type 2 diabetic patients.

Prevalence metabolic syndrome in a young urban population in Sri Lanka with risk factors for cardio-metabolic disease: DIABRISK SL - stage 2

M. Wijesuriya[1], J. Karalliedde[2], T. Fernando[1], J. Charlton[3], L. Gnudi[2], M. Gulliford[3], G. Viberti[2]
[1] *Diabetes Association of Sri Lanka, National Diabetes Centre, Colombo, Sri Lanka*
[2] *King's College London, Cardiovascular, London, United Kingdom*
[3] *King's College London, Public Health, London, United Kingdom*

Background and aims: Metabolic syndrome (MS) defines subjects at increased risk of metabolic and cardiovascular disease. The prevalence of obesity is growing worldwide in particular among young children and adults. This study aimed to evaluate the prevalence and clinical relevance of MS and its components in children and young adults from an urban Sri Lankan population.
Methods: A general population screening of 22,577 (10,612 M, 11,965 F) subjects aged between 6-40 years estimated the prevalence of physical inactivity, family history of type 2 diabetes, raised body mass index and raised waist circumference. Those subjects with two or more of these risk factors were further assessed for clinical and biochemical measures in the fasting state and after an oral glucose tolerance test. The IDF definition for MS in children and adults was used.
Results: To date 4109, (46% M) subjects selected for increased risk have attended; 1398 (45%M) between 6-14 years, 751 (33%M) between 15-19 years and 1960 (52%M) between 20-40 years of age. Obesity (waist>90 percentile for subjects under 16yrs,=>90cm M and =>80cm F) was detected in 70.7%, raised triglycerides (=>150mg/dl) in 19%, low high density lipoprotein

(HDL) [<40mg/dl for M and <16yr and <50mg/dl for F] in 47.8%, raised blood pressure (systolic and diastolic blood pressure =>130 and =>85mmHg respectively or on anti-hypertensive therapy) in 16% and abnormal fasting venous plasma glucose (=>100mg/dl) in 9.1% of the cohort. Below 16 yrs; M>F for prevalence of obesity, low HDL and raised triglycerides (p<0.005 for all). Above 16 yrs; F>M for prevalence of obesity and low HDL and M>F for raised blood pressure, raised triglycerides and abnormal fasting glucose (p<0.005 for all). Below 16 years of age MS was diagnosed in 12.9% of males and 8.7% of females and over 16 years MS was diagnosed in 29.1% of men and 18.9 % of women (M>F p<0.001 for both). Overall 54 (1.3%) subjects had impaired fasting glycaemia, 307 (7.5%) impaired glucose tolerance and 74 a new diagnosis of type 2 diabetes mellitus (1.8%).

Conclusion and discussion: In this sample of children and young adults with 2 or more simple indicators of cardio-metabolic risk there is a high prevalence of MS and its individual components. The effect of intensive [3 monthly] vs. non intensive [12 monthly] non pharmacological intervention with life style modification on cardio-metabolic endpoints is currently under evaluation in a 3 year prospective clinical trial. This study will assist in the development of low cost interventional strategies and cardio-metabolic risk scores for this population.

Metabolic status, insulin resistance and insulin secretion function in first-degree relatives of type 2 diabetic patients in Sichuan province of China

Y. Ren[1], Y. Gong[1], X. Wang[1], H. Tian[2]
[1] *West China Hospital of Sichuan University, Division of Endocrinology and Metabolism, Chengdu, China*
[2] *West China Hospital of Sichuan University, Laboratory of Endocrinology and Metabolism, Chengdu, China*

Background and aims: To investigate the metabolic status, insulin resistance and the islet ß-cell secretory function in the first-degree relatives(FDR)of type2 diabetic patients.

Materials and methods: This is a cross-sectional study.Subjects were divided into 559 first-degree relatives(FDR) of type 2 diabetic patients and 1750 controls without positive family history of Diabetes.Afer oral glucose tolerance test(OGTT), 318 FDR and 1348 controls were defined as NGT-FDR group and NGT-control group.Blood pressure,weight,waist,blood glucose,lipids and insulin were measured.HOMA-IR and HOMA-ß indexes were used to evaluate insulin resistance and beta-cell function.The insulin sensitivity index(ISI) and glucose diposition index(DI)were also used to evaluate insulin resisitance.

Results: (1) HOMA-IR increased, ISI and DI decreased in FDR group when compared with control group(p<0.05).The incidence of co-existed three or above metabolic disorders and the risk of metabolic syndrome were higher in the FDR group than that in controll group(p<0.05).In both groups,HOMA-IR increased, DI and ISI decreased as the number of co-existing metabolic disorders increased(p<0.05).(2) In NGT-FDR group, HOMA-IR and HOMA-ß increased, ISI and DI decreased when comparing with those in NC group(p<0.05).The incidence of co-existing three or above metabolic disorders were higher in the NGT-FDR group than that in the NC group(p<0.05). In NGT-FDR group,HOMA-ß was lower in subjects with one metabolic disorder than those without any metabolic disorder(p<0.05). In normal control group,as the number of co-existing metabolic disorders increased, HOMA-IR increased, DI and ISI decreased.Furthermore,HOMA-ß was lower in subjects with two metabolic disorders than those without any metabolic disorder(p<0.05).

Conclusion: Metabolic disorders occur more frequently in FDR of diabetic patients than individuals without family history for type 2 diabetes.It is necessary to provide early preventive interventions of the metabolic index including diabetes.

Sustained gains from a primary care based Diabetes Prevention Program

J.A. Dunbar[1], N. Davis-Lameloise[1], B. Philpot[1], P. Reddy[1], A. Chapman[1], S. Heistaro[2], E.D. Janus[3]
[1] *Flinders and Deakin Universities, Greater Green Triangle University Department of Rural Health, Warrnambool, Australia*
[2] *National Institute for Health and Welfare, Department of Chronic Disease Prevention, Helsinki, Finland*
[3] *Melbourne University, Dept. of Medicine, Melbourne, Australia*

Aim: The Greater Green Triangle Diabetes Prevention Project (GGT DPP) was a national demonstrator implementation trial of a group-based lifestyle modification program undertaken in an Australian primary health care setting in 2004-2006. Participants were followed up for a further 18 months to examine the sustainability of the changes achieved, and the effectiveness of a structured telephone intervention in maintaining these changes.

Methods: Subsequent to the 12 month GGT DPP, 168 participants aged 40-75 years were followed for a further 18 months, receiving either telephone support (n=67) or self-care only (n=101), and re-assessed using anthropometric, clinical, psychological and general health measures.

Results: No significant differences between the telephone support and self-care groups were found on major clinical outcomes during the 18 month follow-up; therefore results have been pooled. Compared with baseline, thirty months after beginning the original intervention, mean waist circumference decreased by more than 4 cm, and significant improvements were also found in weight, diastolic blood pressure, oral glucose tolerance, HDL- and LDL-cholesterol, and the SF-36 v2 measures of bodily pain, general health, and vitality. Total cholesterol and triglycerides significantly improved both during the initial 12 month intervention and 18 month follow-up. Some measures of mental health, notably depression, regressed to baseline levels. Fasting plasma glucose worsened during the 18 month follow-up resulting in an overall increase of 0.23 mmol/L by comparison with baseline.

Discussion/conclusion: We believe that the present study is the first to report on an 18 month follow-up of participants involved in a "real world" group diabetes prevention program. Most of the improvements from baseline seem to be maintained over this period. Sustained benefits from a diabetes prevention program can be reproduced in a primary care setting for individuals at high risk of T2DM.

[5] *Department of Medicine, Yokohama Rosai Hospital, Yokohama, Japan*
[6] *Division of Diabetes and Endocrinology, Jikei University School of Medicine, Tokyo, Japan*

Aims: Metabolic syndrome, MetS is well known to be one of major risks for development of diabetes. Many previous studies have reported that lifestyle intervention seems to be effective for MetS subjects, but there had been scant data regarding the effect of lifestyle intervention on MetS subjects with IGT, comparing with that on non-MetS subjects with IGT. Thus, we performed a randomized controlled trial, such as lifestyle intervention in order to examine the changes of various laboratory findings, including response of blood glucose and insulin levels to oral glucose tolerance test, in Japanese MetS and non-MetS subjects both with IGT before and after the intervention.

Methods: After getting informed consent, we randomly assigned 29 subjects with IGT to two groups, such as a usual care control group and a lifestyle modification group under the special program, requesting intensely at least a 7 percent weight loss or maintaining modest weight with walking with at least 10,000 steps per day. At baseline the latter group was furthermore divided into two subgroups; 9 subjects with MetS or 9 subjects with non-MetS. The mean age of the subjects was 49 years, and the mean body-mass index (the weight in

kilograms divided by the square of the height in meters) was 25.0; 10 percent were women. In MetS and non-MetS groups, changes (percent) in clinical and metabolic parameters were evaluated and compared before and after the intervention. The diagnosis of diabetes required only one test. All comparisons were performed using two tailed tests wih a nominal significance level of 0.05. Statistical analyses were performed using SPSS version 13.0(SPSS, Chicago, IL).
Results: The cumulative incidence of diabetes which was newly diagnosed after starting the present study was 27.3 percent in the usual care control group and 11.1 percent in the lifestyle modification group, respectively. The lifestyle intervention reduced the incidence by 59 percent as compared with the control group. In MetS subjects, the number of metabolic risk factors decreased significantly (12.9 percent,p=0.046), compared with that in non-MetS subjects who showed significantly a decrease in body weight (4.6 percent, p=0.028), body fat(17.2 percent, p=0.028),2-h plasma glucose(28.8 percent, p=0.028),and the number of metabolic risk factors(68.9 percent, p=0.025).
Discussion/Conclusion: Lifestyle changes could reduce the incidence of diabetes in subjects possessing some of metabolic risk factors. Moreover, clinical and metabolic parameters were much more greatly improved in non-MetS subjects than in MetS subjects.

Comparison of various maternal anthropometric markers of obesity for identifying metabolic syndrome in offspring

V. Hirschler[1], T. Romero[2], A. Ruiz[2], M.N. Ismael[2], R. Dalamon[2]
[1] Hospital Durand, Nutrition, Buenos Aires, Argentina
[2] Hospital Durand, Pediatrics, Buenos Aires, Argentina

Background: Several maternal anthropometric markers have been associated with the metabolic syndrome (MS) in offspring.
Objectives: a) to determine the association between children's MS and maternal anthropometric markers such as BMI, waist circumference (WC), WC/ height, weight/sitting height squared, WC/ sitting height, and b) to compare the abilities of these 5 indices to identify children with MS.
Methods: Data were collected cross sectionally from 5 elementary schools between April 2007 and March 2008. Data for BMI, WC, WC/height, weight/ sitting height squared, WC/sitting height were performed in mothers and their children. Sitting height was compared with total height to predict MS. Tanner stage, blood pressure (BP), fasting serum concentrations of glucose, lipids and insulin were measured in children. Criteria analogous to ATPIII for MS were used for children.
Results: Over 624(307 males) children aged 8.96 ± 1.86 y and their mothers aged 36.25 ± 7.14 y were examined. 107 (17.1%) of children were obese (OB) (BMI>95%ile per CDC norms), and 95 (15.2%) overweight (OW) (BMI>85<95%ile).One hundred and ninety (30.4%) of mothers were OB (BMI>30 kg/m2), and 206 (33.0%) OW (BMI>25<30). Approximately 68% of the children were pre-pubertal. The prevalence of MS was 3.5% overall, 6.7% in OW and 13.9% in OB children. Mothers of children with MS had mean values of anthropometric markers which were significantly higher than those for the mothers of children without MS: BMI (32.96 vs 28.12; p=0.01); WC (100.81 vs 90.57cm, p=0.01); WC/height (0.64 vs 0.57, p=0.006), WC/sitting height (1.20 vs 1.07, p=0.009); and weight/sitting height squared (115.25 vs 98.13, p=0.030). To determine which marker was a better predictor for MS, a ROC curve was generated for maternal BMI, WC, WC/height, weight/sitting height squared, WC/sitting height, with children's MS as the dichotomous variable. The areas under the ROC curves were 0.697 ± 0.07 for BMI, 0.698 ±0.07 for WC 0.717 ± 0.07 for WC/height 0.725 ±0.07 for WC/sitting height and 0.704 ± 0.07 for weight/sitting height squared. There was not a significant difference between the areas of the five maternal anthropometric markers as predictors of MS in their children.
Conclusions: Measurement of maternal sitting height had no advantages over total height in the prediction of children's MS. Maternal BMI, WC, WC/height, weight/sitting height squared, WC/sitting height identified children with MS. This study suggests that any of the five maternal anthropometric markers could identify the MS in their children consistent with known familial associations of obesity and type 2 diabetes.

Factors associated with altered fasting plasma glucose in a population of young adults

A. Pace[1], H. Bettiol[2], M.A. Barbieri[2], M.R. Gutierrez[2], L.J. Franco[3], M.C. Foss-Freitas[4], M.C. Foss[4]
[1] University of São Paulo at Ribeirão Preto College of Nursing, General and Specialized Nursing, Ribeirão Preto - SP, Brazil
[2] University of São Paulo at Ribeirão Preto Medical School, Department of Pediatrics and Child Care, Ribeirão Preto - SP, Brazil
[3] University of São Paulo at Ribeirão Preto Medical School, Department of Social Medicine, Ribeirão Preto - SP, Brazil
[4] University of São Paulo at Ribeirão Preto Medical School, Department of Clinical Medicine, Ribeirão Preto - SP, Brazil

Introduction: Glycemia alterations are important predictors for the development of type 2 diabetes mellitus (DM) and also for cardiovascular diseases which, when associated with DM, will compromise its prognosis and control even more, resulting in the worsening of the patient's quality of life and increasing the costs for the health system. The present study aimed to determine the frequency of fasting plasma glucose alterations in young adults and analyze the factors associated to these glycemic changes.
Methodology: This descriptive, cross-sectional study is part of a cohort study of children in Ribeirão Preto, Sao Paulo state, Brazil, born between June 1st 1978 and May 31st 1979. An exploratory analysis was carried out, calculating the gross odds ratio, after which a multiple logistic regression model was used, as the answer was binary (glycemia ≥ 100 mg/dl and < 100 mg/dl). The study was approved by the Research Ethics Committee.
Results: The frequency for fasting plasma glucose alterations (glycemia ≥100 mg/dl) was 3.1%, higher for male (4.5%) when compared to female (1.8%) gender. The gender and abdominal circumference variables remained in the final model, with an adjusted odds ratio of 2.5 (1.29-4.81) and of 4.74 (1.34-16.79), respectively. The effect of the family history among first-degree relatives, a variable that can express the genetic component associated with DM, as well as the levels of fasting plasma insulinemia and blood pressure levels, had their effects annulled by the presence of obesity-related variables.
Conclusion: The frequency of glycemic alterations was significant and it can also be concluded that gender and abdominal circumference are independently associated variables for fasting plasma glucose alterations in young adults participating in this study.

A two-step risk stratification tool to identify persons at risk for cardiovascular disease and type 2 diabetes in primary care - The Hoorn Study

M. Alssema[1], G. Nijpels[1], C.D.A. Stehouwer[2], J.M. Dekker[1]
[1] VU University Medical Center, EMGO Institute for Health and Care Research, Amsterdam, The Netherlands
[2] Academic Medical Center Maastricht, Department of Internal Medicine, Maastricht, The Netherlands

Aim: Since strategies for prevention of cardiovascular disease (CVD) and type 2 diabetes (T2DM) largely overlap, we developed a tool that predicts the combination of end-points. To fit into current primary care practice, for the general population, we developed a questionnaire to identify those at high risk for the combined end-point, and investigated whether a clinical model improved risk stratification.
Methods: The study population consisted of 1258 participants, aged 50-75 years, from the Hoorn Study who had an OGTT at baseline in 1989 and at the follow-up examination in 1996, and who had complete follow-up information on CVD morbidity and mortality until 1996. All were free of prevalent CVD or known T2DM at baseline. The predicted outcome was a composite end-point of cardiovascular disease morbidity and mortality (ICD-codes 390-459), sudden death (ICD-code 798) or T2DM. Logistic regression analysis with backward selection was used to develop both models. The questionnaire was developed in the general population and the clinical model was developed in those at high risk according to the questionnaire. Discrimination was assessed by the area under the receiver operating characteristic curve. In the high risk group, risk classification of the models was compared by calculation of net reclassification improvement.

Results: During 6.4 years of follow-up, 375 out of 1258 persons developed the composite end-point. For the risk questionnaire, age, sex, waist circumference, use of anti-hypertensive medication, history of gestational diabetes, family history of T2DM, myocardial infarction or stroke, shortness of breath during walking and current smoking were selected as predictors. Discrimination of the risk questionnaire was 0.74 for the composite end-point. The separate outcome measures were equally well predicted (data not shown). A cut-off at optimum sensitivity and specificity, considered 44% of this elderly population as having high risk; 48% of these indeed developed the end-point. For the clinical model in the high risk group, age, current smoking, family history of stroke or myocardial infarction, glucose, HDL- and total cholesterol and hypertension were the most important predictors. Discrimination of this model was better as compared to the questionnaire (data not shown), and the clinical model improved classification in 9% of those who developed the outcome and in 11% of the cases who did not develop the outcome ($p<0.01$).
Conclusion: In the general population, risk of CVD and T2DM can be predicted by one single risk questionnaire which is useful for public health purposes. For those at high risk, subsequent blood testing and blood pressure measurement which is needed for treatment decisions, can contribute to further refine risk prediction.

Development of a European action plan for the prevention of type 2 diabetes

P.E.H. Schwarz[1], U. Gruhl[1], A. Felton[2], M. Hall[3]
[1] TU Dresden, Internal Medicine III, Dresden, Germany
[2] Federation of European Nurses in Diabetes, London, United Kingdom
[3] International Diabetes Federation (IDF), European Region, Brussels, Belgium

Background: The UN Resolution for Diabetes in December 2006 acknowledged type 2 diabetes as a serious threat for the world's health and asked for national and international political action especially to improve prevention in this field. Both the WHO Global Action Plan for non-communicable diseases (2008-2013) and the Together for health strategy of the EU Parliament (2008-2013) have continued to define this topic as very important on the health politics agenda of all - industrial and developing - countries. Nevertheless, until today only a few countries have taken active steps, e.g. by developing a National Action Plan for Diabetes, to change the political and financial framework in order to facilitate the implementation of diabetes prevention programs. As the experiences in the pilot phase of the EU project IMAGE (Development and Implementation of a European Guideline and Training Standards for Diabetes Prevention) have shown, in most countries there are people who would like to offer high quality prevention programs but the implementation is inhibited by the missing support for and through the health care system.
Therefore the Diabetes Prevention Forum, the prevention initiative of IDF Europe, has decided to compile a European Action Plan for the prevention of type 2 diabetes to define the most important cornerstones of action on a European and national level.
Current status: The prepared European Action Plan names goals, areas of responsibility and partners for collaboration. The implementation of diabetes prevention action needs to involve the different levels of "health care provision" from health politics and policy making through to health care providers and also through to the general public. A first draft of the European Action Plan was presented to the members of the Diabetes Prevention Forum. This plan will be completed and presented to and endorsed by European Institutions like WHO, European Centre for Disease Prevention and Control (ECDC), PCDE, EURADIA, EASD, DESG and ISPAD.
Perspectives: Actions and successes documented up to now for the prevention of diabetes have been limited to ad-hoc strategies that for the most part pertain to educational measures. It would be desirable for the stakeholders to subordinate their interests to the cause itself. In the future, it will be crucial to (i) better coordinate already existing resources and potential, (ii) win over new partners, (iii) develop shared strategies that encompass many areas of society and implement them as actions. With this European Action Plan a first step in this direction is taken.

Protein tyrosine phosphatase 1B gene expression in skeletal muscle is linked to metabolic flexibility in African Americans

A. Stull[1], Z. Wang[1], X. Zhang[1], Y. Yu[1], W. Cefalu[1]
[1] LSU-Pennington Biomedical Research Center, Diabetes and Nutrition, Baton Rouge, USA

Metabolic flexibility (MF) is the ability of the body to switch from fat to carbohydrate oxidation in response to feeding or with insulin administration. Limited research studies have documented that individuals with insulin resistance have impaired MF. However, cellular factors modulating this effect are not precisely known. We sought to determine the relationship of negative regulators of insulin signaling in skeletal muscle, i.e. protein tyrosine phosphatases, on metabolic flexibility. Specifically, we evaluated gene expression and protein content of protein tyrosine phosphatase 1B (PTP1B) in skeletal muscle and assessed its relationship to MF.
Methods: Respiratory quotient (RQ) and substrate oxidation of carbohydrate and fat were evaluated by indirect calorimetry during baseline (fasting) and hyperinsulinemic-euglycemic clamp (insulin infusion of 120 $mU \bullet m^{-2} \bullet min^{-1}$) in 17 African Americans with type 2 diabetes (AA-T2D) (Mean ± SE; age, 56 ± 2 y; BMI, 32.5 ± 1.2 kg/m^2) and 16 African Americans with no diabetes (AA-ND) (age, 34 ± 2 y; BMI, 28.8 ± 2.1 kg/m^2). MF was calculated as the change from the fasting (pre-insulin) to insulin stimulated (during clamp) states (ΔRQ = clamp RQ – fasting RQ). PTP1B gene expression (assessed by rtPCR) and protein content (assessed by western blotting) were determined in skeletal muscle biopsies taken from the vastus lateralis muscle at the baseline (pre-insulin) of the clamp.
Results: PTP1B gene expression was higher in AA-T2D (mean ± SE; 1.50 ± 0.28) vs. AA-ND (0.17 ± 0.05, $P < 0.0001$). AA-T2D (0.06 ± 0.01) had lower MF than AA-ND (0.12 ± 0.01, $P < 0.0001$). During the fasting state, there were no significant differences between carbohydrate and fat oxidation. However, after insulin stimulation carbohydrate oxidation was lower in the AA-T2D (145.0 ± 6.8) vs. AA-ND (225.1 ± 11.9, $P < 0.0001$). In addition, fat oxidation was higher in the AA-T2D (32.4 ± 3.9) vs. AA-ND (5.4 ± 3.6, $P < 0.0001$). PTP1B gene expression was negatively ($P < 0.0001$) related to MF ($r_s = -0.70$), insulin-stimulated carbohydrate oxidation ($r_s = -0.65$) and insulin sensitivity ($r_s = -0.68$) whereas a positive association was observed with insulin-stimulated fat oxidation ($r_s = 0.64$). PTP1B gene expression was not associated with fasting carbohydrate and fat oxidation. Also, PTP1B protein content was not associated with any of the parameters.
Conclusion: This study demonstrated that a higher PTP1B gene expression is observed in African Americans with type 2 diabetes and the gene expression is related to lower metabolic flexibility (i.e., metabolic inflexibility). The mechanism by which a negative regulator of insulin signaling induces this clinical effect is not known, but is the subject of ongoing investigation.

Lower postprandial branched chain amino acids (BCAA) may contribute to altered protein metabolism but not insulin resistance of glucose in men with type 2 diabetes mellitus (T2DM)

R. Gougeon[1], M. Bassil[1], C. Mourad[1], S. Chevalier[1], J.A. Morais[1], E.B. Marliss[1]
[1] McGill University Health Centre, Nutrition Centre McGill, Montreal, Canada

Elevated 24h fed-fasted protein flux and 50% reduced net balance in hyperglycemic men with T2DM vs. nondiabetic men is partly explained by insulin resistance of protein metabolism. They show 12.5% lower net anabolic response to hyperinsulinemia during euglycemic (5.5mM) isoaminoacidemic (postabsorptive levels) clamps (Pereira et al, 2008). As net anabolism occurs postprandially, we tested whether protein metabolism would be further altered during an hyperinsulinemic (600pM), hyperglycemic (8mM), hyperaminoacidemic (BCAA= 700µM) clamp, with levels at peak concentrations found in lean following a mixed meal. This clamp was performed in 8 hyperglycemic T2DM (57±2 yrs; BMI: 34±2; FPG: 8.4±0.6mM) and 9 lean nondiabetic men (29±2 yrs; BMI: 21±1; FPG: 5.3±0.1mM) with glucose and

leucine kinetics measured using ^{3}H-glucose and ^{13}C-leucine infusions, after 5-6d of weight maintaining, protein controlled (1.5g/kg.d) diet. In T2DM, insulin sensitivity of glucose (endogenous glucose production: 1.7±0.4 vs. -0.2±0.1; glucose disposal: 4.8±0.6 vs. 9.2±0.7 mg/kgFFM.min) was less (p<0.005). Surprisingly, the positive net protein balance (0.88±0.10 vs. 1.00±0.09 µmol/kgFFM.min) was not different.

Therefore, we tested whether the insulin and substrate responses to a mixed meal over 5h could account for lesser 24h anabolism in T2DM. Fasting, postprandial peak, total and net area under the curve (AUC) of insulin, glucose and BCAA were measured in 9 hyperglycemic T2DM (61±4 yrs; BMI: 31±4, FPG: 7.7±0.7 mM) during a 689 kcal meal (34g protein). Results were compared to those of 9 lean and 5 obese nondiabetic with a similar protocol. In T2DM, 1) fasting glucose (8.0±0.2 vs. 5.5±0.1, 5.5±0.1mM), peak (12.4±0.5 vs. 8.3±0.3, 8.0±0.3 mM) and net AUC (668±137 vs 145±40, 196±36 mM/5h) were higher (p<0.02) vs. lean and obese, respectively 2) fasting BCAA (495±20 vs. 339±28, 365±25µM) were higher (p<0.004) vs. both groups. 3) Peak BCAA (662±24 vs. 748±15, 571±35µM) and net AUC (29.2±5.5 vs. 55.0±9.2, 34.8±6.8mM/5h) were lower (p<0.03) only vs. lean. 5) Insulin at 30min post meal (307±65, vs. 674±56, 939±193 pM) was lower (p<0.02) vs. both groups, and total AUC (121±17 vs. 74±10, 131±24 µM/5h) higher (p=0.05) only vs. lean. Fasting and peak insulin were not different from other groups.

Thus, altered substrate responses to mixed meals in poorly controlled T2DM might contribute to their reduced 24h fed-fasted net protein balance. Their insulin resistance of glucose metabolism cannot be explained by high postprandial BCAA, as postulated by others.

Pathway selective insulin resistance: a potential link between obesity, inflammation and hypertriglyceridaemia in type 2 diabetes

S. Mangiafico[1], S.H. Lim[1], B.C. Fam[1], S. Andrikopoulos[1], J. Proietto[1]
[1] University of Melbourne, Medicine AH/NH, Melbourne, Australia

Background: Hypertriglyceridaemia, in the face of low HDL-cholesterol, hyperinsulinaemia and chronic low-grade inflammation is considered a pro-atherogenic cocktail for patients with Type 2 diabetes. Insulin resistance has been implicated in the pathogenesis of hypertriglyceridaemia, although the precise mechanisms by which insulin resistance in various organs causes hypertriglyceridaemia remain unclear.

We previously reported that hyperinsulinaemia increases the expression of the proinflammatory cytokine interleukin-6 from insulin-resistant rat muscle, but not insulin sensitive muscle. Proinflammatory cytokines increase plasma triglycerides, by increasing hepatic triglyceride secretion and reducing peripheral triglyceride clearance. Therefore our current hypothesis is that hyperinsulinaemia raises the production of proinflammatory cytokines in insulin resistant tissues, and leads to mildly elevated plasma levels of cytokines, which cause hypertriglyceridaemia.

Methods: Transgenic rats over-expressing the gluconeogenic enzyme phosphoenolpyruvate carboxykinase (PEPCK) were studied as a model of obesity-induced insulin resistance. Lean PVGc rats served as controls. Fasting plasma triglycerides, glucose, whole body glucose turnover and insulin sensitivity were assessed in 4 and 24 week-old rats under baseline conditions and during the hyperinsulinaemic/euglycaemic clamp. White quadriceps were obtained for assessment of the IL-6, TNF-a and IL-1ß mRNA via Real Time PCR. Insulin signalling through PI-3kinase and MAPKinase were assessed via western blotting. Hepatic triglyceride secretion rate was estimated following intravenous administration of Triton-WR 1339, a non-ionic detergent that prevents triglyceride-rich lipoprotein clearance. Twenty four week-old rats underwent a hypertriglyceridaemic clamp to estimate triglyceride clearance rate.

Results: Compared to controls, 4 week-old PEPCK rats have mildly elevated plasma triglycerides (0.5±0.1 v 1.0±0.1 mM) which is associated with increased IL-6 mRNA in muscle (p<0.05 vs control). At 24 weeks of age, PEPCK rats exhibit fasting hyperinsulinaemia, mildly elevated glucose and hypertriglyceridaemia (0.5±0.2 v 1.8±0.3 mM, p<0.05 vs control). Hyperinsulinaemia in PEPCK rats is associated with increased muscle IL-6,TNF-a and IL-1ß mRNA and impaired insulin signalling through PI-3 Kinase, but not MAPKinase (p<0.05 vs control). Hypertriglyceridaemia in old rats is associated with a 60% increase in hepatic triglyceride secretion rate and a 20% reduction in triglyceride clearance(p<0.05 vs control).

Conclusion: The current study provides further evidence that hyperinsulinaemia induces proinflammatory cytokine production in insulin resistant tissue, supporting the hypothesis that hyperinsulinaemia-induced proinflammatory cytokine production is a possible cause of hypertriglyceridaemia in Type 2 Diabetes.

Induction of Insulin Resistance (IR) by a sucrose-rich diet in rats is accompanied by increased corticosterone secretion and lipid infiltration of the adrenal cortex

C. Martinez Calejman[1], E.M. Repetto[1], F. Astort[1], R. Sanchez[1], M. Mercau[1], J.M. Di Gruccio[1], C.B. Cymeryng[1], P. Arias[2]
[1] university Of Buenos Aires. School Of Medicine, Department Of Human Biochemistry/conicet-cefybo, Buenos Aires, Argentina
[2] university Of Buenos Aires. School Of Medicine, Department Of Physiology, Buenos Aires, Argentina

Hyperactivation of the hypothalamic-pituitary-adrenal axis has been described in humans and in animals with insulin resistance (IR). However, biochemical and cellular abnormalities associated to IR (e.g. elevated plasma glucose [GLU], serum insulin [INS], free fatty acids [FA] and triglyceride [TG] levels, changes in nitric oxide synthase [NOS] activity, oxidative stress) could directly affect adrenal steroid synthesis and release.

Aims: We studied the effects of the development of IR in adult male Wistar rats fed a sucrose-enriched diet (SED, 30% w/v of sucrose added to drinking water) for 12 weeks on serum corticosterone levels, as well as on histological changes and NOS activity in adrenocortical cells. Furthermore, the effect of high GLU, INS and palmitate concentrations (10 mM, 50 mIU/l and 80 µM respectively) on steroid production by cultured murine adrenocortical Y1 cells was evaluated.

Results: Fasting hyperinsulinemia was observed in SED-treated rats from week 3 (1.97±0.24 vs. 0.99±0.14 ng/ml; p<0.005 vs. control animals; mean±SD) onwards. After 7 weeks of SED, rats showed higher fasting plasma GLU (130±6 vs. 74±5 mg/dl; p<0.001) and serum TG (605 ± 60 vs. 105±52 mg/dl; p<0.001) levels. SED-treated animals also showed increased body weight and fat depots. Interestingly, after 12 weeks of SED administration, their adrenal glands showed a marked lipid infiltration as demonstrated by light microscopy. Simultaneously, an impairment in the insulin signalling pathway was detected in adrenocortical homogenates: lower p-Akt levels were detected by immunoblot analysis. Adrenocortical NOS activity was increased in treated animals between weeks 3 and 9. Moreover, significantly elevated serum corticosterone levels were detected in these rats between weeks 5 and 9. Only a three-day long incubation of Y1 cells with elevated palmitate concentrations induced a clear increase in steroid (progesterone) release.

Conclusions: IR induced by a sucrose-rich diet in rats is accompanied by histological and functional changes in the adrenal cortex. In particular, IR seems to develop also in adrenocortical cells, probably related to lipid infiltration of these glands. Lipid metabolites and/or locally produced adipokines could also increase adrenal steroidogenesis. In addition, an increase in NO generation could trigger post-transcriptional modifications of proteins involved in steroid biosynthesis and its modulation, and/or adversely affect insulin sensitivity in adrenocortical cells. Other factors (hypothalamic/pituitary activation, decreased corticosterone clearance) could be also responsible for the observed hypercorticosteronemia. Elevated glucocorticoid levels could contribute to the somatic and metabolic changes observed in subjects with IR.

Insulin signaling in human primary astrocytes

M. Heni[1], A.M. Hennige[1], M. Guthoff[1], H. Staiger[1], H.-U. Häring[1]
[1] Eberhard-Karls-University Tübingen, Department of Internal Medicine IV, Tübingen, Germany

Aims: Insulin receptors are thought to be nearly ubiquitously expressed throughout the brain. However, in our recent fMRI and MEG studies with systemic or intranasal insulin applications, modulation of neuronal activity was detected only in some very specific brain regions.

One hypothesis for this observation is a modulation of neuronal activity by other insulin-sensitive cell types. Since astrocytes represent the predominant cell type in the brain and modulate neuronal function in several ways, they are potential candidates. Astrocytes (i) store glycogen and supply neurons with lactate as energy source; (ii) take up and release neurotransmitters, and (iii)

form the blood-brain barrier together with endothelial cells and pericytes.
In this study, we (i) examined whether primary human astrocytes are insulin-responsive at the molecular level and (ii) whether glucose uptake or lactate secretion is altered by insulin.
Methods: Commercially available Normal Human Astrocytes (Lonza) were grown in the recommended media. Prior to insulin stimualtion, they were starved in media containing 0.5 % FCS for 48h. Cells were lysed and the protein content of the lysates was determined using the Bradford method. Proteins were separated by SDS-PAGE. Major players in the insulin signaling pathway were detected by Western blotting using specific antibodies. Phosphorylation levels were detected with phospho-specific antibodies and the ECL system.
Glucose uptake was determined using ^{3}H-deoxy-D-glucose and lactate levels were measured enzymatically.
Results: We detected relevant expression of key proteins of the insulin signaling cascade such as insulin receptor ß-subunit, insulin receptor substrate-1, Akt / protein kinase B and glycogen synthase kinase 3 in Normal Human Astrocytes. In addition, dose-dependent (0 - 50 nM) phosphorylation of these proteins was detected following insulin stimulation for 15 minutes.
However, neither significantly increased glucose uptake after insulin treatment for 15 minutes (0-100 nM) nor lactate secretion after insulin stimulation for 6-8 hours (0-100 nM) was present in this cell type.
Conclusion: This study demonstrated that astrocytes are insulin-sensitive at the molecular level as they displayed relevant expression of the key signaling molecules of the insulin signal cascade. In addition, detection of phosphorylation of certain signaling molecules proved the functional activity of this signaling pathway. In contrast to many other cell types, insulin does not affect glucose uptake in commercially available Normal Human Astrocytes. Another important nutritive function of astrocytes, the secretion of lactate is also unaltered by insulin in these cells. Together, we show that human astrocytes represent an insulin-responsive cell type that might be involved in insulin-mediated changes of neuronal activity.

A paradoxical role for pyruvate dehydrogenase kinase in insulin action

M.C. Sugden[1], L.G. Fryer[2], M.J. Holness[2]
[1] Barts and the London, Centre for Diabetes and Metabolic Medicine ICMS, London, United Kingdom
[2] Imperial College, Division of Clinical Sciences, London, United Kingdom

Background and aims: Substitution of long-chain omega-3 fatty acids (FA) for a small percentage of dietary saturated fat prevents the development of peripheral insulin resistance with respect to glucose uptake. Distal to this, glucose 6-phosphate can be used for glycogen formation, enter glycolysis or be oxidized by the pyruvate dehydrogenase complex (PDC). Long-term regulation of PDC due to stable increases in pyruvate dehydrogenase kinase (PDHK) activities occurs in skeletal muscle in response to high-saturated fat. Our aim was to determine whether insulin sensitizing effects of long-chain omega-3 FA on muscle glucose uptake is accompanied by reversal of the adverse PDHK isoform profile induced by saturated fat.
Materials and methods: We quantified insulin action (hyperinsulinemic-euglycemic clamps) with PDHK expression profiles (Western blotting), PDHK and PDC activities (spectroscopy) and FA profiles (gas chromatography) in slow- and fast-twitch skeletal muscles of rats maintained for 4 weeks on a high saturated fat diet (HF diet) or a saturated fat diet in which 7% of saturated FA were replaced by omega-3 FA (omega-HF diet).
Results: We demonstrated increases in skeletal muscle PDHK activity and PDHK4 protein expression in conjunction with insulin resistance in response to dietary saturated fat, despite compensatory insulin secretion for lipid-induced insulin resistance. Supplementation of HF diet with omega-3 FA attenuated effects of HF diet on muscle lipid profiles. In slow-twitch muscle, reversal of insulin resistance by omega-3 FA was accompanied by reversal of PDHK activity and partial reversal of increased PDHK4 protein expression. However, there was a failure to reverse effect of a high-fat diet on the PDHK isoform profile in fast-twitch muscle. Furthermore, despite improved insulin action and unchanged PDHK activity, PDC activity was lowered. The suppression of PDC activity was not seen in this muscle type in response to HF alone.
Conclusion: Our findings suggest that, although PDHK4 expression is sensitive to suppression by insulin, its response is less than that of glucose transport to insulin. Sustained increases in PDHK activity in fast-twitch muscle are suggested as a mechanism to force FA oxidation secondary to suppressed glucose oxidation, so as to limit cytoplasmic accumulation of insulin-desensitising lipids and resultant glucose intolerance when insulin secretion is compromised.

Resistance to fat accumulation and increase in insulin sensitivity on high-fat diet in transgenic mice overexpressing spermidine/spermine n1-acetyltransferase

E. Pirinen[1,2], J. Skommer[1], S. Heikkinen[1,2], A. Virkamäki[3], L. Alhonen[2], M. Laakso[1]

[2] University of Kuopio, A.I.Virtanen Institute for Molecular Medicine, Kuopio, Finland
[3] University of Helsinki, Department of Medicine, Kuopio, Finland

Spermidine/spermine N^{1}-acetyltransferase (SSAT) is the key enzyme in the catabolism of polyamines. Activated polyamine catabolism in transgenic mice overexpressing SSAT leads to enhanced consumption of cellular ATP levels in white adipose tissue (WAT) with concomitant activation of 5′-AMP-activated protein kinase which induces peroxisome proliferator activated receptor (PPAR)γ co-activator 1α (PGC-1α). The overexpression of this co-activator caused severely reduced WAT mass, reduced tissue triglyceride content, enhanced energy expenditure and high insulin sensitivity in SSAT mice. In this study, we investigated whether SSAT mice are protected from obesity and insulin resistance on high-fat diet (HFD).
Five-month-old female SSAT-TG (n=12) and wild-type mice (n=12) were challenged with HFD (42% calories from fat) for 13 weeks. Fasted SSAT and wild-type mice were subjected to intraperitoneal glucose tolerance test before and after 10 weeks of HFD feeding. At end of diet, fasted mice were sacrificed and tissues were collected for quantitative RT-PCR analysis.
Weight gain during HFD was lower in SSAT mice as compared to wild-type mice. HFD-induced epididymal WAT gain (27% vs. 76%) and hepatic lipid accumulation was also minimal in SSAT mice. After HFD, wild-type mice showed increased glucose and insulin levels in response to glucose load whereas SSAT mice exhibited further improved glucose tolerance (area under the glucose curve above baseline: 140±30 vs. 230±40 mmol/l•min, $p<0.05$) and reduced insulin levels similar to the levels before starting the diet. Furthermore, skeletal muscle expression of PGC-1α(1.25±0.09 vs 1.66±0.12 fold wt, $p<0.05$), PPARγ (1.32±0.23 vs 1.99±0.16 fold wt, $p<0.01$), PPARα(1.98±0.23 vs 3.32±0.30 fold wt, $p<0.01$), lipoprotein lipase (1.55±0.15 vs 2.33±0.20 fold wt, $p<0.01$), CD36 antigen/fatty acid translocase (1.36±0.14 vs 1.84±0.11 fold wt, $p<0.01$) and uncoupling protein 3 (1.44±0.14 vs 2.30±0.11 fold wt, $p<0.001$) were significantly higher in SSAT mice on HDF than in SSAT mice on standard diet. In HFD-treated wild-type, no significant changes were observed in gene expression.
We concluded that SSAT mice are protected from HFD-induced obesity. As HFD caused a significant increase in the muscle PGC-1α expression and fat oxidation in SSAT mice, HFD most likely enhanced activated polyamine catabolism and ATP consumption in skeletal muscle of SSAT mice. Increased insulin sensitivity of SSAT mice on HFD was apparently attributable to the induction of PPARγ in skeletal muscle. Taken together, these results suggest that activated polyamine catabolism modulates energy balance and glucose metabolism in mice.

Association of the IL2RA/CD25 gene with type 1 diabetes in the Belgian Population

F. Aminkeng[1], J. Van Autreve[1], E. Quartier[1], C. Van Schravendijk[1], B. Van der Auwera[1]
[1] Vrije Universiteit Brussel, Medical Biochemistry, Brussels, Belgium

Background and aims: Genome wide association studies and genome wide linkage scans have identified at least 15 independent type 1 diabetes (T1D)

susceptibility loci. But, to date only the 6p21, HLA; 11p15, INS; 2q33, CTLA4; and 1p13, PTPN22 loci have been evaluated in the Belgian Diabetes Registry (BDR) for risk prediction and prevention. Therefore, the aim of the study was to evaluate the fifth susceptibility locus: 10p15, IL2RA/CD25 in a registry-based European Caucasian population and its relationship with age at onset for T1D.
Methods: T1D patients (n = 1721) with clinical onset before age 40 and positive for at least one type of diabetes autoantibodies (IAA, ICA, GADA, IA2A) and control subjects (n = 1371) were recruited via the BDR. IL2RA/CD25 was analysed by genotyping the IL2RA SNP ss52580101(C>A) using Custom TaqMan® SNP genotyping assay. Statistical methods include: chi square test, OR for relative risks (RR), PcPPV (Prevalence corrected Positive Predictive Value) for absolute risk (AR) and PS software for power and sample size calculations. The power of the study is 95%. $P < 0.05$ is considered statistically significant after Bonferroni correction.
Results: The C allele (91.2%) is more frequent compared to the A allele (8.8%), while the CC genotype (83.7%) is more frequent compared to the AC (15.1%) and AA (1.2%) genotypes. The C allele is associated with susceptibility to T1D (94.5% of patients vs. 91.2% of control subjects, RR = 1.67, AR = 0.41%, $p < 10^{-6}$), while the A allele is associated with protection (5.5% of patients vs. 8.8% of control subjects, RR = 0.60, AR = 0.25%, $p < 10^{-6}$). Similarly, the CC genotype is associated with susceptibility to T1D (89.2% of patients vs. 83.7% of control subjects, RR = 1.62, AR = 0.43%, $p < 10^{-5}$), while the AC (10.6% of patients vs 15.1% of control subjects, RR = 0.67, AR = 0.28%, $p < 10^{-3}$) and the AA (0.2% of patients vs. 1.2% of control subjects, RR = 0.14, AR = 0.03%, $p < 10^{-3}$) genotypes confer protection. The C allele (95.5% in 0-14 yrs vs. 93.5% in 15-39 yrs, p = 0.01) and the CC genotype (91.3% in 0-14 yrs vs. 87.2 % in 15-39 yrs, p = 0.008) were preferentially associated with childhood-onset diabetes (0-14 yrs), while the A allele (4.5% in 0-14 yrs vs. 6.5% in 15-39 yrs, p = 0.01) and the AC genotype (8.5% in 0-14 yrs vs. 12.7% in 15-39 yrs, p = 0.006) were preferentially associated with adult-onset diabetes (15-39 yrs).
Discussion/conclusion: IL2RA/CD25 is associated with T1D in the Belgian population. The C allele and the CC genotype confer susceptibility while the A allele and the AA and AC genotypes confer protection. In addition, the IL2RA/CD25 is associated with age at onset for T1D, suggesting that IL2RA/CD25 could be a marker for progression but confirmation requires further genotype-phenotype correlation analysis.

Islet remodeling during diabetogenesis in NOD mice

A. Plesner[1], J. Ten Holder[1], C.B. Verchere[1]
[1] *University of British Columbia, Pathology and Laboratory Medicine, Vancouver, Canada*

Autoimmune diabetes culminates when the majority of islet ß-cells have been selectively destroyed by infiltrating T-cells. Non-ß islet endocrine cells are spared this autoimmune destruction resulting in an islet remodeling that includes an apparent increase in the number of non-ß cells in the islet center. To determine how this islet remodeling occurs, we assessed islet morphology during the development of autoimmune diabetes in NOD mice. Pancreata were excised from 4-20 wk old NOD mice and age-matched Balb/c controls and immunostained for islet hormones and the leukocyte marker CD45. a-, ß- and d-cells were quantified in 4 (non-diabetic), 12 (pre-diabetic) and 20 (diabetic) wk old mice both as a proportion of total islet area and as endocrine cell mass. To address the importance of insulitis, hyperglycemia and hypoinsulinemia in islet remodeling, Balb/c mice were rendered diabetic by administration of a single dose of streptozotozin (STZ) and insulin was replaced by islet transplantation or implantable pump. The proportion of total islet area comprised of ß-cells in NOD mice decreased from 63.5±1.4% in 4 wk old mice, to 46.6±2.1% in 12 wk old mice and down to 4.0±1.1% in 20 week old mice ($p<0.001$), corresponding to a relative change in total pancreatic ß-cell mass in the 4, 12, and 20 wk old mice of 0.79±0.15, 1.3±0.23 and 0.002±0.001 mg. This decrease was accompanied by a marked increase in CD45-positive islet-infiltrating cells in 12 wk old mice that peaked in 20 wk old mice. In contrast, the percent of islet area comprised of a- and d-cells increased from 16.4±1.1% and 6.2±1.1% respectively in 4 wk old mice to 33.0±1.6% ($p<0.001$) and 23.2±1.1% ($p<0.001$) in 20 wk old mice. Surprisingly, only slight changes in a- and d-cell mass were observed during NOD mouse diabetogenesis suggesting that a- and d-cell mass are not significantly altered during progression of diabetes. BrdU immunostaining revealed a high proportion of proliferating insulin-positive cells that did not change with aging in NOD mice (4 wk: 2.6±0.1%; 12 wk: 2.7±0.3%; 20 wk: 3.3±0.5%). In contrast, the proportion of proliferating glucagon cells decreased with age from 2.9±0.2% in 4 wk old NOD mice to 1.7±0.2% and 0.9±0.2% in 12 and 20 wk old mice ($p<0.001$), respectively. Proliferation of both a- and ß-cells in Balb/c mice decreased with age although the proportion of islet cells undergoing proliferation was higher in NOD mice. In STZ-diabetic mice exhibiting no insulitis, islet remodeling of non-ß islet cells occurred regardless of whether insulin was replaced or not. Therefore, reorganization of a-, d- and PP-cells following loss of ß-cells in STZ-diabetic mice does not appear to be driven by insulitis, hyperglycemia or hypoinsulinemia. We propose that non-ß islet endocrine cells redistribute to fill the void left by loss of ß-cells within the diabetic islet once insulitis dissipates.

Effects of exendin-4 on NOD and streptozotocin-diabetic C57BL/6 mice

J.H. Juang[1], Y.W. Chien[1], Y.H. Van[2], M.Y. Lin[1], C.H. Kuo[3]
[1] *Chang Gung University and Memorial Hospital, Division of Endocrinology and Metabolism, Taoyuan, Taiwan*
[2] *Chang Gung University and Children's Hospital, Division of Pediatric Endocrinology, Taoyuan, Taiwan*
[3] *National Chiao Tung University, Department of Biological Science and Technology, Hsinchu, Taiwan*

Aims: Recent studies showed most type 1 diabetic patients still preserve their residual ß-cells. On the other hand, glucagon-like peptide-1 (GLP-1) can expand ß-cell mass by stimulating ß-cell proliferation and inhibiting ß-cell apoptosis. Therefore, we hypothesized that treatment with Exendin-4, a GLP-1 analogue, might preserve ß-cell mass or even stimulate ß-cell regeneration to maintain or restore normoglycemia in NOD and streptozotocin (STZ)-diabetic mice.
Methods: NOD and C57BL/6 mice were used. The onset of diabetes in NOD mice was recognized by nonfasting or intraperitoneal (ip) glucose-stimulated blood glucose >=200 mg/dl. C57BL/6 mice, aged 8-12 weeks, were made diabetic by STZ 200 mg/kg single ip injection or 50 mg/kg/day ip injection for 5 days. Hyperglycemia was defined as nonfasting blood glucose >=200 mg/dl. Diabetic mice were treated with or without Exendin-4, 3 µg/kg bid subcutaneously, for various time periods. Intraperitoneal glucose tolerance test was performed every 2 weeks with a 5% glucose solution (1.5 g/kg). At the end of study, the pancreases were removed for insulin content measured by radioimmunoassay as well as immunohistochemistry with insulin staining to count ß-cell number.
Results: In 6 spontaneously diabetic NOD mice, 6-week Exendin-4 treatment improved glycemia in 2 mice with baseline nonfasting blood glucose >=200 mg/dl and maintained glycemia in the other 2 mice with baseline ip glucose-stimulated blood glucose >=200 mg/dl during a follow-up period up to 50 weeks. These 4 mice maintained their body weights. In diabetic NOD/scid mice induced by adoptive transfer, 6-week Exendin-4 treatment starting at the onset of hyperglycemia did not improve their blood glucose. However, 6-week Exendin-4 treatment starting from the day of adoptive transfer, 2 out of 6 mice remained euglycemic at day 49. In contrast, 5 out of 5 control mice became diabetic by day 49. For diabetic C57BL/6 mice induced by STZ 200 mg/kg single ip injection, 5-week Exendin-4 treatment starting from 1-week prior to STZ injection did not improve their blood glucose, glucose tolerance, pancreatic insulin content and ß-cell number. Treated mice had lower body weights than controls. For diabetic C57BL/6 mice induced by STZ 50 mg/kg/day ip injection for 5 days, Exendin-4 treatment, starting from 1-week before STZ injection or starting at the onset of hyperglycemia after STZ injection until 4 weeks after first STZ injection, did not improve their blood glucose, glucose tolerance or pancreatic insulin content. The former group also had lower body weights than controls.
Conclusion: Our results indicate that Exendin-4 treatment may delay the onset of diabetes in NOD mice and improve glycemia in newly-onset diabetic NOD mice, but has no beneficial effect on STZ-diabetic C57BL/6 mice.

Otelixizumab – dose regimen optimization of a chimeric/ humanized aglycosylated anti-CD3 monoclonal antibody (MAb) in adult subjects with type 1 diabetes mellitus (T1DM)

M. Rosenzweig[1], D. Mehta[1], D. Forman[1], C. McKee[2], L. Vaickus[2]
[1] Tolerx, Preclinical Development, Cambridge, USA
[2] Tolerx, Clinical Development, Cambridge, USA

Aims: Otelixizumab, an Fc-disabled IgG1 MAb directed against the T cell antigen CD3e, is being developed for the treatment of autoimmune diseases, including T1DM. Phase 1b/2 open-label dose-escalation studies were conducted to identify a dosing regimen that markedly reduced pro-inflammatory cytokine release (PIC), immunogenicity, and perturbation of viral immunity, yet preserved clinical activity and targeted pharmacodynamic (PD) parameters. A prior Phase 2 study and studies in the NOD mouse model guided dose optimization.
Methods: Eleven different dosing regimens with total doses ranging from 0.3 mg to 6.85 mg otelixizumab were assessed. Over 100 T1DM adults were enrolled in 3-, 4-, or 8-day dosing regimens. Serum concentrations of cytokines, otelixizumab, and anti-otelixizumab antibodies were measured along with standard safety parameters. Viral load (EBV, CMV, HSV, VZV) and viral serology (EBV, CMV, Hepatitis B and C, VZV) were measured before and after otelixizumab administration. PD parameters were monitored using flow cytometry. Stimulated C-peptide levels were measured at baseline and up to 12 months after otelixizumab administration.
Results: A cumulative dose of 3.1 mg otelixizumab administered over 8 days was identified for use in a Phase 3 clinical trial in new-onset T1DM adult subjects (DEFEND-1). This regimen utilizes increasing doses on the first 3 days, followed by 5 higher doses that do not evoke significant PIC release. This regimen resulted in no lymphocyte depletion or other cytopenias, no electrolyte abnormalities, no clinically significant changes in liver function tests, no rashes or unexpected AEs, no SAEs, no immunogenicity and no perturbation of viral immunity. Down modulation and saturation of the CD3/TCR complex occurred after dosing, mirroring results from efficacious regimens in the NOD model. In the peripheral blood of T1DM adult subjects, increases in CD4+CD25+FOXP3+ T regulatory cells were observed. Lastly, preliminary results show that in T1DM adult subjects who were enrolled in Phase 1b/2 studies within 2 years of diagnosis and were less than 35 years-of-age, stimulated C-peptide levels for 1 year post dosing remained similar to the levels found at study entry, suggesting preservation of residual beta cell function.
Conclusion:. An optimized 8-day otelixizumab dosing regimen was identified that resulted in targeted PD changes, had no significant safety issues, and was well tolerated. The reduced pro-inflammatory profile observed after dosing may potentially contribute to efficacy via 2 mechanisms, as pro-inflammatory cytokine release is associated with negative effects on islet cell and T regulatory cells. These data provided the rationale for evaluation of this dosing regimen in an ongoing Phase 3 clinical trial (DEFEND-1).

Reg2 attenuates streptozotocin- and cytokine-induced apoptosis in Min6 cells by abrogating pro-apoptotic changes in the mitochondria

L. Liu[1], J.-L. Liu[1], C. Srikant[1]
[1] Royal Victoria Hospital McGill University Health Centre, Medicine, Montreal, Canada

Reg proteins constitute a conserved family of proteins in human and rodents. We have previously reported that Reg2 is expressed predominantly in islet b-cells and in pancreas-specific IGF-I deficient mice, the enhanced expression of Reg2 in b-cells correlates with protection against streptozotocin (Stz)-induced cell damage and delays the onset of diabetes. We hypothesized that Reg2 may protect b-cells from apoptosis and examined the protective effect of ectopically introduced Reg2 in Min6 insulin-producing mouse islet cell line against Stz- and cytokine- induced apoptosis. Enforced expression of Reg2 in stably transfected cells was confirmed by real time PCR analysis. Cells were incubated with 10 mM Stz or a cytokine cocktail (containing 200 pg/ml mouse IL-1b and 100 pg/ml mouse TNF-a) for 24 h following which they were labeled with Annexin-V-FITC and propidium iodide and subjected to dual label FACS analysis in order to detect and quantitate cells undergoing apoptosis. A significant increase in apoptotic cells was observed in empty vector transfected (Min6-vec) cells treated with Stz as well as cytokines (14.2 ± 2.8% and 32 ± 4%respectively) compared to untreated cells (3.2 ± 0.8%). By contrast, in Reg2 expressing cells (Min6-Reg2) the percentage of cells undergoing apoptosis induced by Stz and cytokines was significantly lower (5±1% and 15 ±2% respectively). A marked increase in the number of Min6-vec cells displaying a reduction in mitochondrial membrane potential (Dym) was seen following treatment with Stz (28.9 ± 3.3%) and cytokines (69.3 ± 6.2%), values that were significantly higher than that seen in Min6-Reg2 cells (14.5 ± 2%and 33.3 ± 6% respectively). Finally, Reg2 abrogated Stz- and cytokine-induced activation of caspases 9 and 3. We conclude that Reg2 prolongs the survival of insulin producing Min6 cells by attenuating pro-apoptotic events originating at the mitochondria.

Vitamin D3 upregulates expression of Islet Neogenesis Associated Protein (INGAP): a potential treatment for diabetes?

J.M. Patapas[1], M. Petropavlovskaia[1], L. Rosenberg[1]
[1] Montreal General Hospital, Surgical Research, Montreal, Canada

Diabetes is characterized by a complete (type 1) or partial (type 2) loss of pancreatic beta cells. Regeneration of beta-cell mass is an important goal of diabetes research. Development of strategies to induce beta-cell regeneration ***in situ*** involves identification of candidate molecules with islet regenerating activity. Islet Neogenesis Associated Protein (INGAP), identified in our laboratory, has been shown to stimulate neo-islet formation. INGAP, an endogenous pancreatic protein, is a member of the Reg3 family of proteins. We have previously shown that INGAP expression is regulated by inflammatory cytokines, more specifically by interleukin (IL)-6. It would be of interest to identify other factors, preferably of non-inflammatory nature, that upregulate INGAP expression and subsequently induce islet neogenesis. Here, using an ***in vitro*** hamster cell model and real time qRT-PCR, we show that INGAP gene expression is induced by $1,25(OH)_2D_3$, the hormonally active form of vitamin D. Our data indicate that $1,25(OH)_2D_3$ upregulates INGAP mRNA (up to 3-fold) in a dose- and time-dependent manner. We also show that nicotinamide, the amide derivative of vitamin B3, potentiates the effect of $1,25(OH)_2D_3$ resulting in a 12-fold increase in INGAP mRNA. A computer analysis of the INGAP promoter region identified three candidate vitamin D responsive elements (VDREs), which bind the ligand-activated nuclear vitamin D receptor (VDR). The role of this classic mechanism of vitamin D signaling in the upregulation of INGAP expression, as well as a potential involvement of rapid, membrane-linked signal transduction pathways remain to be elucidated.
This is the first study to provide evidence for regulation of INGAP, and possibly, of other Reg proteins by vitamin D. Interestingly, $1,25(OH)_2D_3$ can be partially activated in beta cells and is implicated in cell growth and differentiation. Given the presence of VDRs in endocrine and exocrine pancreatic tissue, the potential role of vitamin D in islet neogenesis should be further investigated. Taken together, these data suggest an important role for vitamin D in beta-cell regeneration, which may prove to be a cost-effect, natural and safe treatment for type-1 and type-2 diabetes.

Selective resistance of mouse islets versus immune cells to indoleamine 2, 3 dioxygenase induced tryptophan deprivation stress response

R. B. Jalili[1], F. Forouzandeh[1], A. Moeenrezakhanlou[1], G. Rayat[2], R. Rajotte[2], H. Uludag[3], A. Ghahary[1]
[1] University of British Columbia, Surgery, Vancouver, Canada
[2] University of Alberta, Surgery, Edmonton, Canada
[3] University of Alberta, Chemical & Materials Engineering, Edmonton, Canada

Aim: Indoleamine 2, 3 dioxygenase (IDO) is a cytosolic enzyme that catalyses tryptophan, the least available essential amino acid in the human body. IDO has a profound immunoregulatory activity on T-cells probably due to providing a tryptophan-deficient microenvironment and/or accumulation of toxic metabolites of tryptophan. Tryptophan deprivation can initiate the amino acid deprivation integrated stress response pathway in T-cells which will induce cell apoptosis in turn. As local expression of IDO in bystander fibroblasts suppresses islet allogeneic immune response, IDO can function as a local imunosuppressive factor in islet transplantation. However, it is essential to confirm that IDO

induced tryptophan deprivation does not compromise islet viability and functionality. As such, the aim of the present study was to investigate the impact of IDO on viability and function of mouse islets embedded within IDO-expressing fibroblast-populated collagen scaffold.
Methods: Mouse islets were embedded within collagen matrix populated with IDO adenovector-transduced or control fibroblasts. Islet viability, insulin content, glucose responsiveness, and activation of general control nonderepressible-2 kinase (GCN2) stress-responsive pathway were then measured in IDO-exposed islets. In vivo viability of composite islet grafts was also tested in a syngeneic diabetic animal model.
Results: No reduction in islet cells viability was detected in both IDO-expressing (96.8%±5.3) and control (94.2%±7.1) composites compared to the baseline rates. Islet functional studies showed normal insulin content and secretion in both preparations (stimulation indices of 5.3±0.5 and 5.7±0.4, respectively). In contrast to lymphocytes, GCN2 pathway was not activated in islets cocultured with IDO-expressing fibroblasts suggesting T-cell selective suppressive activity of IDO. When transplanted to diabetic mice, syngeneic IDO-expressing composite islet grafts were functional up to 100 days tested.
Conclusion: This study collectively confirms normal viability and functionality of islets in a low tryptophan microenvironment generated by IDO-expressing cells and indicates the feasibility of development of a non-rejectable IDO-expressing composite islet graft.

Data mining technology for predicting glycaemic control in new patients with type 2 diabetes

H. Sakura[1], T. Haruki[1], S. Maruyama[1], H. Kanno[1], Y. Iwamoto[1]
[1] Tokyo Women's Medical University, Diabetes Center, Tokyo, Japan

Aims: Data mining technology is the process of extracting hidden patterns from large amounts of data, and a number of algorithms are developed. It is widely used in marketing, surveillance, and scientific discovery. However, its usefulness in the field of medicine has not been established. In this study, we compared data mining methods with conventional multivariate analyses in order to predict glycemic control in new patients with type 2 diabetes.
Methods: The study was conducted on 788 Japanese patients with type 2 diabetes, who newly visited our hospital with HbA1c levels above 6.5%. The baseline clinical characteristics (explanatory variables) and HbA1c levels after 6 months (response variables) were extracted from the hospital's electronic medical record system. Data mining algorithms (decision-tree, neural network, etc.) were compared with conventional multivariate analyses (logistic regression analysis, multiple regression analysis) for the prediction of glycemic control after 6 months.
Results: It was observed that the HbA1c levels improved from 9.0±1.9% to 7.3±1.4% during the 6 months, and 38.2% of the patients attained good glycemic control (HbA1c <6.5%) after 6 months. The duration of diabetes, mode of therapy, body mass index (BMI), total-cholesterol, HDL-cholesterol, uric acid, and creatinine were identified as common significant factors in all the analyses. For the prediction of HbA1c, the correlation coefficient between the estimated and real values was best in the neural network algorithm (r=0.536) and was superior to that in the multiple regression analysis (r=0.424). Furthermore, for the classification of good (HbA1c <6.5%) and poor (HbA1c =6.5%) glycemic control, accuracy was best in the decision-tree (C5.1) algorithm (79.8%) and was superior to that in the logistic regression analysis (72.5%).
Conclusion: Strictly speaking, the application of conventional multivariate analyses is appropriate only when the explanatory and response variables are connected with a linear combination. However, this is not true in the case of complicated diseases such as diabetes. In fact, this is why data mining algorithms were superior to conventional multivariate analyses in the present study. Diabetes is a pandemic disease, and a large amount of clinical information was collected in the database with the advancement of the electronic medical record system. Soon, data mining technology will become a powerful tool in producing useful information for evidence-based medicine (EBM).

[9] European Commission Project, European Commission, Brussels, Belgium

Aim: The Report on the Status of Health in the European Union confirms that information on diabetes is heterogeneous, fragmented and still relatively unreliable across the EU. The increasing prevalence of diabetes calls for new forms of collaboration that would ensure timely and broad data collection. Aim of the project is to build a European information system for diabetes through the structured use, the improvement and the permanent connection of regional diabetes registers addressed by the public health project "Best Information through Regional Outcomes" (BIRO) started in December 2005.
Methods: In 40 months, representatives from seven European countries (Austria, Cyprus, Italy, Malta, Norway, Romania and Scotland) completed the following tasks: clinical review, definition of a diabetes data dictionary, privacy impact assessment, and development of fully operational software featuring the following components: database and statistical engines, communication software, and a dedicated web portal.
Results: Clinical review allowed the definition of N=54 target evidence-based parameters/indicators to be directly estimated from diabetes registers. The required common dataset included N=45 patient items and N=22 clinical site descriptors. An XML data dictionary has been designed to include all definitions and coding. A BIRO export has been defined to load standardized data in a Postgres database. The report template includes as sections: demographic characteristics, clinical characteristics, health system, population, and risk adjusted indicators. Privacy impact assessment has been carried out to identify the best architecture for the BIRO information system. Two-level R statistical routines have been developed to produce a standardized report for each local register, and to deploy a set of de-identified aggregate tables that are sent to a central server. Cumulative data is loaded in a central Postgres database and further processed to deliver the global report through a central engine. Results are uploaded to a EU web portal repository every 6 months. BIRO software is released under the GPL license.
Conclusion: The BIRO project sets new standards for public health information systems through an innovative architecture for data exchange and automated delivery of standardized diabetes indicators. Its sequel "EUBIROD", started in september 2008 and co-funded by DG-SANCO, will apply the system in 20 countries. Complete reports are available at www.biro-project.eu.

Risk factor profile and lifestyle habits of people with impaired glucose tolerance in European populations 45-74 years-of-age within the framework of the DE-PLAN study

X. Cos[1], J. Tuomilehto[2], N. Barengo[2], B. Costa[3], X. Mundet[4]
[1] Institut Catala de la Salut, Sant Marti de Provençals Primary Health Care Center, Barcelona, Spain
[2] University of Helsinki, Public Health, Helsinki, Finland
[3] Institut Catala de la Salut, IDIAP Jordi Gol, Barcelona, Spain
[4] Institut Catala de la Salut, Barcelona Primary Care Research Unit, Barcelona, Spain

Aims: To assess the risk factor profile and lifestyle habits of people with impaired glucose tolerance in the European population and to investigate which component of the FINDRISC questionnaire predicts best IGT.
Methods: Within the DE-PLAN (Diabetes in Europe - Prevention using Lifestyle, Physical Activity and Nutritional intervention). The FINDRISC questionnaire was distributed using opportunistic sampling techniques in 17 European countries during 2006-2008. In addition to the FINDRISC questionnaire, serum lipids, fasting and 2-hour glucose levels as well as systolic and diastolic blood

pressure were measured in all study participants. The risk of IGT was calculated using logistic regression analysis. The odds ratios (OR) and the respective 95% confidence intervals (CI) are presented.

Results: The final sample size consisted of 12 692 men (46%) and 14 938 women (54%) with both a mean age of 59 years. Mean body mass index (BMI) was 28.5 kg/m2 in men and 29.8 kg/m2 in women, respectively. Mean waist circumference was 101 cm in men and 95 cm in women. Men with less than 30 min daily physical activity had a 23% increased risk of IGT (95% CI 2-49%). The respective odds ratio (OR) for women was 1.25 (95% CI 1.06-1.48). Overweight (OR 1.40 (men) and 1.33 (women)) and obesity (OR 1.93 (men) and 2.13 (women)) were significant predictors of IGT before additional adjustment for central obesity. After additional adjustment for central obesity, the OR became non-significant in both gender. However, central obesity increased the risk of IGT in men (OR 1.46; 95% CI: 1.14-1.88) and women (OR 1.76; 95% CI: 1.40-2.22) even after adjustment for BMI.

Conclusions: Physical activity and central obesity seem to be independent predictors of IGT in both men and women in European population. Waist circumference may be the better predictor for IGT than BMI.

Disparities in carotid revascularisation procedures exceed disparities in cerebrovascular disease burden among people with diabetes of South Asian and Chinese origin

B.R. Shah[1], S. Anand[2], D.G. Manuel[1], J.E. Hux[1]

[1] Institute for Clinical Evaluative Sciences, Toronto, Canada

[2] McMaster University, Hamilton, Canada

Aims: Diabetes prevalence is known to vary between ethnic groups. However, variations in macrovascular complication rates between ethnic groups have been less well established, as have utilisation rates for medical services to treat these complications. The aim of this study was to compare the rates of diabetes macrovascular complications and procedures to treat these complications between people of South Asian and Chinese origin versus the general Canadian population (mostly of European origin).

Methods: The study used administrative data sources that provided detailed information on the health care utilisation of all residents of the province of Ontario (population=12 million). Ontario is one of Canada's most ethnically diverse provinces, with 6.6% of the population reporting South Asian origin and 4.8% reporting Chinese origin. The entire population with prevalent diabetes as of 1 July 2006 in Ontario was identified from an administrative data-derived disease registry. South Asian and Chinese ethnicity was assigned based on surname, using lists of surnames specific for each ethnic group that have been validated against self-reported ethnicity. All other people were assigned to the general population group. The rates of hospitalisation for myocardial infarction and stroke, and of coronary and carotid revascularisation procedures were measured for the following one year. Baseline differences between groups in age, sex, socioeconomic status and diabetes duration were adjusted for using logistic regression.

Results: The crude prevalence of diabetes was 12.9% among people of South Asian origin, 7.2% among people of Chinese origin, and 9.1% in the general population. Compared to the general population, hospitalisations for myocardial infarction were similar for people of South Asian origin (OR 0.99, 95% CI 0.88-1.12, p=0.9) but less common for people of Chinese origin (OR 0.37, 95% CI 0.31-0.45, p<0.001). Coronary revascularisation procedures followed these trends (OR 1.09, 95% CI 0.98-1.21, p=0.1 for South Asian; 0.39, 95% CI 0.32-0.47, p<0.001 for Chinese). Stroke hospitalisations were less common in both ethnic groups (OR 0.79, 95% CI 0.65-0.96, p=0.02 for South Asian; 0.73, 95% CI 0.60-0.88, p=0.001 for Chinese), but carotid revascularisation procedures were much less common (0.26, 95% CI 0.10-0.70, p=0.007 for South Asian; 0.32, 95% CI 0.13-0.78, p=0.01 for Chinese).

Conclusion: Compared to the general diabetic population, people of South Asian origin had fewer strokes, while people of Chinese origin had fewer myocardial infarctions and strokes. However, the difference in carotid revascularisation procedures was even greater than the difference in disease burden. These findings suggest a disparity in access to carotid revascularisation and/or a difference in distribution of cerebrovascular disease for diabetic patients of South Asian and Chinese origin.

[4] Madigan Army Medical Center, Department of Clinical Investigation, Tacoma, USA

[5] Analytic Services Inc., Analytic Services Inc., Arlington, USA

[6] University of California San Diego, Division of Epidemiology/Family and Preventive Medicine, San Diego, USA

Aims: Little prospective data exist on the risk of diabetes in persons serving in the military. We examined potential risk factors for self-reported diabetes mellitus over a 3-year follow-up period that included the initiation of military conflicts in Afghanistan and Iraq in members of the Millennium Cohort Study who did not self-report diabetes at baseline.

Methods: Study subjects included a random sample of all active duty, Reserve, and National Guard U.S. military on Oct 1 2000. Of the 77,047 subjects who completed a baseline self-administered paper or online survey in 2001, 53,844 also completed a follow-up survey in 2004 and did not report diabetes at baseline. The survey instruments elicited information on demographics, height, weight, lifestyle, military service, clinician-diagnosed diabetes, and other physical and mental health conditions. Presence of post-traumatic stress disorder (PTSD), panic disorder, and depression symptoms were assessed using the Patient Check List and the Patient Health Questionnaire. Deployment information since Sept 2001 was obtained from electronic U.S. Department of Defense databases, while combat exposure was assessed by self-report at follow-up. Odds of newly self-reported diabetes mellitus in relation to exposures of interest were estimated using logistic regression analysis. Exposures were assessed at baseline except for deployment and combat exposure that mainly occurred after baseline.

Results: Occurrence of self-reported diabetes mellitus during follow-up was 3/1000 person-years. Persons reporting diabetes at follow-up compared to those who did not at baseline were significantly older (41 yrs versus 36 yrs, p<0.001), had greater BMI (29 kg/m^2 versus 26 kg/m^2, p<0.001), were less likely to be of Caucasian race (64% versus 72%, p<0.001), but were similar by gender. Relative odds of self-reported diabetes mellitus (95% confidence interval) for mental health conditions in 3 separate models adjusted for age, gender, educational level, BMI, and ethnicity were as follows: depression 1.4 (0.9 - 2.3), panic disorder 2.7 (1.5 - 4.8), and PTSD 2.1 (1.4 – 3.0). Deployments since Sept 1 2001 were not significantly related to self-reported diabetes mellitus risk with [1.0 (0.7 – 1.4)] or without [0.7 (0.5 – 1.1)] combat exposure adjusted for age, gender, educational level, BMI, and ethnicity.

Conclusions: In this relatively young U.S. military cohort, a history of panic disorder and PTSD symptoms at baseline were significantly associated with future risk of self-reported diabetes mellitus. Military deployment or symptoms of depression were not found to be significantly associated with this outcome. To our knowledge these are the first data from a prospective study that support an association between PTSD symptoms and the development of diabetes.

Metabolic syndrome in patients with bipolar disorders and the general population of Spain: findings from a population-based case-control study, BIMET-VIVA study

R. Gabriel[1], L. Lorenzo[1], M. Alonso[1], A. González[2], E. Vieta[3], J.M. Montes[4], J. Rejas-Gutiérrez[5], F.J. Mesa[5]

[1] Hospital Universitario La Paz, Clinical Epidemiology, Madrid, Spain
[2] Hospital Santiago Apóstol and Stanley Research Center Psychiatry CIBERSAM, Department of Psychiatry, Vitoria, Spain
[3] Hospital Clínic University of Barcelona IDIBAPS, Institute of Neuroscience, Barcelona, Spain
[4] Hospital del Sureste, Department of Psychiatry, Arganda del Rey Madrid, Spain
[5] Pfizer-Spain, Medical Unit, Madrid, Spain

Aims: To compare the frequency of Metabolic Syndrome (MS) and its components between patients with Bipolar Disorder (BD) under psychiatric pharmacological treatment with the general population in Spain.
Methods: The BIMET study enrolled 532 (321 females-60.3%), patients (mean age 46.3±13 years), according to DSM-IV TR criteria, from Spanish mental health centres. The VIVA Study is a multicentre (9 sites), population-based, epidemiological study. Both studies were performed between 2007-2008. A random sample of 1560 individuals (three controls per case), matched by age (mean age 47.6±9.4 years) and sex, were selected from the VIVA data set (n=2828). Fasting blood glucose (FBG), HDL-cholesterol, triglycerides, BMI, waist circumference and blood pressure were measured in both study groups. The National Cholesterol Educational Program NCEP/ATP III and the International Diabetes Federation (IDF) definitions were used for MS.
Results: Overall, the prevalence of MS-NCEP was 25.1% (95%CI 21.1-29.5) in BD patients and 19.3% (95%CI 17.4-21.4) in controls (p<0.05). Corresponding figures for IDF were 34.8% (95%CI 30.1-39.6) vs. 29.8% (95%CI 27.5-32.1) (p<0.05). Gender-related differences between BD patients and controls were only observed in males (28.5% vs 16.8% for NCEP and 40.2% vs. 26.4% for IDF) (all p values <0.001). Among BD patients, males showed a higher frequency of MS than females (28.5% vs. 23.0% by the NCEP criterium and 40.2% vs. 30.9% by the IDF). There was a higher prevalence of IDF-abdominal obesity in the Spanish female population (78.7% in BD and 66.2% in controls) compared with male population (64.7% in BD and 49.8% in controls). BD patients, males or females, had also higher values than controls in BMI 28,2±5,4 vs. 27,6±4,5 (p=0.02); waist circumference: 96±17,1cm vs.88,4±11,5cm (p<0.001); triglycerides: 145,4±102,2 mg/dl vs.116,8±81,4 mg/dl (p<0.001); and systolic blood pressure in males:129±14,6 mmHg vs.125,9±19,2 mmHg (p=0.02). Logistic regression identified the waist circumference and triglycerides as the two main independent variables explaining the higher frequency of MS observed in BD patients than in controls.
Conclusion: One out of three BD patients under psychiatric pharmacologic treatment in Spain, have MS according to the IDF criteria. This is significantly higher than in the general population, where the prevalence of abdominal obesity is already very high, particularly in women. The components of the MS which better explain the observed higher prevalence of MS in BD patients than in the general population, are waist circumference and triglycerides.

O-0407

Prevalence of central obesity, raised body mass index, physical inactivity and family history of type 2 diabetes in young urban persons in Sri Lanka (DIABRISK SL stage 1): a general population study

M. Wijesuriya[1], J. Karalliedde[2], T. Jayasekera[1], T. Fernando[1], J. Charlton[3], L. Gnudi[2], M. Gulliford[3], G. Viberti[2]

[1] Diabetes Association of Sri Lanka, National Diabetes Centre, Colombo, Sri Lanka
[2] King's College London, Cardiovascular, London, United Kingdom
[3] King's College London, Public Health, London, United Kingdom

Background and aims: The prevalence of Type 2 diabetes (T2DM) and associated cardio-metabolic disease is rising rapidly in South Asia, especially in young adults, and is of global public health concern. The prevalence of risk factors that predispose to cardio-metabolic disease in young persons in this population is unknown. Earlier studies had identified physical inactivity (defined as less than 30 minutes continuous exercise per day for less than 3 days of the week), raised body mass index (BMI), raised waist circumference (WC) and first degree family history (FH) of T2DM as the main risk factors associated with a diagnosis of T2DM in those below 40 years of age.
Methods: To evaluate the prevalence of these risk factors we studied 22,577 (10,612 M, 11,965 F) healthy subjects aged between 6-40 years representative of the general population demographics of Colombo District in Sri Lanka. A detailed previously validated questionnaire was used to assess physical activity and family history of T2DM and measurements of weight, height and waist circumference were taken.
Results: Of the 22,577 subjects, 8814 (46%M) were between 6-14yrs, 4,703 (41%M) between 15-19yrs and 9060 (51% M) between 20-40 yrs of age. The prevalence of a raised BMI (age appropriate) between 6-14 and 15-19 yrs was 19.7% and 15.4% respectively with no significant differences between men and women. Over 20 years 28.1% of men and 21.9% of women were overweight (BMI=>23)(p <0.001 M vs. F). A prevalence of a raised WC[age and gender appropriate] was significantly greater in women for each age group: 42.9% vs. 32.0% 6-14 yrs; 28.2% vs. 16.0% 15-19 yrs; 34.4% vs. 25.9% 20-40 yrs (F vs. M p<0.05 for all). Similarly physical inactivity was significantly greater in women compared to men for each age group: 39.9% vs. 15.0%; 51.6% vs. 19.5%; 63.0 % vs. 41.1% and rose in both sexes with age (p<0.05 for F vs. M and with increasing age). A FH of T2DM was documented in 26.2% of all subjects. Only 32.6% of the population studied had no risk factors, with 33.1% displaying one risk factor and 34.2 % two or more risk factors. Two or more risk factors were noted in 32.0% of subjects aged 6-14yrs, 28.7% in 14-19 yrs and 39.3% in 20-40 yrs.
Discussion and conclusion: There is a high prevalence of early modifiable cardio-metabolic risk factors in the general population of Sri Lanka aged below 40 years. Physical inactivity and raised WC are significantly more prevalent in women across all age groups and physical inactivity rises significantly with increasing age. Intervention strategies are required to address early these risk factors.

Diabetes-related information and behavioral/psychological outcomes in the Diabetes Attitudes, Wishes and Needs Youth Study

K. Lange[1], M. Peyrot[2], H.J. Aanstoot[3], T. Danne[4], B. Anderson[5], S.E. Skovlund[6]

[1] Medizinische Hochschule, Medical Psychology, Hannover, Germany
[2] Loyola College in Maryland, Dept of Sociology, Baltimore, USA
[3] Diabeter, Diabetes Center for Children and Youth, Rotterdam, The Netherlands
[4] Kinderkrankenhus Auf der Bult, Dept. of General Pediatrics and Endocrinology/Diabetology, Hannover, Germany
[5] Baylor College of Medicine, Pediatrics, Houston, USA
[6] Novo Nordisk, Dawn, Copenhagen, Denmark

Aims: To assess the relationship of diabetes-related information with behavioral/psychosocial outcomes in youth with diabetes.
Methods: The Diabetes Attitudes, Wishes and Needs (DAWN) Youth Study conducted two cross-sectional internet surveys with independent national samples of: (1) parents of children/adolescents (age 0-18) with diabetes (N=4099) and (2) young adults (age 18-25) with diabetes (N=1905). Respondents from the US, Japan, Brazil and 5 European countries provided self-report data for diabetes-related information received at diagnosis and sources of current diabetes-related information, as well as 5 outcomes: school performance impact, burden of diabetes, psychological well-being, successful self-care and diabetes-specific coping. Multiple regression assessed significant (p<.05) independent associations of information measures with each outcome, controlling for country of residence and a variety of demographic and disease characteristics.

Results: For young adults several findings were observed. Number of information topics at diagnosis was independently associated with better outcomes for 3/5 measures (all except self-care and well-being); number of current information sources with better outcomes for 4/5 measures (all except school impact). Specific sources of current information were independently associated with different numbers of better outcomes (people with diabetes = 4/5, health care providers = 3/5, family-friends = 2/5, diabetes organizations = 2/5, diabetes education programs = 1/5, internet = 0/5). No information measure was significantly associated with any worse outcome.
Findings were similar for parent-reported outcomes. Number of information topics at diagnosis was independently associated with better outcomes for 4/5 measures (all except well-being); number of current information sources with better outcomes for 4/5 measures (all except school impact). Specific sources of current information were independently associated with different numbers of better outcomes (diabetes education programs = 3/5, diabetes organizations = 2/5, health care providers = 1/5, people with diabetes = 1/5, family-friends = 1/5, internet = 0/5). Internet information was significantly associated with worse well-being.
Discussion/conclusions: Information at diagnosis and multiple sources of ongoing information may contribute to good outcomes among youth with diabetes and their parents. Information from sources other than traditional diabetes education/care providers shows potential to have positive effects. Benefits of information extend beyond educational and health care outcomes to include a broad range of psychosocial outcomes.

Sharing experiences in groups - diabetes a lifelong psychological challenge

M. Due-Christensen[1], M. Lau[2], E. Hommel[3], A. Hougaard[4], A.G. Skouboe[5]
[1] Steno Diabetes Center, Nursing research, Gentofte, Denmark
[2] Psykoterapeutisk Center, Psychiatry, Gentofte, Denmark
[3] Steno Diabetes Center, Medicine, Gentofte, Denmark
[4] Steno Diabetes Center, Nursing, Gentofte, Denmark
[5] Steno Diabetes Center, Nutrition, Gentofte, Denmark

Living with type 1 diabetes is a lifelong psychological challenge, and many patients feel lonely and not fully understood by relatives and health professionals.
Aim: The aim of this study was to:
1. design an empowerment based support group for patients with type 1 diabetes in which they could share experiences related to life with diabetes
2. examine how the participants valued the intervention

Material and method: The criteria for participating in the support groups were: type 1 diabetes for more than two years and being older than 21 years of age. Five support groups based primarily on motivational and empowerment theory were established. Each group met 8 times for 2 hours and 15 minutes.
The outcome was evaluated both by qualitative and quantitative methods. Focus group interviews were conducted after each support group and were analysed using thematic analysis. The following questionnaires were applied when the group started and ended: PAID (Problem Areas in Diabetes), WHO-5 (Well-Being Index), SCL-90R (general psychological distress) and Sheehan Disability Scale. HbA1c were measured at the same time.
Results: 41 participants signed up for the support groups and 34 (82, 9%) of these completed 6.8 sessions on average. The 34 persons were between the age of 22 and 63 with diabetes duration of 22,8 years (±10,9) and HbA_{1C} of 7,9 % (±0,98) respectively.
The focus group interviews showed that sharing experiences among peers was appreciated most. The group process stimulated the feeling of normalcy and not 'being alone'. They felt recognized and supported participating in this kind of diabetes mini-society. They gained new insights on different perspectives of living with diabetes, which for some resulted in a change in both attitude and behaviour for instance concerning SMBG. Three of the five groups have continued to meet after the support group ended.
The study showed significant reduction of diabetes related distress measured with PAID ($p<0,001$), general psychological distress measured with Symptom Check List 90-R ($p<0,01$) and the depression subscale on SCL-90R ($p<0,05$). Well-being measured with WHO-5 also improved ($p<0,05$) right after participating in the support group. No change in social function measured by Sheehan Disability Scale or HbA1C was seen.
Conclusion: There is a need for participating in diabetes support groups regardless of HbA1C level. The format of the groups was suitable for a diabetes setting. The participants found the group valuable in order to manage psycho-social aspects of living with diabetes in a better way. Wellbeing as well as diabetes related distress improved significantly.

Self-reported physical stress signs and risk of type 2 diabetes mellitus: a prospective cohort study

N. Cho[1], H.C. Jang[2], S. Lim[2], S.H. Choi[2], H.R. Kim[3]
[1] Ajou University School of Medicine, Preventive Medicine, Suwon, Korea
[2] Seoul National University College of Medicine, Internal Medicine, Seoul, Korea
[3] Korean National Genome Institute The Korean Center for Disease Control and Prevention, CDC and Prevention, Seoul, Korea

Type 2 diabetes mellitus (T2DM) is one of the fastest growing chronic diseases in Korea and its prevalence affects over 10% of the population. The putative risk factors for T2DM, in the Korean population includes, but is not limited to, older age, urban living, female gender, higher obesity level, smoking, family history of diabetes, liver function, metabolic syndrome status, elevated blood pressure, and triglyceride level. However, chronic stresses, such as psychological, physical, and physiological responses to the onset of diabetes are unknown. Extended exposure of the cortical, from chronic stress, could result in a number of negative health outcomes, such as obesity, hypertension, and cardiovascular diseases. However, its relationship to T2DM is unknown. Thus, in this prospective study we evaluated the incidence of diabetes and stress.
This is a community based, prospective cohort study, consisting of a total of 10,038, (5,018 rural and 5,020 urban), Korean men and women in the age range of 40-69 yrs. Anthropometric parameters and social factors, as well as biochemical parameters, were measured. All participants, except those on oral hypoglycemic medications or insulin therapy, underwent two-hour, 75g oral glucose tolerance tests at baseline and then were followed up biennially. Physical stress was ranged from a minimum score of 0 to a maximum of 10, based on 10 different physical stress signs, such as difficulty in breathing, dry throat or mouth, difficulty in sleeping, headaches, asthemopia, stiff neck or shoulders, chest discomfort, nausea, loss of appetite, constant constipation or diarrhea, and chronic fatigue. For the analysis, we only included subjects who had completed 6 years of follow-up examinations and were free of T2DM at the baseline examination. Thus, a total of 6,466 people are the subjects of our current analysis. Of the 6,466 follow-up subjects, 629 developed T2DM during the 6-years of the follow-up period.
According to the ROC analysis, we identified a threshold stress level of 5 and 8 to differentiate T2DM in men and women, respectively. After adjusting for age, place of residence, waist circumference, number of pregnancy, systolic blood pressure, family history of diabetes, education levels, monthly income, living with a partner, ALT, WBC, total cholesterol, HDL, LDL, Triglyceride, ß-cell function, HOMA-IR, and HbA1c, 25 out of 156 men who reported more >5 physical stress signs developed type 2 diabetes in the risk of 1.93 folds (95% CI 1.21 – 3.09), whereas 16 of 93 women who reported >8 physical stress signs developed T2DM in the risk of 2.24 folds (95% CI 1.22– 4.1).
In conclusion, our study demonstrated that stress was associated with the onset of T2DM in a large multi faceted population. The study results suggest each sex had a different threshold level of stress predict T2DM.

Treatment adherence, diabetes-related stress and support in their relation with disease control in adolescents with type 1 diabetes

J.A. Malik[1], H.M. Koot[1]
[1] VU University, Developmental Psychology, Amsterdam, The Netherlands

Aims: The study aims to test hypotheses on:
1. The effect of treatment adherence on diabetes control/severity.
2. The role of diabetes-related stress in contexts of adherence and diabetes control,
3. the differential role of tangible and social support in diabetes control.

Methods: The study included 11-19 year-old youngsters with type 1 diabetes, who are all on daily insulin injection or pump. A total of 437 adolescents

(54.8% girls; mean age 14.7 years; mean diabetes duration 6.1 years) participated in the study. Metabolic control was assessed by measuring HbA1c and adolescents filled out questionnaires during their visits in their local clinics in presence of diabetes nurse, whereas questionnaires for family members were sent and returned by mail. A model was constructed based on hypotheses drawn from a review of relevant literature, testing the relations between study variables representing the three aims. Each hypothesis was tested using Amos version 7.0. Multi group analysis was conducted on the final model to test generalizability of the model across gender and age.

Results: Structural equation modeling showed a strong effect (ß=-.40, p<.01, 16% variance explained) of treatment adherence on diabetes control (including A1c, and Hospital Admission due to Ketoacidosis, Hypoglycemia, and Hyperglycemia) with good indices of model fit X^2(df = 1) = 2.44, GFI = .99, TLI = .96, CFI = .99, and RMSEA = .057. Inclusion of diabetes-related stress in the model explained an additional 7% variance in diabetes control whereas specifying role of diabetes-related stress as a mediator between treatment adherence and diabetes control in the third model explained an overall 36% variance in diabetes control with good fit indices. In line with the hypothesis, although diabetes specific support appeared to improve treatment adherence (ß=.28, p<.01) it also added to diabetes-related stress (ß=.44, p<.01). General social support not only appeared to have a positive effect on treatment adherence (ß=.18, p<.01), it also decreased diabetes-related stress (i.e., ß=-.16, p<.01; X^2(df = 14) = 21.46, GFI = .99, CFI = .98, and RMSEA = .035). Although multi group analysis generally confirmed the fit of the model across gender and age, some regression weights were rendered nonsignificant, possibly indicating lack of statistical power given the complexity of the model.

Conclusion: Diabetes-related stress plays a critical role in the relation between adherence, social support, and diabetes control, and should be addressed by diabetologists and diabetes educators. To gain maximum from treatment adherence, need-based diabetes-specific support should be provided and adolescents shall be encouraged to engage in general (non-diabetic) activities like their normal counterparts.

Impact of personalised cardiovascular disease (CVD) risk estimates on physical activity

H.C. Price[1], S.J. Griffin[2], R.R. Holman[1]
[1] University of Oxford, Diabetes Trials Unit, Oxford, United Kingdom
[2] University of Cambridge, MRC Epidemiology Unit, Cambridge, United Kingdom

Aim: Population screening for cardiovascular disease (CVD) risk factors and estimation of risk is widely practised. To determine if the provision of personalised risk information can motivate behaviour change, we assessed the effects on physical activity levels over one month of providing a personalised 10-year CVD risk estimate to individuals at increased CVD risk.

Methods: A total of 215 individuals, aged 40 to 70 years, without known CVD but at increased CVD risk (defined as a Framingham-derived 10-year CVD risk =20%) were recruited from 4 UK general practices. 194 eligible participants were randomised in a 2x2 factorial design, to receive a personalised 10-year CVD risk estimate (n=99) or information on their blood pressure (BP), total cholesterol and fasting glucose values, and if any of these were elevated according to current guidelines (n=95). The intervention group had their 10-year CVD risk estimated using the UKPDS Risk Engine and were shown their current risk as well as their 'achievable risk'. The latter was defined as the risk estimate they would have assuming they could achieve current guideline targets for BP, LDL cholesterol, HbA1c and smoking cessation (if applicable). Participants were simultaneously randomised to receive or not receive a brief lifestyle advice intervention. We report here the personalised risk estimate arm. The primary outcome was change in physical activity measured by a hip-worn accelerometer (MTI Actigraph), with 80% power at the 5% level of significance to detect a difference of 30,000 total accelerometer counts per day between groups (approximately equivalent to 10 minutes brisk walking). Accelerometer, anthropometric and biochemical information was collected before and one month after randomisation.

Results: Participants had median (IQR) age 62.3 years (54.9, 66.1) and HbA1c 5.7 % (5.3, 6.1), 67% were male and 19% had known diabetes. At baseline, blood pressure was mean (SD) 140 (18)/ 81 (11) mmHg and LDL cholesterol 3.1 (0.9) mmol/L. Body mass index was median (IQR) 28 kg/m^2 (26, 31) and estimated 10-year CVD risk 48 % (34, 60) in men and 31 % (22, 43) in women. In the 185 (95%) participants attending follow-up, there was a non-significant 0.5% (p=0.56) greater increase in accelerometer counts in those receiving personalised CVD risk estimates. No significant within or between group differences were seen except a net 7% decrease in mean LDL cholesterol (p=0.004) in the intervention group. This was not related to an increase in new prescriptions for lipid lowering therapies (4 in the intervention group, 5 in the control group, P=0.74).

Conclusions: Provision of personalised 10-year CVD risk estimates alone did not appear to influence physical activity or estimated CVD risk in adults at increased risk of CVD.

Depression and self-care activities in Korean patients with diabetes mellitus

S. Kim[1], E.H. Jang[1], J.W. Son[1], Y.B. Ahn[1], K.W. Lee[1], K.C. Won[2], D.K. Song[3], K.H. Song[1]
[1] The Catholic University of Korea, endocrinology, Seoul, Korea
[2] Yeungnam University, endocrinology, Daegu, Korea
[3] Keimyung University School of Medicine, Physiology, Daegu, Korea

Background: Depression is known to be a risk factor for diabetes mellitus. Conversely, diabetes is also shown to be a risk factor for depression. Patients with diabetes have twice the risk of depression as the general population. Depression in patients with diabetes may cause worse clinical outcome through lower adherence to several self-care activities. Furthermore, diabetic patients with depression may be more likely to have diabetic complications. We aimed to explore the prevalence of depression and its impact on self-care activities in Korean diabetic patients.

Method: We surveyed diabetic patients using questionnaires such as Harvard Department of Psychiatry/National Depression Screening Day Scale (HANDS) and the Summary of Diabetes Self-Care Activities (SDSCA) to assess depressive symptoms and self-care activities, respectively. Patients were categorized as having major depressive disorder if HANDS score was =9.

Results: Of the 191 respondents, 39 (20%) patients had depression. Only 6 (15.3%) of them had been managed for their psychiatric problem previously. The proportion of women was significantly higher than men in patients with depression (74.3% vs. 25.7%, P<0.001). Moreover, women exhibited higher HANDS score than men (6.15 ± 5.38 vs. 3.45 ± 4.82 P<0.001). Patients with depression showed worse diet control and fewer self-glucose monitoring as compared with those without depression. However, there was no difference in exercise, foot care, smoking status, metabolic control and diabetic complications between the two groups.

Conclusions: Many diabetic patients in Korea, especially women, have depression which seems to have an adverse impact on self-care activities. Early identification and proper treatment of depression should be considered in the management of diabetes.

Link between psychopathology and quality of life in diabetic patients

M. Pereira[1], C. Neves[1], J.P. Pereira[2], E. Carqueja[3], M. Alves[4], D. Carvalho[4], R. Coelho[3], J.L. Medina[4]

[1] *Hospital S. João, Service of Endocrinology, Porto, Portugal*

[2] *Maia's Superior Institute, Health & Occupational Health Psychology, Maia, Portugal*

[3] *Hospital S. João, Psychiatry Service, Porto, Portugal*

[4] *Hospital S. João, Endocrinology Service, Porto, Portugal*

Introduction: Psychopathological symptomatology, namely anxiety and depression, is known to be present in chronic diseases like diabetes. Quality of life (QoL) is a multidimensional aspect of each individual that combines physical, psychological, emotional and social well-being perceptions. Therefore QoL is an outcome measure which can, somewhat, reflect issues related to psychopathology.

Aims: To evaluate the psychopathological symptomatology and its contribution to QoL in type 1 (DM1) and type 2 (DM2) diabetic patients.

Patients and Methods: We gathered a sample of 94 diabetic subjects, 50% males, 55.3% type 1, with a mean age of 42.02 ± 16.68 (17-77) years. To accomplish our work we applied several instruments: a general biographical questionnaire, the Audit of Diabetes-Dependent Quality of Life (ADDQoL) and the Brief Symptom Inventory (BSI).

Results: We found significant negative correlations between ADDQoL and six sub-scales of the BSI and, above all, its general symptom index ($r = -0.27$; $p = 0.009$). In concern to differences between type of diabetes, we noticed that DM2 tend to reveal more phobic anxiety ($p = 0.04$) and somatization symptoms ($p = 0.002$) rather than DM1 patients. These results are also true when we compare gender, this is women report higher values in those two sub-scales. These two symptoms also relate themselves negatively with self-monitoring of diabetes and the level of education of the patients. The impact of psychopathological issues in QoL is greater in DM1 rather than in DM2 patients. In the whole sample, we observed that mean psychopathological values are below the normal Portuguese range for emotional disturbances.

Conclusions: In this sample it is clear the influence of psychopathological symptomatology in the QoL of diabetic subjects. These symptomatologies are more often found in patients with DM2 but its impact in QoL is greater in patients with DM1. There are some QoL aspects that are more directly linked with a particular kind of symptomatology.

WORKSHOP

ASSOCIATION DEVELOPMENT

Setting up national health programmes

0415

Workable ideas from the field on how to develop diabetes national programmes in resource restrained settings

R.E. Mtonga[1]

[1] *Diabetes Association of Zambia, Research Education and Advocacy, Lusaka, Zambia*

Setting the scene: Zambia's healthcare delivery system is still a work in progress.

With a Gross Domestic Product of US$330, a population of nearly 12 million, Zambia's road towards quality, cost-effective and affordable healthcare as close to the family as possible will be long and difficult.

Zambia's resource envelope is biased towards communicable diseases. Currently there is no National Policy for Non-communicable diseases including Diabetes Mellitus.

According to the Abuja Declaration on Health and Microeconomics, Zambia would need US$33 per capita per year to provide a basic package of care but at present the national average is only between US$6 and US$10.

Diabetes care: Diabetes Mellitus management is less than ideal. Long distances from health centres, chronic shortage of Diabetes Medicines, lack of a cold chain, lack of trained healthcare providers, poor motivation of staff, the brain drain and urban drift, lack of political will are some of the problems besetting Diabetes care in Zambia.

Local solutions: instead of abandoning People-living with Diabetes (PLD), local solutions are being used to help PLD.

The Diabetes Association of Zambia (DAZ) through its branches provide from time to time one to two days training seminars for health workers and PLD, and organise annual Youth Camps and an Insulin Bank for Children at the University Teaching Hospital.

Partners such as LifeScan, Norwegian Diabetes Federation, Ministry of Health are on board etc. Local Radio Stations and newspapers have been used to raise awareness, advocacy, education and recruit new members.

Diabetes care also innovatively piggybacks on HIV/AIDS programme by poaching Laboratory facilities. Some DAZ branches benefit from joining nutritional programmes. Diabetes medicines are transported using local buses. The use of cellular phones has also helped in part to resolve communication problems.

Outcomes: Innovation rather than National Policy has helped PLD. Diabetes awareness has improved. There is better access to decision makers. A National Policy to be put in place soon?

Assessment of implementation and outcome of national diabetes programmes

L. Etu-Seppälä[1]

[1] *Finnish Diabetes Association, National Diabetes Programme Dekho 2000-2010, Tampere, Finland*

Aims: The Finnish National Diabetes Programme (DEHKO 2000-2010) was prepared by a group of 100 voluntarily working researchers, doctors, nurses and people with diabetes under coordination of the Finnish Diabetes Association in 1998-2000. In addition to the 13 clear objectives, the programme includes 25 action recommendation for achieving the objectives, and a plan for regular evaluation and assessment of the progress and results. The goal with assessment was to keep the ten-year programme running in the right direction, to make corrections, if needed, and to update the objective, especially the key actions, according to development of the situation in health care.

Methods: Following the assessment plan of the DEHKO Programme, the Finnish Diabetes Association, as coordinator of the programme, hired researchers and companies to make the following assessments: 1) The DEHKO Programme as a health programme (2000), 2) The glycemic control level of the Finnish diabetic population in 2000-2001, 3) Satisfactory of the Finnish diabetic patients in 2000, 4) The first intermediate assessment of the progress of the DEHKO Programme (2003), 5) The regular follow-up surveys on the quality of diabetes care and resources in the health centres and hospitals 2003-2009, 6) The first Diabetes in Finland Study on prevalence of diabetic complications (2005), 7) The intermediate assessment of DEHKO`s prevention of type 2 project (FIN-D2D) 2005 and 2006, 8) The intermediate assessment of the progress and preliminary results of the DEHKO Programme (2006) 9) The second Diabetes in Finland Study on the prevalence of complications (FINDM2, 2009) and 10) The cost of diabetes in Finland (CoDiF, 2009).

Results: 2 The official and scientific assessment of the programme, in addition to the regular evaluation in annual meetings and in the bigger educational days every three years, are, according to the experience of the Finnish Diabetes Association in DEHKO Programme, the keys for the overall coordination of a national diabetes programme. The regular evaluation and assessment and dissemination of their reports have given the programme credibility amongst the health care providers, decision makers and people with diabetes. In addition, leading and annual planning of this long-term programme has been easier with all the information received through the regular follow-up studies in assessment. Finally, the results of the DEHKO Programme can be measured through the outcome of the assessments.

Discussion: The national diabetes programmes should include objectives, concrete action plans, clear time frame, and at least some sort of evaluation on the action and results. Hiring outside researchers and companies to make assessment is normally quite expensive but that is the way to receive neutral view on the progress of the programme, its strengths and weaknesses. All this helps you to navigate the ship to the right direction and final end.

The status of national diabetes programmes: from siloes to synergies

R. Colagiuri[1]
[1] *Menzies Centre for Health Policy, The Diabetes Unit, Sydney, Australia*

In the 20 years since the St Vincent Declaration, national diabetes programmes (NDP) have become entrenched in many countries. Despite this there has been little progress in developing robust evaluation frameworks for NDP on a collective basis. This presentation will explore and analyse the changing face of NDPs over the past decade or so, and possible strategies for evaluating NDPs. In doing so it will:

a. track the evolution of NDPs from their initial narrow focus on health systems alone to their current broader focus on prevention and care of the diagnosed, and integration with related chronic diseases
b. analyse and discuss possible reasons, benefits and drawbacks of these changes
c. present the results of a global survey of IDF members organisations on the current status of NDPs which was undertaken in 2008
d. discuss ways of promoting and ensuring the quality and effectiveness of NDPs and
e. considerations for evaluating NDPs

[6] *ASL 8, Diabetes and Metabolism Unit, Chieri (TO), Italy*
[7] *Consorzio Mario negri Sud, Clinical Pharmacology and Epidemiology, S. Maria Imbaro (CH), Italy*

Aims: Direct measurement, feedback, and reporting of intermediate outcome levels or of level of medication management may enhance the effectiveness of care. We evaluated the impact of a continuous quality improvement effort implemented by a network of diabetes outpatient clinics in Italy and promoted by the Associazione Medici Diabetologi (AMD).
Methods: Overall, 122 clinics participated, of whom 87 joined the initiative since 2005 (Group A) while the remaining 35 were first involved in 2008 and served as control group (Group B). Centres providing valid data for 4 years were selected in both groups, leaving 67 centres in goup A and 18 centres in group B included in the analysis. All centres used electronic medical record systems. Process and intermediate outcomes indicators were identified and a software was developed, enabling the extraction of the information needed for the profiling of quality of care. Data were centrally analyzed anonymously and results were published annually (AMD Annals). The performance of the different centres was ranked against the "best performers". We compared quality indicators between the two groups of centres over four years (from 2004 to 2007). For each indicator, a multilevel model adjusted for gender, age, diabetes duration and clustering effect was performed.
Results: Over 100,000 patients with type 2 diabetes were evaluated every year. The table shows for the two groups of centers the annual proportion of patients with at least one value registered during the year (process measures), the percentage of patients reaching specific favorable or unfavorable targets (intermediate outcome measures), and rates of use of drugs.
Discussion/conclusions: Diabetes care profiling and benchmarking activities implemented by a large network of diabetes clinics were able to improve clinical outcomes and, to a lesser extent, process measures. Increasing rates of use of different classes of drugs were also documented. The same positive trends were not systematically found in those centres not previously involved, thus suggesting a direct, positive effect of the initiative.

O-0419

Assessment of the risk of foot wound based on a systematic screening, designed for the professional practices evaluation necessary for French hospitals certification

S. Moracchini[1], *M.E. Stutzmann*[1], *E. Hamon*[1], *C. Masclet-Bertrand*[1], *C. Garcia*[1]
[1] *Begin Hospital, Endocrinology, Saint-Mandé, France*

Aims: A professional practices evaluation based on the prevention of foot complications in diabetics led to create measures for professional practices improvement during the certification visit (V2), ordered by the French National High Authority for Health, in order to guarantee the best level of medical care. During the year 2005, more than 1000 diabetics were hospitalised in our department, 368 foot assessments and punctual prevention measures were provided. In a certification approach education tools should be improved, regular acts for prevention should be realised, and standardisation of health care follow-up should be also encouraged.
Methods: A form was thus created for the screening of all hospitalised diabetic patients, including foot grade. A short evaluation form was filled during all hospitalisations. An educational and playful tool was created: the 7 feet game, inspired by the famous happy families game. It was tested and validated for use, allowing weekly therapeutic education sessions. We evaluated these measures by analysing random diabetic patients files, in order to assess both the tools appropriation and the improvement of practices.
Results: Foot grade was mentioned in only 2% of the 57 files evaluated in 2005, 14% of the patients declared to know about prevention bases and 32% were taught for specific informations. These rates increased respectively in 2006 to 65%, 65% and 70%, and in both years 2007 and 2008 to 100%, 90% and 90%. A survey designed to know patient's risk perception in 2007 showed that 53% of them needed more information, 94% were aware about the risk, but less than 20% were able to give precise examples of adapted actions. Lastly, more than 80% were satisfied or very satisfied about their education session because of the game and estimated having increased their level of knowledge.

Conclusion: Obligation of assessment of professional practices in a certification approach allows to create new projects and to focus on perfectible domains.

Characteristics of patients with type 2 diabetes referred for the first time to a diabetes clinic

M. Rossi[1], G. Vespasiani[2], A. Cimino[3], G. De Bigontina[4], D. Fava[5], C. Giorda[6], G. Graziano[1], I. Meloncelli[7], F. Pellegrini[1], U. Valentini[3], A. Arcangeli[8], A. Nicolucci[1]

[1] *Consorzio Mario Negri Sud, Clinical Pharmacology and Epidemiology, S. Maria Imbaro (CH), Italy*
[2] *Madonna del Soccorso Hospital, Diabetes Unit, S. Benedetto del Tronto (AP), Italy*
[3] *Spedali Civili, Diabetes Unit, Brescia, Italy*
[4] *Cadore Hospital, Diabetes Unit, Dolomiti-Belluno, Italy*
[5] *A.O.S. Giovanni dell'Addolorata, Diabetes Unit, Roma, Italy*
[6] *ASL 8, Diabetes and Metabolism Unit, Chieri (TO), Italy*
[7] *Madonna del Soccorso Hospital, Diabetes Unit, S.Benedetto del Tronto (AP), Italy*
[8] *AUSL 4, A.S. Diabetes and Metabolic Diseases, Prato, Italy*

Aims: Recent results of large scale clinical trials have emphasized the importance of early intensive interventions on metabolic control and cardiovascular risk factors to reduce the burden related to diabetes complications. On the other hand, an aggressive approach aiming to reduce HbA1c below 6.5% in individuals with a long history of diabetes does not produce the expected benefits on cardiovascular outcomes. Starting from these premises, we evaluated the characteristics of patients with type 2 diabetes referred for the first time to a diabetes clinic.
Methods: A continuous quality improvement effort was promoted in Italy by the Associazione Medici Diabetologi and implemented by a network of diabetes outpatient clinics. Overall, 122 clinics participated, all using electronic medical record systems. A software was developed to enable the extraction from the clinical databases of the information needed for the analysis. Data on all patients referred for the first time to a diabetes clinic between 2004 and 2007 were analyzed.
Results: Overall, 102136 patients were seen for the first time during four years, representing on average 18% of all the patients cared for by the clinics. Fifty-seven per cent of patients were males; patients had a mean age of 64.6±11.7 years, a BMI of 29.6±5.3, and a diabetes duration of 7.3±8.2 years. Only 50% of the patients had HbA1c values ≥7%, while 14% were referred to specialist care with a value ≥9%. Nineteen per cent of the patients were still treated with insulin±oral agents, while 17% were on diet alone. Blood pressure levels ≥140/90 mmHg were found in 58.9% of patients, while LDL-cholesterol values ≥130 mg/dl in 35.2%.
Moreover, a wide variation in these patients characteristics among 18 different Italian regions was identified, in terms of mean age (from 61 to 68 years), average levels of HbA1c (from 6.6 to 8.0%), diabetes duration (from 6.0 to 10.4 years), and proportion of patients on diet alone (from 1.0 to 28.8%).
Discussion/conclusions: The evaluation of a large sample of individuals with type 2 diabetes seen for the first time in diabetes clinics shows that patients are usually referred to specialist care many years after diagnosis and frequently show poor metabolic control and very high cardiovascular risk profile. Organization of diabetes care at the regional level, and the degree of implementation of shared care programs between general practice and diabetes clinics, strongly influence the pattern of referral to specialist care. Major efforts are needed to improve communication and collaboration between primary and secondary care in order to provide better quality of care and reduce clinical and economic consequences of diabetes.

O-0421

English national diabetes strategy: understanding the drivers of improvement

A. Morton[1], R. Hillson[2], E. Allan[3]

[1] *NHS Diabetes and Kidney Care, NHS Diabetes, Hexham, United Kingdom*
[2] *Department of Health, Diabetes, London, United Kingdom*
[3] *NHS Diabetes and Kidney Care, Diabetes, Hexham, United Kingdom*

Service Quality is often intangible. If we measure tangible, easy-to-collect data, organisations may reach "target" without revealing service improvement (or not). Organisations may look good, without ***being*** good. We aim to break this cycle and reset expectations and performance at a higher level of quality and performance. In a service business this requires assessment of quality, capability and capacity delivered within available resources.
Aims: To develop and implement a series of measures to support people with diabetes, healthcare professionals and commissioners to raise the quality of diabetes care across a nation.
To respond to context and develop tools of improvement to support current and future clinical and national strategic needs.
To understand what is required by people with diabetes, healthcare providers, commissioners and organisations, and how to build the capability and capacity to ensure their needs are met.
Methods: Using a national network of stakeholders to work in specialist advisory groups, overseen by a national steering group, to work on fundamental issues of commissioning, information/audit and culture change in diabetes. This includes open space methodology to allow active national engagement, pilot and evaluation, literature review and development of guidance and standards to answer the question of 'how do we engineer quality improvement across a nation'. We have diabetes-related public health information for each locality and a national diabetes audit (NDA) covering about 75% of known patients. This will help commissioners and providers assess local needs, tailor local care, and audit outcomes.
Results: The combined outputs of the advisory groups via the Steering Group, have developed a programme of improvement to be delivered over four years. Open space events held include pregnancy issues and future national diabetes audit needs. New commissioning documentation is being developed using a 'Teams without Walls' integrated care model. An enhanced NDA is out to tender. Fundamental changes will be made in supporting commissioning, information/audit and a culture change to support people with diabetes in self care.
Conclusion / next steps: The next step is to establish national adult and paediatric networks that will assure the work of the Steering Group and Specialist Advisory Boards, and to offer the opportunity for all those delivering and receiving diabetes care to engage in the delivery of this programme of improvement, and raise awareness of the work. It is hoped that the national feedback may generate further innovation and improvements concepts for diabetes care.

O-0422

Transition of patients from a specialty diabetes program to a family health team: a work in progress

J. MacLeod[1], C. Miller[1], A. Kaethler[2], T. Hussey[2]

[1] *Hamilton Health Sciences, Diabetes Care and Research Program, Hamilton, Canada*
[2] *Hamilton Family Health Team, Nutrition Program, Hamilton, Canada*

Aims: As the prevalence of diabetes continues to increase, so do waiting times for specialty diabetes services. Discharge of individuals from specialty diabetes programs to primary care have not been well studied despite the introduction of interdisciplinary teams into many primary care offices. The aim of this project was to identify the criteria and process that would support the transfer of patients from a specialty diabetes program to primary care.
Methods: The participating diabetes program had two sites to the program: a nurse/dietitian model and a team led by diabetes physician specialist. Twelve primary care physicians, one endocrinologist and a diabetes nurse and dietitian agreed to participate in the pilot project. We retrospectively studied a cohort of common patients followed by the specialty diabetes program and primary care, who were seen between January to November 2007 by diabetes program site and provider. Participating primary care providers and diabetes specialty staff were each requested to review their own patients' clinical data and determine

if their diabetes care could be returned to primary care. The rationale for this determination was then collated, and informed the development of agreed-upon criteria for discharge. A discharge summary was developed to support the transfer of relevant clinical information back to primary care to support the transition.

Results: There were 113 patients at the nurse/dietitian site of the program and 67 patients at the other site on program for the participating primary care practices. Only 16 out of the 67 patients belonged to the participating endocrinologist and were included in the project. Application of the methodology identified 12 matching discharge criteria and identified 57 patients for discharge at the nurse/dietitian site (50%) and 2 out of the 16 patients from the endocrinologist team (12%). At the nurse/dietitian site, 26 of the 57 patients (45%) were related to patients not attending the diabetes program hence "falling off" the system. This was a significant finding since neither party was aware of these patients' diabetes status. A discharge summary form was pilot tested to support this transition and received positive feedback from the participating primary care practices.

Conclusion: This project suggests that discharge criteria and a transition process can be established between primary care and specialty diabetes programs to support the appropriate use and access of diabetes education and management resources.

The rehabilitation publication fulfils needs

S. Koski[1]

[1] *Finnish Diabetes Association, Development Programme for the prevention and care of diabetes (DEHKO 2000 - 2010), Tampere, Finland*

Background: Education and counselling are vital preconditions for coping with illness in the treatment of persons with type 1 diabetes. Knowledge and instructions alone do not help in self-care, treatment motivation or changing one's way of life. In the complex modern world persons with diabetes must be able to solve problems and apply information in practice.

Methods: The group of twelve diabetes-professionals planned the Personal treatment and rehabilitation plan for adult persons with type 1 diabetes in Finland. In making the plan, the key idea was how to implement existing guidelines and recommendations to every-day diabetes-care and to improve the quality of counselling results. The publication was completed in two parts in autumn 2008. The first part helps health care professionals recognise rehabilitation needs of persons with diabetes. The second part has been designed for persons with diabetes to help them with disease management and to live a fuller life.

Results: Finnish Diabetes Association conducted a survey in spring 2009 to explore how health care professionals have become acquainted with the publication. The survey was web-based and it was sent in Finland to health care professionals who deliver diabetes care. The survey was conveyed by a contact person in every 21 hospital districts in Finland. About 1 000 surveys was sent and slightly over 600 answers (61%) were received. The most answers were from diabetes-nurses (57% of respondents). Other subgroups were medical doctors (29% of respondents) and other health care professionals (14% of respondents), like dieticians, podiatrists and health care leaders.

Regarding the survey, the publication has proven its importance in everyday health care. There are about half of the professionals who haven't seen the publication, but of remaining 50% a quarter uses the publication in everyday education and counselling of persons with diabetes.

Conclusion: The quality of diabetes care is in great extent based on training and competence of the health care professionals. Persons with type 1 diabetes are treated in central or university hospitals straight after they are diagnosed, but resources are not enough for them to be treated there all the time. Therefore community health centres must cooperate. In addition, the treatment of persons with diabetes as such is marked by regional and local divergences. In order to diminish the divergences, more attention has to be paid to the development of further education and counselling in future. The personal treatment and rehabilitation plan is a great help with that. It has proven its importance.

Access to insulin and diabetes care in developing countries – the experience of the International Insulin Foundation

D. Beran[1], *J.S. Yudkin*[1]

[1] *International Insulin Foundation, London, United Kingdom*

Introduction: The International Insulin Foundation (IIF) has as its aim to prolong the life and promote the health of people with diabetes in developing countries by improving their access to insulin and diabetes care. In order to meet these objectives the IIF developed a process to provide an in-depth in-country assessment to assist countries in improving their medicines supply and health system, the Rapid Assessment Protocol for Insulin Access (RAPIA).

The RAPIA has been implemented in Mozambique (2003), Zambia (2003), Mali (2004), Nicaragua (2007) and Vietnam (2008). It has also been implemented in the Philippines by the WHO, and the implementation in Vietnam was supported by the IDF Task Force on Insulin, Test Strips and Other Diabetes Supplies.

Methods: The RAPIA provides a practical field guide to assist teams in the collection, analysis and presentation of data to evaluate and inform the development of health care services for diabetes management in low and middle income countries.

Results: From the results of the different countries using RAPIA, it is important to look at the issue of affordability and accessibility of insulin at different levels of the health system; namely the central, facility and individual patient as well as the private sector.

Equally as important is that insulin alone is not sufficient for diabetes care. Syringes are needed to deliver it, testing equipment is needed for initial diagnosis and follow-up, as well as trained healthcare workers to prescribe, monitor and adjust dosage, and a health system capable of managing diabetes, including patients with complications.

Factors of affordability and accessibility also impact the person with diabetes' access to these aspects.

Discussion: The supply of insulin alone will not improve outcomes for people with diabetes. Insulin, syringes and testing equipment need to be present at the adequate facilities with the right infrastructure and personnel. The IIF has identified 11 points necessary for a "positive" diabetes environment and two relate directly to the issue of affordability and availability of insulin, but the issue of improving the lives of people with Type 1 diabetes needs to look beyond this.

The use of the RAPIA as a tool to improve diabetes care in resource poor settings has now been adopted by the WHO Essential Drugs Division and the IDF Task Force on Insulin, Test Strips and Other Diabetes Supplies and is being developed into a standardised tool and implemented in different countries to clearly identify the barriers to access and develop recommendations for action.

What is the best practice of alcohol drinking associated with the lowest risk of diabetes in Canadian adults ?

R. Fang[1], *A. Kmetic*[1], *J. Millar*[1], *L. Drasic*[1]

[1] *Provincial Health Services Authority, Population & Public Health, Vancouver BC, Canada*

Aims: Several epidemiological studies have shown that moderate alcohol consumption has a protective effect on the risk of diabetes. Drinking moderately reduces the risk of diabetes, largely by raising HDL-cholesterol levels, reducing inflammation and improving the blood vessels' ability to respond to demands on the cardiovascular system, which are linked to diabetes risk. The objectives of this study were to examine how often and how much to drink alcohol in order to approach the lowest risk of diabetes in Canadian adults.

Methods: Data used in this study are from the 2005 Canadian Community Health Survey Cycle 3.1. Residents of Indian reserves, institutions, some remote areas and military bases are not included in the survey. Using data for Canadians aged 45 and older, our analyses were implemented in two steps. In the first step, we used multivariate logistic regression to examine the risks of diabetes for various frequencies of alcohol consumption while controlling for demographical, socioeconomic and lifestyle factors. Next, we examined whether the amount of alcohol consumed changes the likelihood of reporting diabetes for those people who drink at the frequency associated with the lowest risk for diabetes. The bootstrap technique was used to test the statistical significance of odds ratios and to estimate 95% confidence intervals.

Results: We found the best protective effect of alcohol drinking for diabetes is

drinking more than once a week for men and at least once a week for women, respectively. In men significant higher risks of diabetes are found in men who do not regularly drink (odds ratio (OR): 2.04 [95% Confidence interval (CI): 1.73-2.41]), drink less than once a month (OR: 2.28 [95%CI: 1.92-2.71]), drink less than once a week (OR: 1.40 [95%CI: 1.16-1.70]) and drink once a week (OR: 1.44 [95%CI: 1.16-1.78]) compared to men who drink more than once per week. Similar elevated diabetes risks were found in women who do not regularly drink (OR: 3.19 [95%CI: 2.67-3.79]), drink less than once a month (OR: 2.17 [95%CI: 1.79-2.63]), and drink less than once a week (OR: 1.36 [95%CI: 1.09-1.71]) than who drink at least once per week. No significant difference of diabetes risk was found for the amount of alcohol consumed in regular drinking in both men and women.

Conclusions: This study has confirmed the protective effect of regular alcohol consumption for diabetes risk. However, heavy alcohol use should always be avoided since it can cause fatty liver and alcohol hepatitis, chronic inflammation of the pancreas, brain damage, some types of cancer, kidney failure, physical and behavioral abnormalities in the fetus and other complexities.

LIVING WITH DIABETES

Music as a medium of communication

0426

Music as a medium of communication

E. Yamin[1]
[1] *Los Angeles, USA*

As Yamin remains in the spotlight, he plans to use his celebrity to educate the public about type 1 diabetes and to encourage young people with diabetes to reach for their dreams.

This article was originally published in Diabetes Health in February, 2008.

With his naturally soulful singing voice, listeners feel his raw emotion and they like it. When you hear him, you know immediately that few guys in any musical genre sing with this kind of authenticity.

There's also an innocence about him. Watching Yamin grow from nobody to somebody, while carrying his diabetes proudly, has inspired diabetics everywhere.

Yamin had sung karaoke as a teen, which was how he had discovered his own talent. The untrained youth began singing in local bands and in amateur venues, and his influences came to include the likes of Whitney Houston, Stevie Wonder, Tony Bennett and Ray Charles.

Regimen on the Road: The ideal daily regimen for optimal control is not easy on the road, says Yamin, who has been traveling.

It's very important to have good blood glucose control before going on stage, says Yamin, who tests with his meter before and after going on stage. Hypoglycemia on stage could mean devastating effects on a performance - and not just because of the low blood glucose level, but also because it's hard to get up fast in front of a waiting audience.

One time this was not the case.

"I stepped on stage, opened up with the first song and I felt my blood glucose dipping down pretty low," Yamin explains of the incident. "I asked somebody to go grab me a couple of Pepsis and I finished the first song. But, between the first two songs I sucked both of them down pretty quick. I had to correct my blood glucose fast."

He explained to his audience what was going on at that point - openness about his diabetes with his fans has always been a strength for Yamin, from his first American Idol performance when he was very clear with the judges about his disease.

The problem came once he was done drinking.

"I drank the two Pepsis very fast. You don't really want to drink carbonated beverages on stage," he says. "It was hard not to burp on stage after that. It was ugly, man. It was just ugly. I kept having to pull away from the mike to burp."

Hypoglycemic episodes are not common for Yamin on stage.

"I notice my blood glucose level gets higher on the road," he says. "I've been on the road maybe a total of seven months, adding everything up on three tours."

There isn't always time on the road to do the exercise he would like to.

"I go to bed around 4 or 5 in the morning and wake up early to do morning radio shows, do sound checks, meet and greets on the shows," Yamin explains of his days on tour. "I do everything I can to promote every show in every town I go to. My time is very limited. I'm very busy - the first single has just been very busy and very taxing."

Yamin says although his most recent hemoglobin A1c was 8, he has plans to get his diabetes in tighter control, he advocates a healthy lifestyle and he knows his results would be more favorable if he were not traveling from city to city, riding the tour bus and airplanes constantly.

Music as a medium of communication

J.L. Colquhoun[1]

My life is the synopsis of an opera - comedy, tragedy, romance, determination, passion and a message.

Music has moulded my life. Although living with Type 1 diabetes since age 10, I refused to let anyone or anything stop me.

Diabetes gave me the drive and passion to succeed in music – I always felt I needed to prove to everyone I could be a successful international opera singer, travel the world, keep irregular hours and party hard despite living with diabetes.

I have sung with international opera companies in Australia and Germany and presented recitals and concerts in London, Paris, Bermuda, Seoul and Chicago. After my full-time opera career was cut short by diabetes related blindness, I used music to spread the message.

I have already told my story – music; diabetes; blindness; cancer; dialysis; a kidney pancreas transplant; overseas travel; my entertainment and production company; involvement on health, disability, arts, advocacy and support boards and committees - to health professionals and consumers around the world.

A guest speaker finishing with a song (or three), a person experiencing chronic illness and disability yet exhibiting a positive attitude and passion for life, has proven very successful in spreading the diabetes message.

Music is the means I use to communicate the message of healthy living, diabetes, prevention of chronic illness and complications.

Life for a Child Program documentary

G. Ogle[1]
[1] *International Diabetes Federation and HOPE worldwide (Australia), Life for a Child Program, Sydney, Australia*

In the developed world, children with diabetes have access to full care, and grow up to lead healthy and productive lives. In contrast, children with diabetes in low-income countries frequently die or remain chronically unwell with early development of complications, as insulin and other components of care are unavailable or unaffordable. The International Diabetes Federation ***Life for a Child*** Program supports diabetes centres in 19 countries around the world. Over 1,200 children benefit directly from the program, which provides insulin, monitoring, education, capacity building, and technical advice as needed.

A documentary on the Program has recently been produced by the IDF and Eli Lilly and Company. This shows the lives of three children with diabetes in Nepal. ***"Life for a Child"*** was filmed in bustling Kathmandu and the rugged mountainous Sindhuli region. The film powerfully and movingly demonstrates how the diagnosis of diabetes has affected their and their families' lives, and how with courage and sacrifice they are overcoming this challenge.

The film premiered at the Tribeca Film Festival, and was awarded Best Short Documentary at the Film Festival in San Jose California in March 2009.

How the seeds of adult adiposity and diabetes are sown in the womb

C. Yajnik[1]
[1] K. E. M. Hospital, Diabetes Unit, Pune, India

Conventional model of aetiology of adiposity and type 2 diabetes (T2D) envisages a role for genetics, aging and unhealthy lifestyle. Role of intrauterine environment has been highlighted over last 3 decades.
Children of mothers who were pregnant during the Dutch Hunger Winter were obese if they were exposed in the first two trimesters. Frienkel and colleagues demonstrated that maternal diabetes led to a range of developmental problems (anomalies, neurocognitive affection, adiposity and T2D) depending on the time of exposure in pregnancy, and coined the term 'fuel-mediated teratogenesis'. Hales and Barker demonstrated an inverse association between birth weight and T2D. They proposed that maternal undernutrition was an important factor in fetal 'programming' of T2D.
Approximately a third of babies in the Indian subcontinent are born low birth weight, and India is the world's capital of diabetes. Research in India has linked low birth weight and short length with later T2D. Pune Maternal Nutrition Study highlighted the role of maternal nutrition in fetal growth and demonstrated that the relatively thin and short Indian babies are more adipose (higher body fat percent) compared to European babies. Low circulating levels of maternal vitamin B12 but high levels of folate predicted childhood adiposity and insulin resistance. We have called this 'nutrient mediated teratogenesis'. In urban India micronutrient undernutrition and gestational diabetes may combine to produce larger effects.
Animal models demonstrate the importance of periconceptional nutrition in fetal programming. This is thought to result from altered gene expression ('epigenetics'). DNA methylation (influenced by folate and vitamin B12) and histone acetylation are proposed mechanisms. Periconceptional exposure to Dutch Hunger Winter was associated with hypomethylation of IGF2 gene.
These ideas are the basis of Developmental Origins of Health and Disease theory (DOHaD). Improvement of health and nutrition of young girls might contribute to prevention of adiposity and diabetes.

Appetite control networks and the metabolic syndrome: a step towards type 2 diabetes?

S.A. Amiel[1]
[1] King's College London School of Medicine, Diabetes Research Group, London, United Kingdom

The thrifty genotype gives rise to a metabolic phenotype that is designed for a simpler lifestyle, when food is only periodically abundant and requires energy expenditure to be obtained. An appetite control system that permitted excess food ingestion when food is available would also have evolutionary benefit in a hunter-gatherer society. Neither is beneficial in societies with reduced requirement for physical exertion and easy availability of energy-rich food. We and others are seeking evidence for treatable changes in appetite control systems that might upset the ability to control energy balance and normal weight maintenance in people with or at high risk for obesity and diabetes. We have found an insulin-sensitive element to brain glucose metabolism which is less effectively stimulated by insulin in people with peripheral insulin resistance. Specifically, insulin stimulation of brain glucose uptake and metabolism (surrogate markers of neuronal metabolism) was less effective in brain regions involved in appetite and satiety. In contrast, brain regions normally activated by anxiety and need for increased vigilance were equally suppressed by insulin in insulin resistant and sensitive subjects. This combination might underlie impaired satiety sensing and increased comfort after eating in insulin resistance, which would tend to drive further eating. Using functional magnetic resonance imaging, altered hypothalamic responses to food ingestion in obese and Type 2 diabetic individuals have been reported. We have found changes in the extent of brain activation in appetite control centres and in the visual cortex in insulin resistance after nutrient ingestion. Food ingestion can also be shown to influence the brain's response to subsequent food cues. The techniques used in these studies are now available to seek differences in the brain's ability to control appetite and food intake and explore new therapies to target overeating, obesity and progression from insulin resistance to Type 2 diabetes.

MEET-THE-EXPERT

In-hospital glycaemic management of diabetes

0431

In-hospital glycaemic management of diabetes

G. Umpierrez[1]
[1] Emory University School of Medicine, Medicine, Atlanta, USA

There is substantial observational evidence linking hyperglycemia in hospitalized patients (with and without diabetes) to poor outcomes. Although, several cohort studies as well as early randomized clinical trials (RCTs) suggested that tight glucose target (80 to 110 mg/dL [4.4 to 6.1 mmol/L]) improved clinical outcomes (reduced hospital complications and mortality), this target has been difficult to achieve without increasing the risk for severe hypoglycemia. In addition, recent RCTs in critically ill patients have failed to show a significant improvement in mortality or have even shown increased mortality risk with intensive glycemic control.
The 2009 AACE and ADA task force on inpatient glycemic control guidelines recommended raising glycemic targets in the ICU and non-ICU setting. For the majority of patients in the ICU setting, using insulin infusion and targeting blood glucose levels between 140 and 180 mg/dL (7.8 and 10.0 mmol/L) is recommended. Despite the lack of strong scientific evidence, lower glucose targets between 110 and 140 mg/dl (6.1 and 7.8 mmol/L) may be appropriate in selected ICU patients (i.e., ICUs with extensive experience and appropriate support, CABG surgical patients, stable glycemic control without hypoglycemia, total parenteral nutrition). Blood glucose targets > 180 mg/dl or < 110 mg/dl are not recommended.
For the majority of noncritically ill patients treated with insulin (or insulin secretagogues), the new ADA/AACE guidelines recommended maintaining a pre-meal BG target between 100 and 140 mg/dL (5.6 and 7.8 mmol/L), with random BG <180 mg/dL (10 mmol/L), as long as this target can be safely achieved.
This meet-the-professor session will discuss the evidence in support of improving glycemic control for inpatients with hyperglycemia, recommended glycemic targets in different patient populations, treatment options available for safely achieving glycemic targets avoiding hypoglycemia, available strategies for transitions to outpatient care, and areas of need for future research.

MEET-THE-EXPERT

Assessment of cardiovascular risk in type 2 diabetes

0432

Assessment of cardiovascular risk in type 2 diabetes

J.B. Meigs[1]
[1] Harvard Medical School Massachusetts General Hospital, General Medicine Division, Boston, USA

Type 2 diabetes (T2D) and cardiovascular disease (CVD) arise together from a "common soil" of obesity and insulin resistance. This risk state is identifiable by the presence of T2D and CVD risk factor clustering, or "metabolic syndrome." Metabolic syndrome recognizes that CVD risk factors are T2D risk factors and vice versa, and that the joint presence of several even mildly abnormal risk

factors heightens risk for future disease. Metabolic syndrome predicts CVD, but is especially useful to predict T2D.
The coincident development of T2D and CVD probably explains some of the persistent excess risk of CVD in T2D observed over past decades. T2D confers an at-least two-fold increased risk for all types of CVD, including CHD, PVD, stroke, and death, and shortens life by a dozen years from CVD. In addition to metabolic syndrome risk factors, additional novel risk factors increase CVD risk in diabetes, including insulin resistance and endothelial dysfunction. These markers point to novel disease pathways that may be used to aid T2D prevention and treatment.
However, in T2D, novel risk factors do not seem to add too much to discrimination of future CVD risk. Here, standard risk factors continue to be the most useful clinical discriminators of higher versus lower-risk individuals. Standard risk factors also continue to be the target to prevent T2D (obesity, sedentary lifestyle, poor diet), and treatment in T2D to prevent CVD events (glycemia, blood pressure, lipids, smoking, aspirin). The long-term follow-up of the UKPDS study shows that better glycemic control ultimately reduces risk for CVD as well as diabetic microvascular disease. Combined with attention to all standard risk factors, the Steno 2 Study shows that intensive multifaceted standard risk factor management in T2D is a very powerful approach to prevent vascular complications.

DEBATE

Glucose-lowering for the prevention of cardiovascular disease: positive, negative or neutral?

0433

For

H.C. Gerstein[1]
[1] *McMaster University, Department of Medicine, Hamilton Ontario, Canada*

People with type 2 diabetes are 2-3 times more likely to die from cardiovascular disease than people without diabetes. Moreover, the higher the HbA1c level, the higher the risk of fatal and non-fatal cardiovascular disease. Four trials published in 2008 assessed whether targeting normal glucose levels reduces cardiovascular events in people with type 2 diabetes: long-term follow-up of the UKPDS study of people with ***newly diagnosed diabetes*** and the ACCORD, ADVANCE and Veterans Administrations (VA) Trial in people with long duration type 2 diabetes.
The UKPDS showed that intensive glucose control reduced eye and kidney disease by 25% after 10 years and myocardial infarction and death by 15 and 13% after an additional 8 years of passive follow-up. ADVANCE showed that intensive glycemic control reduced the risk of composite outcome of either micro or macrovascular disease, reflecting mainly diabetic nephropathy with no effect on cardiovascular events or mortality. The VA trial showed no significant effect on any of its outcomes. The ACCORD study was stopped early because of increased mortality in the intensive group after 3.5 years. At that time there was also a 25% reduction in myocardial infarction and a 30% increase in cardiovascular death.
The most conservative interpretation of these trials is:

a. A policy of tight glycemic control can reduce eye, kidney, vascular consequences and mortality in people with new type 2 diabetes, and reduce renal disease in people with established type 2 diabetes.
b. Such a policy has uncertain effect on cardiovascular disease in people with well-established type 2 diabetes; some studies suggest a neutral effect, others suggest reduced myocardial infarction but increased cardiovascular death, and others show no effect.
c. More data are expected over the next 3 years.

Therapy for an individual patient needs to be individualized depending on his or her circumstances.

0434

Against

M. Cooper[1]
[1] *Baker IDI Heart & Diabetes Institute, Diabetes Division, Melbourne, Australia*

Although epidemiological studies have demonstrated a clear relationship between plasma glucose levels and cardiovascular events and mortality, clinical trials have not been able to show significant benefits on cardiovascular endpoints with intensified glycaemic control. In the original UKPDS, a modest reduction in cardiovascular events was observed but this did not reach statistical significance. Since that time, 3 large studies (VADT, ACCORD and ADVANCE) have reported no benefit of intensification of glycaemic control on cardiovascular disease and in particular mortality. Indeed, in the ACCORD study there appeared to be an adverse outcome in terms of cardiovascular and total mortality with an aggressive blood glucose lowering regimen.
The underlying explanation for the failure of glucose lowering to confer major benefits on the macrovasculature remains elusive. It is possible that once there is established vascular disease, it is very difficult to reverse the disease process. Indeed, pathways linked to hyperglycaemia-induced end-organ injury such as advanced glycation may lead to accumulation of products within the blood vessels which have slow turnover and/or are difficult to degrade. In addition, the phenomenon of "metabolic memory" where vascular injury progresses despite restoration of better metabolic control may be operating, with increasing data suggesting that oxidative stress pathways, possibly activated by epigenetic mechanisms, promote ongoing vascular injury in diabetes.
In summary, there remain no convincing data, including from recent large well performed multinational clinical trials, to recommend intensification of treatments that reduce blood glucose as a first line approach to reduce the cardiovascular burden in diabetes. Indeed, other non-glycaemic approaches such as lipid and blood pressure lowering regimens may be more appropriate as the central focus for the prevention and management of cardiovascular disease in diabetes.

HEALTHCARE AND EPIDEMIOLOGY

International diabetes management practices study (IDMPS)

0435

IDMPS: background, aims, target population, tools and methodology and programme implementation

P. Aschner[1]
[1] *Universidad Javeriana and Asociación Colombiana de Diabetes, Research Center, Bogotá, Colombia*

Background and aims: Despite the findings of the DCCT and the UKPDS and the recommendations of the ADA, EASD and IDF, a large number of people with diabetes are not well controlled. The IDMPS is an international, multicenter, observational study designed to raise awareness by documenting the current practices in type 1 and type 2 diabetes management worldwide, their compliance with management guidelines and their trends over time. It can also help identifying predictors of treatment goals achievement and diabetes-related hospitalisations and absenteeism and to estimate resource consumption.
Material and methods: IDMPS is a 5-year study with 5 waves. Each wave consists of a cross-sectional period and a 9-month longitudinal follow-up. Physicians were randomly selected among diabetes specialists as well as other specialists and general practitioners with experience in insulin therapy, and requested to enrol the first 10 patients with type 2 diabetes (T2D) and the first 5 patients with type 1 diabetes (T1D) who visited their office during a 2-week recruitment period.
In this session we report results from data collected during the first two cross-sectional periods (2005 & 2006) in 18 countries within Africa, Asia, Eastern Europe, the Middle East and Latin America comprising almost 25.000 people with T2D and 1.898 people with T1D.

Study implementation: A steering committee advised the project team on study design and registry structure, monitored study progress, reviewed and validated all study-related documents, and proposed and approved decisions on protocol amendments, analyses, and publications.

Diabetes care quality: clinical profile, care processes and metabolic outcomes

J.C.N. Chan[1]
[1] *Chinese University of Hong Kong, Medicine and Therapeutics, Shatin NT Hong Kong, China*

Objectives: To document changes in diabetes practice in developing areas with a 5-year survey.
Research and methods: In 2005, during a 2-week period, 937 doctors from 18 countries enrolled 5888 diabetic patients from Asia, 3519, East Europe and 2116, Latin America. Collected data included clinical parameters, self-care, access to education, follow-up patterns, work absenteeism and hospitalizations. Treatment goals were defined as HbA_{1c} <7%, BP <130/80 mmHg and LDL-C<100 mg/dL.
Results: In 9901 type 2 diabetic (T2DM) patients, 10% reported hospitalization or absenteeism from work in the last 6 months, 33% have no health coverage, 36% never had HbA_{1c} measured and 11-36% have not screened for chronic complications in the last 2 years. In all 3 regions, 20-40% of patients were at target for HbA_{1c}, BP and lipids. In patients with all three risk factors measured (n=3896), only 3.6% attained all 3 targets. Clinical profile was similar across 3 regions (means: age 58 years and disease duration 8 years), with Asians having the lowest BMI and waist circumferences. Overall, 3% of patients were treated only with diet and exercise, 66% with oral glucose lowering drugs (OGLDs) alone and 31% with insulin with or without OGLD. Overall, 42% never received diabetes education, 32% performed SMBG and 8% belonged to a diabetes association.
Conclusions: While T2DM patients from developing areas have differences in clinical profiles, they share similar care patterns with suboptimal performance indicators in terms of processes and outcomes. Such performance must be improved in order to get better outcomes and decrease the socioeconomic burden of diabetes.

0437

Prescriptive style and predictors of treatment goals achievement

A. Ramachandran[1]
[1] *Dr. A. Ramachandran's Diabetes Hospitals, Epidemiology, Chennai, India*

Objective: To study medication use and predictors for attaining glycemic goal (A1c<7%) in people with diabetes from developing areas.
Subjects and methods: During a 2-week period in 2005, 937 doctors from 18 countries recruited 1898 T1DM patients and 9901 T2DM patients from Asia, East Europe (EE), Latin America (LA). Collected data included medical history, drug use, self monitoring of blood glucose (SMBG), access to diabetes education and physicians' perception of glycemic control status.
Results: In 1898 T1DM patients, the commonest insulin regimens were basal plus bolus in LA and EE and premix regimen in Asia. Mean insulin dose ranged from 0.5 to 0.8 IU/kg with the highest values for basal plus bolus regimen. In 9901 T2DM patients, 3% were treated with lifestyle modification, 66% with oral glucose-lowering drugs (OGLD) and 31% with insulin, with or without OGLD. In both T1 and T2DM patients, 20-30% achieved glycaemic goals (A1c<7%) with physicians tending to overestimate their control status. In T1DM, diabetes education and SMBG predicted glycemic control in all regions. In T2DM, despite regional heterogeneity for predictors, short disease duration and use of fewer drugs predicted A1c<7% in all regions. Other predictive factors included old age (Asia/LA), normal weight, SMBG and self adjustment of insulin (Asia), access to educators and adequate coverage for health care (SA).
Conclusions: These results suggest that early diagnosis, prompt intervention and self-management are important determinants for attaining glycemic goals with factors pertinent to patients, care providers and system all having impact on quality of care.

Resources consumption: direct medical and indirect costs

J.J. Gagliardino[1]
[1] *on behalf of the IDMPS investigators, CENEXA (UNLP-CONICET LA PLATA), La Plata Buenos Aires, Argentina*

Aims: To estimate resource consumption by people with type 2 diabetes (T2DM) in 24 countries.
Methods: Cross-sectional observational record of resource use in 15,016 people with T2DM (Asia 4678, Latin America [LA] 6090 and Middle East & Africa [ME&A] 4248), within the second wave of IDMPS. Annual quantities (mean ± SD) were measured, and predictors of diabetes-related hospitalisations and absenteeism were determined using negative binomial regression.
Results: Patient doctor visits: 3.4 ± 6.9, 5.4 ± 6.7 and 2.5 ± 4.4 times/year in Asia, LA and ME&A, respectively. Percentage of hospitalization: 8.5%, 6.5% and 8.8%; average stay: 3.8 ± 18.1, 2.2 ± 13.9 and 2.6 ± 13.5 days/year, respectively (total of 42.000 days/year). Mean days of absenteeism: 5.0 ± 23.1, 6.4 ± 33.2 and 5.7 ± 24.3 in the regions (total of 86.000 days lost/year). The regression analysis showed that chronic complications and inadequate glycaemic control (HbA1c > 7.0%) were the major predictors of resource use. The annual hospitalisation rate was significantly greater in patients with than without macrovascular complications in Asia (incidence rate ratio (IRR) 4.7, 95% CI 2.8-7.8, n2551), 5.4 times greater in LA (IRR 5.4, 95% CI 3.0-9.8, n 3228) and 4.4 times greater in ME&A (IRR 4.4, 95% CI 2.8-6.9, n2630).
Conclusions: In developing countries, micro- and macrovascular complications and inadequate glycaemic control are significant predictors of resource use in T2DM. These results confirm the importance of appropriate diabetes control to prevent the development/progression of chronic complications and the consequent increase in the cost of care.

Training foot care assistants in Jamaica and the Caribbean

0439

Training foot care assistants in Jamaica and the Caribbean

O. Bernard[1]
[1] *Diabetes Association of Jamaica, Clinical / Admin, Kingston, Jamaica*

Diabetic foot is a major problem that can lead to other complications for both the patient and the Health Care givers. Foot Care is still regarded as a minor matter and is still not yet fully understood and appreciated. There are so many risk factors that need to be looked at and indeed it can so easily be recognized at primary care level. We talk about the Diabetic foot but what we should be saying is "prevent the diabetic foot with simple interventions".
Diabetes management embraces a multidisciplinary approach because diabetes affects the eyes, heart, kidneys and the limbs. With this in mind, you need the team. The team should and must include the Chiropodist/Podiatrist. However, sad to say, there are none in any of the Government Hospitals/Clinics here in Jamaica and indeed the Caribbean.
The solution is to train Foot Care Assistants to meet this shortfall. In Jamaica, we have developed the Foot Care Assistant programme whereby we have been training Community-based people to deal with the basic foot problems such as nail problems, corn, calluses, etc. As a result of the success of this programme, it has been exported to other Caribbean Islands such as Bahamas, Belize etc.
Before, we did not have any formal foot clinic where foot care was offered

to clients by trained people. I am pleased to say that that has now changed; many of our clinics are now offering such service. The outcome of this simple intervention is almost immediate.
Additionally, since the start of this programme, Foot Care is now recognized as part of the routine screening programme. The next phase is to offer the work through the University of Technology.

MEET-THE-EXPERT

Is self-monitoring useful in type 2 diabetes: what is the evidence? in whom?

0440

Is self-monitoring useful in type 2 diabetes: What is the evidence? In whom?

O. Schnell[1]
[1] *Munich Diabetes Research Institute, Munich, Germany*

Diabetes is globally increasing at the rate of an epidemic. In the majority of patients however, the targets for glycemic control of diabetic patients, which are recommended by national and international guidelines of scientific associations, are not achieved.
Longer-term near-normal glycemia is critical for the prevention of micro- and macrovascular complications. The evidence is growing that postprandial blood glucose excursions and glycemic variability are associated with vascular damage and, therefore, may be harmful for diabetic patients. Concomitant structured self-monitoring of blood glucose enables the visualization of individual levels of glycemia and is essential for an optimized diabetes management. In both diabetic patients with and without insulin, long-term optimized diabetes management in the range of near-normoglycemia cannot be achieved without the implementation of self-monitoring of blood glucose (SMBG). Simply measuring HbA1c is not enough: Patients with identical HbA1c-levels may have significantly different glucose profiles. Both severe and smooth glucose excursions of glucose levels may result in comparable HbA1c values. These can be visualized by SMBG.
It goes without saying that SMBG has to be accompanied by structured educational programmes, which do not only empower patients to modify nutrition and physical activity according to the measured blood glucose values, but also encourage them to critically look at targets of metabolic control and also to potentially suggest the need for an alteration of medication. Patients (and physicians) must be well trained to convert data into meaningful information and appropriate therapeutic action. Clearly, this requires a substantial commitment for diabetes care from the patients themselves each and every day!
The Global Guidelines for treatment of patients with Type 2 Diabetes of the International Diabetes Federation (IDF) and the IDF Guidelines for Postmeal Glucose Management are a major achievement in the process of standardization of global diabetes care. The guidelines present pathways for clinical practice based on the current scientific evidence. The guidelines emphasize that SMBG is an integral part of self-management.
The Guidelines on Diabetes, Prediabetes, and Cardiovascular diseases of the European Society of Cardiology (ESC) and the European Association for the Study of Diabetes (EASD) also emphasize the importance of self-monitoring of blood glucose. In the ESC/EASD Guidelines, SMBG is presented as a major part of comprehensive management to reduce cardiovascular risk in patients. The Guidelines recommend SMBG due to studies which demonstrated that SMBG is associated with an improvement of glycaemic control.
Apart from the new global guidelines, the level of implementation of self-monitoring of blood glucose for diabetes management varies significantly among different countries. A homogeneous, structured and evidence-based approach across the national borders is still missing. Subsequently, this leads to major differences in medical care of diabetic patients across the world.

FOUNDATION SCIENCE

Insulin signalling - where and how to study it?

0441

Insulin signalling - where and how to study it?

M. Saad[1]
[1] *Campinas State University, Department of Internal Medicine, Campinas, Brazil*

At the molecular level, insulin signaling begins when activation of the insulin receptor (IR) results in tyrosine phosphorylation of several substrates, including the IR substrate 1 (IRS-1) and IRS-2. After tyrosine phosphorylation, IRS-1 and IRS-2 bind and activate the enzyme phosphatidylinositol 3-kinase (PI3-K). The activation of PI3-K increases serine phosphorylation of protein kinase B (Akt), which in turn stimulates the glucose transport in the muscle and adipose tissue, stimulates glycogen synthesis in the liver and muscle, and stimulates lipogenesis in the adipose tissue. Therefore, the PI3-K/Akt pathway has an important role in the metabolic effects of insulin. In the hypothalamus, the activated PI3-K/Akt pathway suppresses feeding, and insulin resistance in this tissue has recently been described.
Protein tyrosine phosphatase (PTP1B) has been implicated in the negative regulation of insulin and leptin signaling. PTP1B knockout mice are hypersensitive to insulin and leptin and resistant to obesity when fed a high-fat diet. In this presentation we will show the role of hypothalamic PTP1B in the regulation of food intake, insulin and leptin actions and signaling in rats through selective decreases in PTP1B expression in discrete hypothalamic nuclei. We generated a selective, transient reduction in PTP1B by infusion of an antisense oligonucleotide designed to blunt the expression of PTP1B in rat hypothalamic areas surrounding the third ventricle in control and obese rats. The selective decrease in hypothalamic PTP1B resulted in decreased food intake, reduced body weight, reduced adiposity after high-fat feeding, improved leptin and insulin action and signaling in hypothalamus, and may also have a role in the improvement in glucose metabolism in diabetes-induced obese rats. In conclusion, it is important to emphasize not only the insulin signaling in classical insulin-sensitive tissues, such as liver, muscle and adipose tissue, but also the hypothalamus, which has a role in the control of peripheral glucose metabolism.

Prevention initiatives for type 1 diabetes and type 2 diabetes

0442

Cost-effective and simple strategies so that we do not miss the diagnosis of type 1 diabetes: the Parma Campaign

M. Vanelli[1], *G. Chiari*[1], *B. Iovane*[1], *K. Errico*[1], *C. Scarabello*[1], *C. Mele*[1], *V. Fainardi*[1]
[1] *University of Parma, Department of Paediatrics Children Hospital, Parma, Italy*

Diabetic ketoacidosis (DKA) in children with type 1 diabetes at onset is generally related to a long duration of misdiagnosed hyperglycemia-associated symptoms. In the period of 1991–1997, we demonstrated that, thanks to a physician campaign centred on the earliest symptom of diabetes (nocturnal enuresis in a "dry" child) as reported by 89% of parents, it was possible to shorten the latency period and to prevent DKA. Due to this program, cumulative frequency of DKA at diagnosis decreased from 78% during 1987-1991 to 12.5% during 1991-1997. Eight years after the publication of the results, Parma campaign continues to be effective. In the period of 1999-2006, only 5 (15%) of newly diagnosed diabetic children from the province of Parma (n. 32) had a severe DKA. Today's data confirm that enuresis is an important warning symptom for the early diagnosis of type 1 diabetes. An extension of this anti-DKA initiative

could be considered the Telephone Hotline Service (THS), implemented in 2001 at the same University Hospital, in order to help the parents to manage their child's diabetes during an intercurrent disease without having to leave home. Thanks to THS, the admittance to hospital because of a DKA acute illness-related fell from an average of 10 cases per 100 children per year in the Nineties to 3 cases per 100 children per year in 2001-2006 period. The costs for admittance decreased of 60%. These two low-cost experiences, which effectively reduced the number of children needing emergency hospitalisation due to DKA, could be considered to be worldwide extended.

Risks and preventive strategies in the Gulf region

A. Ben-Nakhi[1]
[1] *The Dasman Centre for Research & Treatment of Diabetes, Clinical Department, Kuwait, Kuwait*

Diabetes and other non-communicable diseases (NCD) has become a major health concern for the six countries of the Gulf Cooperation Council (GCC). 5/6 and 3/6 of the GCC countries are among the top 10 in the prevalence of diabetes and impaired glucose tolerance respectively. The situation will remain the same by the year 2025. The prevalence of other risk factors for NCD such as obesity, inactivity, unhealthy eating habits, hypertension, dyslipidemia and smoking are also of alarming significance. Figures as high as 75% and 58% for obesity and inactivity were reported in a recent survey from Kuwait.
A 10 year strategic plan, endorsed by the highest political bodies in all GCC countries, was approved. In this plan seven goals have been identified:

1. Primary prevention of Type 2 diabetes
2. Secondary prevention of Type 2 diabetes
3. Improvement of the quality of service provided to people with diabetes
4. Empowerment of methods of evaluation and auditing the services provided
5. Conduction of research in the different areas of diabetes
6. Empowerment of patients and their families role in their management
7. Empowerment of the role of NGOs.

Each goal has its realistic and achievable targets, strategies, application tools and indicators of application tools.
This could be an important step towards fighting diabetes in the GCC countries, an area of high prevalence of diabetes and its associated risk factors, the outcome of which is awaited.

DEBATE

Are the highly academic clinical guidelines useful to the patient on the ground?

0444

Do the highly academic clinical guidelines make a difference to diabetes care delivery at ground level ? No

F. Fraige Filho[1]
[1] *FENAD, Medical Education, Sao Paulo, Brazil*

Guidelines produced by institutions such as IDF, ADA, EASD, AACE, and even smaller institutions, make no difference concerning diabetes care delivery at the ground level, where treatment and care of the diabetics is provided by primary healthcare physicians.

1. **Are Guidelines available to most Primary Healthcare Physicians? No.**
   Most physicians are not acquainted with the guidelines, or have difficulties to access them.
2. **Are guidelines easy to reach? No.**
   All guidelines, including IDF's are copyright protected and cannot be reproduced. The internet is not a popular tool in developing countries, and the access to institutions are usually paid.
3. **Do primary healthcare delivery centers get recent orientations based on guidelines? No.**
   Information reaches them indirectly, much later. Professionals are usually not adequately trained, nor specialized.
4. **Are there specialists in the primary healthcare delivery? No.**
   Endocrinologists and diabetologists are minority groups who perform their work in tertiary clinics and hospitals. Some of them are not familiar with the guidelines. Other who are, do not necessarily apply them in practice.
5. **Do the Public Healthcare System apply the guidelines? No.**
   Knowledge is not spread. It is considered as a "specialty". "Continuous Medical Education" is unavailable. Most of the time is spent within a deficient and slow health service. Physicians are not sponsored nor encouraged to take updating courses.

Conclusion:
General guidelines embrace **2 worlds:**

1. The **Scientific World** for a minority of specialists who study, read publications, go to international congresses and are constantly updated.
2. The **Real World** where most physicians are, delivering actual treatment to the diabetics. 70 to 80% of the patients are treated by them. When they have complications they are referred to a specialized treatment.

0445

Yes: if implemented practically

M. Allende-Vigo[1]
[1] *Sociedad Puertorriqueña de Endocrinología y Diabetología, Medicine, San Juan, Puerto Rico*

Aims: Several organizations worldwide have published and recommended clinical guidelines for the evaluation and management of persons with diabetes. Guidelines are based on scientific clinical evidence that points towards the prevention of chronic diabetic complications. The guidelines aim towards improved blood glucose control, an overall increase in quality of life, reduced sickness absence and reduced mortality. Financial benefits will follow directly from clinical benefits. Primary care may benefit through a reduction in the number of consultations and secondary care should benefit from a reduction in the number of hospital admissions for adverse events as a result of poor glycemic control. Clinical guidelines recommend the management of other cardiometabolic risks factors to reduce the morbidity and mortality associated with the highly prevalent atherosclerosis and cardiovascular disease present in people with diabetes. Academic clinical guidelines aim at the present and future well being of the patient. The aim of the presentation is to probe that highly academic clinical guidelines are useful to the patient on the ground if implemented practically.
Methods: Review of the literature
Results: Guidelines are written recommendations well thought by experts. A consensus is reached and recommendations are made. Guidelines are published for individuals, physicians and institutions to follow. Guidelines should be adopted and documentation provided on the outcomes of this implementation. Given that the guidelines are disseminated and followed, outcomes should be documented and published.
In order for patients to adhere to the guidelines, they should be widely distributed, easy to read and understand and relatively easy to follow. By taking these measures, patients should be able to stick to them. Implemented guidelines are expected to produce long lasting benefits.
Achieving the recommended levels of glycated haemoglobin and blood glucose levels are expected to have a sixty three percent reduction in retinopathy, fifty four percent reductions in nephropathy, sixty percent reduction in neuropathy and fourteen percent reduction in cardiovascular events.
Conclusions: Practical implementation of academic guidelines and attainment of targets will translate into less chronic complications, less expenses in health care, better nutrition, better productivity and better quality of life.

LIVING WITH DIABETES

Living with diabetes and its complications: perspective of someone with diabetes

0446

Accepting diabetes

E. Yamin[1]
[1] Los Angeles, USA

Elliott Yamin has learned to manage his Type I diabetes and, as spokesperson for the American Diabetes Association, help others do the same.
In an exclusive interview, Yamin spoke with Parade.com's Caitlin O'Toole about his illness.

On Being Diagnosed With Diabetes

"I was diagnosed at a very young age. I was 15 going on 16. It was hard for me to adjust to treating my diabetes, but it was also hard to admit that I had it. I was in denial. That was a big hump for me to get over. I didn't understand how I could just go from being a normal kid to having this incurable lifelong disease in a matter of a day's time. I was very angry. I was very upset. I didn't know how to deal with it and I didn't want to tell people, I was embarrassed by it. And I certainly didn't want to seem like some charity case."

On 'Inspired by Diabetes'

"There's a competition called **Inspired by Diabetes**. It's a freedom of expression competition where diabetics can share their stories through art, through music, through paintings and so forth. They can win trips to Italy, they can win backstage passes and concert tickets to my shows, it's a really cool way for people to share their stories with everybody through art."
"It benefits another program called Life for a Child, which raises money for developing countries around the world where there are kids with diabetes that lack insulin and medical care. So we're also raising money to bring diabetics insulin who don't have insulin."

On Managing His Diabetes on Tour

"There are times during the day where I'm just relaxing and then I start getting dizzy and start getting anxious leading up to show time. All the anxiety that comes along with this gig affects my blood sugar. I just have to be more keen about how my body feels and check my blood sugar more often. Even so, I still get my highs and lows. But as long as I recognize the signs right away and correct them, I am fine."
"Quite frankly, I'm tired of taking insulin and pumping my stomach every three days and pricking my finger and drawing blood out of it every day – it's a tedious, meticulous, annoying disease that never goes away. And I want to get rid of it like everybody else does."

Impaired kidney function

J.L. Colquhoun[1]
[1] Brisbane, Australia

Living with Type 1 diabetes was manageable; part of my daily routine. Living with daily dialysis was an ordeal; limiting, demoralising and dominating every routine.
My 33 years of living with diabetes has included "field testing" most diabetes complications – diabetic retinopathy, mastopathy, autonomic neuropathy, peripheral neuropathy, coronary artery disease and nephropathy.
I am unable to give a control in my personal research, none were trialled in singularity.
Living with each complication was hard, resulting in further restrictions, treatments and lifestyle changes.
My kidneys progressed from showing signs of minor damage through impaired renal function, chronic kidney failure, 3 years of 10 hour daily home dialysis and ultimately a "combined simultaneous pancreas kidney transplant".
Medications and restrictions increased the further deterioration of my kidneys. An easy-to-stick-to low carbohydrate, low fat, low sugar diabetes diet advanced to a difficult renal diet - cutting out sodium and all but low potassium containing foods. The diet became extreme on dialysis, when phosphate intake was also controlled and fluids were limited to 500ml/day. I survived on protein bars and the 21 litres of glucose dialysate used to wash my blood each day. After a while I didn't mind the restrictive diet; I didn't want to eat at all.
Following a kidney pancreas transplant, I now have Type 4 diabetes – I am still living with the diabetes complications; I just no longer have Type 1 diabetes.
I traded dialysis, multiple daily injections and BGL monitoring for handfuls of immunosuppressants and the high risk of infection.
The only good treatment for kidney disease is prevention.

0448

Impaired sight

K. Hirst[1]
[1] Edinburgh, United Kingdom

At the age of 23, following 18 years of insulin-dependent diabetes, I developed diabetic retinopathy. As a result of macular oedema and vitreous haemorrhages, my vision deteriorated rapidly. Within the space of a few months, my visual impairment made it difficult for me to lead a normal life and I became reliant on the care of my parents. For a young person who had previously enjoyed a full and active life, this loss of independence had serious ramifications for my social and psychological wellbeing. Fortunately, due to careful monitoring and timely surgical intervention, my eyesight has been preserved and stabilised. I was lucky enough to be brought back from the brink of a potentially bleak future.
Reflecting back on my experience of impaired sight, I will draw out several issues which I feel need to be recognised and addressed. Diabetic complications, particularly reduced vision, can diminish the ability to manage one's life independently. People facing this need adequate support, both practical and emotional. Further, as a temporarily incapacitated person, I experienced some of the prejudiced attitudes that others can hold towards those with a perceived disability. Such barriers of misunderstanding and ignorance need to be broken down.
Ranging beyond this need to raise public awareness, my story also highlights several key messages for medical services. The emotional impact of diabetic complications must be recognised and matched with the provision of appropriate psychological support. Secondly, the necessity for routine, regular retinal screening at diabetic clinics and timely referral to ophthalmological services and targeted treatment is paramount. Finally, and perhaps most importantly, every practitioner involved in the care of children and young people with diabetes must take responsibility for educating and encouraging their patients to maintain good control, with a view to avoiding the potentially debilitating effects of diabetic complications.

Impaired sleep

M.T.U. Barone[1]
[1] Instituto de Ciências Biomédicas - Universidade de São Paulo, ICB-USP, São Paulo, Brazil

Sleepiness and sleep loss, acute symptoms of glucose variation?
It is well known, and individuals complaints are frequent, that hypoglycemia as well as hyperglycemia can lead to sleepiness and impair night sleep. As we will discuss in this presentation, sleep impairment does not seem to be only an acute symptom of glucose variation, but also a consequence of poor glycemic control in individuals with both types of diabetes, affecting sleep and wakefulness. Moreover, sleep disorders have been shown to impair metabolic control. For this reason, sleep impairment and poor metabolic control should be understood as constituents of a vicious circle, where the deterioration of a component impacts and worsens the other as well. Furthermore, some already known links of this interaction will be discussed, including: sleep disordered breathing; activation of the sympathetic nervous system, leading to stimulation of the hypothalamic-pituitary-adrenal axis, resulting in hypersecretion of cortisol; insulin resistance; and impairment of appetite regulation.

Novel therapies for glucose-lowering

0450

Therapeutic implications of SGLT2 (sodium glucose co-transporter 2) inhibition

R. Henry[1]
[1] *VA San Diego Health Care System, Medicine, San Diego, USA*

The kidney plays a major role in glucose homeostasis, not only producing but filtering glucose through the glomerulus and reabsorbing it in the proximal tubule. In non-diabetic individuals, the kidney filters and reabsorbs approximately 180 g glucose daily. Filtration occurs via passive diffusion and the amount of glucose filtered is proportional to its plasma concentration. Reabsorption of glucose occurs in the proximal tubule via sodium glucose cotransporters - SGLT1 and SGLT2. SGLT1 is found primarily in the intestines and kidneys, where it is responsible for ~ 10 % of renal glucose reabsorption. SGLT2 is found only in the S1 segment of the proximal tubule and accounts for ~ 90% of glucose reabsorption. In uncontrolled diabetes, the amount of filtered glucose is increased and can exceed the reabsorptive capacity of the SGLTs, resulting in variable amounts of glycosuria. Recently, compounds have been developed that specifically target SGLT2 and inhibit these transporters by 30-50% resulting in glycosuria. SGLT2 catalyzes the active transport of glucose uphill across the apical (luminal) proximal tubule membrane against a concentration gradient, by coupling it with the downhill transport of Na+. The inward Na+ gradient across the luminal epithelium is maintained by ATP-driven active extrusion of Na+ across the anti-luminal surface into blood. Glucose diffuses passively out of the cell down a concentration gradient via basolateral GLUT2 (and GLUT1) facilitative transporters.
When used in individuals with diabetes, SGLT2 inhibition can result in a lowering of both fasting and postprandial plasma glucose levels and weight loss due to calories lost as glucose. Through this unique mechanism, SGLT2 inhibitors may have therapeutic value in both type 1 and 2 diabetes as well as obesity. Several highly selective SGLT2 inhibitors are currently undergoing phase II and phase III clinical trials and appear to be safe, effective and well tolerated based on the short-term data.

Glucagon receptor antagonists

D.E. Moller[1]
[1] *Lilly Research Laboratories, Endocrine and Cardiovascular, Indianapolis, USA*

Existing therapies targeting the treatment of hyperglycemia in patients with diabetes provide modest degrees of efficacy or are associated with liabilities such as excessive hypoglycemia and weight gain. Therefore, there is a continuing need for more effective and better tolerated approaches to diabetes treatment. Glucagon action has a critical role in the pathogenesis of hyperglycemia in both Type 1 and Type 2 diabetes, contributing to both fasting and postprandial hyperglycemia. Via the activation of a specific G-protein coupled receptor (GCGR) and subsequently increased cellular cAMP levels, glucagon drives hepatic glycogenolysis and gluconeogenesis. Further validation of GCGR antagonism as a possible therapeutic approach derives from several lines of evidence: GCGR null mice have improved glucose tolerance; inhibition of GCGR expression (***e.g.*** antisense oligonucleotides) ameliorates hyperglycemia in diabetic rodents; importantly, several structural classes of orally bioavailable small molecule GCGR antagonists are also efficacious in animal models of Type 2 diabetes. These data will be reviewed along with an assessment of the challenges associated with targeting GCGR antagonism as a possible means of achieving new therapies for diabetes.

Assessing the potential of glucokinase activators (GKAs) in diabetes therapy

F.M. Matschinsky[1]
[1] *University of Pennsylvania, Dpt. Biochem. & Biophys./Diabetes Center, Philadelphia, USA*

The rationale and current status of using glucokinase activators (GKAs) for oral treatment of T2DM will be discussed. GKAs are small molecules (MW around 500) which were discovered about a decade ago in high through-put screening of a large library with a screening test involving human glucokinase (GK) inhibited by glucokinase regulatory protein (GKRP). GKAs increase GK's glucose affinity as much as tenfold and increase its kcat as much as twofold. They may lower the Hill coefficient of GK dose dependently as much as 40% but have practically no effect on MgATP affinity. Activation of GK has profound effects on glucose homeostasis in healthy common laboratory animals and in humans. It enhances glucose induced insulin release and potentiates the glucose dependent action of amino acids, fatty acids, acetylcholine and GLP-1 on insulin secretion. GKAs enhance glycogen synthesis and inhibit gluconeogenesis in the liver. GKAs are postulated to influence glucose dependent processes in other GK containing cells (e.g. hypothalamic neurons, entero-endocrine cells and pituitary gonadotropes). GKAs have been demonstrated to lower blood glucose in patients with T2DM dose dependently such that the diurnal glucose profiles were practically normalized at the highest dose. These pharmacological results in normal and diabetic subjects strongly support widely accepted views about the central role of GK in the maintenance of glucose homeostasis, that is as glucose sensor in the insulin producing pancreatic beta-cells and other GK containing glucose sensor cells, and as predominant regulator of hepatic glycolysis, glycogen metabolism and gluconeogenesis. The results also indicate that GK serves as viable drug receptor in patients with T2DM. It remains to be evaluated in clinical trials whether GKAs fulfil their promise for novel oral antidiabetic drugs with a unique mechanism of action and considerable potential for mono- and combination therapy.

0453

Novel PPARs

B. Staels[1]
[1] *Institut Pasteur de Lille, Département d'Athérosclérose, Lille, France*

The greatest clinical challenge in type 2 diabetes mellitus (T2DM) is the prevention of its long-term complications, many of which are of cardiovascular nature. Despite the progress in cardiovascular risk management of diabetic patients using lipid-lowering and anti-hypertensive drugs, a substantial residual risk persists. Indeed, treated diabetic patients experience a similar risk as untreated nondiabetic individuals. Although glycemic control through the use of antihyperglycemic agents improves microvascular complications, macrovascular disease risk is not reduced. These observations point to the need for additional therapeutic approaches in order to better control global cardiovascular risk. The PPAR family members play major roles in the regulation of lipid and glucose metabolism and immune-inflammatory processes, making these transcription factors ideal targets for such therapeutic strategies. This presentation will discuss our current knowledge of the effectiveness of PPAR-based therapeutics focussing on cardiovascular disease in T2DM, and the future prospects for novel generation PPAR agonists.

Brain glucose and glycogen metabolism in diabetes and hypoglycaemia unawareness

E. Seaquist[1], I. Tkac[2], P.G. Henry[2], G. Oz[2]
[1] University of Minnesota, Medicine, Minneapolis, USA
[2] University of Minnesota, Radiology, Minneapolis, USA

Hypoglycemia unawareness (HU), the condition where patients are unable to detect hypoglycemia until neuroglycopenia develops, is an important factor that limits the intensity with which glycemia can be managed. The underlying pathogenesis of HU remains uncertain, but compensatory changes in brain glucose metabolism that support cerebral energy metabolism have been hypothesized. Using 1H magnetic resonance spectroscopy (MRS) we previously demonstrated that patients with type 1 diabetes and HU have higher steady state brain glucose concentrations than controls at the same blood glucose levels. Subsequent studies in which 13C MRS was used to measure rates of cerebral glucose metabolism in controls and in patients with type 1 diabetes and HU suggested that an upregulation in glucose transport, as opposed to a reduction in glucose metabolism, may contribute to the development of HU. Changes in brain glycogen metabolism are also hypothesized to play a role in HU, although little has been known about its role in brain energy metabolism. To determine if brain glycogen could be mobilized during hypoglycemia, we measured the rate of label washout from [1-13C]glycogen in the brains of healthy humans during hypoglycemia. We found the rate was higher during hyperinsulinemic hypoglycemia than during hyperinsulinemic euglycemia (0.12 ± 0.05 vs. 0.03 ± 0.06 µmol/gm/hour, $p < 0.02$, $n = 5$). To determine if brain glycogen content is increased following an episode of hypoglycemia, we measured the levels of newly synthesized glycogen up to 80 hours after experimental hypoglycemia in healthy humans and found it was significantly higher than that measured after euglycemia ($p< 0.01$, $n = 5$). These observations suggest brain glycogen supports energy metabolism during hypoglycemia and that levels of glycogen may rebound to a higher than normal level following a period of reduced blood glucose. Subsequent experiments will determine if changes in brain glycogen metabolism contribute the development of HU.

Hypoglycaemia: basic mechanisms for HAAF

D. Figlewicz Lattemann[1], S. Al-Noori[1], N.M. Sanders[1]
[1] VA Puget Sound Health Care System, R&D (151), Seattle, USA

Hypoglycaemia, and the syndrome of hypoglycaemia-associated autonomic failure (HAAF), represent a significant complication and barrier to the use of intensive anti-hyperglycemia therapy in diabetic individuals. HAAF may occur as a result of impaired glucose-sensing mechanisms or impaired central nervous system (CNS) activation of neuroendocrine counterregulatory responses (CRR). Research from our laboratory suggests that both mechanisms may contribute to the impaired CRR, of which glucagon and the sympathoadrenal epinephrine responses are most critical. We have mapped the pattern of brain activation in response to single vs. multiple bouts of hypoglycemia and have observed that the medial hypothalamus shows decreased activation (c-Fos expression) with recurrent hypoglycemia. Further, expression of the alternative transcription factor FosB is increased in the medial hypothalamus, suggesting that there is both altered and re-programmed CNS activity with recurrent hypoglycemia. Our studies also show an important relationship between medial hypothalamic neurons and glia, as disruption of the specialized glial cells lining third ventricle impairs CRRs to hypoglycemia. The pattern of brain activation with hypoglycemia also implicates the involvement of brain stress circuitry which modulates activity of the medial hypothalamus. Our initial findings, as well as clinical observations that support this model, suggest the early onset of neuroplastic changes with the experience of a hypoglycemic event. Finally, studies implicating the involvement of CNS serotonergic neurons in both behavioral and neuroendocrine responses to hypoglycemia, and a protective effect of the serotonin-based antidepressant sertraline, will be reviewed and implications for therapeutic approaches to prevent or blunt hypoglycemia will be discussed.

Insulin resistance and depression

R. McIntyre[1]
[1] University of Toronto, Psychiatry and Pharmacology, Toronto, Canada

A nascent explanatory theory regarding the pathophysiology of major depressive disorder posits that alterations in metabolic networks (e.g. insulin and glucocorticoid signaling) mediate the allostatic load associated with this syndrome. Disturbances in metabolic networks: e.g. insulin-glucose homeostasis, immuno-inflammatory processes, adipokine synthesis and secretion, intra-cellular signaling cascades, and mitochondrial respiration are implicated in the pathophysiology, brain volumetric changes, symptomatic expression (e.g. neurocognitive decline), and medical comorbidity in depressive disorders. The central nervous system, like the pancreas, is a critical modulator of the metabolic milieu and is endangered by chronic abnormalities in metabolic processes. We propose the notion of "metabolic syndrome type II" as a neuropsychiatric syndrome in which alterations in metabolic networks are a defining pathophysiological component. A comprehensive management approach for depressive disorders should routinely include opportunistic screening and primary prevention strategies targeting metabolically mediated comorbidity (e.g. cardiovascular disease). Innovative treatments for mood disorders, which primarily target aberrant metabolic networks, may constitute a potentially novel, and disease-modifying, treatment avenue. This presentation will review the critical role that insulin plays in neurotrophism, neuroplasticity, and neuromodulation. Genuinely novel therapies for psychiatric disorders will be presented during this symposium.

Secondary prevention programmes for prevention of complications

0457

Overview of prevention of complications

R. Holman[1]
[1] OCDEM University of Oxford, Diabetes Trial Unit, Oxford, United Kingdom

Hyperglycaemia is a statistically independent and modifiable risk factor for both the microvascular and macrovascular complications of type 2 diabetes. Improving glucose levels has been shown in randomised controlled trials, such as ADVANCE and the UKPDS, to reduce microvascular risk substantially and to effect a modest reduction in cardiovascular risk, as confirmed by meta-analyses of the ACCORD, ADVANCE, UKPDS and VADT trials. In addition, the UKPDS post-trial follow-up data have shown that significantly reduced risks of both myocardial infarction and all-cause mortality are associated with earlier improved glucose control. In this third millennium, the epidemic of type 2 diabetes mellitus and the recognition that improved glycaemia can substantially reduce morbidity have made early and prolonged effective glucose control an essential requirement, in addition to the exemplary management of other proven interventions that reduce the risk of complications, such as blood pressure control, smoking cessation and optimization of lipid levels. Type 2 diabetes mellitus, however, is a progressive condition in which glycated hemoglobin (HbA1c) levels rise inexorably over time as beta cell function declines. Maintenance of near-normal glycaemia in order to minimise the risk of diabetic complications, particularly in the longer term, is difficult to achieve despite the use of multiple antidiabetic therapies. What is required is a comprehensive but flexible treatment strategy which, when instituted from

the time diabetes is diagnosed, can effectively manage the life cycle of the condition whilst ensuring maximum benefit for each individual.

The importance of comprehensive diabetes management to prevent complications

N.S. Levitt[1]
[1] *University of Cape Town, Medicine, Cape Town, South Africa*

There is a substantial body of knowledge gained from clinical trials that a variety of interventions can prevent or retard the progression of complications. These include improved blood pressure control, improved glycaemic control and regular screening for eg retinopathy and foot pathology, with timely referral. Yet in the year 2009, the quality of diabetes care even in well resourced settings remains suboptimal, and complications with their resultant human and societal cost remain common. This highlights the complexity that constitutes effective diabetes care and the difficulty of translating evidence into practice beyond the individual. Considerable barriers to optimal management, care and thus outcome exist. These are to be found at three levels involving the health care system, health care personnel and the individual in his/her community. Health care delivery to prevent diabetic complications will of necessity require a comprehensive approach and programme to overcome the multi-levelled and multifaceted barriers. Such an approach requires a positive policy framework, provision of adequate numbers of well trained staff - skilled in both communication and clinical care, clinical guidelines that are appropriate to the setting, sufficient equipment for monitoring and screening, an uninterrupted supply of drugs as well as a process of enabling patients to take an active role in their own care. It is essential to ensure that regular monitoring and evaluation of the effectiveness of such a management programme is in place so that gaps and problem areas can be identified and acted upon.

0459

Cost-effectiveness of treatment for prevention of complications

M. Engelgau[1,2]
[1] *Center for Disease Control and Prevention, Division of Diabetes Translation, Atlanta, USA*
[2] *World Bank Group, Washington DC, USA*

The overall purpose of economic evaluations of interventions for preventing diabetes complications is to lead toward policy development improving the efficiency of resource utilization. Most studies find improving glycaemia, blood pressure, lipids, and prevention oriented screening and care, not cost saving, but rather, most having favorable cost effectiveness. Over time, the use of more standardized methodology and reporting has improved study quality. However, in spite of this trend, quality remains highly variable. In addition, the ultimate goal for uptake into policy remains limited for several reasons including: poor understanding of the technical methods, use of simulations models, and interpretation of the results; generalizability into other settings, especially evaluations from high income countries translated for low and middle income countries; health system capacity and its ability to implement what was done (or something similar) in studies; single intervention studies while a package is needed for comprehensive policy; a dearth of short-term budget information for annual planning and implementation; and finally, competing policy goals that consider not only efficiency but also disparities and equity. In conclusion, while our understanding of the economics of diabetes interventions is improving, the ultimate goal of using this evidence for new policies is lagging.

No conflict of interest

0460

Implications of glycaemic control, therapeutic strategies and clinical practice guidelines

A. Adler[1]
[1] *Addenbrooke's Hospital, Institute of Metabolic Science Wolfson Diabetes & Endocrine Clinic, Cambridge, United Kingdom*

Taken together, trials of glucose-lowering in diabetes show a marked reduction in both microvascular and macrovascular disease. With respect to cardiovascular disease, lowering of blood glucose appears to lower the risk of non-fatal MI, but does not prolong survival. Marked differences exist among trials regarding safety with respect to hypoglycemia, congestive heart failure and death, and differences by trial in therapies and strategies likely account for these observations. The results of trials, augmented by observational studies, provide the evidence for the development of guidelines.
The rationale for evidenced-based guidelines is that their use will achieve better health outcomes for patients, or better value for money, than would have been achieved otherwise. Guidelines for the care of patients with diabetes include both targets for glycemia and suggestions for specific therapies; the development of guidelines depends on epidemiologic, interventional and economic studies, often incorporating all three into disease models. Whereas placebo-controlled trials are required for drug licensing, diabetes guidelines depend on trials of active comparators, reflecting "real-life" clinical practice. Since the price of new drugs usually exceed those of older, off-patent drugs (yet may not be more effective), newer drugs generally must be associated with fewer side-effects. Guidelines may include recommendations based on whether they represent a good use of health care resources, acknowledging that diabetes is but one of many diseases for which payers direct health care resources.

LIVING WITH DIABETES

Gestational diabetes

0461

Critical issues for mother and child

N. Shera[1]
[1] *Samad Clinic, Gynaecology and Obstetrics, Karachi, Pakistan*

In regions where genetic predisposition for diabetes mellitus is high and where education, awareness and resources are low, critical issues for mother and child should be addressed in this context. Foetal, neonatal and maternal outcome will depend on screening for gestational diabetes mellitus (GDM), monitoring, treatment, time and mode of delivery, and neonatal care. Preconception screening of women with high risk factors should ideally be done. If diabetes is detected, pregnancy should be planned and optimisation of blood glucose, HbA1C and blood pressure should be done at least two months prior to conception. This reduces congenital malformations in the foetus.
If diabetes was not detected prior to conception, screening at first antenatal visit is compulsory. Repeat screening is performed at 24-28 weeks gestation to detect GDM. Method of screening could be a casual reading of blood glucose and confirmation by modified WHO-OGTT. SMBG with frequent dose adjustment should be encouraged. Ultrasound scans at 12 weeks and at 18–20 weeks are essential to detect foetal abnormalities. If required, scans should be repeated to monitor foetal growth.
Behavioural change and life style modification are essential. Insulin (short and intermediate acting) given in combination in two divided doses is more acceptable than four injections (3 short and one intermediate acting) in 24 hours. Oral hypoglycaemic agents e.g. glibenclamide, are a cost-effective and convenient alternative to insulin. With good blood glucose control, the aim should be to achieve time and mode of delivery similar to that of non-diabetic women. Neonatal care should be available and breast feeding encouraged. Post partum screening at 6–12 weeks is recommended to detect reversal of GDM and subsequent annual screening is advised. Since recurrence of GDM can result in early onset of overt diabetes, oral contraceptive advice with low oestrogen or progesterone-only pills should be given.

Peri-natal management

B. Harms[1]
[1] *Locum Consultant Paediatrician, Community Paediatrics, Southampton, United Kingdom*

Gestational diabetes impacts on the mother and the baby during the pregnancy and after birth.

The definition of the perinatal period according to the WHO in 1992 is 'as commencing at 22 completed weeks (154days) of gestation (the time when birth weight is normally 500g) and ends seven completed days after birth'.
Diabetes is the most common medical condition in pregnancy. Despite optimizing metabolic control in the mother before pregnancy in pre pregnancy diabetes, and during the pregnancy for pre pregnancy and gestational diabetes, a range of birth defects are described. Diabetes affects 3-10% of pregnant women and causes 5.5 – 10% of congenital malformations. It also increases the rate of stillbirths and perinatal mortality by a factor of 4-5.
The perinatal period can be divided into three different periods. During the antenatal period congenital malformations appear and problems with growth become apparent. The time around the birth also gives rise to difficulties. This includes the gestational age (prematurity) at birth, size of the baby, the mode of delivery, and complications during delivery related to the size and delivery mode. Postnatal complications include hypoglycaemia, respiratory distress syndrome, hyperbilirubinaemia, polycythaemia, feeding problems and symptoms related to congenital malformations (e.g. cardiac malformations, gastroschisis).
The management of the baby depends on the complications that are encountered and will often require paediatric management either on the maternity ward if the symptoms are mild or a neonatal unit with specialist support. The specific management issues will be discussed.

New treatment modalities

G. Rafique[1]
[1] *Aga Kahn University, CHS, Karachi, Pakistan*

Hyperglycaemia in Gestational diabetes mellitus (GDM) is directly associated with adverse pregnancy outcomes. Recognising and treating GDM results in lowering of maternal and foetal complications. Currently, the standard management for women with GDM consists of lifestyle interventions that incorporate Medical Nutrition Therapy (MNT) with planned physical activity for at least 30 minutes each day. Women who fail to achieve adequate glycaemic control through diet and exercise therapy are given insulin injections. During the last decade, much interest has been generated in the new treatment modalities in the management of gestational or preexisting diabetes mellitus. Use of insulin analogues and oral antihyperglycaemic drugs has been explored in GDM but the use of these recent drugs is still limited due to concerns about their safety in pregnancy. The evidence available to date suggests that the rapid-acting insulin analogues (lispro and aspart) do not have adverse maternal or foetal effects during pregnancy in women with diabetes. However, evidence about the use of long-acting insulin analogues during pregnancy is limited. Data from clinical trials, retrospective studies and the published clinical experience have not demonstrated an increased risk of neonatal hypoglycemia and other neonatal morbidities with glyburide or metformin and there is strong evidence for their effectiveness and safety in the management of GDM. The American Diabetes Association and the American College of Obstetricians and Gynecologists, have not yet approved the use of insulin analogues or oral antihyperglycaemic agents in the treatment of GDM, however, the reissued July 2008 NICE clinical guidelines of NHS, UK on 'Diabetes in Pregnancy' have revised recommendation on how to utilize insulin analogues or oral antihyperglycaemic agents in the treatment of GDM. This presentation will review the latest research and published outcome results and objectively assess the value of these exciting new drugs in the management of GDM.

0464

Postnatal prevention for mother and child

P. Wickramasinghe[1]
[1] *University of Colombo, Paediatrics, Colombo, Sri Lanka*

Gestational diabetes (GDM) is a well recognized condition that will progress into T2DM. It is an illness that needs prevention and could have targeted preventive programmes.
Majority of females with GDM are unaware of the risk they carry in developing T2DM following GDM. Life style modification is a key factor in prevention of progression of GDM to T2DM. Proper dietary habits and regular physical exercise helps to prevent obesity thus prevent development of T2DM. Long term breast feeding reduces incidence of T2DM in mothers with a past history of GDM. Pharmacological interventions have shown promise although still in research stage. Strengthening long term post natal screening of GDM mothers for diabetes is very important for early detection and management of the condition.
Similarly offspring of GDM mothers have a higher chance of developing T2DM later in life. Their genetic predisposition is a key factor for this, but early growth contributes significantly. Even independent of genetic predisposition, prevalence of overweight/obesity, IGT, hyperinsulism and insulin resistance is higher among babies born to mothers with GDM. Similarly children with poor growth due to GDM, having an accelerated growth in postnatal period, have a higher risk of developing obesity and related metabolic complications later in life. Therefore the centile of birth weight should be honoured and allowed to grow along that rather than trying to achieve a higher growth rate.
Primary prevention of development of metabolic complications in later life is possible by having optimal foetal and postnatal environment. Therefore it is important to identify and optimally manage pregnant mothers with GDM. Prolonged breast feeding practices and scientific weaning practices will help in preventing childhood obesity and related metabolic complications. As most obese children remains obese adults, it is important to adopt proper behaviour practices to prevent childhood obesity.

[7] *Kaiser Permanente Centre for Health Research, Health Economics, Portland, USA*

Background: The economic and social impact of type-2 diabetes has not been measured in most low- and middle-income countries, including countries in sub-Saharan Africa. These data are important in justifying improvements in access to medicines, education, and medical care.
Methods: The study was initiated in five countries namely Cameroon, Kenya, Mali, Tanzania and Republic of South Africa. After selecting study locations in each country, persons with diabetes (cases) were identified from the populations of medical facilities and, if they consented, interviewed using a standard schedule. The interview schedule included questions about health-related quality of life; recent utilization of medical care and traditional healers; barriers to access to care; out-of-pocket payments for medical care; sources of funds to pay for medical care; complications of diabetes; other chronic and acute medical problems; effects of ill health on the subject's participation in work and social activities; effects of subjects ill health on other family members (education, nutrition, ability to work); and diabetes care (drugs currently taking, glucose testing). Control subjects were persons without diabetes who were of the same age and sex and lived in the same neighborhoods as the cases. Controls were selected by asking each case to identify his or her five nearest neighbors of the same age and sex. Interviewers contacted these potential cases in random order until a qualified and willing respondent was obtained. Responses were validated and additional information about expenditures were obtained by reviewing institutional records. The incremental impacts of diabetes were measured by subtracting mean values for controls from mean values for cases. Ratios were also calculated.
Results: Between 1000 and 2000 interviews have been completed in each country. Data entry is almost complete. Results will be available in time for presentation.

Diabetes impact study results for Kazakhstan

A. Bazarova[1], G. Sadibekova[2], R. Kasimalieva[3], E. Uteliev[4], N. Tukalevskaya[5]
[1] Kazakh Medical Academy, Postgraduate Education, Astana, Kazakhstan
[2] National Medical Holding, Institute of Motherhood and Child, Astana, Kazakhstan
[3] Private Hospital, Endocrinology, Almaty, Kazakhstan
[4] City Health Department, Internal Diseases, Chimkent, Kazakhstan
[5] Diabetes Association Of Republic of Kazakhstan, Director, Almaty, Kazakhstan

Aims of study: to understand the economic impact of diabetes in Kazakhstan.
Methods: During the survey, 3 regions will select total 1500 cases and 1500 controls (each 50 with DM1 and 450 with DM2 and 500 control respectively).
Discussion: Kazakhstan – is a country with location in Central Asia and in Eastern Europe. Population: 15,399,437 (2009). The area with severe pollution, expensive transportation, tradition of nutrition, differences in illness is a problem for the health care. In the past a plentiful supply of health personnel with autocratic management allowed to solve problems of social equity and justice, despite its economic non-effectiveness. Pharmaceutical industry was not development. The most of important medicines are admitted from abroad and are very expensive.
The financial reforms allowed increasing the Health Care expenditures during the last 5 years. But disintegration of Management, unsatisfactory health statistic data are the main barriers for effectiveness results. For the effective management the introduction of State Information Database ("The National Diabetes Register") was perfomed. In 2008 the amount of DM patients - 153 000, 8% - DM Type 1. The prevalence of DM – 1 %. But survey in 1999-2000 demonstrated that 3,8 - 4,0% of population have known diabetes. The most of them were faced with difficulties in access to medical and social service. Despite fact that Direct Medical Cost for DM was increased for 2 times during the last 5 years (9,6 M EUR - 16, 3 M EUR), the IDF experts estimate the total diabetes cost for Kazakhstan as more than 300 M EUR or 10-19% from all health care budget.
Studying of real cost of a diabetes both for patients, and for public health services system are necessary for introduction of the optimal standards for treatments, preventive and social programs.

Diabetes Impact Study results in 14 provinces in China

W. Yang[1], J. Lu[2], J. Weng[3], W. Jia[4], L. Ji[5], J. Xiao[1]
[1] China-Japan Friendship Hospital, Endocrinology, Beijing, China
[2] PLA General Hospital, Endocrinology, Beijing, China
[3] Third Hospital Sun Yat-sen University, Endocrinology, Guangzhou, China
[4] Shanghai 6th People's Hospital, Endocrinology, Shanghai, China
[5] Peoples' Hospital Peking University, Endocrinology, Beijing, China

Aims: Several studies have clearly demonstrated a rising trend in the prevalence of diabetes mellitus (DM) with increasing urbanization in the Chinese population. In 1994, we conducted a large epidemiological study involving 19 provinces in China and reported a 2.5% prevalence of DM in people aged 25-64 years. The prevalence of diabetes in China has increased rapidly in recent years. The purpose of the survey was to estimate the prevalence of diabetes.
Methods: Diabetes survey was a cross-sectional study from 14 provinces and municipalities in China. A standard 75 g oral glucose tolerance test (OGTT) was performed to define undiagnosed diabetes or Impaired Glucose Regulation (IGR) using 1999 WHO diagnostic criteria, while subjects with self-reported diabetes underwent a meal test.
Results: The crude prevalence of diabetes and IGR was about 10.0% and 15.0 %, respectively. After adjusting for other risk factors, men had an increased risk of diabetes, while subjects with a high level of education had a decreased risk of diabetes than those with a low education level. The prevalence of DM was 4-fold higher than that of the 1994 survey.
Conclusions: The current survey showed that the prevalence of diabetes and IGR has increased markedly in recent years in China, indicating that diabetes has become a major public health problem. Given the proven effectiveness of primary prevention of DM, our results call for an urgent establishment and implementation of a national diabetes prevention program to detect, prevent and provide early treatment for people with high risk.

Diabetes Impact Study results for Argentina

J.J. Gagliardino[1]
[1] CENEXA (UNLP-CONICET LA PLATA), Fac. Cs. Médicas UNLP, La Plata Buenos Aires, Argentina

Background: Diabetes care quality is poor worldwide and outcomes do not reach international guidelines target values. We hypothesize that care quality depends on 1) healthcare providers knowledge and motivation; 2) patient accessibility to care and treatment, 3) patient active participation in disease control and treatment; 4) education is an efficient tool to improve it. Data from Argentina support this hypothesis: General Practitioners (GPs) Education Program: 900 Type 2 diabetes mellitus patients from 500 GPs were evaluated one year before and after attending interactive theoretical practical courses, showing significant improvement in: Procedures performance: Fundus oculi 52 vs. 86%; cardiovascular assessment 63 vs. 88%; SMBG 27 vs. 66%. Treatment prescriptions: physical activity 23 vs. 73%; metformin 31 vs. 40%; insulin 5 vs. 18%. Outcomes: BMI 29 ± 5 vs. 27 ± 5 kg/m^2; SBP 144 ± 22 vs. 124 ± 23 mm Hg; DBP 96 ± 22 vs. 80 ± 9 mm Hg; fasting blood glucose 210 ± 71 vs. 150 ± 40 mg/dL; A1c 9.8 ± 2 vs. 7.8 ± 1 %; total cholesterol 239 ± 79 vs. 207 ± 28 mg/dL; triglyceride 215 ± 92 vs. 165 ± 51 mg/dL; severe hypoglycemia episodes (frequency) 8.5 vs. 5.9 %; yearly hospitalizations 25 vs. 17 %. Integral Diabetes Care Program (PROPAT): Case-control study matching patients by age and gender implemented in a HMO of the Province of Buenos Aires. All recommended practices recorded at baseline increased significantly one year after PROPAT implementation, with a concomitant significant improvement in all clinical and biochemical parameters tested and a 28% decrease in total annual per capita costs (Diabetes Res Clin Pract 72:284, 2006).
Conclusions: Education improves the quality and the corresponding costs of diabetes care.

Carbohydrate counting: an effective tool or setting people up for failure?

S. Waldron[1]
[1] Dorset County Hospital, Nutrition and Dietetic Department, Dorchester, United Kingdom

Dietary management is a difficult aspect of diabetes care. Therefore dietary advice should be individualised and interventions be evidence based. Historically carbohydrate counting (CC) was used to regulate intake, but advances in insulin treatment allow adjustment of rapid acting analogues to balance variable amounts of carbohydrate. Studies have used CC as an integral part of structured education, they involve knowledge and skills training in: estimating CC in either grams, or 10/15 gram portions; monitoring pre-prandial and often post-prandially blood glucose levels (BG); establishing the carbohydrate:insulin ratio; calculating correction doses of insulin; injecting calculated boluses of rapid acting insulin either before or after the meal, depending upon the carbohydrate estimation. This procedure needs to be performed 4 – 7 times daily - a very demanding and intensive regimen. However, CC is associated with better glycaemic control if counting is precise and in the context of BG excursions after food intake, CC does not need to be more precise than ±10 gms.
The complexity of this approach to management may not be suitable for more than a minority of highly motivated individuals. The DCCT used CC in the context of supportive relationships with the diabetes team, and the management was based on problem solving and goal setting. In isolation, without fully supportive and structured education, CC has not been shown to be effective. Thus, if care plans are not individualised and CC is part of an excessively demanding regimen, many people may be unable to cope. In addition people with diabetes are an extremely vulnerable group. Type 1 diabetes can increase family conflict/dysfunction and contribute to psychopathology such as depression and eating disorders. Therefore the style of dietary management should be carefully chosen

and continually supported to prevent detrimental side-effects such as feelings of failure and consequent reduction in quality of life.

Controversies in nutrition therapy

J. Mann[1]
[1] *University of Otago, Dept of Human Nutrition, Dunedin, New Zealand*

Lifestyle modification is universally accepted as the key to stemming the tide of the epidemics of obesity and Type 2 diabetes in high risk populations, and reducing the risk of progression to diabetes in individuals with prediabetic states. Appropriate nutrient intakes and regular physical activity are also cornerstones in the management of established diabetes. Lack of compliance has typically been the explanation for failing to achieve the full benefit of "lifestyle therapy". More recently a number of controversies regarding the dietary prescription for the treatment and prevention of diabetes have been highlighted and these have caused confusion in the minds of health care professionals and patients to the extent that adherence to dietary advice may be further reduced. The optimal macronutrient distribution of the diet, the role of dietary fibre and the extent to which knowledge of the glycaemic index of foods should inform food choice, have been some of the major topics of debate. Other issues which relate to nutritional advice for the population at large, such as nature of dietary fat and the extent to which dietary sugars may be safely incorporated into the diet, apply also to people with diabetes. This review will describe the controversial aspects of the nutritional management of diabetes, and will conclude that these are readily reconciled and should in no way detract from the potential of lifestyle therapy in the management of diabetes.

Nutrition and diabetes: global challenges for children and parents

S. O'Neill[1]
[1] *Diabetes UK, Care Information and Advocacy, London, United Kingdom*

This presentation focuses on the growing global challenge of childhood obesity and its effect on the long term health of children and their families, especially with the rise in Type 2 diabetes amongst children. It also touches upon the importance of education for families living with Type 1 diabetes, in terms of carbohydrate management (amount and type) and the adjustment of insulin.
The WHO states that childhood obesity is one of the most serious public health challenges of the 21st century. In 2007, an estimated 22 million children under the age of 5 years were overweight throughout the world. More than 75% of overweight and obese children live in low- and middle-income countries so this is not just a problem for the developed world.
The IDF announced last year that, in the US, Type 2 diabetes represents between 8 and 45% of new-onset diabetes cases in children; that Type 2 is more common in children in Japan than Type 1 and; in native and aboriginal children in North America and Australia, Type 2 prevalence is as high as 5.3% (Source: Diabetes Atlas 3rd Ed, IDF, 2006). Diabetes Care published an Australian study in 2006 that showed young people with Type 2 diabetes had significantly higher rates of microalbuminuria and hypertension, despite a shorter duration of diabetes and lower HbA1c. (Eppens et al.; Prevalence of diabetes complications in adolescents with Type 2 compared with Type 1 diabetes. Diabetes Care 2006; 29; 1300-6)
The presentation will focus on various interventions, both local and national, to curb the rise in childhood obesity, and hopefully Type 2 diabetes, and to support those children and young people who have already developed either Type 1 or 2 diabetes to improve their long term health outcomes.

Generation of islet ß-cells from stem cells

0472

Understanding ß-cell development: the departure point for the generation of new ß-cells

O. Madsen[1]
[1] *Hagedorn Research Institute, Developmental Biology, DK 2820 Gentofte, Denmark*

Beta cell failure causes diabetes and is currently treated by insulin replacement. Absolute or relative beta cell deficiency characterize diabetes type 1 (T1D, autoimmune) and T2D (life style induced), respectively. Diabetes associated late complications are devastating to T1D and T2D patients, and are caused by inadequate insulin replacement therapy (as measured by elevated HbA1c).
Beta-cell replacement therapy of T1D (organ donor islet transplantation combined with immunotherapy) can normalize HbA1c without insulin injections – and protect against development/escalation of late complications as long as sufficient numbers of functional beta cells survive in the graft.
Stem cells provide a realistic alternative source of therapeutic beta-cells, and directed differentiation of pluripotent embryonic stem cells towards pancreatic cell fates – including the insulin-producing beta cells – is in progress.
Robust protocols are yet to be defined that will coax different sources of pluripotent stem cells (ES cells and iPS cells) towards identical cell types.
Other useful stem cell stages may exist during the ontogenic path of the developing pancreatic beta cell – or even in the adult (diabetic) pancreas – that might be activatable to induce regeneration.
The use of pluripotent stem cells provides unique future opportunities in diabetes therapy/cure/prevention and will be reviewed.

Mechanisms of human ß-cell expansion

T. Otonkoski[1]
[1] *University of Helsinki, Biomedicum Stem Cell Center, Helsinki, Finland*

Although the pancreatic beta-cell mass can increase in response to metabolic demands, the mechanisms of this expansion in the human pancreas remain poorly understood. Based on rodent experiments, it is known that beta cells preferentially expand through proliferation, but neogenesis (differentiation from precursor cells) also contributes. It appears that in the human pancreas, both types of mechanisms are operative, but proliferation may be less important than in the rodents. Understanding of the mechanisms controlling beta-cell expansion in the human is of great importance for the development of novel therapies for all types of diabetes. Various in vitro models have been developed to address this issue. We have recently described the molecular composition of the human islet basement membrane which embraces the beta cells. We have then studied the impact of components of the physiological microenvironment for human beta-cell proliferation and differentiation. The results show that proliferation of adult beta cells, which is otherwise negligible, can be recorded when the beta cells are in contact with the laminin isoform which is found in the human islets (laminin 511). When cultured in the absence of contacts with the correct type of extracellular matrix, human beta cells rapidly undergo epithelial-mesenchymal transition and dedifferentiate into a proliferative mesenchymal-like cell. This dedifferentiation can be completely blocked by laminin 511. Likewise, our results show that laminins play an important role in the in vitro differentiation of beta cells from pancreatic duct cells. These results may prove useful for the development of methods for the expansion of human beta cells for cell therapy of diabetes.

Functional beta cells from hESCs

E. Baetge[1]
[1] *Novocell Inc, San Diego, USA*

Embryonic stem (ES) cells are unique among stem cell populations, set apart by their extensive proliferative capacity and extremely broad differentiation repertoire. These two properties make ES cells an attractive source for production of differentiated and mature cell types useful in cell therapies for many degenerative diseases. However, substantial scientific challenges exist when employing ES cells, because differentiation to a discrete population of mature cells must first be developed before any realization of a therapy, or for development of cell-specific high-throughput screening assays. Successful strategies to harness the differentiation potential of ES cells must follow developmental biology principle to guide them sequentially and synchronously through progenitor cell intermediates en route to more mature cells. Through a step-wise differentiation protocol modeled after pancreatic development, we have generated pancreatic endoderm progenitor cells from human embryonic stem cells. Implantation of the hES cell-derived pancreatic progenitors into mice results in the efficient generation of glucose-responsive endocrine cells. Glucose stimulation in grafted mice produces insulin and C-peptide in the sera and at levels comparable to that of mice transplanted with 3000 human islets. Moreover, the insulin-expressing cells generated after implantation exhibit many properties that are characteristic of functional beta cells, including expression of critical beta cell transcription factors such as PDX1, NKX6-1, and MAFA, appropriate processing of proinsulin, and the presence of mature endocrine secretory granules. Finally, as a critical test of their therapeutic potential, we demonstrate that the hES cell-derived pancreatic islet tissue protects against streptozotocin-induced hyperglycemia. Glucose-responsive islet cells are capable of maintaining stable blood glucose levels in mice graffed for more than one year. Together, these data provide definitive evidence that hES cells are competent to generate glucose-responsive, insulin-secreting cells with characteristics similar to human islets and validates the use of hES cells for the production of a renewable human islet source.

Multipotent stromal cells from human bone marrow (MSCs) to repair ß-cells in vivo

D. Prockop[1], *D. Kota*[1], *R.H. Lee*[1]
[1] *Institute for Regenerative Medicine, Texas A&M College of Medicine, Temple TX, USA*

We first reported (Lee, Seo et al. 2006) that the signs and symptoms of streptozotocin (STZ)-induced diabetes in NOD/scid mice were partially rescued by systemic administration of the adult stem/progenitor cells from human bone marrow referred to as mesenchymal stem cells, multipotent mesenchymal stromal cells, or hMSCs. The hMSCs decreased blood glucose levels and increased serum levels of mouse insulin without any increase in human insulin. There was also a slight decrease in mesangial thickening of glomeruli. A small number of the human cells engrafted into both pancreatic islets and glomeruli, but there was little evidence of differentiation of the cells. The observations were subsequently confirmed and extended by reports from three other laboratories that used rodent MSCs in immunocompetent rodents with STZ-induced diabetes (Dong, Chen et al. 2008; Ezquer, Ezquer et al. 2008; Boumaza, Srinivasan et al. 2009). To examine how the hMSCs produced their beneficial effects, we recently co-cultured the cells with mouse islets that were treated with STZ. In the presence of the hMSCs, there was an increase in proliferation of the islet cells and a decrease in apoptosis as assayed by TUNEL. We are currently testing the possibilities that the results can be explained by our recent observations in two other systems: (a) Intravenously administered hMSCs improved the hearts of mice with permanent ligation of the left anterior descending coronary artery because the cells were trapped as microemboli in the lung where they were activated to express the anti-inflammatory protein TSG-6 (Lee et al., Cell Stem Cell, in press). (b) hMSCs suppressed apoptosis in co-cultures with apoptotic lung epithelial cells by the hMSCs being activated to express the calcium regulating protein stanniocalcin-1 (Block, et al., Stem Cells 2009;27:670-81).

ASSOCIATION DEVELOPMENT

State of diabetes associations around the world

0476

Diabetes in different countries: different solutions, different associations ?

R. Rodriguez[1]
[1] *FISIOLOGÍA, Physiology, BUENOS AIRES, Argentina*

The various stages in the diagnosis and treatment of diabetes are faced in many different ways in the countries around the world and two types of institutions were created.
The scientific ones, with professional members of the health areas and others, the so-called lay societies, with diabetic patients or relatives with diabetics in their families, interested in some non medical problems of the disease.
Both can work as individual institutions or, as it happens in many countries, only one society exists, exchanging ideas and effects in order to cover all the areas to reach a better life for diabetic patients.
In Latin America the first institution was created in 1951 in Uruguay, by the Sociedad Uruguaya de Diabetes (Asociación de Diabéticos del Uruguay), with a diabetic doctor in medicine Roca as President and Engineer Mr. Copetti as Vicepresident.
Few years later in August 24, 1954, in Argentina, a scientific society SAD (Sociedad Argentina de Diabetes), was founded by a group of professors of the University of Buenos Aires, clinicians with Dr. Pedro B. Landabure and a basic research doctor of physiology, Virgilio G. Foglia. Professor Landabure was the first president and Professors Pedro Escudero and Bernardo A. Houssay were appointed as Honorary National Members.
In 1956 the creation of a Lay society of Diabetes was considered and on December 1st. 1964, LAPDI (Liga Argentina de Protección al Diabético) was founded, the statutes approved by SAD with President Captain Luis B. S. Perazzo, Vicepresident Architect Antonio J. Varela and Secretary Dr. Mario Calvagno.
These two societies, SAD and LAPDI, had a very close and good colaboration in the organization of the 7th. International Congress of IDF, Buenos Aires, Argentina, August 1970.
Some other lay institutions were created afterwards, in order to improve the care of diabetic patients.

The state of diabetes in Poland

A. Bauman[1], *A. Plebanek*[2]
[1] *Polish Diabetes Association, Bydgoszcz, Poland*
[2] *Polish Diabetes Association, Czestochowa, Poland*

In Poland, there are over 2.5 million diagnosed cases of diabetes and about as many undiagnosed. Direct cost of diabetes is about 655 million euros (over 8% of the total healthcare spending). However, indirect costs, such as early pensions, absence from work etc. are much higher.
For a long time, Poland was one of the countries that placed the lowest in Europe in various diabetes care rankings, mostly due to the fact that insulin pumps and long-lasting insulin analogues were not reimbursed. While for the last 15 years there have been no problems with the access to glucometers, strips, pens, and needles, it is only this year that after many years of struggle, insulin analogues have finally become reimbursed and insulin pumps and accessories have become free for children and youth under 18 years of age.
One of the main problems in Poland is the lack of education of both patients and doctors. Also, there are no professional educators. A major consequence of this is foot amputations, which amount to 14 500 every year. Other diabetes complications are also very common, for example retinopathy, nephropathy, hypertension, and cardio-vascular diseases.
Moreover, diabetes to many is still a social problem. It happens fairly often that people conceal the fact that they have diabetes from their friends and especially from their employers. Fear of losing one's job because of diabetes is not rare, and unemployment among diabetics is a problem. Attempts are being made to activate those who are unemployed and socially excluded.

Improving diabetes care in the Caribbean: how do we go about this?

C. Yearwood[1]
[1] *Diabetes Association of Barbados, Education, Christ Church, Barbados*

The World Health Organisation (WHO) describes diabetes as a chronic, debilitating and costly disease that poses severe risks for families, countries and the entire world. WHO further states that diabetes can be traced to overweight, obesity and physical inactivity and can be prevented through increased activity and a healthy diet.
Regionally, diabetes prevalence ranges from 18% in Jamaica to 8% in St. Lucia with lower extremity amputations in Barbados being among the highest in the world. It has been posited that by the year 2010, prevalence in the Caribbean will reach 25% of the adult population.
In 2003, the Caribbean Heads of Government mandated the establishment of the Caribbean Commission on Health and Development and in 2007 they met at the Regional Summit on Chronic Non-Communicable Diseases (CNCDs) and established a collective agreement to stop the epidemic of CNCDs entitled the Declaration of Port-of-Spain: Uniting to Stop the Epidemic of Chronic NCDs.
Where do we go from here?
As a Region – Fulfil the action promised by CARICOM and implement major aspects of the Port-of-Spain Declaration i.e., re-introduction of physical education in schools; provision of incentives and resources to provide healthy school meals and promote healthy eating in children; promotion of policies and actions aimed at increasing physical activity in the entire population and increasing public facilities to encourage physical activity by the widest cross-section of our citizens.
As Individual Countries – Reduce the costs related to the management of diabetes e.g. supplies and medication. Establish the post of diabetes educator specialist in our hospitals and clinics.
As Diabetes Associations – Promote behavioural change and improved self-management through education.
As individuals – Take steps to prevent or delay the onset of diabetes and its complications.
Awareness of diabetes is not the problem; it's time to motivate action.

Diabetes associations in Africa: overcoming the barriers

S. Delport[1]
[1] *University of Cape Town, Paediatric Endocrine and Diabetes Unit, Cape Town, South Africa*

There are four diabetes associations in South Africa namely; the Diabetes Association of South Africa (SADA), the Society for Endocrinology, Metabolism and Diabetes of South Africa (SEMDSA), the Paediatric and Adolescent Endocrine and Diabetes Society of South Africa and the Diabetes Education Society of South Africa (DESSA). These organisations are affiliated and share a common goal of improving diabetes care in South Africa.
SADA is a national welfare organisation which provides support and information to people living with diabetes and to the public. It is run by the lay public but enjoys broad membership. SEMDSA, PAEDS-SA and DESSA are scientific bodies. Membership consists of health care professionals. This talk will review the function of these organisations and their roles in overcoming the barriers to comprehensive diabetes care.
SEMDSA is the parent body and was established in 1962 with the objectives of furthering scientific study and clinical practice and to promote clinical research in all branches of endocrinology, metabolism and diabetes. Over the years this role has evolved to include the development of education programmes and overseeing post-graduate training in the field of endocrinology. The establishment of the affiliated societies DESSA and PAEDS-SA arose out of specific needs identified. These organisations face on-going challenges in a complex health care system which consists of both public and private sectors.

WORKSHOP

Twinning: a way forward for association development ?

0480

Is "twinning" the way forward for smaller European associations?

V. Augustiniene[1]
[1] *Lithuanian Diabetes Association, Vilnius, Lithuania*

Aims: To introduce experience of the Lithuanian Diabetes Association what is achievable through twinning, and to encourage diabetes associations to initiate a twinning in their own countries.
Methods: Establishing the partnership, setting achievable objectives, evaluation of benefits.
Results: Main aims for diabetes associations are to seek a better and longer life for people living with diabetes and to help health-care professionals develop their own diabetes skills. Once an association has established that forming a twinning partnership would be of benefit, it needs to decide its aims and objectives. With well defined, achievable objectives, any association can be confident in the knowledge that those engaged in the twinning process are committed to a specific goal consistent with its own objectives. As a consequence, the twinning exercise will be more focused and manageable. Then it is time to make personal contact between the potential twin associations. It is usual for the association seeking a twin to make the initial approach to the association it wishes to twin with. Both partners should look seriously at their resources and needs to make sure that developing a relationship will be helpful. Priorities established by the twinning partners to improve the diabetes care situation in Lithuania 1992-1997 included: Postgraduate education. Danish hospitals agreed to educate a small group of Lithuanian doctors and nurses. Support for the production of the Lithuanian diabetes magazine. Provision of insulin and other diabetes equipment for children under 15 and pregnant women. The drafting of a national diabetes plan with help from a Danish expert. The establishment of outpatient clinics.
Conclusion: The twinning programe has been mutually beneficial. It has helped the Lithuanian Diabetes Association to function more efficiently on behalf of people living with diabetes and has generally strengthened the organization. The government has been continue to invest in diabetes care.

0481

Inequities in diabetes care in Africa: is twinning the way forward?

C.F. Otieno[1]
[1] *University of Nairobi, Department of Medicine, Nairobi, Kenya*

Background: People with type 2 diabetes are increasing globally. Consequently, the diabetes-associated morbidity and mortality will rise significantly amid challenges of care.
Worldwide various regions exhibit disparities amongst populations, in resources, priorities and governance. This is replicated in diabetes care. There is need, therefore, to develop strategies within healthcare providers to interact and network with nations to accommodate less endowed regions to support scarcity of resources to improve care `of persons living with diabetes.
Twinning or symbiotic partnership is an appropriate strategy within and between countries to improve care of patients living with diabetes. Operationalizing twinning or partnerships within countries involves large institutions endowed with resources, skilled manpower and care facilities forming partnership with the smaller health units to enhance diabetes care. Likewise, countries with higher resource bases can partner at institutional levels (with hospitals, in operations research, staff development and training institutions) to establish and enhance capacities for diabetes care.
The partnerships can be achieved through exchange of personnel, technical support, technology transfer, telemedicine, collaborative research and broader educational activities. Anticipated constraints include unconstructive partnerships, disparities in socio-cultural factors, prioritizing levels of need; intricacies in co-financing; inadequate skilled personnel; poor infrastructure; bilateral uncertainties amid diminished latitudes in decision-making; negative attitudes from poor outcomes in less endowed institutions. These partnerships often lack guidelines to engage, how to monitor and evaluate the programs, consistency and sustainability or change of objectives downstream.

Established institutions like IDF should play a key role in facilitating partnerships amongst interest groups of member states, by providing a forum that develops global policy guidelines in twinning for diabetes care through different mediums.

WORKSHOP

Twinning and the Mozambique experience

0482

The twinning initiative in Mozambique: a model for improving diabetes care in resource poor settings

D. Beran[1]
[1] *International Insulin Foundation, Centre for International Health and Development, London, United Kingdom*

Mozambique is located on the East coast of Africa and faces a large burden of Communicable Diseases, but Non Communicable Diseases such as diabetes are increasing. The Ministry of Health (MISAU) estimates the prevalence of diabetes at 3.4% with increasing rates of overweight and obesity especially in urban areas.
In 2003 the International Insulin Foundation (IIF) in collaboration with MISAU implemented the Rapid Assessment Protocol for Insulin Access (RAPIA). The RAPIA provided an analysis of the barriers to care for people with diabetes in addition to increasing the overall data available about diabetes in Mozambique. Following this assessment the IIF provided technical support to Mozambique. In 2006 a delegation from Diabetes UK visited Mozambique to see if a "Twinning Project" could be possible. Following this visit in 2007 the Diabetes UK-Mozambique Twinning Project was launched with a series of objectives that built on the RAPIA assessment, took into account local priorities and Diabetes UK's capacity.
Results from this Twinning have been the development of a comprehensive diabetes and Non Communicable Disease policy and Diabetes UK's support assists in the implementation of this plan. Through the training of healthcare workers, support to the different branches of the diabetes association and support for World Diabetes Day, Diabetes UK is helping improve care, increase awareness and promote prevention of diabetes in Mozambique.
From this experience a series of lessons learnt could assist other countries in developing similar programmes.

1. Base activities on a clear situation analysis and understanding of the local situation and needs
2. Develop relationships with local partners
3. Adapt objectives of project to local and external partner's aims
4. Flexibility
5. Develop North-South and South-South Links
6. Objectives should address different aspects of diabetes (e.g. policy, healthcare worker training, patient education, World Diabetes Day activities, etc.)

0483

Effective implementation of the co-operation

C. Silva Matos[1], *D. Beran*[2]
[1] *Ministry of Health, Non-Communicable Diseases, Maputo, Mozambique*
[2] *International Insulin Foundation, Centre for International Health and Development, London, United Kingdom*

The Mozambican Diabetes Association (AMODIA) was established in 1995 and has gone through three distinct development phases.
1995-2003: Creation and legal registration of AMODIA. The association did not have its own facilities, its activities were limited to a consultation as care for diabetes within the National Health Service was characterised by long waiting times and a chronic shortage of medicines with high prices for these.
2003-2006: The association's development, during this period, coincided with the creation of the Non Communicable Disease (NCD) department within the Ministry of Health, leading to an agreement between the Ministry and AMODIA for providing care to patients. AMODIA also received support from the World Diabetes Foundation, which helped establish two new branches of the association.
2007-present: A delegation from Diabetes UK visited Mozambique in 2006 with the objective of exploring the possibility to establish a "Twinning" project between Mozambique and Diabetes UK.
This "Twinning" project was finalised in 2007 with the following objectives:

1. Support healthcare worker training
2. Support specialised training.
3. Study visit from Mozambican Ministry of Health to the UK
4. Development of patient education materials
5. Organisation of World Diabetes Day
6. Advocacy and policy support for Ministry of Health
7. Development of a core group of people involved in diabetes
8. Development of AMODIA
9. Long term research programmes in Mozambique

All Provinces now have a team of trained healthcare (total 247 healthcare workers) workers in diabetes management. In addition 2 healthcare workers trained in Tanzania on diabetes education.
10 patients have been trained as diabetes educators and held education sessions in the community using locally developed materials. 3 branches of AMODIA now exist and follow a total of 3,600 people with diabetes (increase from 1,200 in 2006).
World Diabetes Day events were organised in 2007 and 2008, which helped raise awareness of diabetes directly in the community.
The National Plan for NCDs has now been finalised and NCD focal points have been nominated in 6 out of 10 Provinces.
A research project following a cohort of people with diabetes in Maputo has been initiated in collaboration with the University of Kwa Zulu Natal.
Besides these concrete results with direct impact on diabetes, this project helped reinforce the National Health Service. This "Twinning" was also based on both partners being in accord with regards to the defined priorities and the implementation of the planned activities.

OPEN FORUM

LIVING WITH DIABETES

Discrimination and diabetes

0484

Home and siblings

S. Murray[1]
[1] *Baker IDI Heart and Diabetes Institute, Epidemiology, Caulfield, Australia*

Diabetes is a chronic life-long condition that impacts upon almost every aspect of life. Living with diabetes is not easy. Medication is usually self-administered, whilst lifestyle changes involving diet and physical activity require commitment and active involvement.
Those with Type 1 diabetes have to balance the risks of hypoglycaemia against the longer-term risks of hyperglycaemia. Those with Type 2 diabetes usually need to make changes in their lifestyle, but this can be difficult to do if the individual does not feel ill or the impact of not doing so does not have immediate repercussions.
Diabetes is still one of those medical conditions in which discrimination may impact on the individual who has the disease. Many communities may direct unfavourable attitudes, beliefs, and policies toward people who have diabetes including their loved ones, family members, and / or close associates.
Ignorance and fear are the main causes of discrimination. However cultural beliefs may also play a role. In some societies diabetes is hidden because it prevents them and their siblings getting married.
Families too, of course, can suffer loss of earnings as a result of diabetes and its consequences A number of diabetes patients may not be able to continue working or work as effectively as they could before the onset of their condition and this can cause resentment within the family. Siblings have to learn to make adjustments when a brother or sister is diagnosed. They sometimes resent the attention given to the child with diabetes

0485

Marriage and society

A.S. Bhoraskar[1,2]
[1] Raheja Hospital, Diabetology, Mumbai, India
[2] Asian Heart Institute, Diabetes and Endocrinology, Mumbai, India

In spite of the rising level of education and increasing awareness of the disease diabetes continues to be an important social stigma in India, particularly for girls, as it is very complex and operates at many levels. It has both social and psychological aspects and has a serious impact on the health of the individual due to the inaccessibility to the existing Diabetes Care services.
Being born a girl in India is not easy, and if she has diabetes the parents try to hide their daughter's condition from the teachers, friends and relatives. Many parents perceive a girl with diabetes as a burden, difficult to marry off, unable to bear children and best ' disposed of'. This is common even among the educated class. Due to stopping of insulin or giving sub-optimal dosage, many of these young girls have poor glycemic control, frequent genito-urinary and skin infections and tuberculosis.
Our study shows that out of 546 type 1 DM subjects(M364, F182) with an average follow up of 15 years, only 46 girls remained with us out of which 12 completed high school and 8 completed graduation and only 5 got married. While 280 boys are still following with us, 225 graduated and gainfully employed, 62 married.
In Indian societies, marriages are arranged according to the casts, subcasts and family backgrounds. 'Kundali' (horoscope based on birth time and place) play a pivotal role. Although it has a great scientific basis both in terms of compatibility and well being of the couple it is rarely ever practiced accurately. It is not surprising to find a wealthy type 1 DM boy married to a healthy young girl from a poor family without disclosure of either his disease or early complications. Incompatibility is very high following such marriages.

School and sports

A. Chapman[1]
[1] AFDS, Director Policy and Strategy, Clareville, Australia

As a 'hidden' disease, people with Diabetes often encounter some of the most entrenched forms of discrimination - and most of the time the discrimination itself is hidden.
As a young person with Type-1 Diabetes, who was diagnosed at the age of three, I can look back on my life through school and through my professional sporting career and clearly see forms of discrimination that I could not identify were apparent at the time.
Prevention from participating in regular school life, school activities, sporting activities and even representative sports because of inherent discrimination, the only solution to these problems is proper education and awareness.
The presentation will look at my life's examples of discrimination as a young person, a teenager and a young adult. It will go into more detail investigating the variation between different approaches to care for young people with diabetes in schools and sports, as well as legislation apparent in Australia and around the world to protect against discrimination. It will also investigate the shifting paradigms of locating support - from the tradition support methods and structures to a 'new-age' of e-support and the effect of this on young people with diabetes.
Lastly, a recommended model, based on legislation and fairness, will be proposed - with the aim of reducing barriers and unfair social exclusion of people with Diabetes from school activities and sports.

Workplaces

D. Cairns[1]
[1] London, United Kingdom

In 1989 I lost my boyhood dreams to fly jets in the British Royal Air Force when diagnosed with type 1 diabetes.
Around the world there are whole ranges of restrictions that can be encountered for people with diabetes, not just for flying careers, but in everyday workplace environments. In the UK, we are protected by government rules – a Disability Discrimination Act – that protects people from being barred from workplace jobs. In other countries people may not be so fortunate.
In 2000 I was able to return to my boyhood dreams to fly, thanks to a system in the USA that allows people with type 1 diabetes to fly on a full, unrestricted private flying licence. In 2003 a round-the-world flight (www.diabetesworldflight.com) brought me into contact with a wide range of people across 22 countries, some of whom experienced discrimination at normal workplaces. It was an eye-opening experience.
A commercial flying career remains no more than a dream for people with diabetes due to blanket ban policies by aviation authorities around the world at this time. The advent of new diabetes management technologies, including continuous glucose monitoring, may help change this situation. And hopefully work by groups such as www.pilotswithdiabetes.com can help change approaches to blanket ban policies for people with diabetes.
During my session I will highlight the current known situation for a number of career activities that remain restricted by blanket ban policies, and what is being done to try to change this situation.

SPEAKERS' CORNER

Hypoglycaemia - causes and solutions

0488

Hypoglycaemia - causes and solutions

F.G. Bowling[1], A.E. Stocks[2]
[1] Mater Children's Hospital, Metabolic Disease, Brisbane, Australia
[2] Mater Children's Hospital, Diabetes & Endocrinology, Brisbane, Australia

Hypoglycaemia, low blood glucose, was defined in 1938. This definition is no longer adequate for our understanding of this risky and disabling consequence of diabetes. The failure to ensure an adequate supply of glucose to the brain, particularly when due to insulin therapy, means inadequate fuel for brain activity. Our research suggests that abnormal signalling molecules accumulate. These molecules explain the impairment in thinking, personality changes, and seizure activity.
There is considerable variation in how and when our brains respond to low glucose. This makes it difficult to define hypoglycaemia – how low is low? Individual variation depends on our genetics of glucose transport to the brain, whether we have alternative energy sources available, and to what extent our brain signalling molecules are disrupted.
The brain, rather than the blood, is the best target for the detection of hypoglycaemia risk. Blood monitoring has significant limitations in reliability and accuracy and cannot account for differences between individuals. Because we do not fully understand the molecular basis of hypoglycaemia, we cannot yet answer the decreasing awareness that occurs over time.
Innovative strategies for hypoglycaemia detection are focusing on the brain dysfunction and on the abnormal molecules that are generated, rather than unreliable blood measurements.
In a large study of 400 people with diabetes we found that pet dogs could detect the molecules associated with hypoglycaemia and then alert their owners. We are characterising the molecules to understand the underlying mechanisms, and to provide dog trainers with the substances needed to teach our pets to respond.
Other groups are attempting to monitor the brain impairment. Devices mounted into spectacles are being tested for driver awareness. Games in cell phones can also be used. Loss of hypoglycaemia awareness is one of the greatest challenges facing people with diabetes as we age.

CLINICAL RESEARCH

Non-type 1 diabetes in children

0489

Non-type 1 diabetes in youth: the rise and fall of the accelerator hypothesis

S. Arslanian[1]
[1] *Children's Hospital of Pittsburgh, Department of Pediatrics, Pittsburgh, USA*

The most common forms of diabetes in children are traditionally divided into Type 1 and Type 2 Diabetes. Type 1 Diabetes is generally viewed exclusively as an autoimmune disease, associated with high risk HLA antigens, early detection of islet cell autoantibodies, and ultimate demise of the b-cell, with insulin secretion near complete deficiency at the time of clinical presentation. Type 2 Diabetes can not be considered exclusively from the angle of the b-cells, but rather the interaction between insulin secretion and multiple physiological loops that control energy disposal, storage, obesity and insulin resistance.
The accelerator hypothesis first suggested in 2001, postulates that Type 1 and Type 2 Diabetes are not discrete but part of a spectrum of disease caused by three main accelerators. The first accelerator is the intrinsic/constitutional potential for a high rate of b-cell apoptosis, a necessary but insufficient step in the development of diabetes. The second accelerator is insulin resistance, resulting typically from obesity and a sedentary lifestyle. Insulin resistance appears to be the hypothesis linchpin for Type 1 and Type 2 diabetes. The third accelerator, immune damage, is found in a small subset of patients with both intrinsic lesion and insulin resistance who develop b-cell autoimmunity accelerating b-cell loss and expressions of autoimmune Type 1 Diabetes. The lack, however, of clear metabolic evaluations in children to distinguish between the two forms of diabetes leaves open the issue of overlapping forms of diabetes and the testing of the hypothesis. In this lecture data will be presented, using clamp experiments, to demonstrate important differences in ***in vivo*** insulin sensitivity and secretion in children with obesity and evidence of autoimmune diabetes (akin to latent autoimmune diabetes of adults (LADA)) compared with obese youths with Type 2 diabetes and non diabetic children, providing the distinction between these two forms of diabetes.

0490

Monogenetic causes

A.T. Hattersley[1]
[1] *Peninsula Medical School, Diabetes Research, Exeter, United Kingdom*

Monogenic diabetes accounts for around 10-20% of the non Type 1 diabetes in children. The genetic aetiology of most subtypes of monogenic diabetes is now defined and is used to confirm a clinical diagnosis. The previously clinically defined maturity-onset diabetes of the young (MODY) is now defined by etiological mutations in the glycolytic enzyme glucokinase and the transcription factors. Glucokinase patients have mild stable hyperglycemia and rarely require treatment or develop complications, while patients with transcription factor mutations show progressive hyperglycemia and may have severe complications if not appropriately treated. The most striking evidence of pharmacogenetics is in HNF-1a MODY where, in a randomized trial there was a 4 x greater fall in fasting glucose than in BMI matched type 2 patients. HNF-1a patients' glucose control can be improved by taking them off insulin injections after many years and putting them on sulphonylureas.
Diabetes diagnosed in the first 6 months of life is almost entirely monogenic diabetes rather than Type 1 diabetes and is known as neonatal diabetes. Most patients with the resolving transient neonatal diabetes (TNDM) have abnormalities in the imprinted region on 6q and over 50% of PNDM have mutations in the Kir6.2 and SUR1 components of the KATP channel. Despite being insulin dependent, Kir6.2 and SUR1 patients can discontinue insulin injections and show improved glycaemic control on high dose sulphonylureas which act to close the K_{ATP} channel by a non ATP dependent route.
The widespread introduction of diagnostic testing in diabetes has resulted in being able to make a molecular genetic diagnosis which helps explain the clinical features, predicts prognosis and can improve treatment (see www.diabetesgenes.org)

Developing countries

E. Sobngwi[1,2], *V. Siaha*[2]
[1] *Newcastle University, Epidemiology, Newcastle, UK*
[2] *National Obesity Centre Cameroon, Endocrinology, Yaounde, Cameroon*

Type 1 diabetes accounts for the majority of diabetes in children worldwide. However, considering the rising prevalence of obesity and decrease in physical activity in youth that also affects developing countries, an increasing frequency of type 2 diabetes is anticipated. In addition, atypical presentations of diabetes of uncertain classification are seen in young Africans. Ketosis-prone type 2 diabetes (KPD) is one of the most frequent unusual diabetes phenotypes in Africa. KPD is characterised by ketosis or keto-acidosis at onset but a subsequent clinical course resembling type 2 diabetes. This phenotype is recognised worldwide, but tends to present with the highest frequency in populations of African descent in all age groups. KPD may represent 15-25% of all diabetes cases in Africans living in Europe and USA, as well as in populations living in sub Saharan Africa. In order to contribute to a better classification and care of adolescent with diabetes, we recently studied 29 consecutive consenting insulin-treated adolescents followed for diabetes in Yaoundé, Cameroon. After an overnight fast, we measured insulin secretion in response to 75-g oral glucose, and on a separate day, whole body insulin sensitivity using 80mU/m2/min euglycemic hyperinsulinemic clamp. We demonstrated that 67% of the diabetic patients had insulin resistance, while 60% had absolutely deficient insulin response. There was an overlap of these two metabolic abnormalities in 27% of cases. Overall, based on these metabolic characteristics, we could classify 40% of patients as having type 2 diabetes, 33% as type 1 and 27% as having double diabetes. Thus, we concluded that even in sub-Saharan youth, type 2 diabetes is no longer rare. Epidemiological studies are warranted to provide accurate estimates of relative proportions of diabetes subtypes.

FOUNDATION SCIENCE

Which will be the best alternatives to replace the lost ß-cells in diabetes?

0492

Human islet transplantation

C. Ricordi[1], *D. Mineo*[1], *A. Pileggi*[1], *R. Alejandro*[1]
[1] *University of Miami, Diabetes Research Institute, Miami, USA*

The primary goals of islet transplantation (ITX) are achievement of glycemic control in the absence of severe hypoglycemic episodes, improvement of quality of life, and prevention or reversal of the chronic, progressive complications associated with diabetes. Insulin independence, although desirable, is not considered a primary objective of ITX. C-peptide production following islet transplantation may contribute to some of the improvement of diabetic complications observed post-transplant. However, in the context of ITX, a decline of renal function has also been reported in some studies, while more recent reports have shown stable renal function and lack of worsening diabetic nephropathy at long-term follow-up, or an initial decline of renal function that stabilizes without further worsening in the long-term. Strict selection of islet transplant candidates without previous renal dysfunction (***i.e.***, micro-albuminuria and low estimated glomerular filtration rates) and timely implementation of nephro-protective and anti-hypertensive therapies (i.e., Angiotensin-Converting Enzyme inhibitors and/or Angiotensin-Receptor Blockers) may have accounted for the different clinical outcomes observed across different ITX studies. Immunosuppressive protocols void of nephrotoxicity are highly desirable, and indeed, ongoing clinical trials are showing promising results in patients undergoing conversion of either CNI or mTOR-inhibitors to MPA maintenance, with preservation of both renal and islet function. While a steady progress in the 1-year and 5-year ITX survival has been observed, the benefits of ITX need to be carefully weighed against the risks associated with the need for chronic immunosuppression and its side effects. The clinical applicability of ITX beyond the most severe cases of Type 1 DM will require the development of successful immunosuppressive regimens that minimize or eliminate nephrotoxic drugs, and the introduction of novel strategies to

replace systemic immunosuppression with local immunomodulatory strategies, nanoencapsulation and tolerance induction, which are currently being explored in pre-clinical and clinical trials.

Xenotransplantation - can porcine islets solve the supply problem?

G. Korbutt[1]
[1] *University of Alberta, Surgery, Edmonton, Canada*

One of the main obstacles for successful widespread clinical islet transplantation is the limited availability of insulin-producing tissue. Porcine islets are an attractive source of ß-cells for clinical transplantation because pigs breed rapidly, have large litters, and would be ethically acceptable. Reproducible isolation of large numbers of islets from adult pigs has been challenging and very difficult. We developed a simple, inexpensive and reproducible method to isolate a large number of neonatal porcine islets (NPI). NPI are comprised of fully differentiated endocrine cells (45%) and endocrine precursor cells (55%). We have shown that these NPI grafts grow and are able to reverse hyperglycemia after transplantation in mice and allogeneic juvenile pigs. More recently we have data to show that NPIs are resistant to the toxic effects of high glucose, pro-inflammatory human cytokines, hypoxia and the diabetogenic properties of streptozotocin**.** Moreover, we have recently demonstrated that NPI can correct diabetes in a pre-clinical, non-human primate model. In this study seven pancreatectomized primates received NPI grafts and a costimulation blockade-based immunosuppressive regime consisting of induction therapy with two doses of basiliximab (anti IL-2 receptor mAb) and six doses of H106 (humanized anti-CD154 mAb), given over a 2 week period. In addition, animals received ongoing maintenance therapy with belatacept (LEA29Y, a high affinity CTLA4-Ig variant) and sirolimus. Six of the seven animals achieved and sustained insulin independence that was associated with excellent glucose control for the length of the experimental follow-up, with one recipient at >300 d. We therefore feel that NPIs will be the near-term solution to the islet supply problem whereas possibly the more long-term solution may be the use of human pancreatic islet cell precursors to create human insulin-secreting cells.

Pancreas transplantation

D.E.R. Sutherland[1]
[1] *University of Minnesota, Department of Surgery, Minneapolis, USA*

Beta cell replacement, by either pancreas or islet allo-transplants, has been done for over 3 decades. Islet transplantation is minimally invasive but logistically more difficult than pancreas transplantation, thus the latter is still more widely applied. Pancreas transplants routinely restore insulin-independence and euglycemia that is durable unless rejection occurs. Islet transplantation engrafts less beta cell mass and is less likely to establish insulin-independence, but a C-peptide positive state with euglycemia maintained on once daily long-acting insulin is now routinely achieved. With either form of beta cell replacement, immunosuppression is currently required as the trade-off for ameliorating diabetes in attempt to improve quality of life.
Due to the need for immunosuppression, a pancreas (PTA) or islet transplant alone is usually done only in diabetics with hypoglycemic unawareness (HGUA). For nephropathic diabetics who receive a kidney transplant to prevent the need for dialysis, a simultaneous (SPK) or subsequent (PAK) pancreas or islet transplant from a living (segment of the organ) or deceased (whole organ) donor can be done with only the surgical risks to be considered. At least for pancreas transplants, SPK and PAK are more common than PTA, with PAK a particularly attractive option for the ability to do a living donor kidney to preempt the need for dialysis followed by a deceased donor pancreas to achieve insulin-independence.
Neither pancreas nor islet allo-transplants can treat all who could benefit because of the shortage of deceased or living donor tissue. In the USA there are only ~ 7000 deceased organ donors annually while there are >30,000 new cases of type 1 diabetes. Thus, ultimately, either xeno-grafts will solve the shortage (pig to monkey islet transplants can reverse diabetes), or stem cells will be an unlimited source, or endogenous regeneration induced with thwartation of autoimmunity in type 1 diabetes mellitus accomplished.

Meanwhile, pancreas or islet allografts can be done, alone in patients with HGUA, or in any diabetic on immunosuppression (usually for a kidney transplant) in whom the surgical risk is acceptable. More than 30,000 pancreas transplants were reported to the International Pancreas Transplant Registry between 1966 and 2008, including >22,000 from the USA. In a recent analysis of >5800 USA cases done in 2004-8, the 1 yr actuarial patient survival rates for SPK (n=4206), PAK (n=1136) and PTA (n=491) recipients were 95%, 97% and 96%, respectively, and at 3 yrs were over 90% in all categories. The corresponding pancreas graft survival (insulin-independence) rates at 1 yr were 85%, 79% and 79%, and were 59%, 65% and 79% at 3 yrs. The insulin-independent rates currently are much higher long term for pancreas than islet transplants, though C-peptide positive rates are comparable.
Islet transplants are preferable to pancreas transplants from a surgical standpoint, but until the insulin-independence rates for islets are comparable, the logistics of organ procurement for expeditious islet processing are improved, and non-investigational status is granted to islets so insurance coverage is similar to that for pancreas transplant, the latter will continue to be done, with good results as demonstrated.

Technological approaches to closing the loop

H. Wolpert[1]
[1] *Joslin Diabetes Center, Section of Adult Diabetes, Boston, USA*

In the last several years there have been major advances in the development of real-time continuous glucose monitors. This progress has facilitated the development of closed loop systems consisting of a continuous interstitial glucose sensor linked to a continuous subcutaneous insulin pump by a control algorithm to produce an electromechanical pancreas. Prototype versions of this technology have shown promise in preventing and treating hypoglycemia, and optimizing nocturnal glycemic control.

New IDF diabetes guidelines

0496

Type 2 diabetes update

S. Colagiuri[1]
[1] *Institute of Obesity Nutrition and Exercise, University of Sydney, Sydney, Australia*

In 2005, the IDF Clinical Guidelines Task Force developed global guidelines for the care of people with type 2 diabetes. The significant development with this guideline was an attempt to make the guideline recommendations globally relevant by introducing levels of care approach which took into account human and material resources in making recommendations. Central to this levels of care approach was standard care which is the level of care which should be available to all people with diabetes. But in recognition of the difficulty in delivering this level of care in many parts of the world, a minimal care level was also used to describe the most basic care which a person with diabetes should receive, recognising that in many parts of the world not even this level of care was being achieved. At the other end of the spectrum was comprehensive care. Since these guidelines were produced in 2005 new evidence has become available and, in the light of this, the guidelines have been updated to provide more contemporary recommendations, although many recommendations remain unchanged. The updated guidelines also include new sections (eg on care of the elderly with diabetes) and each section suggests indicators to monitor progress on implementation of the guideline recommendations.
The ralionale for producing these guidelines is to help countries examine their own guidelines in light of new knowledge. For those countries which do not have their own guidelines, these guidelines are deigned to provide a template for developing locally relevant clinical care recommendations.

Global IDF/ISPAD guideline for type 1 diabetes in childhood and adolescence

K. Donaghue[1], G. Klingensmith[2], P. Swift[3], R. Hanas[4]
[1] The Childrens Hospital at Westmead Institute of Endocrinology, Diabetes and Endocrinology, Westmead, Australia
[2] University of Colorado at Denver and Health Sciences Center, Barbara Davis Center for Childhood Diabetes, Denver, USA
[3] Leicester Royal Infirmary, Dept. of Pediatrics, Leicester, United Kingdom
[4] Uddevalla Hospital, Dept. of Pediatrics, Uddevalla, Sweden

Education is the vehicle for optimal self-management. ISPAD published its first set of guidelines in 1995 and its second in 2000, placing the education at the center of clinical management of pediatric diabetes. Since then, the acceptance of intensive therapy, also for very young children, has increased around the world. Insulin pump usage has risen in all age groups in countries where this treatment modality can be afforded. Intensive therapy requires better and more comprehensive education for it to be successful.
The ISPAD Consensus Guidelines 2000 have been translated into 11 languages, indicating the need for a truly international document. The 3rd edition, now called "ISPAD Clinical Practice Consensus Guidelines" was published 2006-2008 as separate chapters in the journal Pediatric Diabetes. We have used the American Diabetes Association's grading system for references. Whenever possible, pediatric references have been included, as we want to stress the point "diabetes is different in children".
The guidelines are based on a wide consensus of clinical practice. They were drafted by international writing teams, modified by experts in different specialties from many countries, debated at annual ISPAD meetings by the members, and were reviewed by members via the internet and the ISPAD website.
In 2008 ISPAD was asked by IDF to write a summarized version of our pediatric diabetes diabetes guidelines using the IDF template of Standard, Comprehensive and Minimal Care levels.
These guidelines can be used to:

- improve awareness among governments, state health care providers and the general public of the serious long-term implications of poorly managed diabetes and of the essential resources needed for optimal care
- assist individual care givers in managing children and adolescents with diabetes in a prompt, safe, consistent, equitable, standardized manner in accordance with the current views of experts in the field.

Pregnancy

L. Jovanovic[1]
[1] Sansum Diabetes Research Institute, Working Group for the IDF Pregnancy Guideline, Santa Barbara, USA

Pregnancy is associated with changes in insulin sensitivity which may lead to changes in plasma glucose concentrations. For women with known diabetes or for women who develop diabetes during the pregnancy, these changes put outcomes at risk. The IDF Pregnancy Guideline deals with the means of identifying women for whom such problems are new, and helping them, as well as women already known to have diabetes, to achieve the desired outcome of a healthy mother and baby. Within the IDF Global Guidelines for Type 2 Diabetes (IDF 2005) there was a section on pregnancy, but these Guidelines did not address type 1 diabetes and did not consider the wider issues surrounding gestational diabetes mellitus and prevention of diabetes. The new IDF Pregnancy Guideline includes these other topics, and attempts to present some of the evidence bearing on areas of controversy. The new IDF Pregnancy Guideline was necessary because since 2005 an evidence-based guideline on diabetes in pregnancy has been published in the UK (NICE 2008), the Canadian evidence-based diabetes guideline (including pregnancy) has been revised (CDA 2008), and there has been further deliberation on the implications of the Hyperglycemia and Adverse Pregnancy Outcome Study (HAPO 2008). In preparing the new IDF Pregnancy Guideline, a non-formal evidence review was prepared and discussed by a Working Group in March 2009 and reviewed by an Expert Review Committee. The aim was to recommend Standard Care as envisaged in the Global Guidelines. This lecture will review the major sections of the new IDF Pregnancy Guidelines and highlight the changes and emphasize the treatment targets.

Self-monitoring

C. Parkin[2], D.R. Owens[1], J.J. Gagliardino[3], S. Colagiuri[4]
[1] Cardiff University, Diabetes Research Unit, Cardiff, United Kingdom
[2] CGParkin Communications, 11360 Royal Ct, Carmel IN 46032, USA
[3] La Plata University, Diabetes, La Plata, Argentina
[4] University of Sydney, Institute of Obesity Nutrition and Exercise, Camperdown NSW, Australia

Recent studies have raised important issues regarding the value and utility of self monitoring of blood glucose (SMBG) in non-insulin-treated diabetes (T2DM). In October, 2008, the International Diabetes Federation (IDF) and the SMBG International Working Group convened a conference in Amsterdam to address these issues. Participants included clinical investigators who are actively engaged in SMBG research/research translation. The purpose of the conference was to: 1) review key studies describing the clinical/metabolic impact and the cost-efficiency of SMBG; 2) identify additional studies/study designs that are needed to further define the role of SMBG in T2DM treatment; and 3) identify meaningful approaches for using SMBG in clinical practice to improve treatment outcomes. Participants determined that findings from studies of SMBG used in non-insulin-treated diabetes have been inconsistent due to differences in study designs, populations, and interventions used. Several limitations of published studies, both for and against SMBG, were identified. However, participants agreed that available data do suggest that SMBG is only likely to be an effective self-management tool when results are used appropriately. The following recommendations are proposed: 1) SMBG should be used only when individuals with diabetes and/or their healthcare providers have the knowledge, skills and willingness to incorporate SMBG monitoring and therapy adjustment into their care plan to attain agreed treatment goals; 2) SMBG should be considered at the time of diagnosis to enhance the understanding of diabetes and to facilitate timely treatment initiation and titration optimization; 3) SMBG should be considered as part of ongoing diabetes self-management education to promote better understanding and provide a means for persons with diabetes to actively and effectively participate in its control and treatment, modifying behavioural and pharmacologic interventions as needed; 4) SMBG protocols should be individualized to address each individual's specific educational/behavioural/clinical requirements and provider requirements for data on glycemic patterns and monitor impact of therapeutic decision making; 5) The purpose(s) for performing SMBG and using SMBG data should be agreed upon and subsequent review of data should be documented; and 6) An easy procedure for patients to regularly check on their glucose meter performance should be a requirement for SMBG use. Additional studies are needed and should focus on SMBG as an integral component of diabetes management rather than an independent intervention. Because SMBG can be a component of many different treatment strategies, it is important to study different aspects of SMBG use across the broad spectrum of patient care.

Oral health

M. Massi-Benedetti[1]
[1] *University of Perugia, Internal Medicine, Perugia, Italy*

On the basis of clinical experience, interest is growing on the relationship between oral health and diabetes. However a number of questions still wait for definite answers. In particular, it is not clear whether 1) any pathogenetic association exists 2) oral diseases are expressed with higher prevalence in people with diabetes, 3) suboptimal metabolic control deteriorates oral health, 4) oral diseases induce metabolic instability, 5) periodontitis is the only oral disease related to diabetes, or other conditions like caries, oral infections, xerostomia, etc. can be considered, 6) periodontitis can be considered a microangiopathy-related diabetes complication, 7) specific attention for oral health is to be given to people with diabetes or the already existing indications for prevention and treatment in the general population are sufficient. In order to initiate a process leading to better understanding of such topics, the International Diabetes Federation (IDF) and the International Federation of Dentistry (IFD) joined forces and under the umbrella of the IDF Task Force on Guidelines and, following the "IDF Guidelines for the preparation of guidelines", a document has been produced by an editorial group representing both Federations and comprehensive of members coming from all the IDF Regions. The necessary resources for the production of the Guidelines were generously made available by the Kuwait Foundation for the Advancement of Science. As a result of the analysis of the existing literature it has not been possible to provide exhaustive evidence based answers to the given questions: 1)What level of surveillance for periodontal diseases should be recommended for people with known diabetes? 2) Is active management of periodontitis particularly recommended for people with diabetes? While it has been considered that the already existing guidelines for the general population need to be fully supported by the Diabetes care providers, a strong call for research has been launched to provide the required evidence.

0501

Sleep apnoea

J. Shaw[1]
[1] *Baker IDI Heart and Diabetes Institute, Epidemiology, Caulfield, Australia*

Increasing evidence over recent years has shown that links exist between obstructive sleep apnoea and type 2 diabetes. Much of the association between the two conditions is due to the links that each condition has with obesity. However, a number of studies have suggested that obstructive sleep apnoea predicts the development of type 2 diabetes independently of obesity, and that several features and consequences of obstructive sleep apnoea have a direct effect on carbohydrate metabolism.
Obstructive sleep apnoea is very common in people with diabetes, being reported in up to 90% of patients, and is likely to make blood pressure more difficult to control, increase cardiovascular risk and possibly worsen glycaemic control. Thus, despite most patients with type 2 diabetes being unaware of the presence of obstructive sleep apnoea, screening for obstructive sleep apnoea may be of value, as treatment may improve daytime sleepiness, and reduce cardiovascular risk. Uncertainty remains over how to screen for obstructive sleep apnoea, as the gold standard in-patient polysomnography is not widely available in the developing world and waiting lists for such investigations are often long in the developed world. Focusing screening on those people who report snoring and daytime sleepiness (as they are more likely to comply with treatment), and the use of domiciliary oximetry-based investigations may provide a more practical approach to the identification of undiagnosed obstructive sleep apnoea.
Among people diagnosed with obstructive sleep apnoea, a full assessment of their metabolic status is essential. Such individuals should be screened for diabetes as well as lipid abnormalities and hypertension. To improve patient symptoms and outcomes, it is essential that healthcare professionals primarily involved with the management of either diabetes or obstructive sleep apnoea recognize the likely presence of the other condition, and take appropriate steps to investigate and treat the other condition.

Beta cell mass in the pathogenesis of type 2 diabetes: is it the critical component?

0502

Beta cell mass in the pathogenesis of type 2 diabetes: is it the critical component?

L. Groop[1], *V. Lyssenko*[1]
[1] *Lund University, Lund University Diabetes Centre, Malmö, Sweden*

It has become quite clear that deterioration of beta-cell function predicts and precedes onset of T2D, but it is not known whether this is due to functional defects or a reduction in beta-cell mass. Islet beta-cells are dynamic and must adjust to the needs imposed by e.g. insulin resistance. A typical situation is pregnancy, during which islet mass increases to compensate for the demands imposed by the insulin resistance characteristic of pregnancy. Autopsy studies suggest that patients with T2D show a more than 50% reduction in their beta-cell mass. Recent genetic studies also support the view of a defect in beta-cell mass and cell proliferation. Many of the novel genetic variants increasing susceptibility to T2D encode for cell cycle proteins (CDKAL1) or proteins involved in beta-cell proliferation (TCF7L2). Also carriers of high risk genotypes (the highest 20% risk) cannot increase their insulin secretion to compensate for the increase in insulin resistance. Another surprising finding has been that the same genetic variants which can increase risk of e.g. prostate cancer (HNF1b, JAZF1) or colon cancer (TCF7L") might protect from T2D or vice versa. This has led to the Yin-Yang hypothesis that too much proliferation increases cancer risk but protects from T2D whereas too little proliferation (of beta-cells) increases risk of T2D but protects from cancer. A practical problem is that there are no perfect in vivo measures or images of beta-cell mass. Novel PET techniques might provide some crude tools but at the moment the best measure of beta-cell mass is to measure insulin and C-peptide response to a maximum stimulation by glucose and arginine or GLP-1.
Taken together, whereas existing data clearly demonstrate that failing beta-cells precede onset of T2D, more refined techniques will be needed to explore the relative role of functional defects versus a reduction in beta-cell mass.

CLINICAL RESEARCH

Extrapancreatic effects of the incretins

0503

Basic considerations of incretin action

Y. Seino[1]
[1] *Kansai Electric Power Hospital, President, Osaka, Japan*

The two major incretin hormones are GIP (gastric inhibitory polypeptide/ glucose-dependent insulinotropic polypeptide) and GLP-1 (glucagon-like peptide-1). Both GIP and GLP-1 receptors are expressed in pancreatic β-cells, and GIP and GLP-1 contribute similarly in the promotion of insulin secretion soon after meal ingestion. However, the actions of these incretins can readily be distinguished by their extrapancreatic effects, the physiological importance of which has been clarified using receptor-knockout animal models. Extrapancreatic GIP receptors are found in adipose tissue, stomach, small intestine, osteoblasts, and several regions of the brain. The effect of GIP on fat accumulation is one of its most important extrapancreatic actions. GIP signal inhibition prevents the accumulation of excess fat, ameliorating the accumulation of adiposity by increasing fat oxidation in peripheral tissues, which reduces insulin resistance and improves glucose tolerance. Moreover, in the gastrointestinal tract, GIP inhibits glucose absorption by reducing motility of the small intestine via somatostatin. GIP also has an anabolic effect on bone by protecting osteoblasts from apoptosis. Inhibition of GIP receptor signaling causes high turnover osteoporosis with elevated postprandial plasma calcium levels and increased osteoclastic bone resorption in mice, suggesting

that GIP may link calcium ingested in a meal to its deposition in bone. On the other hand, GLP-1 receptors are expressed in brain, lung, and heart, and the importance of brain and portal GLP-1 receptor signaling in its glucose-lowering effects has been demonstrated. The incretins thus play an integrated and complex role in glucose homeostasis and nutrient intake through both pancreatic and extrapancreatic effects.

Brain effects

R.J. Seeley[1], D.A. Sandoval[1], D. D'Alessio[1]
[1] University of Cincinnati, Medicine, Cincinnati, USA

The traditional model of GLP-1 action is that of a hormone that is secreted by the distal intestine and acts on distal organs to regulate energy balance. This presentation will focus on other aspects of GLP-1 biology that challenge the notion of GLP-1 as a hormone. In particular, growing evidence implicates the CNS as a key site of GLP-1 action not just to regulate food intake but also to regulate blood glucose levels. Implications for GLP-1-based therapies will be discussed.

Incretin biology in the skeleton and cardiovascular system: direct and indirect mechanism

D.J. Drucker[1]
[1] Mount Sinai Hospital, Samuel Lunenfeld Research Institute Room 975C, Toronto Ontario, Canada

Gut hormones are secreted at low basal levels in the fasting and inter-prandial state and circulating levels of most gut hormones increase rapidly following nutrient ingestion. Evidence from rodent and human studies suggests that bone resorption increases significantly in the fasting state, and also falls rapidly following nutrient ingestion. Multiple gut hormones suppress bone resorption following exogenous administration in rodents, and genetic disruption of gut hormone action in mice is associated with a panoply of phenotypes in the skeleton. Specifically, Gipr-/- and Glp1r-/- mice exhibit reduced bone sensitivity via different direct and indirect mechanisms. Gut hormones also regulate cardiovascular function through indirect effects on the autonomic nervous system leading to control of vasomotor function and blood pressure. Moreover, gut hormones may exert direct effects on cardiomyocytes, including regulation of metabolic pathways and cell survival. Gut hormone metabolism, as exemplified by studies of glucagon-like peptide-1, may produce additional diversity in the cardiovascular system, through generation of structurally related peptides which regulate cardiac function through distinct mechanisms. The extrapancreatic biology of incretins, with a focus on skeletal and cardiac biology, will be reviewed.

Inhibition of DPP4 activity

C.F. Deacon[1]
[1] University of Copenhagen, Department of Biomedical Sciences, Copenhagen, Denmark

Dipeptidyl peptidase (DPP)-4 inhibitors are a new class of antidiabetic drugs which, by blocking the enzymatic activity of DPP-4, raise endogenous intact incretin concentrations and result in improvement of glycaemic control. Two inhibitors (sitagliptin, vildagliptin) are already available, and others are undergoing regulatory authority review (saxagliptin, alogliptin) or are in late-stage clinical development (eg linagliptin and others). Although all are small, orally active compounds with selectivity for DPP-4 (versus other DPP-4-like enzymes), the inhibitors differ in their chemistry and pharmacokinetic profiles. Vildagliptin and saxagliptin are peptidomimetics, based upon the dipeptide substrate for DPP-4, while sitagliptin (β-amino acid-based), alogliptin (modified pyrimidinedione) and linagliptin (xanthine) are non-peptidomimetic. Sitagliptin, alogliptin and linagliptin are not appreciably metabolised in vivo, whereas vildagliptin and saxagliptin undergo hepatic metabolism (to an inactive [vildagliptin] or active [saxagliptin] metabolite). Sitagliptin, vildagliptin, saxagliptin and alogliptin (and the vildagliptin and saxagliptin metabolites) are renally excreted, whereas linagliptin has a hepatic route of elimination. The pharmacokinetic half-life varies (from 1½ - 4½ hours for vildagliptin up to 10-40 hours for linagliptin), and although saxagliptin and linagliptin have greater potency (anticipated doses, 5 mg qd) compared to alogliptin (anticipated dose 25 mg qd), vildagliptin (50 mg bid) and sitagliptin (100 mg qd), plasma DPP-4 activity is inhibited by >80% over the full 24-hour period with the therapeutic doses. This is sufficient to raise intact incretin concentrations 2-3-fold, and it therefore seems likely that the anti-hyperglycaemic efficacy of the inhibitors will be similar. As a class, the DPP-4 inhibitors are well-tolerated (side-effect profile similar to placebo), and they lower fasting and postprandial glucose levels with a low risk of hypoglycaemia and without weight gain. They are efficacious as monotherapy, while providing predictable additional efficacy when used in combination with other antidiabetic agents.

LIVING WITH DIABETES

Psychological stress: cause and effect

0507

Psychological stress: cause and effect

G. Chrousos[1]
[1] University of Athens, Pediatrics, Athens, Greece

All organisms exist through maintenance of a complex dynamic equilibrium, homeostasis, which is constantly challenged by intrinsic or extrinsic adverse forces, the stressors. Stress occurs when homeostasis is threatened or perceived as threatened; homeostasis is then re-established by various physiologic and behavioral adaptive responses. Neuroendocrine hormones have crucial roles in the coordination of both basal and threatened homeostasis and mediate the pathogenesis of dyshomeostatic or cacostatic disease states. The stress response is subserved by the stress system, which is located both in the central nervous system and the periphery of the organism. The central effectors of this system are highly interlinked, and include the hypothalamic hormones arginine vasopressin, corticotropin-releasing hormone (CRH) and proopiomelanocortin-derived peptides, and the locus ceruleus and autonomic norepinephrine centers in the brainstem. The peripheral effectors are their end-hormones cortisol, norepinephrine, epinephrine and immune CRH. The targets of these effectors include the executive/cognitive, reward, and fear systems, the wake/sleep centers of the brain, the growth, reproductive and thyroid hormone axes, as well as the gastrointestinal, cardiorespiratory, metabolic, and immune systems. Appropriate basal activity and responsiveness of the stress system is a crucial prerequisite for a sense of well-being, successful performance of tasks, and positive social interactions. By contrast, inappropriately elevated or decreased basal activity and/or responsiveness of this system might impair growth, development and body composition, and may account for many behavioral and somatic pathological conditions. The former include anxiety, depression, psychosomatic disorders, chronic pain and fatigue syndromes, chronic insomnia, and addiction; the latter hypofertility, visceral obesity, metabolic syndrome with or without diabetes mellitus type 2, sleep apnea, and osteopenia/osteoporosis, along with chronic inflammatory cardiovascular and neurovascular sequelae. Chronic stress is thus a major factor of accelerated aging with multiple associated morbidities and premature mortality.

Interaction of aetiological factors in type 2 diabetes - key to prevention?

0508

Genetics

G.A. Hitman[1], S. Finer[1], V. Rakyan[1]
[1] Barts and The London School of Medicine and Dentistry, Centre for Diabetes and Metabolic Medicine, London, United Kingdom

Type 2 Diabetes (T2D) is a multifactorial disease with significant genetic and environmental components. In the last 2 years there has been an exponential increase in the number of genes associated with disease; from 3 to over 20. These include genes in cell cycling control, transcription factors and cell signalling. Many of new genes associated with diabetes are involved in pancreatic beta cell function, underlining the importance of defects of insulin secretion as a prime cause of T2D; other genes identified mediate their effect on weight balance. Recent gene discovery has been made possible by rapid changes in the technology (bioinformatics and analysis) and the use of adequately powered studies to detect modest size effects (odds ratio between 1.1-1.4). Despite this rapid progress, the genes identified do not explain the majority of the genetic component of T2D, indicating that there is likely to be another incremental step required to understand the genomics of diabetes. Additional approaches include mapping aetiological SNPs, study of CNVs, investigation of rare variants accounting for common disease, expression profiling and epigenetics.
The study of epigenetics provides a direct link with the triggering environmental component. For many years it has been realised that ***in utero*** nutritional factors can prime the foetus towards insulin resistance and diabetes. Genome-wide epigenetic reprogramming occurs during gametogenesis, implicating early foetal development as a period susceptible to environmental influence. There is also evidence of trans-generational effects of environmental factors associated with diabetes that can be reversed by correcting the nutritional deficiency. The field of epigenomics is rapidly evolving with a movement away from the study of single genes to whole genome platforms. It is hoped that these advances will provide some of the missing clues in T2D, but more importantly lead to novel strategies to prevent and treat the disease.

The role of the intra-uterine environment in the aetiology of type 2 diabetes

S. Ozanne[1]
[1] University of Cambridge, Clinical Biochemistry, Cambridge, United Kingdom

Epidemiological studies have revealed that there is a relationship between poor early growth and the development of type 2 diabetes. Compelling evidence has emerged over the last fifteen years to suggest that early environmental factors such as nutrition play an important role in this relationship. Studies of individuals who were ***in utero*** during a period of famine, the Dutch Hunger Winter, have shown a direct relationship between maternal nutrition and glucose tolerance in the offspring. Further support for the importance of the fetal environment has come from studies of monozygotic twins who were discordant for type 2 diabetes. These revealed that the diabetic twins had significantly lower birth weights than their non-diabetic co-twins. A number of animal models have been developed to investigate the mechanisms by which the early environment determines future susceptibility to disease. The most extensively studied is the maternal low protein model where rats are fed a low (8 %) protein diet during pregnancy and lactation. The offspring have a low birth weight and undergo an age-dependent loss of glucose tolerance. This is associated with ß cell dysfunction and insulin resistance. The ß-cell dysfunction is accompanied by reduced expression of the transcription factor HNF4a and the insulin resistance is associated with changes in expression of key insulin-signalling proteins (including protein kinase C zeta and the p110ß catalytic subunit of PI 3-kinase) in muscle and adipocytes. These changes in insulin signalling protein expression are strikingly similar to that observed in tissue biopsies from young men with a low birth weight. These proteins may be molecular markers of early growth restriction and thus disease risk. The molecular mechanisms by which a phenomenon that occurs ***in utero*** has a phenotypic consequence many years later are only just starting to emerge and are thought to involve epigenetic modifications.

Stress in early life

D.I.W. Phillips[1]
[1] MRC Centre, University of Southampton, Southampton, United Kingdom

There is a large body of human and animal evidence showing that adverse environments during fetal life or infancy are linked with a higher prevalence of diabetes in adult life. Animal experiments also show that these adverse early environments also result in a heightened biobehavioral response to stress, with increased activity of the classical mediators of the stress response, including the hypothalamic-pituitary adrenal axis and autonomic nervous system. These changes are transgenerational, affecting stress responses in subsequent generations. Recent studies suggest that the same processes operate in human populations and may have important consequences for the susceptibility to diabetes. The evidence suggests that an adverse early environment, or markers of an adverse environment such as low birth weight, are linked with long-term alterations in these neuroendocrine systems. However, these studies also demonstrate that there is a considerable degree of heterogeneity in the responses observed, which appear to depend on a variety of factors such as the nature or timing of the adverse exposure as well as the gender of the offspring. The mediators of these classical neuroendocrine responses such as cortisol and catecholamines are biologically potent and may directly influence diabetes susceptibility by means of their effects on metabolism. However, lifelong changes in the set point of these neuroendocrine systems triggered by early adversity may also influence the course of development during early life leading to the generation of a phenotype adapted for adult adversity. This may predispose to diabetes if the actual environment encountered in adult life differs from that expected, which is likely to occur, for example, with overnutrition and the development of obesity.

Lifestyles intervention

J. Karalliedde[1], M. Koteshwara[2]
[1] King's College London, Cardiovascular, London, United Kingdom
[2] Guy's and St Thomas' Hospital, Diabetes, London, United Kingdom

Type 2 Diabetes Mellitus (T2DM) affects nearly one in 20 adults worldwide and more than 300 million cases are projected worldwide by 2025. At time of diagnosis of T2DM there is often clinical evidence of diabetic complications. Strategies that focus on prevention of T2DM are essential and lifestyle intervention and/or pharmacological intervention have been extensively evaluated. Healthy living with due emphasis on diet and exercise was thought to prevent the occurrence of this disease even in the ancient world. Modern large-scale epidemiological studies have unequivocally proved this ancient wisdom right.
In the Diabetes Prevention Program (DPP) study lifestyle intervention (diet and exercise) reduced the incidence of diabetes by 58% in subjects with impaired glucose tolerance (IGT) whereas metformin demonstrated a 31% reduction. Studies from India and China confirm the effectiveness of lifestyle intervention in preventing T2DM. Recent studies have demonstrated that increased insulin sensitivity is a major factor in this risk reduction, with emerging evidence supporting an effect of physical activity on insulin secretion. In parallel to lifestyle intervention, research has focused on the prevention of T2DM with pharmacotherapy. Metformin, acarbose, thiazolidinediones (TZD) and orlistat reduce the incidence of T2DM by between 30-80% in IGT populations. The combination of metformin or TZD with lifestyle intervention does not have an added benefit in South-Asians. Use of pharmacotherapy can result in drug related adverse events, and there are long term concerns regarding safety, tolerability and compliance with such medications. Data from the DPP study indicate that the treatment effect of pharmacotherapy is not sustained after cessation of treatment. In a recent meta-analysis of T2DM prevention trials lifestyle intervention was as effective as pharmacological intervention.
Pragmatic and practical lifestyle interventions that delay or prevent the onset of diabetes which can be applied to 'real life' clinical practice are required.

Peer diabetes self-management support: does it work?

M. Heisler[1]
[1] University of Michigan, Internal Medicine/Health Behavior and Health Education, Ann Arbor, USA

In light of the growing prevalence and health care costs of diabetes, health care providers must improve the efficiency and effectiveness of their diabetes care. A key element of effective diabetes care is providing effective and sustained support for patients' diabetes self management. Peer support, defined as "support from a person who has experiential knowledge of a specific behavior or stressor and similar characteristics as the target population," may be a particularly potent means of providing sustained and flexible support for diabetes patients' self-management, combining the benefits of both receiving and providing social support. This presentation will provide a brief overview of different approaches to mobilize peer support for diabetes self-management, provide evidence to date on the relative effectiveness of each of these models with an emphasis on research on ways to extend face-to-face programs through the use of innovative technologies, discuss limitations of current research on peer support, and conclude with a discussion of directions for future research in this area.

Role of lay health worker on primary prevention of type 2 diabetes

B. Rodriguez[1]
[1] IDF SACA Regional Office, Education and EC member, Montevideo, Uruguay

The use of community health workers (CHWs) or lay health workers has been increasingly popular as a means to reach minority populations in hard-to-reach and underserved communities who have chronic conditions such as diabetes. The role of lay health workers in primary prevention of type 2 diabetes is an evolving area of interest in the public health arena. In 2009, the National Diabetes Education Program (NDEP) launched the Road to Health Toolkit (RTH) to assist CHWs in the prevention of type 2 diabetes. Following Diabetes Prevention Program study findings, toolkit messages emphasized lifestyle changes. Adult learning theory and Bandura's Social Cognitive Theory were used in the development of the RTH Toolkit to give CHWs guidance in encouraging and supporting behavior change. The purpose of the RTH Toolkit was to prepare trainers to train CHWs in African American and Hispanic/Latino communities, and, in turn, CHWs to use the Toolkit with their communities. This presentation will discuss the role played by CHWs in primary prevention of type 2 diabetes and lessons learned in using the Toolkit and train-the-trainer materials. A series of day-long English and Spanish sessions with CHWs and CHW trainers were implemented. We used information gathered from urban and rural CHWs and CHW trainers, both at these sessions and afterward, to better understand the roles of CHWs and determine tools needed in preventing type2 diabetes. Feedback from the sessions demonstrated that the utilization of CHWs or lay health workers as health educators for primary prevention of type 2 diabetes requires the development of effective training methods to prepare them to make a critical impact. To play a meaningful role, CHWs reported needing low-technology and portable tools, such as flipcharts. They also responded well to using a storytelling approach in the toolkit. Tools, such as the RTH Toolkit, can help increase the effectiveness and community participation of CHWs and allow them to be effective agents of change that contribute to the development, promotion and health recovery of underserved communities.

Peer education in Cambodia

M. van Pelt[1], H. Lucas[2], C. Men[3], V. Ou[4], W. Van Damme[5]
[1] MoPoTsyo Patient Information Centre, Director, Phnom Penh, Cambodia
[2] Institute of Development Studies, Knowledge Technology and Society, Brighton, United Kingdom
[3] Center for Advanced Studies, Research, Phnom Penh, Cambodia
[4] MoPoTsyo Patient Information Centre, Board, Phnom Penh, Cambodia
[5] Institute for Tropical Medicine, Dpt for Public Health, Antwerp, Belgium

Background: Cambodia's health services cannot meet the enormous and rising needs from people with diabetes. Innovative approaches are required to mitigate the impact of the rising epidemic. Since 2005, MoPoTsyo has been establishing diabetes 'peer educator networks' to detect and support diabetes patients.
Methods: The study is based on analysis of routine monitoring data on blood glucose, blood pressure and body weight for 386 rural diabetes patients who have been enrolled in the programme at least three months, and data from two assessments of a random sample of these patients, carried out in July 2008 and January 2009.
Findings: After 18 months, 10 peer educators had found 474 diabetes patients, two thirds previously unaware of their condition. The data on these patients indicate improvements in Fasting and Postprandial Blood Glucose, and Blood Pressure, even though half of them have not yet consulted a doctor. Their reported health expenditure appears much more affordable than that of most diabetes patients in Cambodia.
Interpretation: In the absence of a massive government or international response to the unmet needs of Cambodians with diabetes, peer educator networks may play a useful role in mitigating the disease's negative impacts on the lives of sufferers by providing a low cost but effective care structure despite the low resource environment.

Volunteer educators of National Diabetes Program of Slovak Republic

A. Bukovská[1], A. Davani[2]
[1] Martin Faculty Hospital and Jessenius Faculty of Medicine University of Comenius, Hospital Pharmacy and Diabetology Educational Center, Martin, Slovakia
[2] Slovak National Endocrinology and Diabetology Institute, Diabetes Center, Lubochna, Slovakia

Aims: Diabetes mellitus (DM) is a metabolic and chronic disease which is not only a medical, but also an economic, social and societal problem for more than 350.000 registered diabetic patients in Slovakia. For improving the quality of life of diabetic patients, education, prevention of acute and chronic DM complications and prevention of the disease across the population, the National Diabetes Program of Slovak Republic (NDP SR) was issued in the year 2000.
Methods: The NDP SR started in 2002 and has been adopted by all 27 realization groups. From 2002 to 2004 it was financed through lottery and other similar channels but it would be better if there were more money for all realization groups. NDP SR Chief Coordinator is Doc. MUDr. Jozef Michalek, PhD., director of National Endocrinology and Diabetology Institute in Lubochna and Slovak Liaisor for the Saint Vincent Declaration. All group managers are volunteers. The NDP SR education system involves apart from other also educators from diabetic patients. Realization group Education of educators from diabetic patients in the field of DM is managed by Ms. Andrea Bukovská, Pharmacist-Assistant and Vice-President of Association of Diabetic Patients of Slovakia (ADPS). Besides new and large-scale preventive and screening programs, health monitorings, education activities for children and adults, very importantly the social counseling and more specific education started. According to this the most important is to prepare professionals. The best of this is studying of social work aimed at diabetology.
Results: By virtue of contract of ADPS and St. Elisabeth University College of Health and Social Work, Signatar of Magna Charta Universitarum Bologniense, from school year 2008/2009 special international study of social work for 46 educators from Slovak Republic and Czech Republic a 3-year Bachelor degree with following up 2-year Master degree study program started.

Conclusions: In conjunction with social work and diabetology a new model of complex health and welfare work by professional educators started. It will be the most effective way as to improve complex care of diabetic patients and risk general public is to have full time professionals.

WORKSHOP

ASSOCIATION DEVELOPMENT

The foot in diabetes: collaborations to improve care

0516

Association developed prevention initiatives: the foot initiative in Cyprus

S. Yiangou[1]
[1] *IDF EUR Regional Office, member - CDA Cyprus, Nicosia, Cyprus*

In 1979, a small group of diabetics and parents of insulin dependent children established the Cyprus Diabetic Association with offices in all towns. We are governed by a Board consisting of 17 members. Elections take place every three years at a General Assembly.
Aims: Support diabetics. Exercise pressure on the Government for better medical care. Establishment of Diabetic Clinics. Raise public awareness to fight ignorance. As volunteers trying to succeed we had to establish a financially strong association.
Diabetes is not just a health problem. It affects the person, the family and the state budget. Though there is no cure for diabetes, effective treatment exists.
Our annual budget is around Euros200.000. This covers: Running expenses, Salaries, Publications, summer camps, financial aid to needy persons.
Our sources are:

- Membership fee of Euro17pa
- Grant from the Ministry of Health and Social Services
- Contribution by Cooperative Societies & banks
- Donations from funerals and pharmaceutical companies

Diabetes is a pandemic with heavy financial burden on 10% of the population almost in every country. It is necessary to render assistance from specialists on payment. The association renders services on a voluntaty basis. We are the supporters of government services and we are the right-hand of the Minister of Health.
What should be done? Governments must support the Associations with generosity at least with 2% from taxes or even VAT. The pharmaceutical companies must support the Associations on an equal merit.
IDF must try to secure European Financial support from funds for NGO's. With regard to other regions, the same procedure has to be followed to the appopriate authorities. We expect more from pharmaceutical companies as we are their customers and it was stated by IDF we are co-partners. The needs of all associations are similar and very high. They must have independence in order to have a good background for the negotiations, especially with the Ministry of Health and other government services on a voluntary basis. We are the supporters of government services and we are the right-hand of the Minister of Health.
Activities: Lectures, Educational Seminars for doctors, nurses and supporters
Educational summer camps for all ages, excursions for adults
Christmas and Easter events
Athletic games
14th November WDD: This is extended for a week and we organised many. We organise press conference with the MOH, live programs through MM and the newspapers. We have booths in all towns making blood sugar analysis and giving leaflets on all matters concerning diabetes. We organise a run around Nicosia with the Slogan. Posters are sent to Hospitals, Villages and Municipalities. We light the Municipality with Blue colour.
Medical scheme: The Scheme covers 70% of the population with free treatment and medication. We are in the process of establishing a new Scheme.
Benefits: All diabetics have free examination, referral, Insulins, drugs, Laboratory analysis, Strips for glucose analysis.
Epidemiological research: In Cyprus the percentage is very high, compared with other EU countries. Between 2002 and 2004 a scientific research was carried out and the final result was that the percentage of diabetics is 10.3% of the population.
To tackle the problem of diabetes, we need to learn from each other's experience, especially from the developed countries.

Lower extremity amputation prevention in the Philippines - the value of international collaboration

M.T.P. Que[1]
[1] *East Avenue Medical Center, Department of Internal Medicine, Quezon City, Philippines*

The Philippines is a developing nation with a population of 90 million. In 2005, the National Nutrition and Health Survey reported a diabetes prevalence of 4.6% among adults aged 20 years or more. There are numerous diabetes clinics and diabetes specialists throughout the islands. However diabetes nurse educators are very few and diabetes education programs are limited.
In many hospitals, transfemoral amputation for infected diabetic foot lesions is quite common. In 1995, Mr. Ron Raab from Australia and who is now currently IDF Vice President, paved the way for an Australia Aid grant for footcare training in the Philippines. For five years, footcare and wound training for doctors and nurses were carried out in various regions by 2 Australian podiatrists and one wound specialist nurse. Subsequently, one endocrinologist went to the United States to learn the LEAP program-the Carville approach through a grant from the International Diabetes Federation Education Fund. She also observed various podiatry clinics in Singapore and King's College in London.
There are now some dedicated diabetes foot clinics. Data from the Diabetic Foot Clinic, East Avenue Medical Center (1999) show that foot ulcers are the most common presenting problem. Initial reports from this hospital have also shown a decrease in the rate of lower extremity amputations from 67% (1998) to 22% (2003). Through the national diabetes association and other private entities, foot workshops have been performed since 1996 to date. Physicians obtain knowledge updates by attending scientific conventions and through collaborations with the International Working group on the Diabetic Foot.
Interest in the diabetic foot remains high among physicians who appreciate the multidisciplinary nature of the specialty. Though much more has to be done, the presence of local champions will ensure that the progress that has been achieved so far will be sustained.

LIVING WITH DIABETES

Dealing with diabetes through narration

0518

Dealing with diabetes through narration

C. Feste[1]
[1] *Humedico, Minneapolis, USA*

Stories take an educational offering into its true realm of lived experience. Folktales and personal stories play a role in connecting the intellectual and emotional levels of diabetes information. This understanding translates into personal meaning which will serve to inform and shape a person's behavior. Stories told by patients to healthcare professionals provide helpful information that can reveal problems that may compromise attempts at self-management. Their stories can also reveal strengths to build on as they recall personal successes as well as a family history of courage and problem solving.

Improving the quality of life of people with diabetes in the 21st century: does IDF have a role to play?

M. Ruíz[1], M. Ruiz Morosini[1], C. Pecci[1], F. Lombardo[1]
[1] Sociedad Argentina de Diabetes, Argentine Medical Association, Buenos Aires, Argentina

Quality of life is defined as individual´s perception of the position in life of the person in the context of the culture and value systems in which he lives and in relation to his goals, expectations, standards and concerns. Perception of the health status is modified by different factors: physical, social and psychological. The challenge for the team is to teach the self care of the diabetes taking into account experiences, expectations and believings.
We have to consider how to improve the quality of life of our patients through different ways: creating diabetes associations, making better professional training in the care of people with diabetes, fighting for accessibility, and considering education in special situations such as illiteracy.
The International Diabetes Federation has a challenge to create new tools for education to the patients, to emphasize interaction among pairs, with discussion, learning by playing and entertainment.
The Dawn programme reinforced the idea of attitudes, wishes and necessities of people with diabetes, studying the impact of social and psychological issues, observing that more than 40% has a great emotional suffering, that´s why IDF must consider this area.
Other point is the problem of illiteracy in patients with diabetes. It is difficult to imagine the dimension of the challenge faced by people with diabetes who cannot read or write. A great opportunity to share experiences and education with peers are the camps. In Argentina, there are a lot of them organized by the Federation of Diabetes, the Organization that joint Associations of Diabetes.
Other way to increase the quality of life is teaching the health team. In our experience an importan point is to teach nurses who impact on the quality of life of the patients because generally they are the first step in diabetes care.
We agree with the model that emphasizes the diabetes care centered in the patient with more independence, participation and decision making in contrast with that centered in the physician.
In summary, the quality of life depends on the level of education of the patient.

Diabetes care in Taiwan: present status and possible solution

L. Chuang[1,2]
[1] National Taiwan University Hospital, Department of Internal Medicine, Taipei, Taiwan
[2] Chinese Taipei Diabetes Association, Taipei, Taiwan

The mortality of diabetes has remarkably increased from 3.7/100,000 in 1960 to 44.6/100,000 in 2007 in Taiwan. Due to launch of universal health insurance since year 1995, we could estimate the cost, complications in people with diabetes based on the claimed data.
With the database collected in 1996~2005, we observed an increasing trend in the prevalence of T2DM for both men and women, with the highest growth among those aged <40 and >80 by approximate 50% since year 1999 to 2004. During 1999~2004, we observed a decrease in the rate of newly diagnosed stroke, severe peripheral vascular disease, and severe eye disease, however, the incidence of severe cardiovascular disease and severe renal disease rose substantially, indicating a substantial increasing trend in T2DM disease burden in Taiwan, in particular a remarkable increase of incidence in young male individuals.
To help diabetes self management, since 2004 the Bureau of Health Promotion of the Department of Health of Taiwan has entrusted a non-governmental organization to develop the supporting program of diabetes patients self-help groups. Up to 2008, there are 437 groups (326 communal-based, 102 hospital-based, 9 NGO-based) formed to assist with diabetes prevention work in Taiwan. Which allows the diabetes patients, their families and high risk people to better understand, accept the diseases and to practice self-care that also allow better prevention and management of diabetes in the families and community as early as possible.
Due to governmental instrument, we hopefully can improve diabetes control at the national level in Taiwan.

Is regional co-operation important for economically weak associations?

N.M. Baldé[1], M. Bah-Sangaré[1], A. Kaké[1]
[1] Guinea Diabetes Association, Endocrinology, Conakry, Guinea

The associations are powerful tools for advocacy. However, the objectives of the associations may exceed this depending on the resources available to them. Available resources have a direct impact in the effectiveness of the activities of associations. Thus, the ability to mobilize resources is an important criterion for judging the actual performance of associations. While associations may have a very strong influence in terms of mobilizing resources including financial, the new associations generally lack experience and have no budget. As associations that belong to the same region often share the same problems, the strongest associations and more experienced can share this experience with associations less experienced or weaker. Hence the value of cooperation. Based on the experience in West Africa, we present in this paper how weak associations can benefit from regional cooperation. This regional cooperation can be illustrated by the sharing of ideas and experience, but also by the value of the example to influence policy makers. This may illustrate the value of successful examples how associations can, in the same context, have a positive influence in the cause of diabetes. Thus, regional cooperation between associations is an exceptional teaching effectiveness that can benefit associations to resolve problems.

Digital camera screening for diabetic retinopathy - experience from Ethiopia

A. Reja[1], W. Hailu[2], L. Quant[3], E. Kibru[4], T. Teshome[4], H. Wharton[3], A. Gladwell[3], P.M. Dodson[3]
[1] Addis Ababa University, Internal Medicine, Addis Abeba, Ethiopia
[2] Black Lion Hospital, Diabetes Centre, Addis Abeba, Ethiopia
[3] Heartlands Hospital, Heart of England Diabetic Retinopathy Screening Centre, Birmingham, United Kingdom
[4] Addis Ababa University, Opththalmology, Addis Ababa, Ethiopia

Similar to what is happening in other developing countries, diabetes with its chronic complications is fast becoming an important public health problem in Ethiopia. The magnitude of diabetic retinopathy in Ethiopia is not well known as there has not been screening programme for diabetic retinopathy. The Ethiopian Diabetes Association and the Diabetes Centre of Black Lion Teaching Hospital, Addis Ababa University with the direct support of Heart of England Diabetic Retinopathy Screening Centre (HEDRSC) of Excellence, Heartlands Hospital, Birmingham, UK have started a Programme called LEOPARD - Lions Ethiopian Ophthalmic Programme Against Retinal Diseases and Diabetes. Ethiopian staff were trained on digital camera screening for diabetic retinopathy in Birmingham. Similar technology and protocols to the English Diabetic Retinopathy screening programme have been introduced into the Black Lion Diabetes Centre (BLDC). Primary grading was performed by trained staff in the BLDC. All photographs were rechecked for quality assurance by HEDRSC grading staff. During the first year, a total of 493 diabetic patients completed the screening protocol (47% male, 51% female). Mean age 47 years (range 8 to 78 years). 33/493 (7%) patients had best binocular visual acuity (VA) of 6/60 or worse and 61/493 (12%) had best binocular VA of 6/36. Final grading showed that 190/493 (39%) patients had no DR and 58/493 (12 %) had ungradable image sets. Retinopathy status in the remainder (49 % of total) was background 17 %, pre-proliferative 7%, proliferative 4 % and 28% had referrable maculopathy. Inter-grader agreement between BLDC and HEDRSC was 92% for those returned to annual screening, 69% for those requiring urgent referral, and 98 % for specifically identifying sight threatening DR for referral. After 18 months screening, the digital camera technology employed is sustainable, and the BLDC trained staff have achieved accurate identification and referral for sight threatening DR.

IDF through the decades: have we met our aims?

0523

IDF through the decades: have we met our aims?

M.M. Arab[1]
[1] *Alexandria University, Medicine, Alexandria, Egypt*

After the discovery of insulin, the dream of humanity was to eradicate diabetes and completely prevent it. Unfortunately, the diabetes caring community could never achieve this goal, in spite of the combined efforts of: (1) scientific progress, using advanced technologies, (2) efforts to improve clinical care and prevention procedures and (3) dedicated voluntary work by national and international diabetes caring associations.
Among the major current indicators of global failures in the fight against diabetes are: a high mean global prevalence 6%, which is still increasing, high incidence of several major complications (such as cardiovascular 22%, nephropathies 27%, retinopathies 32%, amputations 3%, etc) and an alarming total global mortality (3.2 millions/ year).
In spite of this, there are several positive global achievements, and the IDF has contributed very well to such achievements.
Among the highly evident achievements of the IDF is its rapid growth since it was established (now 200 member associations from 180 countries). An undoubted IDF success also is the huge development of global awareness about diabetes and its problems, which has been always promoted by the WDD celebrations and was finally rewarded by the UN Declaration on diabetes.
Other outstanding IDF achievements are in the field of education and in developing programs to improve performance of physicians and nurses in diabetes management.
These positive IDF contributions to global achievements were made possible through systematic and dynamic planning of a large spectrum of activities in the form of: periodic IDF Congresses, IDF publications and guidelines, establishing specific Task Forces for particular objectives, organizing workshops and training programs, and several other activities.

LIVING WITH DIABETES

Living with diabetes: a family approach

0524

Living with diabetes: a family approach

M. Hirst[1]
[1] *Stirlingshire Scotland, United Kingdom*

The diagnosis of type 1 diabetes presents particular challenges to the family, especially if the child is diagnosed at a young age. With parents understandably anxious and protective, is there a danger that the siblings may feel resentful at the attention given to their sibling with diabetes, or at the inevitable changes to normal family life following such a diagnosis?
While advances in insulin therapy and diagnostics procedures have certainly made care and treatment easier, there is still a strong emotional challenge for the family. Siblings should be encouraged to feel involved in the care of their brother or sister with diabetes, and should provide support in enabling that brother or sister to live as normal a life as possible.
Members Associations likewise have a role to play, not only in planning activities for young people with diabetes, but also in engaging in a practical way with their siblings.
A diagnosis of type 2 diabetes in a young person, though thankfully comparatively rare, represents a significant failure in parenting, and poses special challenges to the family. Can they all make the dramatic changes to their collective lifestyle in order to help the child who has been diagnosed? Does the psychological support necessary exist, and can it be accessed by the family? And if there is no change in the lifestyle circumstances which led to the diagnosis of type 2 diabetes, what hope is there for the child and other siblings? At what point should health authorities try to intervene, and what can they reasonably do?
Michael Hirst's presentation will reflect on the longer term effects on his family of diagnosis of type 1 diabetes in his youngest child nearly twenty-five years ago. Were there adverse consequences to the other members of his family, and how were they tackled?

Turning diabetes to my advantage

0525

Turning diabetes to my advantage

G.M. Bunyan[1]
[1] *Sydney, Australia*

Aim: Too often diabetes is seen as a "life sentence". It is someone else's fault, and someone else's problem, and if you organise your life around your diabetes, this will always be true.
Turning diabetes to your advantage is about taking control and responsibility. It's your diabetes and you have to decide how you want to live your life.
This presentation is about recounting experiences of someone with no more expertise than 30+ years living with diabetes: years of organising diabetes around a life and finding unexpected advantages.
The experience is just one of many of a life lived, with all of its successes and failures.
The "Unexamined Life"
On diagnosis you have two choices:
- to be a victim; or
- to take control

Socrates famously said the unexamined life is not worth living, and the same can be said of one's life with diabetes. Understanding it, taking control, engaging other people, managing one's partnerships, always searching for ways to live better with diabetes is essential. Unexamined, the diabetes life may not be worth living.
Turning diabetes to one's advantage is about:
- Taking responsibility
- Not being defined by one's diabetes
- Accepting it is "my diabetes" and taking control
- Recognising that diabetes and passion are not strange bed fellows
- Building one's knowledge and confidence to manage one's diabetes and - the medical team
- Telling stories to learn and to reflect on mistakes and to find better solutions
- Recognising the impact of one's diabetes on those closest to you
- Knowing how to influence change and taking the experience into one's life beyond diabetes
- Giving to others and reaping the professional, personal and health benefits
- Realising this is **not** all about you
- Never giving up

Dr Atul Gawande says that saving lives rests on lifting performance. Lifting one's own performance in the way one manages and lives with diabetes is all about living one's life fully, but this is just one story about taking the experiences diabetes can give you, and turning (some of) them to your advantage.

4T final results

R.R. Holman[1], A.J. Farmer[1], M.J. Davies[2], J.C. Levy[1], J.L. Darbyshire[1], J.F. Keenan[1], S.K. Paul[1]
[1] OCDEM University of Oxford, Diabetes Trial Unit, Oxford, United Kingdom
[2] Leicester Royal Infirmary, Metabolic Medicine, Oxford, United Kingdom

Type 2 diabetes mellitus is a progressive condition in which glycated hemoglobin (HbA1c) levels rise inexorably over time as beta cell function declines. Maintenance of near-normal glycemia reduces the risk of diabetic complications but is difficult to achieve, despite the use of multiple oral antidiabetic agents. As a result, oral therapy requires repeated escalation, with the majority of patients requiring insulin in the longer term. There remains, however, considerable uncertainty as to which insulin regimen should be used when oral therapy becomes insufficient to maintain normoglycemia. Analogue insulins are now widely used but there is no consensus about whether therapy should commence with the addition of a biphasic, a long acting or a short acting insulin preparation, or when a second insulin formulation should be introduced. The Treating to Target in Type 2 Diabetes (4-T) is a 3-year, multicentre, open-label, randomized, controlled clinical trial conducted in 58 UK and Irish centres. A total of 708 patients with type 2 diabetes, who had suboptimal glycemic control while receiving maximally tolerated doses of metformin and sulfonylurea therapy, were randomized. We report the final results comparing the efficacy and safety of adding open-label analogue insulin to oral glucose lowering therapy using either twice-daily biphasic insulin aspart 30, once-daily detemir insulin (twice if deemed necessary) or pre-meal aspart insulin, with the substitution of sulfonylurea therapy by lunchtime insulin aspart, thrice-daily insulin aspart or detemir insulin respectively after one year if HbA1c levels were >6.5%.

Update on ACCORD

M. Riddle[1]
[1] Oregon Health & Science University, Medicine, Portland, USA

ACCORD is studying the effects of intensive glycemic control on cardiovascular (CV) outcomes in the context of defined levels of blood pressure and lipid control in persons with high CV risk. The intensive glycemic strategy was stopped early, after 3.4 median years of randomized treatment (about 60% of the planned time) due an unexpected excess of deaths. Subsequent analyses of epidemiologic relationships between mortality and the rate and degree of improvement of A1c itself have been performed, confirming analyses from other trials showing that higher average A1c is associated with higher mortality-risk. They also showed that the excess risk accompanying the intensive strategy occurred for persons who were unable to achieve A1c below 7%, rather than those who did reach that range of glycemic control. Similarly, analyses of the association between severe hypoglycemia and mortality-risk in ACCORD did not clearly confirm hypoglycemia as a major contributor to excess mortality accompanying intensive treatment. Rates of severe hypoglycemia were associated with higher rather than lower A1c levels. These findings focus attention on the participants who were unable to reduce A1c to the levels attempted with an intensive strategy in ACCORD. Analyses continue with the aim of identifying whether hypoglycemia, weight-gain, or specific drugs, drug-combinations, or drug-dosages may have contributed to increased mortality during intensive treatment. Later analyses after conclusion (at the end of June 2009) of the planned 5.6 median years of follow-up will add further information on mortality and other CV and microvascular endpoints accompanying the intensive strategy, as well as effects of randomized comparisons of strategies for treatment of hypertension and dyslipidemia in this population.

[4] Universität Leipzig, Klinik und Poliklinik für Kinder und Jugendliche, Leipzig, Germany
[5] Centre Hospitalier Universitaire, Département de Pédiatrie, Angers, France
[6] Hannover Medical School, Dept. of Medical Psychology, Hannover, Germany

This prospective, international multi-centre open randomised clinical trial (ISRCTN05450731) investigates if pediatric patients using a combination of insulin pump and realtime continuous glucose monitoring from the onset of Type 1 Diabetes have a better glycemic control after 12 months of type 1 diabetes than those using an insulin pump and conventional self-monitoring blood glucose (SMBG) finger-sticks. The last patient visit for the 12 month study period is September 2009.
160 children (aged 1-16, Mean±SD: 8,7±4,4 years.; 47,5% girls) were randomised within 4 weeks of diagnosis of type 1 diabetes into two groups: Group A (Medtronic Paradigm REAL-Time 522/722 insulin pump system with continuous glucose monitoring) versus Group B (Paradigm 515/715 insulin pump with conventional SMBG measurements). Group B was required to wear the Guardian REAL-Time Clinical (blinded continuous glucose monitor) for 6 days prior to two visits. Each subject participated for 15 months, which includes 12 months treatment and 3 months follow-up. During study, patients regularly attended the outpatient clinic according to local standard care. Analysis of HbA1c, diabetes-associated autoantibodies, fasting C-peptide and Quality of Life (parents via KIDSCREEN-27-proxy and WHO-5, a screening-method for disorders of affection, children (≥8yr) via KIDSCREEN-27) will be performed during study.
Data will be presented for the first time regarding the primary objective of the study: to determine whether pediatric patients using insulin pump system with continuous glucose monitoring from the onset of diabetes have a better glycemic control after 12 months than those with CSII and SMBG. In addition, it will be evaluated whether the use of sensor-enhanced pump therapy from the onset of type 1 diabetes leads to lower daily insulin requirements, higher residual β-cell function measured as fasting C-peptide, lower incidence of severe hyopglycemia or diabetic ketoacidosis and a better Quality of Life of children.

New results on ADVANCE

J. Chalmers[1], S. Zoungas[2], T. Ninomiya[2], A.P. Kengne[2], Q. Li[3], A. Pillai[3], M. Woodward[1], A. Patel[2]
[1] *The George Institute for International Health, Professorial Unit, Camperdown, Australia*
[2] *The George Institute for International Health, Cardiovascular Division, Camperdown, Australia*
[3] *The George Institute for International Health, Statistics, Camperdown, Australia*

Aims: In these new analyses from ADVANCE we examine the risks of clinical outcomes and effects of intensive glucose control by baseline or follow-up clinical characteristics in patients with Type 2 diabetes.
Methods: 11,140 participants were randomised to a gliclazide MR-based intensive glucose control regimen targeting an HbA1c of <=6.5% (n= 5,571) or to standard, guidelines-based glucose control (n=5,569). Effects of the intensive regimen were compared with those of guidelines-based regimens in subgroups defined by baseline or follow-up characteristics. Crude and adjusted risks of clinical outcomes were estimated according to risk factors using Cox proportional hazards models.
Results: Predictors of cardiovascular outcomes included traditional risk factors, as well as albumin-creatinine ratio, atrial fibrillation, HbA1c and duration of diabetes. High urinary albumin levels and low estimated GFR were also independent predictors of both renal and cardiovascular outcomes.
A positive log-linear relationship between clinical outcomes and HbA1c was evident, with 20-25% lower risk of mortality, vascular events and renal events for every 1% lower level of HbA1c during follow-up.
There was no heterogeneity in the effects of intensive glucose control among sub-groups defined by baseline characteristics including HbA1c, age, duration of diabetes, urinary albumin, kidney function and gender. Indeed, treatment effects on major cardiovascular and renal events and mortality proved remarkably consistent.
The results of ongoing analyses on the risks associated with severe hypoglycemia during follow-up will also be presented.
Conclusions: These results from ADVANCE provide new insights into factors predicting risks of complications and confirm the efficacy and safety of the intensive gliclazide MR-based glucose control regimen across a broad range of participant subgroups. They reinforce guideline recommendations that HbA1c be lowered below 7% and to levels as low as 6.5%.

Mortality related to IFG, IGT and HbA1c: a 6 year follow-up of a high risk screening program, the ADDITION Study – Denmark

T. Lauritzen[1], A. Sandbaek[1], M.V. Skriver[1], K. Borch-Johnsen[2]
[1] *Aarhus Universitet, Department of Family Practice, Aarhus C, Denmark*
[2] *Steno Diabetes Centre, Research, Gentofte, Denmark*

Background: An international expert group has recently opened a debate regarding the use of HbA1c for the diagnosis of diabetes.
Aim: To compare the distribution and to study the impact on survival of stratification by HbA1c in a population phenotypically at high risk of diabetes.
Method: In a population-based, step-wise screening programme for T2DM in General Practice we identified 25,640 people at high risk for T2DM based on a previously validated diabetes risk score. 19,666 people meet for screening and had HbA1c values and full classification according to WHO criteria. 1,370 with confirmed type 2 diabetes were excluded from the present analysis, as they were included in a randomised trial of early and intensive treatment (the ADDITION study). All individuals were followed from time of screening until death or October 31th 2008, median follow-up time 6,1 years. Excess mortality was estimated using Cox proportional hazard models and all-cause mortality. Hazard Rates (HR) are adjusted for age, sex, BMI, smoking, systolic blood pressure, and stroke, AMI and cancer before screening.
Results: The table shows the distribution and hazard ratio for mortality (HR) by glucose tolerance status, stratified according to the new suggested criteria for diabetes i.e. HbA1c < 6.0%, 6.0-6.4% and >6.4%. People with normal glucose tolerance (NGT) and HbA1c > 6.4% (N=70) as well as people with combined IFG and IGT (N=390) has significant increased mortality compared to people with NGT and HbA1c < 6.0%. The first group is much smaller than the last.

HbA1c <6.0%	HbA1c 6.0–6.4%	HbA1c >6.4%	
N % HR (CI 95%)	N % HR (CI 95%)	N % HR (CI 95%)	N %
14,521 92.8% 1	1,053 6.7% 1.24 (0.9-1.6)	70 0.4% 3.13 (1.6-6.3)	15,644 100%
762 68.5% 1.36 (0.1-1.9)	310 27.9% 0.91 (0.5-1.6)	41 3,7% 1.70 (0.6-5.3)	1,113 100%
372 49.2% 0.95 (0.6-1.7)	342 45.2% 1.33 (0.8-2.1)	42 5.5% 3.79 (1.8-8.2)	756 100%
390 49.8% 2.17 (1.5-3.1)	321 41.0% 1.48 (0.9-2.4)	72 9.2% 2.17 (0.96-4.9)	783 100%
1524 57.5% 1,5 (1.2-1.9)	973 36.7% 1.2 (0.9-1.7)	155 5.8% 2.5 (1.5-4.2)	2,652 100%

Discussion/conclusion: This study shows that elevated HbA1c > 6.4 is associated with increased mortality independent of glucose tolerance status. In individuals with combined IFG and IGT the risk of death was doubled even in those with HbA1c < 6.0 which may stress the need for a global, cardiovascular risk assessment in all individuals phenotypically at high risk of developing diabetes.

Preconception counseling increases women with diabetes' chances of having healthy pregnancies. The ADA recommends, that starting at puberty, preconception counseling should be included in routine clinic visits for all women with diabetes of child-bearing potential. READY-Girls is a preconception counseling program that targets teens with diabetes.
Aims: To examine the level of knowledge regarding diabetes and reproductive health, and its association with: self-efficacy, benefits, and barriers to seeking preconception counseling; perceived severity and risks of pregnancy-related complications; and initiating discussion with health professionals in teen girls (13 -<20 yrs.) with type 1 and 2 diabetes (T1D, T2D).
Method: To begin evaluating the effectiveness of the revised READY-Girls intervention, we developed a comprehensive diabetes specific knowledge measure with 7 subscales confirmed by factor analysis: preconception counseling (14 items); pregnancy (14 items); contraception (2 items); sexuality (4 items); puberty (2 items); general family planning (4 items); and general diabetes (4 items). Questions were multiple choice problem-solving vignettes developed by a mental model technique with groups of expert health professionals and teens with T1D and T2D. Scores can be summed and are based on 100% correctness. Other variables were Likert-type scales and measured using the validated RHATD questionnaire.
In a multisite randomized control trial, a sample of 76 girls were assigned with equal allocation to a standard care group or a treatment group that received the READY-Girls DVD and book over 3 consecutive routine diabetes clinic visits.

Data were collected pre and post intervention at each session. Both groups also received March of Dime pamphlets to read. Presented are data collected pre and post viewing of half the DVD at the first session. The girls' mean age was 15.7 yrs (range 13-19 yrs; 29% ≥ 17), 5% were African American, and 22% had been sexually active.

Results: Baseline mean total knowledge score for the sample was 66.6% (48.8% - 83.7%). Treatment group had significantly higher total, preconception counseling, pregnancy, and sexuality knowledge change scores than controls (7.0 vs. -4.0, 10.6 vs. -3.8, 9.6 vs. -2.7, 22.8 vs. -0.94; p<.001-.016). Change scores for total knowledge were significantly associated with perceived risk of complications (r=-.490; p<.001), severity (r=.397; p=.005), and benefit (r=.318; p=.025).

Conclusion: The proposed knowledge measure demonstrates content and constructs validity. Teens with diabetes lack knowledge regarding diabetes especially with reproductive health. Findings appear to indicate beneficial effects of the READY-Girls program on knowledge and attitudes.

Needs and desires of diabetes patients regarding communication in Europe: a concept tailored to the desires of patients in Europe

D. Gänshirt[1], F. Harms[1]
[1] European Health Care Foundation, Research, Zug, Switzerland

Diabetes Education and Delivery

The present study evaluated 1500 patients with diabetes regarding medication, education, support, behavioural changes, investment in health care, relationship to all health care system institutions including politics. In addition we investigated the information needs of diabetes patients as well as their attitude towards information received from various interest groups.

70% of the patients reported that the degree of coping with their disease is largely dependent on the degree of information they receive. Diabetes patients seem to have the strongest links to their physicians, the reported level of confidence and support being almost 100%. The remaining groups were significantly less well perceived by patients. Pharmaceutical companies (11%) and politics (1%) were the last in line.

Any provided information for chronic patients must meet high standards and it must provide support in coping with the disease. We have ample evidence that the patients' compliance to treatment as well as their lifestyle behaviour is directly influenced by the extent of information they receive and understand. Besides the doctor the patient is the person with the strongest influence on therapeutic outcome. Consequently patients want to have as much influence on therapeutic decisions as their doctors as clearly stated by 90% of the patients. Patient empowerment is theoretically perceived and desired by most chronic patients. 91% of the chronic patients stated that it is important (31%) or very important (60%) for them to get as much information about prescription drugs as their doctors or pharmacists. Nearly 100% of the patients state that the information they want to receive should be correct, balanced, understandable and supportive and it should be supervised by an independent organisation.

Identification of novel insulin resistance metabolites in a non-diabetic population by global biochemical profiling

E. Ferrannini[1], W. Gall[2], M. Nannipieri[1], M. Anselmino[1], M. Rossi[1], K. Beebe[2], K.P. Adam[2], J. Ryals[2], M. Milburn[2]
[1] EGIR-RISC (European Group for the Study of Insulin Resistance – Relationship of Insulin Sensitivity to Cardiovascular Disease) Coordinating Office Department of Internal Medicine University of Pisa, School of Medicine, Pisa, Italy
[2] Metabolon, Metabolomics, Research Triangle Park, USA

An unmet medical need is the early identification of insulin resistance (IR) with high accuracy. Our goal was to carry out a global, non-targeted biochemical profiling analysis on human plasma samples to identify novel small molecule metabolites that can distinguish insulin-sensitive from IR subjects in a non-diabetic population. Fasting baseline plasma samples from the EGIR-RISC cohort that were representative of the spectrum of insulin sensitivity and glycemic status, based on hyperinsulinemic euglycemic clamp and oral glucose tolerance testing, were analyzed. Several hundred metabolites were detected and quantified in each sample using UHPLC and GC mass spectrometry-based platforms and proprietary cheminformatics software. Analysis showed that 2-hydroxybutyrate (2-HB), creatine, certain fatty acids and other lipid metabolites such as lysoglycerophosphocholines and acylcarnitines, were the most highly significant metabolites separating insulin-sensitive subjects from IR subjects. Quantitative, targeted mass spectrometric measurements were carried out to confirm the screening results for the IR/IS metabolites. To test their clinical significance, these IR metabolites were further measured in 11 morbidly obese subjects (aged 44±8 years, mean±SD) undergoing bariatric surgery. One year after surgery, BMI had declined from 52±7 to 35±6 kg/m^2 (p<0.001) and the M value had risen from 22±11 to 39±10 μmol·min^{-1}·kg$_{FFM}^{-1}$, (p<0.01). Consistent with 2-HB being a sensitive marker of IR, we observed a 1.7-fold reduction in plasma 2-HB concentrations post-surgery for this obese cohort. The significance of these IR metabolites is discussed in the context of their production in IR states, and their observed changes when insulin sensitivity and energy balance are improved.

Gastrointestinal rather than intraislet factors are responsible for diabetic postprandial hyperglucagonaemia

K.J. Hare[1], T. Vilsbøll[2], J.J. Holst[3], F.K. Knop[2]
[1] Gentofte Hospital and The Panum Institute University of Copenhagen, Department of Internal Medicine and Biomedical Sciences, Hellerup, Denmark
[2] Gentofte Hospital University of Copenhagen, Department of Internal Medicine, Hellerup, Denmark
[3] The Panum Institute University of Copenhagen, Department of Biomedical Sciences, Copenhagen, Denmark

Aim: In patients with type 2 diabetes mellitus (T2DM), glucagon levels fail to decrease after oral glucose tolerance test (OGTT) while being normally suppressed after isoglycaemic intravenous glucose infusion (IIGI). Inappropriate intraislet inhibition by insulin has been suggested to be responsible. We therefore studied patients with type 1 diabetes mellitus (T1DM) and no residual beta cell function as well as healthy controls (CTRLs) to determine the role of intraislet as opposed to non-pancreatic (gastrointestinal (GI)) mechanisms.

Method: Nine patients with T1DM (age: 25±3 years; body mass index (BMI): 24±1 kg/m^2; HbA_1c: 8.4±0.4%; fasting plasma glucose (FPG): 9.5±0.7 mM (mean±SEM)) and eight healthy control subjects (CTRLs) (age: 28±2 years; BMI: 24±1 kg/m^2; HbA_1c: 5.0±0.1%; FPG: 5.3±0.1 mM (mean±SEM)) were investigated under fasting conditions on two separate occasions: 1) 4-hour 50-g OGTT (+GI stimulation) and 2) IIGI (-GI stimulation). Patients with T1DM took their long-acting insulin the night before investigations, but did not take any insulin in the morning of experimental days.

Results: Isoglycaemia during the two days was obtained in both groups using 53±5 (T1DM) and 30±3 g (CTRLs) of glucose during the IIGIs (p<0.001), resulting in a GI-mediated glucose tolerance (100 % · (($glucose_{OGTT}$(g)-$glucose_{IIGI}$(g)/$glucose_{IIGI}$)) of -6±10 and 67±23% (p<0.01), respectively. The two glucose stimuli resulted in equal glucagon suppression in CTRLs, whereas patients with T1DM exhibited significantly increased glucagon response to OGTT as compared to IIGI (1,519±129 vs. 1,240±86 pM·4h; p=0.03). This difference in glucagon suppression was even more pronounced during the initial 40 min of the two tests with pathologic hypersecretion of glucagon during the OGTT and suppression during the IIGI (27±13 vs. -33±16 pM·40 min; p=0.02).

Conclusion: These results point towards a pivotal role of the GI tract in diabetic postprandial hyperglucagonemia, which seems to be independent of plasma glucose concentration and pancreatic insulin secretion.

O-0535

A strategy implementing initial therapy with a fixed-dose combination tablet of sitagliptin and metformin in patients with type 2 diabetes provides superior glycemic control compared with a strategy using initial metformin monotherapy over 44 weeks

L. Olansky[1], C.A. Reasner[2], T. Seck[3], D. Williams-Herman[3], E. Luo[3], M. Chen[3], L. Reigle[3], Y. Ling[3], W. Taggart[3], K. Kaufman[3], B.J. Goldstein[3]
[1] Cleveland Clinic, Endocrinology Department, Cleveland OH, USA
[2] University of Texas, Texas Diabetes Institute, San Antonio TX, USA
[3] Merck & Company Inc., Merck Research Laboratories, Rahway NJ, USA

Background and Aim: Initial treatment with combination therapy is an alternative therapeutic strategy that has the potential to achieve and maintain adequate glycemic control in a higher proportion of patients over a longer period of time compared with initial monotherapy followed by add-on therapy. The efficacy and safety of initial therapy with the fixed-dose combination tablet of sitagliptin and metformin (SITA/MET) compared with metformin alone (MET) was assessed over 44 weeks in patients with type 2 diabetes mellitus and inadequate glycemic control (hemoglobin A1c [HbA_{1c}] ≥7.5%) on diet and exercise.

Methods and materials: The double-blind treatment period included an 18-week Phase A and a 26-week Phase B. During Phase A, 1250 patients (mean baseline HbA_{1c} 9.9%) were randomized 1:1 to SITA/MET 50/500 mg BID or MET 500 mg BID, each uptitrated over 4 weeks to SITA/MET 50/1000 mg BID or MET 1000 mg BID, respectively. In Phase A, additional antihyperglycemic agents (AHA) were allowed for patients not meeting progressively stricter glycemic criteria. In Phase B, patients continued their double-blind study medication but, unlike in Phase A, investigators received unmasked HbA_{1c} and FPG results and were to add AHAs as appropriate to achieve glycemic goal per clinical practice.

Results: In this study, AHAs were initiated by the investigator half as often in the SITA/MET group compared with the MET group (8.8% vs. 16.7% of patients, respectively). Over the 44-week treatment period, HbA_{1c} reductions from baseline were -2.3% (95% CI: -2.4, -2.1) for SITA/MET administered as initial therapy and -1.8% (95% CI: -1.9, -1.6) for MET alone administered as initial therapy. The between-group difference of -0.5% favored the SITA/MET group. Fifty percent more patients who initiated treatment with SITA/MET reached the HbA_{1c} goal of <7.0% compared with patients initiating MET alone (46% vs. 30%; p<0.001). Reductions in FPG were also greater in the group initially treated with SITA/MET (-65.0 mg/dL) compared with the MET group (-53.4 mg/dL) (p<0.001). Similar reductions in body weight from baseline were observed in both treatment groups (-1.1 kg SITA/MET; -1.2 kg MET). The incidence of hypoglycemia was low and similar across treatment groups. However, the incidences of abdominal pain and diarrhea were significantly (p <0.05) lower in the SITA/MET group compared with the MET group.

Conclusions: After 44 weeks, a treatment strategy implementing early, aggressive initial combination therapy with SITA/MET in drug-naïve patients provided superior glycemic improvement and a greater proportion of patients achieving HbA_{1c}-goal with similar weight loss, and lower incidences of abdominal pain and diarrhea versus a strategy implementing initial therapy with MET monotherapy.

Dapagliflozin monotherapy in T2DM patients with inadequate glycemic control by diet and exercise: a multicenter phase 3 trial

E. Ferrannini[1], S. Jimenez Ramos[2], W. Tang[3], A. Salsali[4], J.F. List[4]
[1] University of Pisa, Internal Medicine, Pisa, Italy
[2] Hospital Jardines De Guadalupe, Endocrinology, Guadalajara, Mexico
[3] Bristol-Myers Squibb, Global Biometric Sciences, Hopewell, USA
[4] Bristol-Myers Squibb, Global Clinical Research, Princeton, USA

Aims: Dapagliflozin selectively inhibits glucose reabsorption through renal sodium-glucose co-transporter 2. We evaluated dapagliflozin monotherapy over 24 wks in drug-naïve T2DM patients.

Methods: This randomized, double-blind, placebo-controlled, parallel-group trial (MB102-013) enrolled T2DM patients, ages 18–77 y, with inadequate glycemic control by diet and exercise. For the primary endpoint, HbA1c change from baseline at Wk 24, 274 patients with enrollment HbA1c 7.0–10.0% were randomized to placebo (PBO), dapagliflozin 2.5, 5 or 10 mg each morning. Key secondary endpoints included changes in FPG and body weight. Exploratory analyses included HbA1c, FPG, and weight changes in 74 patients with enrollment HbA1c 10.1-12.0%, who were randomized to dapagliflozin 5 or 10 mg.

Results: At Wk 24, dapagliflozin groups with enrollment HbA1c 7.0-10.0% showed mean reductions from baseline in HbA1c and FPG, those with 5 and 10 mg being statistically significant (Table). Mean weight decreases were greater with dapagliflozin than PBO, but did not reach statistical significance. For patients with enrollment HbA1c 10.1–12.0%, mean changes from baseline at Wk 24 included HbA1c: –2.88% (5 mg), –2.66% (10 mg); FPG: –77 mg/dL (5 mg), –84 mg/dL (10 mg); and weight: –2.1 kg (5 mg), –1.9 kg (10 mg). Adverse events were generally balanced across groups, with no related deaths or related serious adverse events. Rates of hypoglycemia and hypotension/dehydration/hypovolemia were similar among PBO and dapagliflozin arms. There were no clinically relevant mean changes from baseline in creatinine or electrolytes. Small, dose-related increases in hematocrit were observed with dapagliflozin. The incidence of urinary tract infections was: PBO, 3 (4.0%); dapagliflozin 2.5 mg, 3 (4.6%); 5 mg, 8 (12.5%); 10 mg, 4 (5.7%); the incidence of genital infections was: PBO, 1 (1.3%); dapagliflozin 2.5 mg, 5 (7.7%); 5 mg, 5 (7.8%); 10 mg, 9 (12.9%).

Conclusion: At Wk 24, dapagliflozin monotherapy produced clinically meaningful decreases in HbA1c and FPG and appeared to be generally safe and well tolerated.

Piragliatin, an allosteric activator of glucokinase, greatly enhances glucose-induced pancreatic islet respiration and insulin release

N. Doliba[1], W. Qin[1], H. Najafi[1], D. Wilson[1], J. Grimsby[2], F. Matschinsky[1]
[1] University of Pennsylvania, Biochemistry and Biophysics Institute for Diabetes Obesity and Metabolism, Philadelphia, USA
[2] Hoffmann-La Roche, Metabolic Diseases, Nutley, USA

The recent discovery of drugs that directly stimulate glucokinase (GK) enzymatic activity is a remarkable development with great promise for the treatment of patients with type 2 diabetes mellitus. These GK activators (GKAs) are mixed-type, nonessential activators of the enzyme lowering the glucose $S_{0.5}$ and increasing the k_{cat} at < 1μM. It was previously shown that the GKA piragliatin (RO4389620, US patent 2007115968, Hoffman-La Roche) lowers the threshold for glucose stimulated insulin release (GSIR) in isolated rat and mouse islets. Piragliatin potentiates GSIR and lowers blood sugar following oral administration to normal and diabetic rodents as well as humans. In the present study we emphasized the effect of piragliatin on mouse islet respiration as the most basic parameter of beta-cell function using a novel optical method based on metalloporphyrin phosphorescence quenching by oxygen. These data are supplemented with insulin release measurements, glucose usage and oxidation data and changes in intracellular Ca^{2+} concentration. Perhaps the most striking result is the effect of different concentrations of piragliatin on GSIR and the respiratory response of isolated cultured mouse islets to a "staircase" stimulus with glucose from zero to 3, to 6, to 12 and then to 24 mM. All concentrations of piragliatin (1, 3, 10 and 30 μM) greatly left-shifted the glucose-dependency curve of O_2 use and GSIR and slightly elevated V_{max} at >1 μM. At 10 and 30 μM of the drug, 3 mM glucose caused maximal stimulation of respiration whereas at lower drug concentrations (1 and 3 μM) 6 and 12 mM glucose augmented respiration further. In contrast to enhancement of insulin secretion, 24 mM glucose was ineffective to stimulate oxygen consumption in all cases, even in untreated mouse islets, suggesting a contribution of glycolytic ATP to stimulation of secretion. Additional experiments confirmed that these effects were due to an increase in glucose usage and oxidation and were consistent with changes in the concentration of free intracellular Ca^{2+}. In summary, piragliatin greatly augmented GSIR, glucose induced respiration, glycolysis and glucose oxidation characterized by a left shift of all glucose concentration dependency curves with little change of the maximal effects. These studies provide critical mechanistic data on piragliatin action and demonstrate the potential of GKAs for improving insulin secretion and glucose metabolism in patients with type 2 diabetes.

Innate immunity in insulin resistance and type 2 diabetes: causes and consequences

S. Shoelson[1]
[1] Harvard University, Research Division, Boston, USA

While it is well appreciated that modern lifestyles and obesity promote insulin resistance, type 2 diabetes (T2D), and associated co-morbidities including atherosclerosis and fatty liver disease, detailed molecular and cellular causes are unresolved. Inflammation of visceral fat is a leading hypothesis, as assessed by changes in leukocyte numbers and the excessive production of an array of cytokines and adipokines. Our lab has been especially interested in identifying initiators of inflammation in adipose tissue and potential avenues for suppressing chronic inflammation as a way of diminishing insulin resistance and risk for T2D and associated co-morbidities. Our pioneering studies with salicylates provide a proof-of-principle that the targeting of inflammation can have a positive impact on metabolic and cardiovascular health and pathology. Much of our recent work with preclinical animal models looks at relative roles of non-immune tissues vs. the immune system, including both circulating and tissue resident leukocyte subtypes. For example, recent unpublished findings show that circulating leukocytes are affected by obesity, and this primes certain leukocytes (e.g. Ly6C+ monocytes) for entry into adipose tissue; at the same time other leukocytes (e.g. T regulatory cells, Tregs) appear to exit adipose tissue as obesity progresses. Anti-inflammatory drugs including salicylates reverse some of these trends in parallel with reversing insulin resistance.

Clinical trials of anti-inflammatory agents

A. Goldfine[1], V. Fonseca[2], K. Jablonski[3], L. Pyle[3], S. Shoelson[4], TINSAL-T2D study team (5)
[1] Joslin Diabetes Center, Clinical Research, Boston, USA
[2] Tulane University Health Science Center, Endocrinology, New Orleans, USA
[3] George Washington University, Biostatistics, Rockville, USA
[4] Joslin Diabetes Center, Cellular and Molecular Physiology, Boston, USA

Chronic inflammation mediated by NF-κB may participate in the pathogenesis of T2D. Salicylates inhibit NF-κB activity. We therefore evaluated salsalate, a non-acetylated prodrug of salicylate, for safety and efficacy in glycemic control and other metabolic parameters in patients with T2D.
TINSAL-T2D is an NIH-sponsored, multicenter, placebo lead-in, randomized double-masked, dose ranging placebo controlled trial; 108 patients aged 18-75 years having HbA1c values of 7.0-9.5% were randomized at 17 sites in the USA to receive salsalate (3.0, 3.5 or 4.0 g/d tid) or placebo for 14 weeks as an add-on to current therapy.
Treatment and control groups were of similar age (56 yr), BMI (34 kg/m^2), gender (58% male), ethnicity, current treatment, and baseline HbA1c (7.7%). For our primary endpoint, all doses of salsalate lowered HbA1c by 0.5% ($p<0.01$). Each dose also decreased mean fasting glucose (27-32 mg/dL) and triglyceride (31-49 mg/dL), and increased mean adiponectin (1.7-2.8 μg/ml) concentrations, compared to placebo. Mild hypoglycemia, which was more common in the treatment groups, was documented only in patients taking concomitant sulfonylurea. Reductions in concomitant diabetes medications were required in the treatment groups, ***vs.*** increases in the placebo group, for safety. No drug related serious adverse events occurred. Salsalate was well tolerated with high mean adherence rates (94-98%), although tinnitus was more prevalent in the treatment arms (20% ***vs.*** 11% placebo).
Salsalate improves glycemia and other metabolic parameters in patients with T2D and may provide an effective, safe and inexpensive new avenue for diabetes treatment. A larger pivotal trial comparing placebo and 3.5 g/d salsalate has been initiated to further establish this concept.
NCT00392678, U01 DK074556

Conflict of interest:
Other substantive relationships: The trial was investigator initiated. Caraco Pharmaceutical provided salsalate and placebo. Lifescan, a division of Johnson and Johnson, provided home glucose monitoring supplies. Mercodia provided assay materials.

Islet inflammation and treatment of type 2 diabetes with IL-1 antagonists

M. Donath[1]
[1] Universitätsspital Zürich, Klinik of Endo & Diabetes, Zürich, Switzerland

Islets of patients with type 2 diabetes have the feature of an inflammatory process reflected by the presence of cytokines, immune cells, β-cell apoptosis, amyloid deposits and fibrosis. Indeed, β-cells from patients with type 2 diabetes display inflammatory markers including increased interleukin-1β expression and decreased IL-1 receptor antagonist. Furthermore, increased islet-associated macrophages are observed in human type 2 diabetic patients. These immune cells are most likely attracted by islet-derived chemokines, produced in response to metabolic stress, and under the control of IL-1β. There is also increasing clinical evidence that points to the role of elevated IL-1β in β-cell failure in patients with type 2 diabetes. Recent clinical studies using an IL-1 receptor antagonist and an anti-IL-1β antibody have shown improved glycemic control and β-cell function. Therefore IL-1 antagonism appears as a new therapeutic approach to type 2 diabetes by targeting the master inflammatory cytokine triggering damage to insulin producing β-cells. It follows

that modulation of intra-islet inflammatory mediators, in particular IL-1β, may prevent insulitis in type 2 diabetes and therefore presents itself as a possible causal therapy with disease-modifying potential.

Inflammation and CVD

V. Fonseca[1]
[1] *Tulane University, Medical Centre, New Orleans Louisiana, USA*

Low grade inflammation has been linked to the development of atherosclerosis and cardiovascular disease (CVD) events. Inflammation is also associated with the development of diabetes, and obesity may be a trigger for stimulation of the inflammatory cascade.
Early in the process, adhesion molecules from the endothelium attract monocytes and enhance their migration into the vessel wall, where they interact with oxidized lipids to form foam cells. Late in the process, inflammation in plaque leads to its rupture and thrombotic events. A wide variety of inflammatory markers can be measured in circulation and the vessel wall, and are increased in diabetes, obesity and CVD. Of these, C-reactive protein can be easily measured in clinical practice and may help in risk stratification in some patients. Nuclear factor kappa B (NFkB) is a transcription factor that may be the "master switch" initiating this process, and is an attractive therapeutic target. Several drugs used in diabetes and CVD modulate the actions of this factor.
Proof that inflammation is a key process in CVD requires that its suppression will lead to a decrease in CVD events. In the Jupiter trial, patients were selected on the basis of moderate cholesterol levels but elevated hsCRP indicating low grade inflammation – often associated with obesity. In such patients treatment with rosuvastatin significantly decreased CVD events. However, it is unclear whether the benefit was obtained by inflammation suppression alone, since LDL cholesterol decreased with the treatment. The TINSAL –CVD trial is using an anti-inflammatory agent which does not lower LDL and will test this hypothesis further.

Reductions in lipids and CV risk markers in patients with type 2 diabetes treated with liraglutide: a meta-analysis

J. Plutzky[1], *A. Garber*[2], *A. Falahati*[3], *A.D. Toft*[4], *N.R. Poulter*[5]
[1] *Brigham and Women's Hospital, The Vascular Disease Prevention Program Cardiovascular Division, Boston, USA*

[3] *Novo Nordisk, Biostatistics, Bagsvaerd, Denmark*
[4] *Novo Nordisk, Liraglutide Medical Affairs, Bagsvaerd, Denmark*
[5] *Imperial College, Preventive Cardiovascular Medicine, London, United Kingdom*

Aims: Patients with T2D have abnormalities in their lipid/CV biomarker profiles that are associated with increased CV risk. In a series of phase 3 randomised controlled trials (LEAD: Liraglutide Effect and Action in Diabetes), treatment with the human GLP-1 analogue liraglutide OD improved HbA_{1c} (1.0–1.5%), produced sustained weight reductions (2–3 kg), and reduced SBP (2–6 mmHg). We assessed the impact of liraglutide on lipids and other CV risk markers.
Methods: We conducted a meta-analysis (ANCOVA) of the six trials comparing liraglutide 1.8 mg OD with common T2D therapies (glimepiride [glim], rosiglitazone [rosi], insulin glargine, exenatide) and placebo (n=3967).
Results: After 26 weeks, TC, LDL, FFA and TG levels all decreased significantly from baseline with liraglutide ($p<0.01$ for all) (Table). Decrease in TC was significantly greater with liraglutide ($p<0.01$) than with rosi, glargine or placebo; decrease in LDL was significantly greater with liraglutide ($p<0.05$) than with rosi, glim, or glargine. Compared with baseline, HDL fell significantly with all interventions except rosi. Versus baseline, liraglutide significantly decreased levels of BNP and hsCRP – 2 key biomarkers of CV risk ($p<0.01$). ApoB levels did not change significantly with any treatments.
Conclusion: Liraglutide significantly improved the lipid profile, and reduced BNP and hsCRP levels, in T2D patients over 26 weeks. Liraglutide may have potential CV benefits in T2D in addition to its documented effects on glycaemic control, weight and SBP.

Effect of LY2189265, a long-acting glucagon-like peptide 1 analog, on metabolic outcomes and GI events in obese patients with uncontrolled type 2 diabetes mellitus (T2DM): The EGO study.

G. Umpierrez[1], *T. Blevins*[2], *J. Rosenstock*[3], *C. Cheng*[4], *E. Bastyr*[5], *J. Anderson*[4]
[1] *Emory University School of Medicine, Division of Endocrinology, Atlanta, USA*
[2] *Texas Diabetes and Endocrinology, Austin, USA*
[3] *Dallas Diabetes and Endocrinology Center, Dallas, USA*
[4] *Eli Lilly and Company, Lilly Research Laboratories, Indianapolis, USA*
[5] *Eli lilly and Company, Lilly Research Laboratories, Indianapolis, USA*

Aims: LY2189265, a novel, long-acting glucagon-like peptide 1 (GLP-1) analog, consists of a DPP-IV-protected GLP-1 analog covalently linked to a human IgG4-Fc heavy chain by a small peptide linker. The aim of this phase 2, randomized, placebo-controlled, double-blind study was to investigate the effect of once-weekly LY2189265 on metabolic outcomes and adverse event profiles over 16 weeks in overweight/obese T2DM patients.
Methods: Patients were randomized to once-weekly subcutaneous injections of either placebo or one of 3 LY2189265 dose regimens: 1.0 mg, 16 weeks; 0.5 mg, 4 weeks then 1.0 mg, 12 weeks; or 1.0 mg, 4 weeks then 2.0 mg, 12 weeks. At randomization, patients were taking stable (> 3 months) doses of oral anti-hyperglycemic agents from any 2 of 4 drug classes (sulphonylurea, biguanide, thiazolidinedione, DPP-IV inhibitor). The primary metabolic outcome was change from baseline at 16 weeks in HbA_{1c}. Secondary measures were body weight, solid mixed meal test post-prandial glucose (PPG) and PPG excursion. Treatment emergent adverse events (TEAEs) were recorded at each visit.
Results: Baseline characteristics for randomized patients (n=262; 49% female; mean T2DM 8.3 years; mean BMI 33.9 kg/m^2; and mean HbA_{1c} 8.2%) were not different between treatment groups. Compared to placebo, statistically significant improvements were observed in all metabolic outcomes after treatment with LY2189265, as shown in the following table:

Metabolic Outcome (units)	Placebo	LY2189265		
		0.5/1.0 mg	1.0/1.0 mg	1.0/2.0 mg
Change in HbA_{1c} (%), LSMean	-0.3	-1.3*	-1.3*	-1.5*
Change in weight (kg), LSMean	-0.1	-1.6*	-1.4*	-2.5*
Test Meal PPG AUC, mean	36.4	30.7*	32.2*	28.2*
Test Meal PPG AUC Excursion, mean	10.9	8.9*	9.9*	8.2*

*p<0.05 vs placebo; AUC, area under the curve

The overall incidence of patients with hypoglycemic episodes was not significantly different across the treatment groups (overall p=0.85), although episodes were numerically more frequent in the LY2189265 treated groups. LY2189265 was generally well tolerated and there was no statistically significant difference between groups for nausea (all treatments: 13.0%, p=0.43), diarrhea (8.8%, p=0.45) or abdominal distension (8.0%, p=0.26), which were the most frequently recorded TEAEs.

Conclusions: In conclusion, adjunctive administration of once-weekly LY2189265 in patients with T2DM sub-optimally controlled by OAHs resulted in significant reductions in HbA_{1c}, body weight and AUC for postprandial glucose and glucose excursion.

Exenatide once-weekly versus twice-daily: comparison of diurnal and postprandial glucose patterns using continuous glucose monitoring and ambulatory glucose profile analysis

R. Mazze[1], E. Strock[1], R. Cuddihy[1], B. Morgan[1]
[1] International Diabetes Center, Academic research, Minneapolis, USA

Aims: Our aim was to employ continuous glucose monitoring (CGM), for the first time, to graphically and statistically represent diurnal glucose patterns produced by administration of exenatide once-weekly or twice daily to compare their impact on glucose exposure, variability and stability.

Methods: Progressive loss of GLP-1 is a major underlying defect associated with type 2 diabetes. Exenatide, a synthetic duplicate of exendin-4 with prolonged action, injected twice daily before meals has been used to respond to postprandial hyperglycemia. An extended action formulation of exenatide administered by injection once each week is under investigation. Exenatide once-weekly consists of biodegradable polymeric microspheres composed of exenatide with a stabilizer incorporated into a matrix of poly (D, L-lactide-co-glycolide). Subjects with type 2 treated with oral agents or insulin were administered either exenatide once-weekly or exenatide twice-daily for a period of up to six months. CGM was employed to characterize diurnal glucose patterns at baseline and after stabilization with exenatide. Ambulatory glucose profile analysis (AGP) was used to graphically and statistically represent glucose exposure, variability and stability. Area under the median curve was used to measure diurnal glucose exposure; inter-quartile range was employed to characterize variability and; average absolute hourly rate of change between consecutive CGM values represented stability. Additional study endpoints were HbA_{1c} and weight.

Results: Sixteen patients participated in the study (9 exenatide twice-daily/7 exenatide once-weekly). There was no significant difference in entry age (~61 years), BMI (~34kg/m2) or HbA_{1c} (~8.3%) between cohorts. Summarized in the table below are the changes in glucose exposure, variability and stability from baseline to study end. There was no significant difference between the improvements found in both groups. HbA_{1c} decreased by an average 1% point in the exenatide once-weekly group versus 0.7 % points in the twice-daily cohort (NS). Weight lowered by an average 4 kilograms in both groups.

See table 1

Conclusions: Once-weekly and twice daily formulations of exenatide were equally effective in reducing overall glucose exposure and variability while improving glucose stability.

Weekly, biweekly, and monthly albiglutide improves measures of glycemia in patients with type 2 diabetes on background metformin therapy

J. Rosenstock[1], J. Reusch[2], M. Bush[3], F. Yang[4], M. Stewart[4]
[1] Dallas Diabetes and Endocrine Center, Dallas, USA
[2] Denver VAMC, Endocrinology Metabolism and Diabetes, Denver, USA
[3] GlaxoSmithKline, Clinical Pharmacokinetics, Research Triangle Park, USA
[4] GlaxoSmithKline, Alternative Development Program, King of Prussia, USA

Aims: Combination therapy for type 2 diabetes mellitus (T2DM) often involves adding a second agent to metformin. This study examined the effects of dose and schedule of albiglutide, a GLP-1-receptor agonist, on glycemic response, which included an exenatide arm to provide clinical perspective. Several doses and timing schedules were examined for albiglutide efficacy in the whole population and in a subgroup of subjects on background metformin to more directly compare effects with exenatide.

Methods: 356 subjects (mean age 54, BMI 32.1kg/m^2) with T2DM (mean duration 5 years) inadequately controlled with diet/exercise or metformin (mean baseline HbA_{1c} 8.0%) received subcutaneous placebo, albiglutide [weekly (4, 15 or 30mg), every other week (biweekly; 15, 30 or 50mg) or monthly (50 or 100mg)] or non-blinded exenatide (bid, per label) over 16 weeks in this randomized, double-blind, parallel-group, Phase 2 study. The metformin subanalysis included 245 subjects (mean HbA_{1c} 7.82–8.10%).

table 1

	Baseline Exposure (mg-24hrs/dL)	End Exposure (mg-24hrs/dL	Baseline Variability (mg/dL)	End Variability (mg/dL)	Baseline Stability (mg/dL/hr)	End Stability (mg/dL/hr)

HbA_{1c} for Overall Population	n=34	n=34	n=34	n=29	n=30	n=32	n=34	n=35	n=33
Baseline HbA_{1c}	7.99	8.15	8.00	8.01	8.17	7.96	7.91	7.92	8.06
Week 16 change from baseline	-0.54	-0.11	-0.49	-0.87	-0.56	-0.79	-0.79	-0.55	-0.87
Week 16 change from placebo (treatment effect estimate; LS mean)	--	+0.20	-0.26	-0.62*	-0.22	-0.55*	-0.57*	-0.34	-0.60*
*p<0.05									

Results: Across albiglutide groups and placebo, 66–74% received metformin. At 16 weeks, FPG reductions of -1.26, -2.10, -1.80, and -0.07mmol/L for the 30mg weekly, 50mg biweekly, and 100mg monthly doses of albiglutide and placebo, respectively, were obtained for the metformin subgroup, vs -1.44, -1.32, -1.22, and -0.10mmol/L, respectively, for the overall population. Exenatide decreased FPG by -0.80mmol/L. In metformin patients, the highest albiglutide doses in each treatment schedule significantly reduced HbA_{1c} over 16 weeks: -0.78%, 30mg weekly; -0.83%, 50mg biweekly; and -0.77%, 100mg monthly vs placebo (-0.05%, $p<0.05$); exenatide reduced HbA_{1c} by -0.54%. In the overall population, HbA_{1c} was reduced -0.87, -0.79 and -0.87% by 30mg weekly, 50mg biweekly and 100mg monthly albiglutide dosing, respectively, vs placebo (-0.17%, $p<0.005$). Weight loss with albiglutide ranged from 0.4–2.1kg with metformin and 0.9–1.8kg in the overall population.

See table 2 (page 181)

HbA_{1c}<7% was achieved by 43%, 50%, and 46% of subjects on metformin who received 30mg weekly, 50mg biweekly, and 100mg monthly albiglutide, respectively, vs 15% with placebo and 35% in the exenatide group.
Conclusion: Albiglutide was effective in subjects receiving background metformin and provided numerically greater HbA_{1c} and FPG reductions than exenatide.

Prediction of the glycaemic lowering effect of incretin mimetics prior to therapeutic application

P. Augstein[1], L. Vogt[2], K.D. Kohnert[1], P. Heinke[1], G. Fritsche[1], E. Salzsieder[1]
[1] Institute of Diabetes "Gerhardt Katsch", R&D, Karlsburg, Germany
[2] Diabetes Service Center, Karlsburg, Germany

Background and aims: Incretin mimetics are a new class of antihyperglycaemic agents that have the possibility to improve glycaemic control similar to natural incretin hormones. Exenatide, the first incretin mimetic on the market, mediates the re-establishment of glucose-dependent insulin secretion, suppression of elevated postprandial glucagon secretion, and slowing of gastric emptying. Initial application of Exenatide has also demonstrated that some patients meet the expected effects on glycaemic control but others failed. At present, no pre-clinical method predicting low or high Exenatide responders is available. It was therefore the aim of this project to develop and to verify a method allowing identification of low or high responders prior to the therapeutic application of incretin mimetics.
Materials and methods: The Karlsburg Diabetes-Management System KADIS® was used to develop an ***in silico*** method for outcome prediction of therapeutic application of the incretin mimetic Exenatide. For this purpose, KADIS® was adapted to the special requirements. The modified KADIS®-supported program comprises: (1) continuous glucose monitoring (CGM) which was performed first in each study patient; (2) KADIS®-based identification of the current individual metabolic situation; (3) ***in silico*** testing of the metabolic effect of the application of 20µg Exenatide on the 24-h glycaemic pattern; (4) estimation of an Exenatide equivalence factor by replacing ***in silico*** Exenatide by a long acting insulin and titration of the insulin dose required to achieve the same blood glucose lowering effect as Exenatide; (5) relating the patients to high or low responders according to the estimated Exenatide equivalence factor of insulin action. To verify the proposed procedure, 58 non-insulin treated type 2 diabetic patients were involved into the study.
Results: The overall glycaemic lowering effect of 20µg Exenatide was estimated to be 0.81$\pm$ 0.50 mmol/l and equals an insulin dose of 12.6 $\pm$4.8 IU. 41% of the study patients could be identified to be high responders (equivalence factor of insulin action >12.6 IU) to an Exenatide therapy and 59% were low responders (equivalence factor of insulin action <12.6 IU). In the group of high responders the mean daily glucose pattern (MBG) dropped down by 1.15 $\pm$0.57 mmol/l which equals an insulin dose of 17.2 $\pm$3.2 IU, whereas in the group of low responders the MBG dropped down by 0.57 $\pm$0.23 mmol/l which equals an insulin effect of 9.3 $\pm$2.6 IU. In the group of high responders to an Exenatide therapy a higher BMI (31.4 vs. 28.5 kg/m^2), an enhanced endogenous insulin supply (62.2 vs. 49.7 IU/day), and a higher HbA1c (6.7 vs. 6.2%) was observed at baseline.
Conclusions: The metabolic effect of an Exenatide therapy can be predicted prior to therapeutic application by using CGM in combination with KADIS®-based in silico simulation strategy.

Twelve weeks treatment with the DPP-4 inhibitor, sitagliptin, does not induce feedback inhibition on incretin secretion and does not alter somatostatin secretion in patients with type 2 diabetes – a randomized trial

K. Aaboe[1], F.K. Knop[1], T. Vilsbøll[1], C.F. Deacon[2], J.J. Holst[2], S. Madsbad[3], T. Krarup[1]
[1] Gentofte Hospital University of Copenhagen, Department of Internal Medicine F, Hellerup, Denmark
[2] The Panum Institute University of Copenhagen, Department of Biomedical Sciences, Copenhagen, Denmark
[3] Hvidovre Hospital University of Copenhagen, Department of Endocrinology, Hvidovre, Denmark

Increased levels of intact glucose-dependent insulinotropic polypeptide (GIP) and glucagon-like peptide 1 (GLP-1) from acute dipeptidyl peptidase-4 (DPP-4) inhibition have been shown to induce feedback inhibition on incretin secretion. Furthermore, somatostatin secretion is known to be stimulated by GLP-1, which may possibly be enhanced by DPP-4 inhibition. Whether these effects occur during long-term treatment with a DPP-4 inhibitor in subjects with type 2 diabetes (T2DM) is unknown.
A double-blinded, placebo-controlled study was performed over 12 weeks, in which 24 patients with T2DM were randomized to receive either sitagliptin (Januvia®) 100 mg qd or placebo as add-on therapy to ongoing treatment with metformin (=1000mg). In week 0, 1, and 12, subjects were examined with a 240 min standardized meal test (2,370 KJ). Somatostatin, intact and total GLP-1 and GIP responses were calculated as the area under the meal test response curves (AUC).
22 subjects (sitagliptin n=12, mean age 60 years, mean HbA_{1c} 8.3%; placebo n=10, mean age 61 years, mean HbA_{1c} 7.6%) were included in the post-study analysis. Two subjects originally randomized to placebo were excluded due to a deliberate 12% body weight loss. From week 0 to week 1, sitagliptin increased the levels of intact GIP 2-fold (p=0.002) and intact GLP-1 3-fold (p=0.003). In week 12, levels of intact GIP remained elevated, whereas intact GLP-1 did not (p=0.6, week 0 ***vs*** week 12). The increases in intact GLP-1 and GIP in week 1 were significantly different from the changes in the placebo group (both p<0.001). Sitagliptin had no effect on the levels of total GLP-1 (p=0.2), total GIP (p=0.3), or somatostatin (p=0.9). There were no significant changes in the placebo group.
Twelve weeks treatment with sitagliptin in subjects with T2DM does not seem to alter plasma levels of total GLP-1, total GIP, or somatostatin. Thus, the negative feedback observed during acute DPP-4 inhibitor treatment may not occur during prolonged DPP-4 inhibitor treatment in subjects with T2DM, and increased levels of intact GLP-1 do not seem to increase the peripheral plasma concentration of somatostatin.

[5] *Takeda Global Research & Development Center Inc., Analytical Science, Lake Forest, USA*
[6] *Takeda Global Research & Development Center Inc., Biological Science, Lake Forest, USA*

Aims: Initial combination therapy is an emerging strategy to address the multifactorial nature of T2DM from the outset of disease. This study investigated the efficacy and tolerability of initial combination therapy with the DPP-4 inhibitor, alogliptin (ALO), which improves islet cell function, and the TZD pioglitazone (PIO), which reduces insulin resistance.
Methods: In this randomized, double-blind study, two doses of ALO in combination with PIO were compared with ALO alone and PIO alone in patients with T2DM inadequately controlled with diet and exercise (A1C 7.5%-11%). Subjects received ALO 25 mg/d, PIO 30 mg/d, or combination ALO 12.5 + PIO 30 mg/d or ALO 25 + PIO 30 mg/d.
Results: Baseline characteristics were similar between groups (N=655; mean age 53 yrs; diabetes duration 3.2 yrs; A1C 8.8%; fasting plasma glucose (FPG) 191 mg/dL; BMI 31 kg/m^2). Greater improvements in the least-squares (LS) mean change from baseline A1C were observed in the ALO 25 + PIO (-1.71%) vs either ALO (-0.96%) or PIO (-1.15%) (P<0.001) and for ALO 12.5 + PIO (-1.56%) vs PIO (P<0.001) groups. Compared with the monotherapy groups, a significantly (P<0.01) higher percentage of subjects achieved >/=1.0% and >/=1.5% A1C decreases on the ALO 25 + PIO 30 combination (Table). The changes from baseline in LS mean insulin resistance (HOMA IR) at Week 26 were -1.4, -3.4, -3.5, and -3.6 for the A25 alone, P30 alone, A12.5 + P30, and A25 + P30 groups, respectively, indicating a preserved insulin sensitizing effect of PIO when it was coadministered with either dose of ALO. Moreover, subjects receiving either ALO 12.5 + PIO 30 or ALO 25 + PIO 30 also had improvements in HOMA beta-cell function vs subjects receiving either A25 alone or P30 alone; LS mean changes from baseline at Week 26 were 10.5, 17.5, 24.9, and 39.2 for the A25 alone, P30 alone, A12.5 + P30, and A25 + P30 groups, respectively. Hypoglycemia was rare, with no incidences of severe hypoglycemia reported.
Conclusions: These results suggest improved glycemic efficacy due to persistent reduction of insulin resistance and added improvement of pancreatic beta-cell function of an initial combination therapy with ALO + PIO over that of either monotherapy component. Initial improvement of glycemia by these synergistic modes of action may help to provide glycemic durability in the long term.

Table: Clinical Response at Week 26

	ALO 25 mg	PIO 30 mg	ALO 12.5 mg/ PIO 30 mg	ALO 25 mg/ PIO 30 mg

SYMPOSIUM

LIVING WITH DIABETES

Diabetes and disasters: natural and man-made

0549

Floods in Myanmar and earthquake in China

T. Aloudat[1], D. Stow[1]
[1] *International Federation of Red Cross and Red Crescent Societies, Health and Care department, Geneva, Switzerland*

Aim: To explore the understanding and management of diabetes in natural disasters.
Methodology: Two case studies from cyclone Nargis in Myanmar and Sichuan earthquake in 2008, historical survey of past emergency operations and available tools and approaches to health interventions in natural disasters exploring the understanding and management of diabetes and way forward.
Results: In current approaches to health in emergencies and natural disasters taken by the International Federation of Red Cross and Red Crescent Societies (IFRC) diabetes is roughly grouped as part of non-communicable diseases that are seen by many as less of a priority than direct injuries and communicable diseases (both acute and chronic). This is in part due to the overwhelming burden of those diseases in the early stages of emergencies but also to historic considerations that put non-communicable diseases as a task to be managed 'later and by the MoH'.
Diabetes, especially type I carries a specific difficulty in emergencies where managment is not included in the most commonly used tools such as the Interagency Emergency Health Kit (IEHK2006) among others.
In recent years, and with more analysis of the outcomes of natural disasters, it is now evident that while injuries cause the first wave of cases and communicable diseases the next, non-communicable cause a third wave of cases that comes much sooner than many believed earlier.
Conclusion: Diabetes role as a public health issue in natural disasters should be further explored together between humanitarian organisations and diabetes specialists to establish its burden and needs of people with the disease. Once established, collaboration to achieve proper management of diabetes should be mainstreamed and adapted as best practice. This should cover including diabetes in standard health assessments, diabetes management in standard tools, and involvement of diabetes organisations and specialists in relief and development efforts.

Diabetes and disaster: how can we prepare for the storm and the role that camps played in assisting

L. Abramson[1]
[1] *Diabetes Education and Camping Association, Executive Director, Halifax, Canada*

Diabetes camps have for many years provided supplies that remain at the end of their programs for the use of less fortunate programs throughout the world. With the cooperation of diabetes supply companies, these much-needed supplies are distributed via organizations such as Insulin For Life. There is never enough.
On August 29, 2005, Hurricane Katrina hit the southern USA coast, devastating parts of Louisiana, Mississippi and Florida. We all saw the devastation on our televisions at home. I received a call from Tom Karlya, of dLife Television, who asked what could we do to help. Within 48 hours we had the full cooperation of over 100 camps, as well as a number of courier companies and a collection/ distribution source (Pennington). This provided needed supplies for all folks with diabetes in the affected areas. In this workshop, we will be discussing other alternatives for effective global pre-planning.

The question remains, why were we not better prepared for this disaster and others worldwide. There have been several publications written on the topic of disaster preparedness for people with diabetes: There is a wonderful "Disaster Preparedness Guide: for people with diabetes", prepared by the ADA in 2006, that is available free of charge. The American Red Cross also has a booklet on disaster services.
In a book written by Drs. Richard and Diana Guthrie, the chapter on Disaster Preparedness suggests a few websites to consult: www.cdc.gov/docs/hurricanes.html from the Center for Disease Control (2007), www.diabeteshealth.com/read/2008/03/22/5484.html from Diabetes Health magazine
See you at the workshop. Please come with other ideas for sharing.
Thank you
Lorne Abramson, Executive Director, DECA

Darfur / Ethiopia

A.A. El-Sayed[1]
[1] *Sohag Faculty of Medicine, Internal Medicine, Sohag, Egypt*

Darfur and Ethiopia are two very poor and underdeveloped regions in Africa with closely similar geographic, social and demographic features. Both regions have -originally- low average incomes and inadequate infrastructure for medical care in general and care of diabetes in particular. These circumstances had left the regions totally unprepared to deal with unexpected events. So, when disasters (of political instability and civil war, and lack of rain and famine) hit these regions diabetics faced a very difficult situation.
The problems of both regions are similar with differences only in the details. The situation can be summarized in the following points:

1. Epidemiologic data are scarce and the little available information is too limited to give any significant conclusions. Some areas are difficult even to reach.
2. Health care facilities are very deficient (In Darfur, there are three small, underequipped, and understaffed hospitals serving the 7 million population of the region).
3. There is severe shortage in medications required on a day to day basis for treatment of diabetics, particularly insulin. The available amounts of insulin are very limited and the problems of its transportation and storage in the very hot weather and limited availability of electric supply make its validity and usefulness very doubtful.
4. Management of diabetic complications especially the acute ones is very poor and sometimes impossible.
5. Local herbal therapy is the main available treatment for most diabetic patients in the region.
6. In spite of the efforts made by local governments, WHO, regional and international NGOs the situation is still desperate.

During my planned visit to both regions in late June, more details will be obtained and discussion of the different aspects of the situation will be made.

Gaza and Iraq

A. Nikousokhan Tayar[1], *N. Shakeri*[1]
[1] *Iranian Diabetes Society, Educational and Research Center, Tehran, Iran*

Working at a University of Toronto laboratory in 1921 Fred Banting was able to make Insulin. Before this, for thousands of years, a diabetes diagnosis meant wasting away to certain death. Insulin discovery continues to save millions of lives world-wide. Now we have better Insulin and new methods of treatment to control our diabetes. Unfortunately, even today there are many diabetics who don't have access to insulin. Wars are the main cause of **insulin disasters**. In this article I have tried to show the problems of diabetics in Iraq and Gaza during the recent wars.
On March 20, 2003 with the invasion of Iraq by a multinational force, distribution of insulin was stopped. On June 3, trucks carrying tons of insulin arrived at the Iraq border. The shipment was the first insulin to arrive in Iraq since March. Keeping insulin cool in heat of 40–45^{oC} in Iraq without refrigerator was a major problem for diabetics. Even after the war there are many problems in the insulin supply chain in Iraq.
The situation in the Gaza remains critical as the blockade on the territory leaves Palestinians without electricity and with short supplies of medicine. Gaza is one of the most densely populated places in the world. In 2007, United Nations Relief and Works Agency for Palestine Refugees in the Near East treated approximately 23000 diabetic patients in Gaza. 23% of diabetics were considered to be at high risk of complications and death. Existing diabetes care services are inadequate for the needs of patients. People with diabetes in Gaza do not receive the support of dieticians, foot specialists, psychologists or diabetes educators.
Nevertheless, we hope that this article reminds the motivated readers that in a war zone like Iraq and Gaza, there are people living with diabetes, and that these people need help and hope.

Behavioural therapies: useful in diabetes education?

C.J. Greaves[1]
[1] *Peninsula Medical School, Primary Care, Exeter, United Kingdom*

Aims: Optimal evidence-based strategies for improving diabetes self-care are not well established and strategies vary widely in real world diabetes education. This presentation will provide an overview of what is known about promoting self-care behaviour change, with reference to a systematic "review of reviews" of dietary and physical activity intervention and further reviews of diabetes education interventions.
Methods: We searched electronic bibliographic databases for systematic reviews, published from 1998-2008, of interventions for adults at high risk for type 2 diabetes /cardiovascular disease. Two reviewers undertook selection, data extraction, and methodological quality assessment.
Results: 30 articles met the inclusion criteria. These incorporated 129 analyses relating intervention components with effectiveness. Interventions produced clinically meaningful weight loss (3-5Kg at 12 months; 2-3Kg at 36 months) and increased physical activity (30-60mins/wk of moderate activity at 12-18 months). Greater intervention effectiveness was causally associated with engaging social support, targeting both diet and physical activity, and using well-defined /established behavior change techniques. Increased effectiveness was also associated with increased contact frequency and using a specific cluster of "self-regulatory" behaviour change techniques (specific goal-setting, self-monitoring, providing feedback, goal review). Intervention effectiveness was unrelated to intervention setting, delivery mode, study population and delivery provider. Evidence suggested the need for greater consideration of behaviour maintenance strategies.
Additional reviews of diabetes education interventions will be used to discuss the potential applicability of these findings to supporting other diabetes self-care behaviours.
Conclusions: Supporting behaviour change is possible through well-resourced and well designed behavioural interventions. To maximise the efficiency of interventions to support changes in diet and/or physical activity, practitioners and commissioning organisations should include the specific components we have identified as being associated with increased effectiveness. These recommendations may apply to supporting medication adherence and reducing smoking and alcohol use, but further research is needed to establish optimal intervention methods.

Motivation, coherence, barriers or possibilities

T. Lauritzen[1], *S. Rubak*[2]
[1] *Aarhus Universitet, Department of Family Practice, Aarhus C, Denmark*
[2] *Aarhus University Hospital, Department of Paediatric, Aarhus C, Denmark*

In 2020 lifestyle behaviour is believed to be responsible for 70% of all chronic diseases. It is also believed that 80% of all cardiovascular diseases, strokes and diabetes as well as 40% of all cancers can be prevented by healthy eating, regular exercise and tobacco cessation. The paradox is that we are much more successful in inventing new preventive medicine than in helping people living healthily and taking prescribed preventive medicine as recommended.

This presentation will explain the concept, barriers and possibilities of motivational interviewing which was first described by Miller in 1983 and afterwards developed into a coherent theory by Miller and Rollnick in 1991. Motivational interviewing can be learned by most health care providers in order to achieve recognition of health problems, and to promote and maintain behavior change for people with health problems. It is particularly useful in helping people who are reluctant or ambivalent towards a healthier lifestyle. The strategies of motivational interviewing are persuasive more than coercive, supportive more than argumentative. The overall goal is to increase the inner motivation so that change arises from within rather than being imposed from without.
This presentation will also document that motivational interviewing outperforms traditional advice giving in randomized clinical studies and meta-analysis. Although motivational interviewing is no miracle, it seems to be a step forward in helping people living with diabetes.

0555

Applying psychosocial strategies in diabetic patient education

M. Draheim[1]
[1] *American Association of Diabetes Educators, President, Cedar Rapids, USA*

Diabetes education has long been held to be the cornerstone of effective diabetes care. The National Standards for Diabetes Self-Management Education have quantified the processes and structure that result in quality diabetes education programs. As the evolution of diabetes education has progressed, it has become evident that the patient's psychosocial needs, values, beliefs, and expectations strongly impact success related to the person's willingness to learn, apply their knowledge, and then to integrate it into their lifestyle choices for sustained self-management of their health.
The major goal of diabetes education is to provide knowledge and skill training, as well as to help the person with diabetes identify barriers, facilitate problem-solving and develop coping skills to achieve effective self-care management and improve the quality of life.
The AADE7 Self-Care Behaviors® framework provides an accurate and more encompassing perspective of Diabetes Self-Management Education/Training (DSME/T) by measuring behavioral outcomes, rather than solely focusing on completion of required content areas, thereby truly reflecting the best practice of DSME/T.
Based on extensive review of the literature and expert consensus, 7 health-related self-care behaviors were identified as the unique and measureable outcomes of effective diabetes education, thereby shifting diabetes education from a content-driven practice to an outcomes-driven practice. This movement further facilitated a "patient centered/driven" approach to diabetes education and health management.
Population outcomes measurement is a very critical component of Diabetes Self-Management Education/Training. It is very important for the effectiveness of interventions to be documented, enabling an enhanced understanding of which interventions/strategies are most appropriate for a given population. Among other advantages, it informs the practice about effectiveness of specific interventions. It also informs the patient about their health status, allowing them to make informed and effective decisions/choices regarding approaches they select as a part of their diabetes self-care.

Cultivating effective parent-adolescent teamwork for diabetes management

T. Wysocki[1]
[1] *Nemours Children's Clinic, Center for Pediatric Psychology Research, Jacksonville, USA*

Effective daily management of pediatric type 1 diabetes requires organization and attention to recurring treatment and monitoring tasks, such as blood glucose monitoring, insulin administration, dietary intake and physical activity, as well as problem solving to correct or prevent unwanted glycemic fluctuations. While adolescents must acquire skills that enable them to complete these tasks without direct parental involvement, the notion that parents of adolescents should completely withdraw from diabetes management has come under increasing scrutiny. Mounting research evidence over the past decade indicates that healthy parent-adolescent teamwork is a crucial element of effective family management of type 1 diabetes. Several studies have shown that youth with low levels of supportive involvement in diabetes management are prone to adverse outcomes including inadequate treatment adherence, poor glycemic control, excessive health care utilization and poor quality of life. Conversely, those who enjoy more parental support and involvement tend to realize more favorable diabetes outcomes. Other studies point to ongoing affective support, parental monitoring of diabetes management and effectiveness of parent-adolescent communication as important elements of parental supportive involvement.
This presentation will summarize the above line of research, deriving a conceptual model of the variables that may mediate and moderate an effective evolution of the parental role from one of direct involvement in diabetes management to that of consultative and affective support. Randomized controlled trials of pertinent psychological and behavioral intervention strategies will be reviewed, including several ongoing investigations. Gaps in the available empirical research and suggested directions for future research will be offered. The available empirical research suggests that family management of type 1 diabetes during adolescence presents very difficult challenges, but that the accumulation of more knowledge about the family context of successful management and the empirical validation of pertinent psychological interventions offer cause for optimism.

HEALTHCARE AND EPIDEMIOLOGY

Successful models of intervention from around the world

0557

Africa

K. Ramaiya[1]
[1] *Shree Hindu Mandal Hospital, Internal Medicine, Dar Es Salaam, Tanzania*

Although the exact magnitude of the problem in most of the countries in sub-Saharan Africa is not known, diabetes is becoming a serious threat to public health throughout the region. One of the major factors driving the diabetes epidemic in Africa is urbanization. This migration is usually associated with a change in lifestyle from a relatively healthy traditional pattern to an urban environment of increased food quantity and reduced quality, low levels of exercise, smoking and increased alcohol availability. This rapid epidemiological transition is driving the emergence of increasing prevalence rates of type 2 diabetes and hypertension with increase in mortality. At present infective diseases such as HIV/AIDS, tuberculosis and malaria contribute to predominant mortality in sub-Saharan Africa. It is however predicted that by 2020 non-communicable diseases (NCDs) will proportionately overtake infections as the major cause of mortality. The diabetes care delivery agenda in sub-Saharan Africa is dominated by poverty where 33 out of the 40 (82%) of the world's most heavily indebted poor countries are situated. In most of these countries, costs of managing diabetes and its complications have to compete with other national priorities such as anti-retroviral drugs, tuberculosis treatment and malarial control programs.
This presentation will expand on diabetes epidemiology, diseases burden and care delivery in sub-Saharan Africa emphasizing the different models of intervention in the Region. Justification for such models of intervention were (a) the prevalence of diabetes is gradually increasing causing high morbidity, mortality and disability, (b) the increasing potential impact on livelihoods of local communities and increasing expenditure and economic losses within households which are already in poor state, (c) diabetes and other non-communicable diseases (NCDs) threaten to overwhelm already-stretched health services, and (d) diabetes shares common modifiable risk factors with other NCDs thus making diabetes program an entry point for a national NCD program.

Enhancing quality diabetes care in the Americas; role of the Pan American Health Organization (PAHO)

A. Barceló[1]
[1] Pan American Health Organization, Unit of Non Communicable Diseases, Washington, USA

Diabetes is a staggering health problem in the Americas where its prevalence is expected to double between 2007 and 2025. The Directing Council of the Regional Office of the Americas of the World Health Organization, the Pan American Health Organization (WHO/PAHO) composed of Ministers of Health from all countries of the American Continent approved in 2008 a strategy and resolution entitled **Population and individual approaches to the prevention and management of diabetes and obesity**. This strategy and resolution calls for actions by governments, civil society and WHO/PAHO to prevent diabetes and its complications among individuals and communities. In accordance with its commitment WHO/PAHO is currently providing advice to Member States on a variety of issues related to diabetes and its complications. This presentation outlines information about various diabetes projects led by WHO/PAHO in collaboration with Ministries of Health across the American Region. Data produced by these projects include new diabetes prevalence estimates, as well as new indicators of quality of diabetes care. WHO/PAHO is promoting the need to redesign health systems to better manage diabetes and other chronic diseases in primary care settings, across Latin America and the Caribbean. In order to illustrate how this can be done, quality of care demonstration projects have been established in more than 15 countries. The aim of these projects is to improve quality of diabetes care through a collaborative effort. Good examples of success are the VIDA and the Building Blocks projects in Mexico and Paraguay respectively. Various successful diabetes educational programs have been created including distance education courses for health professionals in Chile, Costa Rica, Cuba and Mexico, and for patients in Chile. As a direct consequence of these activities new health policies have been introduced in many countries in the region, supporting improved diabetes testing and use of medication as well as new programs to improve surveillance and management of diabetes. In conclusion there has been an increase in public and health professional awareness of diabetes during recent years in the Americas, and together with the recent political support from Health Ministers, has led to the creation of many new diabetes prevention and control demonstration projects, programs and policies. It is still to be seen if this renewed interest in diabetes prevention and control will translate in diminishing the burden of the diabetes epidemic in the Americas.

Payment for performance

K. Khunti[1]
[1] Univeristy of Leicester, Department of Health Sciences, Leicester, United Kingdom

Diabetes is one of the most common chronic conditions managed in primary care and previous studies have found large variations in care in people with diabetes. A new contract which included the Quality and Outcomes Framework (QOF) for general practitioners in the UK was introduced to improve the quality of primary care. This is the first time a pay for performance incentive scheme has been used to improve the quality of care delivered to all patients in the entire country. A number of studies have shown that overall, there have been improvements in process and intermediate outcomes of care for people with Type 2 diabetes. There is also some evidence that QOF may have reduced inequalities in diabetes care between affluent and deprived areas, but women and individuals from certain ethnic minority groups appear to have benefited least from this initiative. The magnitude of improvement in diabetes care appears to differ between ethnic groups, thus potentially widening existing disparities in care. There is also currently no evidence on the impact of introduction of QOF on morbidity and mortality. QOF is evolving and the indicators are continuously being revised in the light of achievements of targets. There are also a number of limitations to the indicators and less is known about the impact of QOF on aspects of diabetes care not reflected in the framework, including self management and continuity of care. Future indicators are to undergo numerous changes including shifting the emphasis from process to harder outcomes. From 2009, National Institute for Health and Clinical Excellence will be responsible for developing the indicators using a more transparent review process with input from patients, carers, primary care professionals and other stakeholders. Indicators will be assessed on the basis of the cost, as well as their clinical effectiveness.

The role of IT registries

J. Brown[1]
[1] Kaiser Permanente, Center for Health Research, Portland OR, USA

The use of computers in medicine and management creates electronic data that, with effort, can be archived into databases. These databases can then be searched to identify persons with diabetes, using variables such as drugs purchased, hospital discharge diagnoses, outpatient diagnoses, and test results. However, despite the name, the resulting diabetes "registries" are much more than just lists. Many have evolved into large databases containing all available data about persons with diabetes. This allows them to be used to identify gaps in care, and patients at high risk, so that preventive action can be taken. In countries with centralized purchasing, registries can be used to make better decisions about the kinds and amounts of drugs and testing supplies to buy. Registries are also widely used to measure quality of care. In some countries quality results are posted publicly and/or used to determine the payments that doctors receive. A recent innovation is to feed the results of registry analyses back into the electronic medical record, forming a complete circle of data creation and use. Now, scientists and programmers are building diabetes treatment simulators from registry data. When combined with data from randomized clinical trials and with genetic test results and knowledge, these computer programs estimate the lifetime risks and benefits of each specific treatment for each specific person living with diabetes, empowering individuals to see all their options and choose the ones that will be most beneficial and that they can accomplish and afford. Simulation also helps doctors integrate the growing mass of data, research, and guideline recommendations, which has outgrown any brain's capacity to process and remember. Registry data allow simulation to be much safer and more effective, because assumptions about risks can be based on local data and local circumstances, anywhere in the world, including in developing countries.

Conflict of interest:
Employee: The author is an employee of Kaiser Permanente, a not-for-profit health system that has been a leader in developing and using diabetes registries for its own members.
Commercially-sponsored research: Since 1996, Dr. Brown's Center has had research contracts to support the development of a diabetes treatment simulation program, the Evidence-Based Medicine Integrator, from SmithKline Beecham (now GSK), Merck, Sanofi (now Sanofi Aventis), and Takeda Pharmaceuticals North America. Grants also were received from the US National Library of Medicine and the US Agency for Healthcare Quality and Research.
Other substantive relationships: Dr Brown leads the team that developed the Evidence-Based Medicine Integrator, a free, open-source diabetes simulator that is available on Google Code.

A website about diabetes in children and adolescents: interactive contents and evolution

C. Marín[1], V. Salaverría[1], M. Beléndez[2], R. Suria[2]
[1] Fundación para la Diabetes, Madrid, Spain
[2] University of Alicante, Communication & Social Psychology, Alicante, Spain

Introduction: In November 2007, Fundación para la Diabetes launched a site on Diabetes in Children and Adolescents at www.fundaciondiabetes.org, where parents, children and teenagers, teachers, healthcare workers and

the public at large can find information on: training courses and the latest techniques and therapies; forums where to exchange experiences and extend knowledge on recent developments.
Most of the protocols involved in assessing the excellence of health-related websites include such standard indicators as: transparency; ease-of-access; user-friendly; up-to-date content; reliable information sources; degree of interactivity. The site's interactive side comprises forums and message boards, introduced to promote patient empowerment.
Objective: To describe and analyze the evolution of the "Diabetes in Children and Adolescents" site, since its launch, in November, 2007.
Specifically:
1. Describe contents and quantify how different sections on the website have evolved.
2. Analyze levels of activity and user message-content, as exchanged on the site's various forums.

Method:
1. News items, articles, reading material, legal issues, interviews, surveys, activities, letters, links and the Newsletter were all quantified, from inception date through to March 2009.
2. 164 user messages were analyzed. Each message was established as a unit of analysis and assigned several codes; they were also analyzed to establish presence/absence of various coding categories - subsumed under other broader categories: social support, illness and treatment issues, social processes and/or expressing emotions.

Results:
1. Between November 2007 and March 2009: over 350,000 pages were visited; 400 news items, 26 articles and 12 pdf-format books published; 50 legal questions dealt with; resident experts answered over 1,500 user-questions in our Interview section; 1,000 people were polled, in 25 surveys; as many as 30 new activities and projects were announced; 200 Quick Links were created; we received over 200 letters from over 22,000 Newsletter subscribers.
2. Forums: topics discussed were: family (70.1%), symptoms (63.4%), informational support (51.2%), optimism (55.5%), gratitude (48.2%), emotional support (34.1%), discrimination (6.7%), sadness (5.5%).

Conclusions: This website answers the need for information and experience-exchange among those users whom it was designed for, as proven by the rapid growth rate shown by each of the site's interactive sections.
In addition, the forum section provides users with a space where to express specific needs and feelings of a psychological nature and/or matters relating to their families.

The peculiarities of quality of life of adolescents with type 1 diabetes

M. Rusalenko[1], A. Rozhko[1], T. Mokhort[2], E. Moskaleva[3], T. Sharshakova[4]
[1] *The Republican Center For Radiation Medicine and Human Ecology, Endocrinology, Gomel, Belarus*
[2] *Belarusian State Medical University, Endocrinology, Minsk, Belarus*
[3] *Gomel State University of F. Skorina, Endocrinology, Gomel, Belarus*
[4] *Gomel State Medical University, Public health, Gomel, Belarus*

Morbidity rate of diabetes mellitus all over the world point out to the necessity of comprehensive studying the psychological peculiarities of specific social group — adolescents with T1DM, and also their QOL and psychological components.
Objective: To find out the peculiarities of QOL and the psychological well-being of adolescents with T1DM in comparison with their healthy fellows.
Materials and methods: Total 62 **adolescents** with T1DM (28m, 34f), mean age (M±s) 15,1±2,8 yrs (13,00-18,00), age of T1DM manifestation 5,1±3,9 yrs were provided with the questionnaire General and Diabetes Modul PedsQL™4.0 including estimation of «Physical Functioning» (PF), «Emotional Functioning» (EF), «Social Functioning» (SF),), «School Functioning» (ScF); and Scales of Psychological Well-being Inventory (SPWB): «Positive relationships with others» (PR), «Autonomy» (AU), «Environment Mastery» (EM), «Self-acceptance» (SA), «Personal Growth» (PG) and «Purpose in Life (PL).
Results: The decrease of all indices was defined according to General Modul PedsQL™4.0: PF (58,4±16,2; p<0,05), EF (70,8±18,8; p<0,01), SF (75,1±17,4; p<0,01), ScF (42,3±22,1; p<0,05) and Diabetes Modul PedsQL™4.0: EF (49±11,3), DF (60,3±16,2), PF 1 (73,2±21,9) at adolescents in comparison with the healthy ones. The decrease of all the indices was revealed in adolescents with T1DM according to all scales: PR (61,1±10,9; p<0,001), AU (56,4±11,1; p<0,0001), EM (60,1±10,1; p<0,0001), SA (56,6±11,1, p<0,0001), PG (62,8±10,7; p<0,001), PL (62,2±11,1; p<0,001). On having analyzed the data of QOL according to the sex of adolescents and the data of General Modul PedsQL no differences have been received, Diabetes Modul — the indices of DF at boys noticeably lower than at girls (56,6±20,6; p<0,01), as for other scales the boys are leading — on scale EF (57,1±23,8; p<0,01) end SF (77,9±24,8; p<0,01). According to SPWB the data of SA appeared to be higher at boys (60,1±10,1; p<0,01). The analysis of the results allows us to suppose that girls perceive themselves more critical with underestimated self-appraisal and as the result, they better follow the special diet, physical exercises, glucose self-control and all these factors influence positively on their psychological functioning.
Conclusion: The received data point out to the importance of studying in detail QOL phenomenon and ways of optimization for the delivery of professional health and psychological care to the given group of adolescents. The work on anxiety correction is necessary as an excessive mental tension may influence on the physical recovering. This does not have less significance than biological methods of treatment but often turns out to become decisive factors defining the disease outcome.

Impact of sexual dysfunction on the relationship between type 2 diabetic men and their female partners

A. Adegite[1], A. Ohihoin[2], E. Aniekwensi[3], O. Areo[4], E. Okoro[3], F. Puepet[3]
[1] *University of Cape Town/Groote Schuur Hospital, Diabetic Medicine and Endocrine Division, Cape Town, South Africa*
[2] *Jos University Teaching Hospital, Department of Obstetrics and Gynaecology, Jos, Nigeria*
[3] *Jos University Teaching Hospital, Department of Medicine Endocrine and Metabolism Unit, Jos, Nigeria*
[4] *Jos University Teaching Hospital, Department of Surgery Urology Unit, Jos, Nigeria*

Background and objective: Male sexual dysfunction among type 2 diabetics would include disorders of libido, erectile dysfunction(ED), retrograde ejaculation and premature ejaculation.Sexual dysfunction has been associated with a range of negative psychosocial consequnces including anxiety, depression, distress in men and their female partners.Sexual dysfunction compromises multiple aspects of a patient's life and interpersonal relationships. The current study examines the effects of sexual dysfunction on the relationship between type 2 diabetic men and their female partners.
Methods: Consecutive type 2 diabetic men attending a diabetic clinic in Jos,Nigeria were interviewed with the aid of a questionnaire for the presence of ED, reduced libido, premature ejaculation and retrograde ejaculation. Information was also abtained on sociodemographic characteristics, duration of diabetes, relationship consequence of sexual dysfunction and fertility.
Results: Information on sexual function was obtained from 66 patients. The patients' age(Mean±SD) was 56±8.8 years, median diabetes duration was 7 years(range<1-20) and median duration of sexual dysfunction was 3 years.
Fifty three(80.3%) of the patients had one form of sexual dysfunction or the other with overall prevalence of ED, reduced libido, premature ejaculation and retrograde ejaculation being 51.5%, 53.0%, 19.7% and 18.25% respectively. Only three(4.5%) of the participants had relationship problem not attributed to sexual dysfunction.Seventeen(32.1%) of those with sexual dysfunction had relationship problems with their female partners resulting from sexual dysfunction.Nine(17%) suffered resentment and 1 abuse(1.9%) from their partners.Two(3.8%) complained of infidelity while Five(9.4%) said that their partners were not happy/satisfied. Four(7.5%) of the patients had fertility problem.
Conclusion: Relationship problems are quite common between type 2 diabetic men and their female partners.This could impact negatively on the psychic and overall quality of life of these individuals. Sexual dysfunction may also contribute to infertility among these patients.Management should also include addressing the relationship problems and its psychosocial consequences. A study to assess the psychosocial consequences of sexual dysfunction directly from the female partners of type 2 diabetic men may be more revealing

O-0564

Spirituality, transformation and diabetes management in young adults with diabetes

N. Parsian[1], T. Dunning AM[2]
[1] Deakin University, Nursing, Melbourne, Australia
[2] Deakin University, Nursing, Geelong, Australia

Background: Spirituality is an important aspect of wellbeing; which enables people with diabetes to manage their diabetes and stressful situations.
Aims: To explore: 1) how young adults with diabetes defined spirituality, 2) the relationship between spirituality and coping in young adults with diabetes. 'Spirituality' referred to the inner self that empowers people to manage difficult situations, find meaning in life situations and connect with other people and the whole universe.
Methods: An exploratory study was conducted in three phases:
- Survey (n=100) young adults with diabetes aged 18-30 years. Data were collected using the coping questionnaire for young adult with diabetes (CQYAD) and the spirituality questionnaire (SQ) developed and validated for the study.
- Interviews (n=15) with young adults with diabetes.
- Focus groups (n=5) with young adults with diabetes.

Results and findings: Males had higher self-efficacy score and social-focused coping behaviours ($p<0.003$ and $p< 0.004$ respectively). Females were more spiritual ($p< 0.01$). There was no significant difference in spirituality between religious and non-religious participants. Shorter duration of diabetes was associated with higher spiritual needs ($p< 0.02$) and spiritual practices ($p< 0.01$). Coping was correlated with spirituality, Kendall's tua ($p< 0.01$). Self-awareness was significantly related to coping ($p=0.000$) and lower HbA1c ($p<0.01$). The higher the spirituality score, the lower HbA1c ($p<0.04$).
The interview data revealed that participants defined spirituality as 'sense of self', 'connectedness with people and nature', and 'finding meaning in life'. The themes central to the definitions and participants' coping ability were regarding as 'spirituality an essential aspect of life', 'the diabetes journey' and 'the need for holistic care'.
Significantly, these data were confirmed in the focus group; but the group discussion enriched the data and the definition. Participants felt spirituality encompassed 'body, mind, soul and connections to health,' that 'diabetes was a transformational journey,' and that 'health professionals treat diabetes rather than the whole person'.
Conclusions:
- Young adults with diabetes defined spirituality as an essential to holistic care and a transformational journey.
- Spirituality is an important coping strategy for young adults with diabetes and helps them cope with stressful situations and self-manage diabetes.

Development and validation of an 'Activity-Friendliness Index' and its association with residential obesity and diabetes rates

M. Creatore[1], R. Moineddin[2], G. Booth[3], P. Gozdyra[4], F. Matheson[4], J. Weyman[4], J. Dunn[4], R. Glazier[4]
[1] St. Michael's Hospital, Centre for Research on Inner City Health, Toronto, Canada
[2] University of Toronto, Department of Family and Community Medicine, Toronto, Canada
[3] St.Michael's Hospital, Endocrinology, Toronto, Canada
[4] St.Michael's Hospital, Centre for Research on Inner City Health, Toronto, Canada

Aims: There is an association between neighborhood characteristics and the health and health behaviors of residents. This is particularly evident in the development of obesity and type 2 diabetes, conditions which are greatly influenced by a person's physical activity and diet. Herein we describe the development and validation of an urban residential 'Activity-Friendly Index' (AFI). We also examine how activity friendliness relates to obesity and diabetes.
Methods: Through a comprehensive review of the literature and factor analysis we identified a set of variables that formed the AFI. Identified components included the availability of banks, convenience stores, grocery stores and restaurants, access to public transit, dwelling density and size and street connectivity. We used network analysis within a Geographic Information System (GIS) to measure these characteristics using residential points in Toronto, Canada. The index was validated using a variety of measures of physical activity from the Canadian census and population health and transportation surveys. Logistic regression was used to examine the association of the AFI with the likelihood of being obese and having diabetes.
Results: As residential activity-friendliness (AFI) increased so also did rates of walking, cycling, general activity levels and transit use. In contrast, residential activity-friendliness was associated with lower rates of driving and car-ownership. In the most activity-friendly areas (highest AFI quintile) the average daily number of walking or biking trips per person was nearly triple, and the percent of people who walk or cycle to work was 5 to 6 times higher than that found in the least activity-friendly areas. Moreover, the percentage of people with obesity was 23% lower in the highest AFI areas as compared to the lowest. When neighbourhood AFI was evaluated as a risk factor for diabetes, we found that people living in the three lowest AFI quintiles had diabetes rates that were 8-17% higher ($p= 0.05$) than those living in the two highest AFI quintiles. These results persisted after controlling for age, sex, income, visible minority status, and education.
Discussion/conclusions: The Activity-Friendliness Index is significantly associated with residential rates of physical activity. Furthermore, it is significantly associated with residential obesity and diabetes rates. This research identifies potentially modifiable urban design characteristics that, if considered in municipal planning and health policies, may improve health status in urban populations.

Sleep duration, lifestyle intervention and incidence of type 2 diabetes in impaired glucose tolerance: the Finnish Diabetes Prevention Study

H. Tuomilehto[1], M. Peltonen[2], J. Tuomilehto[3], J. Lindström[2]
[1] University of Montreal, Dentistry, Montreal, Canada
[2] National Public Health Institute, Diabetes Unit Department of Health Promotion and Chronic Diseases Prevention, Helsinki, Finland
[3] University of Helsinki, Department of Public Health, Helsinki, Finland

Background: Sleep disturbances have become increasingly prevalent in modern society, affecting millions of people. Both short and long sleep duration have frequently been found to be associated with an increased risk for diabetes. However, the underlying mechanisms are still largely unknown.
Objective: The aim of the present study was to examine the association between sleep duration and type 2 diabetes after lifestyle intervention in overweight people with impaired glucose tolerance in a 7-year prospective follow-up.
Methods: 522 individuals (aged 40-64 years) were randomly allocated either to an intensive diet-exercise counseling group or a control group. Diabetes incidence during follow-up was calculated according to sleep duration at baseline. Sleep duration was obtained for a 24 h period. Physical activity, dietary intakes, bodyweight and immune mediators (CRP, IL-6) were measured.
Results: Interaction between sleep duration and treatment group was statistically significant ($p=0.002$). In the control group, the adjusted hazard ratios with 95% CI for diabetes were 2.25 (1.34-3.76) and 2.92 (1.79-4.78) in the sleep duration groups 9-9.5 h and =10h, respectively, compared with that of 7-8.5 hours. In contrast, sleep duration did not influence the incidence of diabetes in the intervention group; for sleep duration groups 9-9.5 h and =10 h, the adjusted hazard ratios with 95% CI were 1.08 (0.59-1.97) and 0.71 (0.33-1.54), respectively, compared with that in the reference group (7-8.5 h sleep). Lifestyle intervention resulted in similar improvement in body weight, insulin sensitivity and immune mediator levels regardless of the sleep duration.
Conclusion: Long sleep duration is associated with increased type 2 diabetes risk. Lifestyle intervention aiming at weight reduction, healthy diet and increased physical activity ameliorates this excess risk.

EDUCATION

Innovations and application of IT to diabetes education

O-0567

Translating a significant personal experience in stage performance: a new approach for patients and health care providers

B. Barabino[1], *M. Malavia*[1], *J.P. Assal*[1]
[1] *Foundation for Research and Training for Patient Education, Dept. Research and Training, Geneva, Switzerland*

Aims: When confronted with a disease, whether acute or chronic, each individual has to bear its psychosocial burden (illness). We tend to hide our inner suffering. Illness therefore becomes "encapsulated", acting as an internal foreign body which may influence our perception of life, our choices and our attitude towards the disease.
With the aim of helping patients to better cope with their ***disease***, we developed a 3-day-workshop in which 5-6 participants write about a significant personal experience. They are subsequently asked to ***stage-direct their own writing*** with the help of two professional actors and a professional stage director.
If writing allows the participants to verbalize their feelings and emotions, the stage direction enables them to physically express, on stage, their internal suffering.
Methods and results: Today 150 people have participated in the workshops: patients (with diabetes and long-term complications) and health-care providers who are confronted with chronic situations and traumatic events.
A qualitative preliminary study has shown that, after the workshop, the majority of participants develop a more positive attitude towards their ***disease***.
Non-directive interviews, participative observation and ***analysis of video-recordings*** allowed us to identify several elements facilitating the change.

Attitudinal changes	Reasons of change
Improved coping capacity with the suffering associated with a negative event	Taking distance from the painful event
Decreased sense of loneliness and isolation	Sharing one's suffering with other participants
Increased awareness of one's personal power to make creative choices (empowerment)	Becoming stage-director of one's own life experience
Transformation of the negative perception of a life experience with an increased sense of meaning and value	Transforming a painful experience in a symbolic artistic theatrical representation

The improvement observed in the patients motivated health-care providers to take part in this process.
Discussion: The translation of a personal painful experience in a theatrical form, with acted words, music, lights and colors, becomes the occasion to view it, not from the rather fixed standpoint of the symptom and the suffering, but from the ever-creative one of the resources and competences that such experience awakens in each individual. The participant becomes the stage-director of his own history, discovering a new sense of empowerment in the way he can influence his own life. The theatrical process is the tool by which a different value and meaning can be attributed to the painful event. All the participants experienced a sense of liberation and lightness following the workshop.
This kind of elaboration of one's personal experience is the result of a creative process in which the participant is accompanied by experts of the creative expression.

O-0568

A "didactic interactive clock" to visualise the interconnections between various aspects of diabetes care and their integration into patients' daily life schedule

G. Cimarelli[1]
[1] *University Hospital of Geneva, Nursing Department, Genève 14, Switzerland*

Background: Many diabetic patients have difficulties to connect the various aspects of their treatment and integrate them in their daily life schedule. Improved strategies to enhance patients' understanding of the interconnections between treatments and their schedule, action of insulin, physical activity and risks for hypoglycaemias are important.

Method: We created a didactic tool which allows having an overview of the various aspects of diabetes care according to daytime, in a dialog with the patient, to help him to become autonomous in the management of its treatment. As a visual support we used a 24 hour circular clock of plasticized cardboard (1 meter diameter) held on a metallic board. Magnetic cards symbolizing various aspects of treatments were placed on the clock at the relevant time: check glycaemia, take oral antidiabetic drugs, inject insulin, take meals and snacks, make physical activity and recognize risk moments for hypoglycaemia. A card reminding of insulin preparations' action profiles was placed in the centre of the clock. The clock was used during collective courses, but couldn't be printed. Between 1993 and 2008, 1000 patients and 700 nurses benefitted from this didactic contribution. The nurses were asked to evaluate their satisfaction with this tool by filling a questionnaire. Tested items included the perception of interaction of treatments, the visibility of action of insulin, and the utility to use such a tool with the patient to estimate what he retained of the teaching and to make a visual synthesis. Outcomes were measured on an analog scale ranging from 0 to 10.
Results:
Understanding how to use the clock: within 5 minutes.
Interaction of the treatments: 9.9
Visibility of the curves of insulin: 9.9.
Capacity of the tool to allow to make connections with the past or future events 9.7.
Utility to give to the patients these syntheses: 9.9.
Contribution of the clock to evaluate and sum up the diabetic knowledge of the patient: 9.9.
Discussion: Most nurses found the clock easy to use and found it a useful contribution
A computerized interactive version will be available as of April 2009. It could be used with all types of computers. Staff can print the results and give them to the patient.
The use of this tool offers wide perspectives for diabetes type 1 and 2 patients followed as well in a hospital environment as private office. The realization of this synthesis with the patient, allows the nurses to estimate the understanding he has of his treatment, and the patient to visualize a typical treatment day. It is even possible for patients to use the program alone at home to anticipate changes and integrate them into their life.
After using the tool, an evaluation with a questionnaire will be given to the patients with diabetes. Same items as for the nurses will be estimated.

No conflict of interest

O-0569

The Physical Activity and Exercise Tool-Kit: Effectiveness of a new resource for diabetes educators

C. Shields[1], *C. Dillman*[1], *J.R. Fowles*[1], *A. Perry*[1], *R.J.L. Murphy*[1], *P. Dunbar*[2]
[1] *Acadia University, School of Recreation Management and Kinesiology, Wolfville, Canada*
[2] *Nova Scotia Department of Health, Diabetes Care Program of Nova Scotia, Halifax, Canada*

Physical activity and exercise (PAE) are essential in the prevention and management of diabetes. Diabetes educators (DEs) are often looked to as the primary source of information for those living with diabetes and are well positioned to provide counselling on PAE. However, DEs often receive little training in exercise prescription and do not feel adequately prepared to effectively counsel patients regarding PAE. While DEs' personal perceptions (e.g., self-efficacy) have been shown to be key determinants of their behaviour, their beliefs in their clients' abilities (e.g., other efficacy, perceived attitudes) have received little attention. The present study examined the effectiveness of the 'Physical Activity and Exercise Tool-kit" in increasing both DEs' perceptions surrounding PAE counselling and of their clients' abilities in, and attitudes towards PAE. Using a 2 (group) by 2 (time) quasi-experimental design, DEs (N = 121) were assigned to either an intervention or standard care condition. The intervention group was provided with training on PAE counselling including the "Physical Activity and Exercise Tool-kit," a theory driven, evidence based resource specifically designed for DEs. The standard care group was referred to Canada's Physical Activity Guide. Measures of counselling efficacy, referral efficacy, attitudes, and perceived difficulty, as well as other efficacy, and perceived client attitudes were administered at baseline and 6 months. To examine the effectiveness of the 'Tool-kit' three separate repeated measures MANOVAs were conducted. Examination of DEs' efficacy beliefs revealed a significant group by time interaction ($p = .03$). Follow-up tests indicated

that the interaction was significant for counselling efficacy (p = .02) such that participants in the intervention group were more confident about PAE counselling at 6 months (M6mo = 68.3) as compared to baseline (Mbase = 54.0) and as compared to the standard care group at both time points (Mbase = 48.9, M6mo = 50.4). In addition, there were multiple significant main effects for time across the separate analyses. Follow-up tests revealed significant increases over time in DEs' counselling efficacy (p = .01), perceived difficulty (p < .001) and confidence in their clients' ability to manage PAE (p = .001). These findings suggest that the 'Tool-kit' represents an effective training resource for DEs in the area of PAE counselling. While there is the need for examination of the effectiveness of the 'Tool-kit' over the longer term, and on the translation of increased counselling efficacy to improved PAE counselling, the present study suggests that incorporation of the 'Tool-kit' may have best practice implications for the way in which PAE is promoted in diabetes care.

Benefits accrued by augmenting traditional diabetes education with self-management education: a randomized controlled trial

P. McGowan[1], S. Lynch[1], M. Bradshaw[2], S. Prasad[2], B. Leslie[2], F. Hensen[3], A. Dauphinee[4]

[1] University of Victoria, Centre on Aging, Delta, Canada
[2] Vancouver Coastal Health Region, Richmond Diabetes Education Centre, Richmond, Canada
[3] Interior Health Authority, Penticton Hospital, Penticton, Canada
[4] Vancouver Coastal Health Authority, Richmond Hospital, Richmond, Canada

Aims: This goal of this randomized controlled trial was to compare the effectiveness of Diabetes Patient Education to Diabetes Patient Education augmented by participation in the Stanford Chronic Disease Self-Management Program (CDSMP).

Methods: Newly diagnosed adults with type 2 diabetes living in Richmond BC were referred to the Diabetes Education Centre at Richmond Hospital by their family doctor. If they were interested in participating in the project they completed outcome measures and were randomly assigned to a group that would receive regular Diabetes Education (Control Group) or to a Group that would receive regular Diabetes Education and then participate in a community CDSMP (Experimental Group). In total 321 people registered and 169 were placed in the Experimental Group and 152 in the Control Group. Of the 169 subjects placed in the Experimental Group, only 82 completed the community CDSMP. Subjects in both groups completed the outcome measures again at six months. Outcome measures included A1C, weight, self-rated health, Health Distress, Role Limitations, Fatigue, Shortness of Breath, Pain, Self-efficacy, Communication with Doctor, and the Diabetes Empowerment Scale.

Tests were conducted which compared the baseline outcome measure scores of the 87 subjects originally placed in the Experimental Group but who had not participated in the CDSMP to the baseline outcome measure scores of the 152 subjects originally placed in the CG, and no differences were found. A pre- and six-month post- program-matched pair design comparison was used with: a) the 82 subjects originally placed in the Experimental Group who had completed the intervention; b) the 152 subjects originally placed in the Control Group; and c) 239 subjects that comprised the 152 subjects originally placed in the Control Group and the 87 subjects originally placed in the Experimental Group but who had not participated in the community CDSMP.

Results: A pre- and six-month post-program matched comparison design analysis found statistically significant improvements in all three groups in A1C and weight. As well, the Experimental Group had statistically significant improvements in 11 additional outcomes.

The RCT analysis investigated whether the changes in the Experimental Group were significantly different to changes in the Control Group. The Experimental Group had statistically significant greater positive changes than the Control Group in seven outcome measures: Perceived Health Status; Health Distress; Fatigue; Total nights in hospital; Self-efficacy to manage symptoms; Communication with Physician; and the three subscales of the Diabetes Empowerment Scale.

Discussion/Conclusion: Augmenting traditional Diabetes Patient Education with Self-Management Education brings about important additional improvements.

No conflict of interest

O-0571

An innovative approach to provision of diabetes education in the inpatient setting

B. Fusek[1]

[1] Hamilton Health Sciences, Diabetes Care and Research, Hamilton, Canada

Objective: This project evaluates the impact of an educational program rollout with content that is evidence-based and a dissemination plan that utilizes adult education principles, continuous quality improvement strategies and change management theory.

Background: Our program had identified that the consultation process for diabetes specialty services in the inpatient setting was becoming increasingly onerous and yet outcomes were difficult to measure. Average numbers of consults for the 07-08 period were 11 per week. The project was designed to build on the opportunities that the environment provided and work in small successes that would then lead to bigger successes. The percentage of inpatients with diabetes in the surgical departments average 19% and medical departments 48%. Average lengths of stay for the same departments during that period were 8.5 and 10.3 respectively. Since the number of diabetes inpatients is on the rise, it is crucial that front-line inpatient staff have the skills to troubleshoot and better manage diabetes care.

Methods: A review of the literature with regards to change theory, and outcome measures of education provided in health care established the basis for the data collection. Staff completed knowledge tests pre education which were repeated again at 1 month and 6 months post education. Chart audits to reflect the translation of knowledge into practice impacts were conducted. Staff and patient interviews provided insight into the impressions and satisfaction of the roll-out. Quantitative measures such as the number of handouts taken from the "Diabetes Resource Box" added a measure that reflected the use of the tools provided.

Results: The "Plan Do Study Act" cycle was used to move the initiatives forward within the organization. Data collection and interpretation of findings with regards to the evaluation of this implementation is ongoing as of the submission of this abstract. Results will be available in September 2009.

Discussion/conclusion: The initial findings suggested that given the opportunity to brainstorm regarding present practices within the hospital, patient care areas had some interest, ideas and internal capacity to enhance their knowledge, tools and ability to support patients with diabetes. Through individualizing a dissemination strategy and empowering participants to proactively engage in diabetes management the intent was to not only enhance the practice of today, but also build a foundation for sustainable change in the future practice.

Practice implications: The outcomes will be used to inform practice in terms of future plans for internal diabetes education and management. The ongoing sustainability plan will include regular evaluation of the process and setting up accountability at the local level.

No conflict of interest

Community based diabetes self-management (DSM) program for individuals with significant mental illness - a pilot program

G. Lakhanpal[1], K. Matchett[2]

[1] St. Josephs Health Centre, Urban Family Health Team, Toronto, Canada
[2] Etobicoke Medical Centre, Family Health Team, Toronto, Canada

Background: Individuals who are socially marginalized and have significant mental illness (SMI) are at higher risk for developing diabetes. Barriers to using traditional interventions and diabetes education include: physical health and social determinants of health such as language, low health literacy, stigma of mental health and socioeconomic status.

Research suggests DSM Education that includes an empowerment framework, adult education principles, and addresses social determinants of health, may be more effective in clinical and self-management outcomes.

Objectives: 1) Provide access to group education for individuals with SMI. 2) Promote increased knowledge and self-efficacy relating to diabetes management while living with a mental health diagnosis. 3) Promote peer support while using adult education principles.

Methods:

- Setting: Urban primary care clinic linked with a teaching hospital.
- Participants: A total of 11 adults with type 2 diabetes with SMI.
- Program: Designed by a multidisciplinary team using the principles of health promotion and adult education. The program emphasized experiential learning with a focus on goal setting and problem solving strategies. Participants attended 6 or 7 weekly sessions which included the following aspects of DSM: blood glucose monitoring, medication, nutrition, physical activity and stress management. Features of the program included healthy snacks, financial assistance for transportation costs, a pedometer and a program-specific Participant Handbook.
- Evaluation: Participants completed pre- and post- measures of a) satisfaction in knowledge of diabetes and b) satisfaction of self-care related to diabetes. Participants completed a short survey to evaluate each session.

Outcome: The program was successful in increasing access to culturally specific education and supports for socially marginalized individuals with diabetes and SMI. There was a 90-100% attendance rate across both program phases. Participants demonstrated an increase in personal satisfaction of both diabetes knowledge and diabetes self-care. Specifically, participants reported increased knowledge with respect to disease progression, weight management and medication effects. Participants reported behaviour change relating to grocery shopping, eating behaviour and physical activity. Participant literacy levels required adjusting delivery and evaluation strategies.

Conclusions: The program provides evidence for the effectiveness of education that includes the following factors: 1) tailored to the culture of the population, 2) based in empowerment & self-management, 3) address socio-economic barriers to access and participation, 4) promote active learning and peer support.

Ambulatory glucose profile (AGP): development of a common, web-based application to record and report continuous glucose monitoring data

R. Mazze[1], E. Strock[1], R. Cuddihy[1], D. Wesley[1]
[1] International Diabetes Center, Academic Research, Minneapolis, USA

Aims: Develop, clinically test and implement a common web-based system for recording and reporting data from **continuous glucose monitoring (CGM)** devices independent of manufacturer.

Methods: Our secure web-based reporting system has the ability to convert data from commercially available CGM devices into a common program, Ambulatory Glucose Profile (AGP) and display all data without regard to date using five time series smoothed curves (10th, 25th, 50th (median), 75th and 90th frequency percentiles) that **visually** and **statistically** portray overall glucose exposure (area under the curve), variability (inter-quartile range within each hour, averaged across a modal day) and stability (consistent change across all hours of the modal day). AGP graphics are interactive and are accompanied by statistical analysis. CGM devices are uploaded at the user's computer. The AGP program is accessed through a password protected system. AGP parses the raw CGM data, validates it against a set of data quality rules, and loads it into a structured database. The user can then generate an AGP for an individual subject or for a group of subjects. Dietary, activity and medication information can also be entered.

Results: Ninety-two subjects were followed for periods of from two-weeks to one year employing DexCom (DexCom), Navigator (Abbott) or Guardian (Medtronic). For all subjects, CGM data were uploaded to a PC and glucose exposure, variability and stability were reported using a common graphic (not shown) and statistical (see table) format. Using AGP analysis we compared the relative glucose exposure, variability and stability for subjects with various degrees of glucose intolerance and different treatment modalities. We found differences in glucose exposure, variability and stability that were inconsistent with levels of $HbA_{1c.}$ For example, subjects with type 2 diabetes treated with non-insulin therapies produced 46% greater glucose exposure than those with type 1 diabetes treated with pump therapy although both groups had similar average HbA_{1c}.

Conclusions: Glucose data from three commercially available CGM devices were uploaded into the AGP analysis program which allowed direct comparison of glucose exposure, variability and stability of people with type 1 or type 2 diabetes.

	HbA_{1c} (%)	Glucose Exposure (mg-24hr/dL)	Glucose Variability (mg/dL)	Glucose Stability (mg/dL/hr)
Type 1 Pump (8)	7.1 ±1.2	2436±245	72±23	8.4±2.2
Type 1 Multiple Injections (19)	7.9±0.9	3419±1152	78±25	11.5±3.3
Type 2 Insulin (19)	7.8±1.0	2738±774	74±28	12.9±8.5
Type 2 Non-Insulin (46)	6.8±1.0	3558±876	52±17	8.5±3.1

No conflict of interest

IT-based life style intervention tool "Metaboli-Net" is developed and applied to high risk patients for type 2 diabetes

S. Taniguchi[1], N. Yamamoto[1], K. Inoue[1], T. Ohkura[1], H. Kinoshita[1], Y. Fujioka[1], H. Shiochi[1], K. Sumi[1], S. Izawa[1], S. Kuwata[2], M. Takechi[3], C. Shigemasa[1]
[1] Tottori University Faculty of Medicine, Multidisciplinary Internal Medicine, Yonago, Japan
[2] Tottori University Hospital, Medical Informative Section, Yonago, Japan
[3] Ebi Clinic, Internal Medicine, Kofu Town, Japan

Aims: Life style intervention is a basic and economical strategy to prevent diabetes. However, it is quite hard for the high risk patients to get the timely education by health-care specialist. We developed the novel IT-based support system, "Metaboli-Net". In this study, we examined the effect of Metaboli-net on the life-style of prediabetic patients(IGT/IFG).

Methods: We applied this intervention tool for prediabetic patients including IFG or IGT(n=30, M/F=13/17). They were divided into 3 groups and managed by each educator(dietitian). The educating program consisted of three components, 1) self monitoring of diet/exercise/body weight, 2)advice and empowerment approach by educator, and 3)virtual-group work using social network service (SNS). Each participant sends the snapshots of consecutive three days diet using cell phone camera and the exercise record of walking to their homepage. Then, the dietitian estimates the diet balance and the exercise level, and advises the tentative habitual goal for each person. Every one week, the dietitian repeats the same step, finds the custom barrier. Moreover, a participant is allowed to see the record of other participants. This SNS analogue enables them to compete with each other.

Results: After 2 months program, the withdrawal rate was (20%,6/30) The main reason for withdrawal was the trouble to send the snapshot. But, the participants were basically satisfied with the information and specialist's advice supplied via "Metaboli-Net". The participants commented the following: "Metaboli-net is very useful for self-monitoring", "the advice of dietitian is very concrete and easy to follow". In fact, participant achieved some habitual change such as the regular diet intake or exercise reinforcement(67%,16/24) and even the reduction of body weight(29%,7/24). Interestingly, SNS is likely to be effective to maintain the life style intervention, since the sharing of other participants' information activates the self motivation and promoted the communication within the group.

Discussion: In this study, we developed Metaboli-net and applied it to prediabetic patients. Although the withdrawal rate(20%) was higher than we expected, we can improve the system to avoid the program bug. In general, the intervention using web site seems less effective than the direct education in real world. This mainly comes from the one-sided flow of communication. In Metaboli-net, the participants can communicate with their own dietitian and even access the other participants' information. They feel protected and very free to communicate. The better communication is the key to establish the web-linked educating system. In conclusion, IT-based tool "Metaboli-Net" is effective and applicable to intervene the diet unbalance and exercise frequency in prediabetic patients. We expect this tool is also applicable to type2 diabetic patients.

Diabetes education in Africa - gains, challenges and the way forward

A. Jalang'o[1]
[1] *Kenyatta National Hospital, Diabetes Clinic, Nairobi, Kenya*

Aims: To highlight the gains in Diabetes education, identify challenges in Diabetes education and propose possible solutions for effective Diabetes Education.
Methods: Descriptive cross sectional survey by means of questionnaires to countries in sub Saharan Africa. Final results to be expressed in descriptive statistics.
Results: Preliminary results show that in most of the countries surveyed Diabetes care is underway though mainly didactic. Behavioral modification approaches are yet to be instituted. Training of staff is underway and many countries are paying more attention to Diabetes education. Care centres are also being set up or exist in a number of countries. However Policies for non communicable diseases are nonexistent and this often hampers progress in Diabetes care. Particular concerns are lack of guidelines for education and no certification for educators. Career pathways for educators are lacking and trained personnel are often channeled to other departments. All is however not lost, deliberate steps need to be taken to enhance trained staff retention such as providing incentives, certification and career pathways. Care teams for effective care are also not in place in many centres. Political will is also wanting.
Conclusion: Diabetes Education in most African countries is still a novel approach. In most countries, Diabetes Education has been in place for less than a decade. It is imperative that changes are put in place to ensure the adoption of behavior change approaches in Education, and provision of cost effective culturally sensitive material to maximize on limited resources. Staff retention issues also need to be addressed. Research should be an ongoing process to inform the process especially evaluation of centres being set up and the education process and outcome.

Evaluation of the Diabetes Association of Jamaica's Lay Diabetes Education Program

L. Less[1], *E. Morrison*[2], *D. Ragoobirsingh*[3], *M. Boyne*[4]
[1] *Diabetes Association of Jamaica, Education, Kingston 5, Jamaica*
[2] *University of Technology, President, Kingston 7, Jamaica*
[3] *University of the West Indies, Faculty of Medical Sciences, Kingston 7, Jamaica*
[4] *University of the West Indies, Tropical Metabolic Research Institute, Kingston 7, Jamaica*

Objective: To evaluate the effectiveness of lay diabetes facilitators to increase knowledge and improve control among persons with diabetes.
Methodology: A randomized control study on persons with diabetes was done in 16 primary health care centres in Jamaica to compare the effect of ***lay diabetes facilitators*** on Glycaemia, Body Mass Index (BMI) and knowledge. 160 persons with diabetes were recruited for intervention and 160 as a control. HbA1c and BMI were measured at baseline and six months.
Results: Mean A1c at baseline for the intervention and control groups were 7.9% and 8% respectively. After 6 months the intervention group showed a mean decrease of 0.6% while the control group showed an increase of 0.6% ($P<0.001$). There was no statistically significant change in their body mass index between groups. Among the intervention group, 96% had an increased knowledge of diabetes compared to 19.3% in the control group ($P <0.001$).
Conclusion: Patients educated by lay diabetes facilitators were more knowledgeable about diabetes and had improved metabolic control.

0577

Updating primary health care personnel to improve health care delivery in diabetes

T. Johnson[1]
[1] *Lagos University Teaching Hospital, Diagnostic Center, Lagos, Nigeria*

The bulk of diabetes care is provided at the level of primary health care (PHC) and > 80% of adults with diabetes receive their care from primary care physicians.
PHC personnel work as a team (PHCT). They vary in cadres, disciplines and levels of qualification.
Education: in diabetes is a must for the PHCT. It is evidence based and is regularly updated from within the diabetes education community. Education should apply to new and existing workforce and to all cadres in the team as part of continuing professional development.
Diabetes self-care management is critical for persons with diabetes (p.w.d). National standards for diabetes self-management education (DSME) exist for use of care providers for p.w.d. They increase adherence to standards of care.
There is no one "best" education programme/approach.
Clinical care: Training of PHCT in clinical care when supported by written guidelines, clinical algorithms, target setting, clearly defined goals and protocols have been shown to improve and maintain standards of care. Early referral as indicated to higher tiers of care saves life and helps improve care delivery.
Non-pharmacological therapy: comprise lifestyle changes. Medical nutrition therapy combined with physical /exercise therapy offer successful intervention for prevention and curative care. Currently standards and guidelines exist for both modalities of treatment.
Expertise in behavioural change is required to support patients making lifestyle changes.
Pharmacotherapy: Early introduction of insulin therapy for improved management of Type 2 diabetes (T2 DM) is now widely accepted and practiced. Guidelines for the use of the newly introduced agents arise from clinical trials which have shown clearly improved clinical care outcomes.
No one drug has emerged a one-size-fits-all medication.
Most of the newer agents have drawbacks on expense and ready availability which may limit their use for now in certain settings.
Conclusion: The opinion is expressed that primay care practice personnel are a logical focus for implementing strategies that improve diabetes care delivery.

Co-operation and strategic partnerships – a way to multiple influencing in society

J. Huttunen[1]
[1] *Finnish Diabetes Association, General management, Tampere, Finland*

Background: Diabetes education, in a broad sense, should be targeted to the whole society. If 10 % of population (which is the case in Finland) has diabetes, basic knowledge of the disease should be included in the all-round education. In addition 13 % of the population are in risk of diabetes. These numbers demand public awareness of diabetes and its risk factors. Crucial important is that political decision-makers are aware of diabetes and its complications.
Co-operation and strategic partnerships are needed. In a joint statement in May 2009 the International Diabetes Federation, International Union Against Cancer and World Heart Federation fully support the WHO Action Plan for the Global Strategy for the Prevention and Control of non-communicable diseases 2008-2013. Health systems cannot be built vertically, disease by disease. Comprehensive and integrated action at country level is the means to achieve success.
Methods: In Finland Diabetes Association and Finnish Heart Association have systematically developed strategic partnership already 10 years. Both associations are implementing national public health programmes, i.e. National Diabetes Programme DEHKO 2000-2010 and Action Plan for Promoting Finnish Heart Health 2005-2011. These programmes have provided a framework for common action and development. Together we have developed training for health care personnel and volunteers. We also have implemented common campaigns before parliamentary and municipal elections.
Results: Public awareness of diabetes and cardiovascular diseases has significantly increased. The new government established a Policy programme for health promotion. Group activities at the local level have increased.
Conclusion: Other parties in the field social and health care should not be seen as competitors. Common action means that we are stronger in influencing

in society. Co-operation and partnerships are appreciated by financiers because it builds up resources. Of course different organisational cultures face each other and it may cause troubles, but also produce a fruitful learning process.

DEBATE

LIVING WITH DIABETES

To vitamin D or not to vitamin D: a question on the aetiology of type 1 diabetes

0579

Against

R. Swaminathan[1]

[1] *St.Thomas' Hospital, Chemical Pathology, London, United Kingdom*

Although vitamin D status has been associated with development of type 1 diabetes mellitus, there are several reasons to suggest that it is premature to advocate vitamin D in the prevention of type 1 diabetes mellitus.

1. Epidemiological studies have shown strong association between sunlight exposure and the incidence of type 1 diabetes. From this, is it is assumed that the factor responsible is vitamin D. However vitamin D may be a surrogate marker of other effects of sunlight/UV exposure. There is evidence that both UVA and UVB radiation have direct immunosuppressant effect as well as indirect effect via neuropeptides such as α-melanocyte stimulating hormone, calcitonin gene related peptide and melatonin. The link between vitamin D and type 1 diabetes is similar to the effect of vitamin A and cancer as well as vitamin E and cardiovascular disease. In both instances randomised control trials failed to show any beneficial effect of supplementation of A and E on cancer or cardiovascular disease respectively. The inference from these observations is that there are other unmeasured confounding factors.
2. Second reason for doubting the link between vitamin D and type 1 diabetes is in the assessment of vitamin D status. Assays for the circulating form of vitamin D have problems. The most popular assay, an immunoassay, does not adequately detect 25-hydroxy vitamin D2. Even the more definitive method using tandem mass spectrometry has standardisation problems as evidenced by the recent episode in one of the largest laboratories in the US. Furthermore there is no consensus as to what is an adequate level of serum 25-hydroxy vitamin D which is optimal for health. Recommendations vary from 50nmol/L to >100nmol/L of 25 hydroxy vitamin D.
3. Observational studies show a moderate effect of vitamin D intake and the risk of developing type 1 diabetes. There are no randomised controlled trials with long term follow-up to substantiate the claim that vitamin D can prevent the risk of developing type 1 diabetes.

No conflict of interest

0580

For

L. Gnudi[1]

[1] *King's College London, Unit for Metabolic Medicine Cardiovascular Division, London, United Kingdom*

Vitamin D is either synthesized endogenously, through skin exposure to sunlight, or exogenously from ingestion of foods and supplements. Of note, in northern geographical regions (northern United States, Canada, northern Europe etc.), little or no vitamin D is produced in the skin during winter months. The observed higher prevalence of type 1 diabetes in the northern hemisphere and a recognised similar "opposite" scenario for the southern hemisphere has triggered speculations about a possible role of vitamin D in the pathogenesis of type 1 diabetes.

It is important to remember the low concordance for type 1 diabetes among identical twins which suggest that, besides genetic predisposing factors, environment plays an important role.

Type 1 diabetes is characterised by autoimmune destruction of insulin-producing beta cells in the pancreas; vitamin D is known to retain an immune-modulatory function (tolerance) that could prevent/ modulate beta cell autoimmunity.

Studies have highlighted the importance for active vitamin D in inhibiting the induction of other autoimmune diseases such as autoimmune thyroiditis, inflammatory bowel disease, rheumatoid arthritis, and others.

Evidence of lower plasma vitamin D levels at diagnosis of type 1 diabetes compared to controls has been described, and studies on vitamin D supplementation to children or pregnant mothers have been associated with lower incidence of type 1 diabetes, although results have not always been consistent.

Vitamin D appears to be not only involved in calcium metabolism, but it seems to have other important physiological functions mainly as an immune-modulator and inhibitor of inflammation.

Future applications of vitamin D in the pathogenesis of type 1 diabetes are conceivable, especially because its effects on calcium metabolism can be dissociated from its immunomodulatory effects by the use of structural analogues of the molecule.

Randomised prospective clinical trials are needed to investigate this new potential approach.

OPEN FORUM

Diabetes x 4 - it's just a way of life

0581

Diabetes x 4 - it's just a way of life

S. Renouf[1], *E. Renouf*[1]

Before May 2002 Steve and Elissa had five healthy children aged between 9 ½ and 1. By March 2004 three of their young boys were diagnosed with type 1 diabetes, Charlie was 3, Billy was 8 ½ and Fred 2 ¾. Steve had previously been diagnosed with Type 1 diabetes in 1992 aged 22. All three boys and Steve face a life of finger prick tests, balancing insulin injections, food and exercise just to keep them alive and healthy. Billy and Fred were also diagnosed with Coeliac Disease shortly after they developed diabetes. This means they can't eat foods containing wheat, oats, barley, rye and malt.

Steve and Elissa Renouf's story is one of inspiration, determination and courage. It's a story of a family united to share their knowledge and practical experience, by instilling confidence in their own children as well other diabetics, while helping to simplify the lives of people living with Diabetes.

Steve and Elissa hope by telling of the disbelief, grief, frustrations and emotional ordeals they experienced, along with the risks, compromises and challenges they faced and still face today, their story will assist in relieving the anxiety for all who are surrounded by similar situations, like theirs.

There is no better story than one of someone successful in fulfilling an aspiration, especially one that benefits the lives of other people. This story will leave you inspired, motivated and uplifted. In today's world, we all live with daily challenges and risks and we find we can never get enough of those enriching, genuine life stories that prove how, together with the help and experience of others, we can carry on each day and live life to the entirety, no matter what defies us.

INCOMING PRESIDENT'S ORATION

From yesterday to tomorrow: making a difference to global diabetes

0582

From yesterday to tommorrow: making a difference to global diabetes

J.C. Mbanya[1]

[1] *International Diabetes Federation, Brussels, Belgium*

The misperceptions of diabetes are diminishing in the face of mounting evidence. The evidence shows that diabetes does not distinguish between rich and poor; that it is not a disease of the elderly; and that in many cases it can be prevented. But these misperceptions are not diminishing quickly enough for millions of people with diabetes. According to new figures from the International Diabetes Federation (IDF), some 285 million people will have diabetes in 2010 and this is expected to increase by more than 50% to almost

440 million in 2030. Developing countries will continue to bear the brunt of the burden of diabetes, and those most affected remain in the productive age group of between 40 and 59. Governments must intervene now with preventive and cost-effective measures if people with diabetes and those at risk are to have a better tomorrow. The treatment and technology exist today for people with diabetes to manage their disease successfully and to enable them to lead full and productive lives. Yet, the reality is that for millions of people with diabetes, modern treatment and technology is but a dream, and the right to live a full life has been denied through ignorance, lack of resources and education, and inadequate health facilities. We have to act today to make a difference for people with diabetes tomorrow. For many that day cannot come soon enough. IDF has an obligation as the global advocate for people with diabetes to ensure that no child should die of diabetes from lack of insulin, that no person should suffer needlessly from complications such as the diabetic foot resulting in amputation because of the lack of proper care and medication, and that no family should carry the heavy financial burden of the disease from lack of resources. These challenges have to be met full on at every level. It is time to think creatively and to break down old paradigms. Studies show increasingly strong linkages between diabetes and many other diseases, such as heart disease, tuberculosis and HIV/AIDS. The way forward is to address the common challenges together of optimal healthcare, low-cost treatment, access to care, and improved training and education that are faced by countries in dealing with diabetes and these diseases. IDF will strengthen its alliances with international organizations representing heart disease and cancer, forge new ones and lead the way in global advocacy. It will support the WHO Noncommunicable Diseases Action Plan, 2008-2013, which recognizes diabetes as a development issue. At the same time, health resources should not be perceived as being in competition between communicable and noncommunicable diseases within a health system. The objective should be to work across the board to develop a health system that can offer optimal care to all those who need it. Our aim is to achieve sustainable health systems as called for in United Nations Resolution 61/225, and to build a global fund for health committed to helping health systems develop sustainable, cost-effective measures for prevention and care. IDF policy and strategy will centre on the person with diabetes. The success of our global advocacy must be measured by an improved quality of life for the person with diabetes. In the next three years, IDF is committed to strengthening its regional organizations to enable them to drive programmes that will develop and equip member associations to be powerful advocates and equal partners in building sustainable and effective health systems in their countries. IDF will enlist new and non-traditional partners to further national, regional and global advocacy to improve the quality of life of people with diabetes everywhere.

CLINICAL RESEARCH

Blood pressure management in diabetes

0583

Blood pressure management in diabetes

R. Gilbert[1]
[1] *St Michael's Hospital, Medicine, Toronto, Canada*

Blood pressure lowering and blockade of the renin-angiotensin system are key strategies in the prevention and treatment of the renal and cardiovascular complications of diabetes. Despite our knowledge of its importance, it is often difficult to get blood pressure to target levels in a substantial proportion of patients. Moreover, the results of recent studies have created some controversies in the choice of anti-hypertensive agents that should be used and in the order in which they should be prescribed. Finally, the importance of masked hypertension and the role of ambulatory blood pressure monitoring in managing diabetic subjects may also need to be considered.

Management of prediabetes and type 2 diabetes in adolescence

0584

Management of prediabetes and type 2 diabetes in adolescence

S. Caprio[1]
[1] *Yale University, Pediatrics, New Haven, USA*

The prevalence of type 2 diabetes (T2D) has increased significantly in children and adolescents in the last decade. What initially seemed to be a localized North American problem is appearing in other European, Asian, and South American countries. Moreover, multiple publications have recently reported an increasing prevalence of impaired fasting glucose and impaired glucose tolerance (IGT) - two pre-diabetic conditions - in children and adolescents. Thus, a disease that was until recently considered an adult phenomenon appears to be emerging in younger individuals and developing at an accelerated tempo.
Our group has been studying the metabolic defects leading to the development of impaired glucose tolerance in obese youth. Using epidemiological and physiological approaches, we reported a high prevalence of impaired glucose tolerance (IGT) in a multiethnic clinic based cohort of obese children and adolescents This work set the stage for a series of studies aimed at understanding the metabolic phenotype of pre-diabetes in youth, greatly emphasizing the emerging problem of T2DM in childhood obesity. Insulin resistance emerged as the best predictor of the 2hr glucose level and we demonstrated that alterations in the partitioning of fat in both muscle and abdominal tissues are closely linked to insulin sensitivity in obese adolescents with IGT. In a longitudinal study of 102 obese children and adolescents we investigated the dynamics of changes in insulin sensitivity and secretion and their interactions with weight changes over a period of 2 years. After only two years, we found a significant transition from IGT to T2DM in 30% of obese adolescents. This rapid rate of progression occurred with significant weight gain. Compared to youngsters whose glucose tolerance did not worsen, subjects who progressed from IGT to T2DM had severe insulin resistance and lower early insulin responses to glucose at baseline.
The results of the work described above have pointed out the pressing need for an intervention study in this high risk group in order to prevent progression of the disease.
We here will present some recent studies that have used insulin sensitizers to restore normal glucose tolerance in obese adolescents with IGT. This presentation will also discuss current treatment of type 2 diabetes in youth.

Glucose variability: does it make a difference ?

0585

Glucose variability: does it make a difference ?

I. Hirsch[1]
[1] *University of Washington School of Medicine, Metabolism Endocrinology and Nutrition, Seattle, USA*

One of the most controversial aspects of diabetes this decade has been the relative importance of glucose variability in the pathogenesis of diabetes-related complications. A figure from a report from the DCCT research group in 1995 was interpreted as suggesting a reduction of glucose variability in type 1 diabetes (due to more physiologic insulin regimens) resulted in an approximate 60% reduction in diabetes retinopathy progression. Later studies by Ceriello and Monier suggested glucose variability contributed to increases in oxidative stress which has been implicated in the fueling of diabetes vascular complications. Other large retrospective studies in a variety of different populations (including critically ill patients) also noted the importance of glucose variability in patient outcomes. However, this question is far from settled. Other studies have not noted difference in glucose variability result in improvements in outcomes. Retrospective analysis of the quarterly 7-point glucose measurements from the DCCT did not suggest differences in retinopathy or nephropathy progression, although interestingly variability of

A1C levels did. Last year the DCCT research group re-analyzed their 1995 data and concluded that there were no differences between the two groups in that study in ability of A1C to predict retinopathy or nephropathy. What is clear, and what is often over-looked, is that variability of glycemia predicts severe hypoglycemia. The final answer about the relative importance of glucose variability on both microvascular and macrovascular complications is far from settled, and can only be answered by a randomized controlled study. It is quite possible that neither A1C nor glucose variability can be examined alone but they need to be factored in together when assessing risks for complications.

EDUCATION

How can we help our patients reduce hypoglycaemia unawareness?

0586

How can we help our patients reduce hypoglycaemia unawareness?

S.A. Amiel[1]
[1] *King's College London School of Medicine, Department of Medicine, London, United Kingdom*

Hypoglycaemia unawareness (HU), the occurrence of low blood glucose concentrations in the absence of any warning symptoms, affects up to a quarter of people with Type 1, and an increasing number of late Type 2, diabetes. New strategies are required to help people avoid or treat HU, which increases risk of severe hypoglycaemia five-fold. HU is associated with defective glucose counterregulatory responses to a falling blood glucose concentration – the normal neuro-endocrine stress responses to any given glucose concentration are reduced in magnitude and require a greater fall in glucose concentration to start at all. As a result, the triggering glucose concentration for symptom generation falls below that associated with onset of cognitive dysfunction. Confusion and abnormal behaviour become the first evidence of hypoglycaemia and the patient is rendered unable to experience symptoms and self-treat. Defective counterregulation and HU are induced by prior exposure to hypoglycaemia and may be an example of stress de-sensitization, a common phenomenon in physiology. Neuroimaging data in HU patients show reduced activation of brain centres involved in generating the stress response but also of brain areas involved in perception of the internal milieu. There is failure to de-activate brain centres involved in reward seeking and pleasure perception. Failure to perceive for oneself that a stress is unpleasant or dangerous reduces the motivation to change behaviour to avoid that stress in future. This may explain why purely educational strategies around improved diabetes control with avoidance of hypoglycaemia (known to restore awareness sustainably in approximately 50% of people with HU) fail to achieve lasting benefit in many other patients and why compliance with therapeutic change in patients with HU is reduced. New strategies based on techniques designed to help people overcome repetitive health-harming behaviours may be beneficial.

Central regulation of food intake and metabolism

0587

Central regulation of food intake and metabolism

J. Brüning[1]
[1] *University of Cologne, Institute for Genetics, Köln, Germany*

The central nervous system serves as a central regulator of energy homeostasis by integrating signals from the periphery of the organism such as hormones as well as nutrient components to adapt food intake, energy expenditure and locomotor activity to the degree of peripheral energy sources. The presentation will focus on the genetic analysis of the interacting neurocircuits involved in these processes and how their activity is regulated by hormones such as leptin and insulin, as well as how hormonal control is further modified through nutrient components such as glucose and amino acids. Moreover, the neurocircuitry underlying the control of peripheral glucose metabolism and its regulation will be discussed. Taken together, deciphering the coordinated central nervous regulation of energy and peripheral glucose metabolism may provide new therapeutic approaches for both the obesity as well as the diabetes epidemic.

EDUCATION

Managing older people with diabetes more effectively - avoiding pitfalls and rejecting some common beliefs

0588

Managing older people with diabetes more effectively - avoiding pitfalls and rejecting some common beliefs

A.J. Sinclair[1]
[1] *University of Bedfordshire, Institute of Diabetes for Older People (IDOP), Luton, United Kingdom*

Background: In many older subjects diabetes is often a dynamic and complex interaction between the relentless process of ageing, a major metabolic disturbance, widespread vascular disease, and functional loss. Cognitive dysfunction, depressive illness and falls are also important complications which require novel and innovative strategies to minimise their risk of development.
Older people with complex needs require multidisciplinary care, which is well coordinated across primary, secondary and residential care and social services. Given the relatively high use of hospital services by older people, hospitals can offer an effective intervention point for earlier diagnosis and better management of diabetes in older people. Information, education and support should be provided for older people to help them manage their diabetes.
Those in institutional care also pose new and difficult problems in management where the balance between effective glucose and blood pressure control and issues relating to quality of life and limited longevity are more striking and challenging.
Use of clinical guidelines: The inclusion of specific guidance on older people in the 2009 IDF Global Type 2 Guideline is a major step forward in enhancing diabetes care for this often neglected and vulnerable group. This presentation will spotlight key guidance and suggest how this can be implemented in routine clinical practice. The presentation will also outline a new global initiative in geriatric diabetes which aims to improve the quality of diabetes care and to stimulate new research.

Is prevention feasible ?

0589

Prevention of diabetes is not feasible in many countries: strategies to change

A. Ibrahim[1], A. Mota[2]
[1] Instituto Nacional De Diabetes(INDEN), General Director, Santa Domingo, Dominican Republic
[2] Instituto Nacional De Diabetes(INDEN), Medical Director, Santa Domingo, Dominican Republic

Diabetes is a leading cause of blindness, kidney failure, heart attack, stroke and amputation. The number of people living with diabetes has increased considerably over the past 30 years. In 1985, an estimated 30 million people worldwide had diabetes. A little over a decade later, the figure had risen to over 150 million. Today, according to IDF figures, it exceeds 250 million. A further 300 million are at high risk of developing diabetes. Unless action is taken to implement effective prevention and control programmes, IDF predicts that the total number of people with diabetes will reach 380 million by 2025.
How can we deal with this pandemic?
Only by Prevention and Education. Prevention is divided itself into two components: prevention of Diabetes, and prevention or delay of Diabetes complications when the disease is already declared.
What are the factors that make the prevention of diabetes effective?:

1. strengthen knowledge about the disease.
2. strict follow of rules.
3. educational, emotional and psychological support.
4. massive advertising campaigns.
5. early detection of disease.
6. identify risk factors: obesity, high blood pressure, increased serum lipids, sedentary life ....
7. identify the family risk factors.
8. others

All these lead us to an essential need for the implementation of such programs: more resources, and the primary role of the state and the health authorities.
But what happens in most countries, especially in the underdeveloped:

1. lack of resources.
2. State policies are short-term policies, since the essential interest is to win the next election, while prevention is a long-term program, and its fruits are safe but may be delayed.

Here arises the need in these countries to create entities that could take control without having to be tied to the state´s aid, but can get help whenever it is offered.
Hence, we will present a model that we have in Dominican Republic for logging purposes.

0590

Prevention of diabetes is feasible with good planning in most countries

A. Flyvbjerg[1]
[1] The Danish Diabetes Association, Medical Endocrine Department (Diabetes and Endocrinology) Aarhus University Hospital, Aarhus C, Denmark

Considering the global increasing prevalence of type 2 diabetes (T2D), as well as the simplicity of identifying individuals at high risk for such disease, implementation of intervention measures for its prevention is of great interest. Several studies have confirmed the benefits of lifestyle changes in preventing or postponing the progression from impaired glucose tolerance to T2D. On average a 50% reduction in incidence is seen in most studies, a result that is better than those reported in studies in which pharmacological interventions were used with the same purpose.
Despite this knowledge, however, the implementation of effective prevention programmes seems to meet various barriers in the general population and among politicians. Despite being a leading cause of death and serious disability worldwide, the public often perceive T2D as a relatively mild condition. Furthermore, many people do not know that T2D is preventable and that steps can be taken to minimise the risk of developing the disease. Further, prevention studies conducted in a routine clinical setting, evaluating the impact on morbidity, mortality and cost-effectiveness as primary outcomes, are needed. Undoubtedly, improved public awareness of T2DM and its link with obesity and physical inactivity is critical, not only to prevention but also management of diabetes. By building understanding of diabetes, changing beliefs and attitudes and promoting positive behaviours, such initiatives can help combat the global diabetes epidemic and improve the health and wellbeing of people.
Three main strategies may be proposed to deal with the problem: 1) to estimate the need and advocate for action; 2) to develop national policies, strategies and plans for prevention and care and 3) promote and implement community participation in prevention and care. T2D is preventable; solutions seem effective and the effort may be cost-effective.

Coronary artery lesions in asymptomatic diabetic patients are intimately associated with carotid artery plaque and renal function: analysis from multidetector computed tomography (MDCT)

Y. Matsuzawa[1], K. Yumoto[2], K. Kato[2], J. Saito[1], M. Omura[1], T. Nishikawa[1]
[1] *Yokohama Rosai Hospital, Diabetes Center, Yokohama, Japan*
[2] *Yokohama Rosai Hospital, Cardiology, Yokohama, Japan*

Indication of MDCT in early diagnosis of coronary artery disease (CAD) in diabetic patient has not been clarified yet. We performed MDCT under written informed consent to 45 type 2 diabetic patients (30 males and 15 females, mean age 58.6±11.0, mean BMI 26.1±3.67**,** mean HbA1c 6.8±1.0, smoker 39.1%) who have no symptoms or history of CAD. Blood pressure and LDL-cholesterol had already been controlled well. Patients treated with insulin or serum creatinine >1.0mg/dl were excluded, and all patients were negative for exercise-tolerance ECG test. As a result, only 15 patients (33.3%) had shown normal coronary arteries, which had neither plaque nor calcification. Coronary plaques were found in 26 patients (57.7%), and calcification was found in 25 patients (55.6%). There were 21 patients (46.7%) who had both plaque and calcification, and 10 (22.2%) of them were suspected of significant (>50%) stenosis. Patients with both plaque and calcification were classified as advanced lesion group (n=21), and other patients were grouped into non-advanced group(n=24). Advanced group was significantly higher than non-advanced group in age, serum creatinine, and carotid artery plaque score evaluated by ultrasonography. HbA1c, waist circumference, visceral fat area, adiponectin, cholesterol, and blood pressure were not significantly different between the groups. In multivariable analysis, plaque score and serum creatinine proved to be independent factors to estimate the existence of advanced coronary lesions. Thus we calculated the product of plaque score and serum creatinine as diabetes atherosclerotic index (DAI). DAI in the non-advanced and advanced group were 0.98±1.27 and 3.49±2.34, respectively (p<0.0001). In summary, high prevalence of coronary artery lesions were shown in asymptomatic patients with type2 diabetes, regardless of their glycemic control or adiposity. Serum creatinine level and carotid artery plaque score were suggested to be main clinical markers of CAD, and MDCT and/or cardioangiography should be considered at least when the patients show >4.0 in DAI (diabetes atherosclerotic index).

Myocardial infarction and abnormal glucose tolerance: is fasting plasma glucose reliable to detect the glycaemic stress ?

L. Varadhan[1], D. Warner[2], D. Barton[2]
[1] *University Hospital North Staffordshire NHS Trust, Diabetes and Endocrinology, Stoke on Trent, United Kingdom*
[2] *Princess Royal Hospital NHS Trust, Diabetes and Endocrinology, Telford, United Kingdom*

Introduction: Abnormal glucose tolerance (AGT) is more prevalent in patients with Coronary artery disease and doubles the risk of developing cardiovascular complications. There has not been a consensus on the timing and the type of test to assess glucose tolerance to stratify risk in this high risk cohort. The aim of our study was

- To assess glucose tolerance prior to discharge after AMI and
- To assess reliability of fasting plasma glucose(FPG) in assessing glycemic status after the index event and at routine follow-up, using 2hour post glucose (2hPG) as gold standard.

Methods: An initial retrospective analysis was done on patients admitted with AMI and without diabetes during 2006 and 2007. A 75gm glucose tolerance test (GTT) was offered to all patients prior to discharge, ideally on the fifth day after AMI. Family physicians were instructed to do a follow-up glycemic testing on patients with AGT, within a year of the index event. Patients with AGT were then prospectively called up to the diabetes clinic for a repeat GTT.

Results: 102 patients were admitted with AMI during the study period. Only 79 had GTT before discharge and hence were included in this study. 27/79 patients had AGT, with 20 having IGT(FPG-19 normal, 1 IFG) and 7 having 2hPG in diabetic range(FPG- 0 normal, 7 IFG). 2 patients with normal GTT had abnormal FPG (1 IFG, 1 DM). The sensitivity of FPG was only 30%, specificity being 96% with a positive predictive value of 80%. The detection rate of AGT by GTT was 34.1% compared to 12.6% by FPG.

	AGT +	AGT -	Total
FPG +	8	2	10
FPG -	19	50	69
Total	27	52	79

As follow up, FPG was done on 27 patients (2 lost to follow up) after a mean follow up period of 130 days (85-440 days). 19 patients had normal FPG, 1 DM and 7 IFG, giving a prevalence of 29.6%

A GTT was done on these 27 patients after a mean duration of 541 days (283-837 days). Two patients had already been diagnosed with diabetes, adding to 11/27 having AGT, with 7 IGT (FPG- 4 normal, 1 IFG, 2 DM) and 4 DM (FPG- 1 Normal, 3 DM). The sensitivity of FPG was 54%, specificity 100% and positive predictive value 100%. The detection rate of AGT by GTT was 40.8% with GTT compared to 22% by FPG.

	AGT +	AGT -	Total
FPG +	6	0	6
FPG -	5	16	21
Total	11	16	27

Conclusions: A significant number of patients (37%) have glycemic disturbance after AMI, which could represent undiagnosed DM or stress hyperglycemia. GTT has a higher diagnostic rate in this high risk population. FPG, as a single screening test for hyperglycemia, lacks adequate sensitivity to diagnose this metabolic disturbance. Larger studies are required to address the issue of ideal timeframe and the best screening test to detect glycemic status in this high risk cohort.

Relationship between carotid intima-media thickness and silent cerebral infarction in Japanese subjects with type 2 diabetes

K. Nomura[1], Y. Hamamoto[1], S. Takahara[1], O. Kikuchi[1], S. Honjo[1], H. Ikeda[1], Y. Wada[1], Y. Kawasaki[1], R. Okumura[2], H. Koshiyama[1]
[1] *The Tazuke Kofukai Foundation Medical Research Institute Kitano Hospital, Center for Diabetes & Endocrinology, Osaka, Japan*
[2] *The Tazuke Kofukai Foundation Medical Research Institute Kitano Hospital, Department of Radiology, Osaka, Japan*

Aims: Subjects with Type 2 diabetes are at increased risk for cerebrovascular diseases, especially silent cerebral infarction (SCI). Recently, the magnetic resonance (MR) imaging study has enabled us to detect SCI easily. However, it remains to be elucidated how to screen for SCI may be the most suitable for diabetic subjects. In the present study, we investigated the frequency of SCI with the MR imaging study as well as the relationship to the carotid arterial ultrasonography in Japanese subjects with Type 2 diabetes, in comparison with Japanese subjects without diabetes mellitus.

Methods: The MR imaging study of the brain and the carotid arterial ultrasound were performed in 217 consecutive Japanese subjects with Type 2 diabetes (116 men and 101 women, mean±SD age, 67.1±8.6 years). The non-diabetic subjects included 158 Japanese subjects (81 men and 77 women, mean±SD age, 66.3±7.4 years), who visited the health care check-up center of our institute without Type 2 diabetes. They were free of clinical symptoms of cerebrovascular disease. SCI was defined as an area of focal hyperintensity on T2-weighted images with corresponding low signal intensity on T1-weighted images, which was =3 mm in diameter. The relationship between SCI on MR and the intima-media thickness (IMT) of common carotid artery on ultrasonography was investigated using multiple logistic analysis. Various risk factors for SCI were examined using multiple logistic analyses in both groups.

Results: SCI was more frequently found in the diabetic group than in the non-diabetic group (60.4% and 47.5%, respectively, P <0.05). By univariate analysis, the age and PWV were significantly higher in the subjects with SCI than in those without it (68.5 *vs.* 64.4 years, P <0.01; 1731.9 *vs.* 1595.8 cm/s, P <0.01) in the non-diabetic group. In the diabetic group, the age, PWV, SBP and IMT were significantly higher in the subjects with SCI than in those without it (69.3 *vs.* 63.7 years, P <0.01; 1906.7 *vs.* 1718.0 cm/s, P <0.01; 140.6 *vs.* 129.4 mmHg, P <0.01; 1.27 *vs.*1.10 mm, P <0.01). Multiple logistic analyses indicated that the age (odds ratio [OR] = 1.09, 95% confidence interval [CI] = 1.04-1.15), SBP (OR = 1.06, 95% CI = 1.02-1.08) and IMT (OR = 4.16,

95% CI = 1.37-12.62) were independent risk factors of SCI in the diabetic group. In contrast, only the age was significantly associated with SCI in the non-diabetic group.
Conclusion: The carotid IMT, rather than PWV, can be a useful index for screening SCI in Japanese subjects with Type 2 diabetes.

[3] *Calcutta University, Department of Biochemistry, Kolkata, India*
[4] *Medical College, Department of Cardiology, Kolkata, India*

Aims: Patients with diabetes have increased *in vivo* platelet activity. Abnormal platelet function is a major cause of cardiovascular complications and ischemic events in diabetic patients.
Synergistic interactions among several platelet agonists namely collagen, epinephrine, ADP, ATP, serotonin can profoundly increase platelet aggregation. Platelet aggregation induced by synergy between collagen and epinephrine and its inhibition by yohimbine hydrochloride (YH), an a-2 adreno-receptor blocker, has been studied in patients with type2 diabetes and acute coronary syndrome.
Methods: To study the synergism between collagen and epinephrine, aggregometric study was performed with simultaneous application of collagen and epinephrine in 25 diabetic and 25 nondiabetic patients. The concentrations of epinephrine and collagen were so chosen that the individual agonists showed null response to it. Inhibitory effect of yohimbine hydrochloride (final concentration of 10µM) on this synergy was accessed by incubating the sample for 5 mins at 37 °C in the aggregometer.
Results: Synergism with collagen and epinephrine was stronger in diabetic patients. Mean platelet aggregation (synergistic) was 74.3±12.5% in diabetic and 62.8±15.7 % in nondiabetic patients (p=0.0062). The inhibition of synergism by YH (10µM) was less pronounced in diabetic patients in comparison to non-diabetics. But higher concentration of YH (15-20mM) was able to inhibit the synergy in diabetic patients.
Conclusion: Our study showed a key role of the a2A-adrenoreceptor in platelet aggregation in the setting of acute coronary syndrome in diabetic patients. Targeting this receptor and use of a2A-adrenoreceptor antagonists in combination with aspirin and clopidogrel could be particularly efficacious in this setting.

Diagnosis of asymptomatic coronary atherosclerosis in patients with diabetes mellitus type 2 by multislice computed tomography

E. Buchaca[1], L.L. Bencomo[2], D. Hierro[2], F. Fernandez[1], L. Rodriguez[1], S. Bermudez[1], M. Valdes[1], M. Manzur[3]
[1] *Hospital Hermanos Ameijeiras, Internal Medicine, Ciudad de la Habana, Cuba*
[2] *Hospital Hermanos Ameijeiras, Radiology, Ciudad de la Habana, Cuba*
[3] *Policlinico Reina, Internal Medicine, Ciudad de la Habana, Cuba*

A prospective longitudinal study was carried out in 118 patients with diabetes type 2, in which the findings of the determination of coronary calcium score were compared with the findings of the angiography by multislice computed tomography, with the objective of evaluating the usefulness of these techniques in the detection of sub clinic coronary atherosclerosis in patients with Diabetes Mellitus Type 2, and its relationship with some factors of cardiovascular risk.
An agreement of 44.1% was registered being both studies positive. The angiography study was more sensitive when identifying suggestive lesions of coronary atherosclerosis. The presence of soft plaques predominated in 55.9% of the total sample. The most affected blood vessels were left anterior descending (45.8%) and the right coronary artery (44.1) which made no difference with the calcium score technique. A lineal correlation between aging and the number of damaged vessels was demonstrated by both techniques (p = 0.003) and (p = 0.001) respectively.
We conclude that multislice computed tomography is useful for the detection of sub clinic coronary lesions in patients with diabetes which is more relevant as age (people age) advances.

Progression of diabetic nephropathy vs. cross-talk between genetic variability in the RAAS system and its pharmacologic blockade: results of 7-years observational pharmacogenetic study

K. Kankova[1], L. Pacal[1], S. Stepankova[2], M. Pongracova[3], J. Muzik[3], J. Jarkovsky[3]
[1] *Masaryk University, Dept. of Pathophysiology, Brno, Czech Republic*
[2] *Brno University Hospital, Dept. of Gastroenterology, Brno, Czech Republic*
[3] *Masaryk University, Institute of Biostatistics and Analyses, Brno, Czech Republic*

Aims: There are multiple determinants of progression of diabetic nephropathy (DN) such as metabolic and blood pressure control, albumin-/proteinuria and genetics. One of the crucial pathogenic mechanisms is the over-activation of renin – angiotensin - aldosterone system (RAAS). We hypothesized that certain functional variants in the RAAS represent significant independent risk factors influencing the DN progression in subjects. Additionally, therapeutic benefit, predominantly based on the RAAS blockade by ACEIs and angiotensin receptor blockers (ARBs), might also be influenced by genetic variability within the RAAS components. Using clinical data collated during prospective follow-up of the cohort of diabetics with DN and advanced multivariate stat. methods we quantified the pathogenic contribution of main DN risk factors: (i) cumulative glycemia, blood pressure and proteinuria, (ii) other metabolic factors such as body weight and lipids in relation to the DN pharmacotherapy (i.e. cumulative received dose of ACEIs and ARBs) and carrier state of selected candidate (pharmaco)genetic variants.
Methods: Study was designed as a prospective follow-up (~7 yrs) study of subjects with T1DM or T2DM. Inclusion criteria at baseline (2001 - 2003) were as follows: diabetes duration at least 10; DN stage: persistent microalbuminuria to overt proteinuria; follow-up at least half of the period; any age; both genders. Study comprised a total of 215 subjects. Following end-points were considered: [1] renal (rate of GFR decline and/or doubling of S-creatinine over the follow-up time-period and/or reaching the end-stage renal disease stage requiring renal replacement therapy), [2] composite cardiovascular (myocardial infarction, stroke or sudden death) and [3] all-cause mortality. A total of 15 RAAS and RAAS-related variants were genotyped using appropriate methodology (PCR with RFLP, fluorescent-labelled probes (TaqMan) or direct sequencing).
Results and conclusions: Multiple time series analysis (by means of dynamic longitudinal analysis) for repetitive data (e.g. blood pressure or glycemia measurements) for which cumulative exposure (area under the curve) and trend of the particular variable represent potentially relevant information, and event occurrence at specified time-points (Kaplan-Meier curves or Cox regression models] were used to analyse data. All groups of factors – i.e. metabolic/hemodynamic, genetic and pharmacologic were found to significantly contribute to the DN progression rate (all $P < 0.05$). The relative contribution of metabolic/hemodynamic factors was superior to genetic and pharmacologic factors. Mode of interaction between the variables analysed was non-linear.
Supported by the grants from the Ministry of Health of Czech Republic (NR 9443-3/2007).

RAS blockade prevents hypertension, albuminuria, tubular apoptosis and endoplasmic reticulum stress-associated gene expresssion in diabetic akita angiotensinogen-transgenic mice

J.S.D. Chan[1], F. Liu[1], G.J. Lau[1], M.L. Brezniceanu[1], I. Chenier[1], J.G. Filep[2], J.R. Ingelfinger[3], S.L. Zhang[1]

[1] *CRCHUM (Centre de recherche du centre hospitalier de l'Université de Montréal), Hôtel-Dieu Hospital, Montreal QC, Canada*

[2] *Maisonneuve-Rosemont Hospital, Research Centre, Montreal QC, Canada*

[3] *Mass Gen Hosp, Pediatr Nephrol Unit, Boston MA, USA*

Introduction: Apoptosis of renal proximal tubular cells (RPTCs) frequently occurs in the diabetic kidney. The existence of a local intrarenal renin-angiotensin system (RAS) has been well-accepted and angiotensinogen (Agt) is the sole precursor of angiotensins. We have previously reported that transgenic (Tg) mice over-expressing rat Agt in their RPTCs are prone to develop hypertension, albuminuria and renal injury. Furthermore, hyperglycemia and intrarenal RAS act in concert to induce RPTC apoptosis in streptozotocin-induced diabetic Agt-Tg mice (J Am Soc Nephrol, 2008). However, the underlying molecular mechanisms remain incompletely understood.

Aims: The present study investigated whether RAS blockade could prevent hypertension, albuminuria, tubulointerstitial fibrosis, endoplasmic reticulum (ER)-stress and renal proximal tubular cell (RPTC) apoptosis in type 1 diabetic Akita Agt-Tg mice.

Methods: Diabetic Akita Agt-Tg mice were created by cross-breeding Akita mice with Agt-Tg specifically overexpressing Agt in their RPTCs. Non-Akita littermates served as controls. Animals were treated with or without RAS blockade (a combination of losartan (an antagonist of angiotensin II (Ang II)-receptor (AT1-R), 20 mg/kg/day) and perindopril (4 mg/kg/day)). Blood glucose, systolic blood pressure (SBP) and albuminuria were monitored weekly from 9 to 16 weeks of age. Left kidneys were processed for histology and apoptosis studies. Renal proximal tubules were isolated from right kidneys to quantify expression of pro-fibrosis and pro-apoptotic genes by real time-quantitative polymerase chain reaction assay and Western blotting.

Results: Akita Agt-Tg mice developed hyperglycemia and significantly higher SBPs, albumin/creatinine ratios, and kidney/body weight ratios as compared to Akita mice. Unlike kidneys from non-Akita mice, kidneys of Akita Agt-Tg mice exhibited hydronephrosis, severe tubulointerstitial fibrosis and enhanced apoptotic RPTCs. These were associated with increased expression of the transforming growth factor-beta1, collagen IV, fibronectin, plasminogen activator inhibitor-1 and ER-stress induced genes (caspase-12, GRP78 and CHOP), as well as caspase-9 and caspase-3. Treatment with RAS inhibitors prevented hypertension, albuminuria, pro-apoptotic and ER-induced gene expression in diabetic Akita Agt-Tg mice.

Conclusion: Our results indicate that hyperglycemia and intrarenal RAS activation act additively to stimulate SBP, tubulointerstitial fibrosis, RPTC apoptosis, pro-fibrotic and pro-apoptotic gene expression as well as ER-stress gene expression in diabetic kidneys. Furthermore, our data demonstrate the importance of suppressing intrarenal RAS activation in preventing hypertension, ER-stress and ultimately progression of diabetic nephropathy.

Reactive oxygen species up-regulate BcL-2-modifying factor expression and induces apoptosis in renal proximal tubular cells of diabetic mice

G.J. Lau[1], F. Liu[1], N. Godin[1], M.L. Brezniceau[1], I. Chenier[1], J.G. Filep[2], J.R. Ingelfinger[3], S.L. Zhang[4], J.S.D. Chan[4]

[4] *CRCHUM (Centre de Recherche du Centre Hospitalier de l'Université de Montréal), Hôtel-Dieu Hospital, Montreal QC, Canada*

Background: We recently reported that hypertension, albuminuria and renal proximal tubular cell (RPTC) apoptosis are attenuated in type 2 diabetic db/db transgenic (Tg) mice specifically over-expressing catalase (Cat, an antioxidant enzyme) in the RPTCs, indicating that reactive oxygen species (ROS) are involved in the progression of nephropathy in db/db mice (Diabetes, 2008). By gene chip microarray analysis, we recently observed that Bcl-2 modifying factor (Bmf), a pro-apoptotic gene, is up-regulated in RPTCs from db/db mice, when compared to RPTCs from db/m+ (control) and db/db Cat-Tg mice. Bmf is a member of the BH3-only pro-apoptotic protein family and promotes apoptosis by heterodimerizing with pro-survival members of the Bcl-2 family. This finding was further validated by real-time quantitative polymerase chain reaction (RT-qPCR) and immunohistochemistry.

Aims: The present study aims to investigate whether Bmf expression is regulated by hyperglycemia via ROS generation in vivo and in vitro. In parallel, we aim to examine the role for Bmf in RPTC apoptosis.

Methods: Adult mice were left untreated or rendered diabetic with streptozotocin (STZ) with or without insulin treatment. Animals were euthanized at 4 weeks after STZ administration. Kidneys were processed immediately for immunohistochemical and apoptotic activity analysis. To study Bmf biological activity, overexpression assays in RPTCs were performed using cDNAs cloned from human and rat immortalized RPTCs by conventional reverse transcription-PCR. Human and rat immortalized RPTCs were cultured in normal glucose (5 mM D-glucose) or high glucose (25 mM D-glucose) medium in the absence or presence of rotenone (an inhibitor of the mitochondrial electron transport chain complex I) or Cat. Bmf expression in RPTCs was quantified by RT-qPCR.

Results: Immunohistochemical analysis show an increase in Bmf and heme oxygenase-1 (a marker of oxidative stress) expression in RPTCs of untreated diabetic mice, when compared to non-diabetic mice. Insulin treatment normalizes Bmf expression in RPTCs of STZ-induced diabetic mice. Additionally, human and rat RPTCs cultured in high-glucose milieu enhances Bmf mRNA expression, which is attenuated in the presence of rotenone or Cat. Finally, in vitro Bmf over-expression enhances RPTC apoptosis.

Conclusion: Our results demonstrate that hyperglycemia stimulates Bmf expression via reactive oxygen species generation, leading to RPTC apoptosis, and suggest a role for Bmf in inducing RPTC apoptosis and tubular atrophy in diabetic kidneys.

Polymorphisms in the Protein Kinase C-ß gene (PRKCB1) predict development of kidney disease in a 8-year prospective Chinese cohort of type 2 diabetes

R.C. Ma[1], C. Tam[1], W.Y. So[1], Y. Wang[1], V. Lam[1], A. Luk[1], C.C. Chow[1], P.C. Tong[1], M.C. Ng[1], J.C. Chan[1]

[1] *Chinese University of Hong Kong, Department of Medicine and Therapeutics, Hong Kong, Hong Kong China*

Aims: Protein Kinase C-ß is an important cell-signaling intermediate and is believed to play an important role in the pathogenesis of diabetic nephropathy. The aim of our study was to examine the contribution of PKC-ß gene (*PRKCB1*) polymorphisms to diabetic kidney disease in a 8-year prospective Chinese cohort of patients with type 2 diabetes.

Methods: Eighteen tag SNPs (single nucleotide polymorphism) in the promoter region and spanning *PRKCB1* gene at r^2=0.8 based on HapMap CHB data were genotyped in 1172 Chinese patients without past history of chronic kidney disease at baseline. Associations of *PRKCB1* polymorphisms under additive, dominant and recessive genetic models with outcome of end stage renal disease or chronic kidney disease were assessed by Cox proportional hazard regression, adjusted for the conventional risk factors including sex, age, duration of T2D and drug treatments.

Results: During mean follow-up period of 7.9 ± 1.9 years, 90 of 1172 subjects (7.7%) progressed to end stage renal failure. We found that eight common SNPs significantly predict diabetic kidney disease ($P<0.05$). The T-allele and G-allele at polymorphisms rs3760106 and rs2575390, which are in high linkage disequilibrium (r^2 = 0.98 in the present study), showed the strongest association with the transition to end stage renal failure (HR (95% C.I.) = 2.25 (1.31 – 3.87), P = 0.0034; HR (95% C.I.) = 2.26 (1.31 – 3.88), P = 0.0033). There were also significantly increased risk for both CKD and ESRF with increasing numbers of risk alleles (P=0.0011 for CKD and P=0.0007 for ESRF) in the joint effect analysis. The adjusted risk for ESRF was 6.04 (95% C.I. 2.00-18.31) for patients with four or more alleles compared to patients without risk alleles. Likewise, the adjusted risk for CKD was 2.67 (95% C.I. 1.37-5.22) for patients with four or more risk alleles compared to patients without risk alleles.

Conclusion: In summary, our study suggests that genetic variants in the *PRKCB1* gene are important independent predictors for the development of diabetic nephropathy in Chinese population.

Dietary n-3 long chain polyunsaturated fatty acids intake and diabetic nephropathy – cohort analysis of the Diabetes Control and Complications Trial (DCCT)

C.C. Lee[1], S.J. Sharp[1], D.J. Wexler[2], A.I. Adler[3]
[1] Institute of Metabolic Science, MRC Epidemiology Unit, Cambridge, United Kingdom
[2] Massachusetts General Hospital, Diabetes Centre, Boston, USA
[3] Addenbrooke's Hospital, Wolfson Diabetes and Endocrine Centre, Cambridge, United Kingdom

Aims: Despite evidence suggesting potential benefits of intake of fish and fish oil on macrovascular complications in diabetes, their effects on microvascular complications including nephropathy are not well-established. We investigated the association between dietary n-3 long-chain polyunsaturated fatty acids (n-3 LC-PUFAs) and albuminuria in persons with type 1 diabetes.
Methods: We studied 1,436 participants aged 13 to 39 with type 1 diabetes at the beginning of the Diabetes Control and Complications Trial (DCCT) who were followed for up to 9 years, with dietary n-3 LC-PUFAs at baseline. Dietary n-3 LC-PUFAs obtained from diet history was defined as the average intake of eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA), divided into tertile distribution. Incident microalbuminuria was defined as the first occurrence of urinary albumin excretion rate (UAER) of >40 mg/24 hr sustained for at least 1 year. We used Cox proportional hazards regression models to estimate the hazard ratios comparing thirds of dietary n-3 LC-PUFAs with incident microalbuminuria. We used mixed-effects regression models with random intercepts to estimate the association between thirds of dietary n-3 LC-PUFAs and repeated measurements of UAER over the 9-year study period.
Results: In an average follow-up of 6.5 years, excluding 74 people without albuminuria at baseline, 95 people developed microalbuminuria. There was no significant association between dietary n-3 LC-PUFAs and incident microalbuminuria [Hazard ratio 1.30; 95% confidence interval (CI) 0.77-2.18, comparing extreme thirds of dietary n-3 LC-PUFAs] after adjusting for age, sex, body mass index, HbA1c, systolic blood pressure, UAER, creatinine clearance and serum triglyceride at baseline, dietary and lifestyle factors, and treatment randomization (intensive vs. conventional treatment). In an unadjusted analysis of the mixed-effects regression model, we observed an estimated difference in mean UAER between extreme thirds of dietary n-3 LC-PUFAs of -21.1 mg/24 hr (95% CI -37.5, -4.8; p=0.01). Having adjusted for years of follow-up and potential confounders, the difference in mean UAER between extreme thirds of dietary n-3 LC-PUFAs was -14.8 (95% CI -31.1, 1.4) mg/24 hr (p=0.08). In multivariate analyses, we observed a significant interaction between treatment randomization and dietary n-3 LC-PUFAs on the difference in mean UAER (p=0.007). In stratified analyses, we observed substantial differences in mean UAER [-28.8 (95% CI -58.7, 1.1) mg/24 hr for conventional treatment and 5.3 (95% CI -7.8, 18.5) mg/24 hr for intensive treatment], between extreme thirds of dietary n-3 LC-PUFAs after adjusting for potential confounders.
Conclusion: This study suggests that dietary n-3 LC-PUFAs is not associated with the risk of incident microalbuminuria. The effects of dietary n-3 LC-PUFAs on UAER differed between treatment interventions.

GLUT2 expression in kidney of diabetic rats treated with insulin or phlorizin is regulated by HNF-1 alpha and HNF-3 beta

H. Freitas[1], A. David-Silva[1], R. Sabino-Silva[1], M.M. Okamoto[1], U.F. Machado[1]
[1] Institute of Biomedical Sciences, Physiology, São Paulo, Brazil

Aims: We hypothesize that, in kidney of diabetic rats, hepatocyte nuclear factors (HNF-1a and HNF-3ß) play a critical role in the overexpression of glucose transporter protein GLUT2. Considering the important role of HNF-1a and HNF-3ß transcription factors in the regulation of GLUT2 transcriptional activity, we hypothesized that alterations of GLUT2 mRNA in kidney of diabetic rats may involve changes in the activity of these transcription factors. The purpose of the present study was to investigate the possible association between GLUT2 expression, and the expression and activity of HNF-1a and HNF-3ß, in kidney of diabetic rats treated with insulin or phlorizin.
Methods: GLUT2 mRNA (Northern blotting), HNF-1a and HNF-3ß mRNA (RT-PCR) and activity of transcription factors by electrophoretic Mobility Shift Assay (EMSA), were analized in renal cortex of non-diabetic, diabetic rats untreated, acutely (4h- and 12-hour) insulin or phlorizin treated and diabetic rats short-term (1-, 4- and 6-day) insulin or phlorizin treated.
Results: Plasma glucose concentration and 24-hour urinary glucose were increased ($p<0.001$), and plasma insulin concentration decreased ($p<0.0001$) in diabetic rats. Two-fold increase in GLUT2 mRNA ($p<0.001$) was observed in diabetic, accompanied by significant increases in HNF-1a ($p<0.0001$) and HNF-3ß ($p<0.01$) expression and binding activity. Additional 2-fold increase in GLUT2 mRNA ($p<0.001$) and HNF-3ß expression/activity ($p<0.01$) were observed in 12-hour insulin-treated rats. Six-days of insulin or phlorizin treatment decreased GLUT2 mRNA ($p<0.001$ and $p<0.05$, respectively) and HNF-1a expression and activity ($p<0.001$, insulin and $p<0.05$, phlorizin) to levels of non-diabetic rats, whereas HNF-3ß decreased to levels of non-insulin-treated diabetic rats ($p<0.01$).
Conclusion: we demonstrated in kidney of diabetic rats that overexpression of GLUT2 is related to the increased expression and activity of HNF1-a and HNF-3ß transcription factors. Furthermore, insulin therapy-induced regulation of GLUT2 expression also involves these transcription factors. However, the insulin-induced participation of HNF1-a and HNF-3ß is time-course-specific: the rapid transient additional increase GLUT2 expression involves HNF-3ß, and the 6-day induced restoration of the gene expression involves both HNF1-a and HNF-3ß transcription factors. Considering the possible importance of the GLUT2 protein in the genesis and progression of diabetic nephropathy, we hope that the knowledge of the GLUT2 transcriptional regulation may contribute to control the local gene expression in the future.

Incidence and predictors of renal function decline versus renal disease in a cohort of type 1 diabetes

T.J. Orchard[1], T. Costacou[1]
[1] University of Pittsburgh, Department of Epidemiology, Pittsburgh, USA

Aims: As the sensitivity of albuminuria in predicting loss of renal function has been questioned in diabetes, we determined the incidence and risk factors for declining kidney function and, separately, for renal disease in a cohort of individuals with childhood onset type 1 diabetes, participating in the Pittsburgh Epidemiology of Diabetes Complications study.
Methods: At study entry, mean participant age was 28 and diabetes duration 19 years. Mild renal function decline was defined as estimated (by both the Cockcroft-Gault (CG) and MDRD formulae) glomerular filtration rate (eGFR) <60 ml/min/1.73 m^2. Analyses were also conducted to assess predictors of severe loss of renal function (eGFR <30 ml/min/1.73 m^2). Microalbuminuria (MA) was defined as albumin excretion rate (AER)>20 µg/min and overt nephropathy (ON) as AER>200 µg/min in at least 2/3 validated timed urine collections.
Results: During 18 years of follow-up, 16.1% (84/521) and 38.3% (170/444) exhibited mild eGFR decline by CG and MDRD, respectively, whereas 7.1% (CG) and 11% (MDRD) exhibited severe declines of renal function. Moreover, 40.5% (125/309) and 17.3% (75/434) of study participants developed MA and ON, respectively. In multivariable Cox models with backward elimination and adjusting for baseline eGFR, predictors of mild eGFR decline by CG included diabetes duration (HR=1.04, 95% CI=1.002-1.07), female gender (HR=2.21, 95% CI=1.38-3.52), HbA_{1c} (HR=1.34, 95% CI=1.18-1.53), and AER (HR=1.56, 95% CI=1.41-1.72). Although results were similar when the MDRD formula was used, this time men appeared at increased risk compared to women and HDL cholesterol emerged as a protective factor. Diabetes duration (HR=1.03, 95% CI=1.01-1.06), HbA_{1c} (HR=1.49, 95% CI=1.32-1.68) and AER (HR=1.46, 95% CI=1.01-2.10) also predicted MA, whereas this model also included diastolic blood pressure (HR=1.03, 95% CI=1.01-1.27) and white blood cell count (HR=1.15, 95% CI=1.05-1.27). Predictors of severe eGFR decline by CG included insulin dose per body weight (HR=0.12, 95% CI=0.02-0.64), hypertension (HR=2.78, 95% CI=1.40-5.52), non-HDL cholesterol (HR=1.013, 95% CI=1.01-1.02), fibrinogen (HR=3.24, 95% CI=0.84-12.46), and AER (HR=1.40, 95% CI=1.16-1.69). Similar results were obtained using the MDRD formula. Conversely, male participants, those with higher HbA_{1c}, non-HDL, white blood cell count and AER were at increased risk of ON incidence.
Conclusion: While similar risk factors for renal function decline and albuminuria were seen, the differences, e.g. the protective effect of insulin dose for eGFR, merit further evaluation and have clinical implications in type 1 diabetes. These results also underscore the importance of glycemic, lipid and blood pressure control. Furthermore, our findings highlight the difficulty of accounting for gender differences in estimating GFR with current formulae.

GLUT2 transcriptional regulation by PPAR-gamma in kidney of diabetic animals and insulin or phlorizin treated diabetic animals

A. David Silva[1], H. Freitas[1], R. Sabino Silva[1], M. Okamoto[1], U. Machado[1]
[1] *Institute of Biomedical Sciences, Physiology and Biophysic, São Paulo, Brazil*

Introduction: The extracellular glucose concentration in proximal renal tubule is increased by elevations of glycemia and renal glucose reabsorption in diabetes mellitus. Increased expressions of GLUT2 and SGLT2, as well as augmented production of extracellular matrix proteins by mesangial cells could collaborate to development of glomerulosclerosis. We have already investigated the effect of insulin and phlorizin and demonstrated that chronically (6 days of treatment) both insulin and phlorizin downregulated GLUT2 expression, which returned to non diabetic levels, and definitely points out the plasma/interstitial glucose concentration as the key regulator of this gene (Freitas,HS;Nephron Physiology,2007). These results indicate a transcriptional control was involved, and an important transcriptional factor, PPAR-gamma, was indentified and characterized in GLUT2 gene promoter.
Aim: The aim of present study was to investigate the role of this transcriptional factor in kidney of diabetic rats, insulin or phlorizin treated diabetic rats.
Methods: We studied 3 month old Wistar rats, which were randomly allocated into non diabetic (C), diabetic (D), diabetic treated with saline (DS), insulin (DI–1, 4 and 6 days of treatment with daily injection of insulin) or phlorizin (DP–1, 4 and 6 days of treatment with daily injection of phlorizin). Diabetes was induced by single endovenous dose of alloxan (38 mg/Kg). The mRNA of PPAR-gamma was analyzed by RT-PCR. The PPAR-gamma binding activity of nuclear protein into GLUT2 promoter was analyzed by EMSA (Eletrophoretic Mobility Assay)
Results: In comparison to C animals, D rats showed: hyperglycemia, polyuria, glycosuria without ketonuria, increased PPAR-gamma mRNA content and binding activity of nuclear protein into GLUT2 promoter. In comparison to DS animals, the DI animals showed: a) reduction of glycemia in DI rats 10% (1 day), 22% (4 days) and 48% (6 days); b) progressive increase of body weight 2% (1 day), 5,4% (4 days) and 24% (6 days); c) decrease of PPAR-gamma mRNA content after 1, 4 and 6 days and decrease of the PPAR-gamma binding activity of nuclear protein into GLUT2 promoter, after 1, 4 and 6 days of insulin treatment; d) decrease of PPAR-gamma mRNA content after 6 days of phlorizin treatment, decrease of the PPAR-gamma binding activity of nuclear protein into GLUT2 promoter, after 1, 4 and 6 days of phlorizin treatment.
Discussion/conclusion: The present study showed that PPAR-gamma plays important role in the GLUT2 gene regulation, which was demonstrated by increased PPAR gene expression and binding activity into GLUT2 promoter in diabetic rats. These data suggest that in insulin and phlorizin treatment PPAR-gamma could be an important transcriptional regulator of GLUT2 gene and probably acts as mediator on GLUT2 gene in renal cortex of diabetic rats.

Levels of proinflammatory cytokines in patients with different stages of diabetic nephropathy

G. Babina[1], A. Larin[1], B. Mankovsky[1], L. Kondratenko[2]
[1] *Ukrainian Scientifically Practical Center of Endocrine Surgery Transplantation, Department of prevention and treatment of diabetes mellitus, Kiev, Ukraine*
[2] *European Medical Center Eurolab, Immunology, Kiev, Ukraine*

Background and aims: Diabetic nephropathy is one of the main causes of morbidity and mortality in patients with type 1 diabetes. Nevertheless pathogenesis of diabetic nephropathy is studied incompletely. The activation of inflammation could play a role in its pathogenesis. The aim of this study was to evaluate the serum levels of proinflammatory cytokines IL-6, IL-1ß, TNFa in patients with type 1 diabetes with different stages of diabetic nephropathy.
Materials and methods: We measured a serum concentration of cytokines IL-6, IL-1ß, TNFa by immunochemical biochip array technology analyzer EVIDENCE - EV180, in 66 patients with type 1 diabetes - 23 patients without microalbuminuria (age 30,0 ± 2,03 years, diabetes duration 7.1 ± 0.97 years), 22 patients with microalbuminuria (age 33,3 ± 2,5 years, diabetes duration 15.0 ± 1.59 years), 21 patients with proteinuria (age 31,2 ± 2,48 years, diabetes duration 18.27± 1.79 years). Control group included 20 subjects without diabetes mellitus and renal diseases (age 32,2 ± 1,06 years). Statistical analysis was performed using Student test.
Results: We found increased levels of proinflammatory cytokines in a serum of patients with type 1 diabetes with more severe stages of diabetic nephropathy. Levels of IL-6, IL-1ß, TNFa were: in patient group without microalbuminuria - 7.37 ± 3.55 pg/ml, 2.17 ± 0.61 pg/ml, 21.58 ± 8.48 pg/ml, in patient group with microalbuminuria - 12.44 ± 6.01 pg/ml, 5.67 ± 3.78 pg/ml, 24.85 ± 7.58 pg/ml, in patient group with proteinuria - 40.46 ± 15.44 pg/ml, 7.7 ± 3.36 pg/ml, 47.27 ± 15.6 pg/ml, in control group - 2.4 ± 0.76 pg/ml, 1.66 ± 0.17 pg/ml, 6.1 ± 0.58 pg/ml, respectively. P<0,05 between patients with proteinuria and control group (for all cytokines), and between group with microalbuminuria and control group (for cytokines IL-6 and TNFa).
Conclusion: Increased levels of proinflammatory cytokines may reflect an activation of inflammation in patients with diabetes mellitus and could contribute to the pathogenesis of diabetic nephropathy.

Insulin infusion induces a reduction in transforming growth factor ß, PAI-1 and ICAM-1: implications for diabetic nephropathy

P. Dandona[1], H. Ghanim[2], S. Dhindsa[2], K. Korzeniewski[2]
[1] *State University if New York at Buffalo, Medicine, Buffalo, USA*
[2] *State University of New York at Buffalo, Medicine, Buffalo, USA*

Transforming growth factor ß (TGFß) is a key mediator of the pathogenesis of diabetic glomerulopathy. In addition, it regulates the gene expression of PAI-1 which is fibrogenic and may also be involved in this process. ICAM-1 is a pro-inflammatory adhesion molecule whose concentrations predicted the occurrence of nephropathy in the DCCT study. In view of the anti-inflammatory action of insulin, we hypothesized that insulin suppresses the concentration of TGFß, PAI-1 and ICAM-1 in patients with type 2 diabetes (T2DM). Ten patients with T2DM were infused with 2U/h of regular insulin and 100 ml of 5% dextrose with KCl (10 mmol/h) for 4h. These patients were also infused with 5% dextrose or saline on two separate days. Blood samples were collected at 0,2,4 and 6h. Blood glucose concentrations were similar on all 3 days. Insulin infusion led to a significant reduction in TGFß concentrations at 2h by 25±5% ($p<0.05$); this was maintained at 4h. TGFß concentrations reverted towards the baseline at 6h. There were parallel reductions in plasma concentrations of PAI-1 and ICAM-1. There was no significant change in these mediators following dextrose or saline infusions. We conclude that insulin suppresses TGFß and two other inflammatory molecules involved in the pathogenesis of diabetic glomerulopathy. It may thus have a role to play in the prevention of diabetic nephropathy.

The implementation of Helium-neon laserotherapy in complex treatment of diabetic angiopathy of lower extremities

E. Hairapetyan[1], K.S. Asoyan[1], E.B. Meliksetyan[1]
[1] *Yerevan State Medical University aft. M. Heratsi, Endocrinology, Yerevan, Armenia*

Background and aims: The aim of our study to assess changes of blood coagulation among type 2 diabetic patients with angiopathy of lower extremities after treatment with 5 days laser course.
Materials and methods: 700 patients (350 male, 350 female) with Type 2 diabetes were recruited during 9 years and had the following characteristics: age 40-65, fasting plasma glucose (FPG) 5.89±0.44 mmol/l. Fibrinogen A (FA), prothrombin index (PI), haematocrit (Ht), blood coagulation time (BCT), platelets aggregation time (PAT) were increased. Patients were randomized into 2 groups, one group patients received treatment of 15 days heparin (H) course while the second group received treatment of 5 day laser (L) course. H group patients received heparin by the following plan: 3 days-20000 U, 3 days-15000 U, 3 days-10000 U, 3 days-5000 U, 3 days-2500. Intravenous laser course was performed in dosage of 2-5 MVt, increasing the time gradually, from 15 minutes to 30 minutes. The reovasographic examination was performed in both groups. All patients were treated with oral hypoglycemic agent gliclazid 80 mg twice-daily, but during the last year with gliclazid 30 mg MR (Servier, France) once or twice- daily.
Results: After treatment with 5 days laser course there were significant reductions in FA 90 %, PI 87 %, Ht 82 %, BCT 58 %, PAT 84 %. In H group

after 5 days there were no significant changes. After 15 days in H group there were significant changes in parameters: FA 97 %, PI 94 %, Ht 92 %, BCT 78 %, PAT 93 %. After the laser course a significant improvement in blood circulation of lower extremities was assessed by reovasography in 71% patients, while in H group the improvement was in 28% patients.

Conclusion: Our data support that 5 days course of treatment with laser (on treatment with oral hypoglycemic agent Gliclazid 30-60 mg/Diabeton MR-Servie/) is more effective than 5 days heparin course among Type 2 diabetic patients with angiopathy of lower extremities.

Anti-atherosclerotic potential of leaves of Cassia auriculata L. in experimental diabetes

S. Gupta[1], S.B. Sharma[1], U.R. Singh[2], S.K. Bansal[3], K.M. Prabhu[1]

[1] *University College of Medical Sciences (University of Delhi), Biochemistry, Delhi, India*

[2] *University College of Medical Sciences (University of Delhi), Pathology, Delhi, India*

[3] *Vallabhbhai Patel Chest Institute (University of Delhi), Biochemistry, Delhi, India*

Aims: Cardiovascular diseases constitute the main causes of morbidity and mortality in diabetic patients. Diabetes mellitus is very often associated with atherogenic lipid profile, increased oxidative stress and endothelial dysfunction that can develop atherosclerosis which in turn leads to the development of cardiovascular diseases. Medicinal plants with reputed traditional use to treat cardiovascular diseases may provide valuable drugs. Therefore, the present study was designed to evaluate the anti-atherosclerotic potential of aqueous extract of *Cassia auriculata* L. leaves in streptozotocin (STZ)-induced diabetic rats.

Methods: The rats were rendered diabetic by STZ (45 mg/kg body weight, intraperitoneal). *C. auriculata* extract was orally administered to diabetic rats at a dose of 100, 200 and 400 mg/kg body weight per day for a period of 21 days. Fasting blood glucose (FBG), lipid profile parameters (triglycerides, total cholesterol, high-density lipoprotein, low-density lipoprotein, apolipoprotein A1 and apolipoprotein B), lipid peroxidation and markers of endothelial dysfunction {oxidized low-density lipoprotein (OxLDL), nitric oxide (NO), vascular cell adhesion molecule-1 (VCAM-1) and fibrinogen} were estimated at the end of the experiment. The ratio of LDL and Apo B was used to determine small, dense LDL. Histopathological studies were also performed in heart tissue.

Results: The extract produced significant reduction in the levels of FBG in a dose dependant manner. Treatment with the extract (400 mg/kg body weight) exhibited significant reversal in the altered lipid profile with significant decreased level of small, dense LDL in diabetic rats. The lipid peroxidation was found to be significantly suppressed in extract-fed diabetic rats. The significant reduction in the levels of OxLDL, VCAM-1 and fibrinogen with a concomitant elevation in NO level was observed in diabetic rats following supplementation with the extract. Histopathogical examination of heart sections from extract-treated diabetic rats revealed reversal of fatty change towards normal.

Conclusion: It is evident from the data that *C. auriculata* aqueous leaf extract exerts anti-atherosclerotic effect in STZ-induced diabetic rats and this suggests that the extract may help to prevent the progression of cardiovascular diseases.

Antihyperglycemic actions of Ocimum sanctum extract are associated with enhancing tissue glucose utilization and delaying carbohydrate digestion and absorption

J.M.A. Hannan[1], B. Rokeya[2], J. Khaleque[1], M. Akhter[2], S.A.M. Khairul Bashar[1], L. Ali[2]

[1] *North South University, Pharmacy, Banani Dhaka 1213, Bangladesh*

[2] *BIRDEM, Pharmacology, Dhaka 1000, Bangladesh*

Aims: Previous studies on ethanol extract of *Ocimum sanctum* leaves have shown it to flatten the glucose tolerance curve in type 2 diabetic rats, and its antihyperglycemic activity in the postprandial state indicates that the extract may interfere with the glucose absorption in the gut. The present study aims to explore the mechanism of its antihyperglycemic activity, specifically related to the inhibition of carbohydrate digestion and absorption in the gut and tissue glucose utilization.

Methods: The dried powder leaves of O *sanctum* were extracted with 80% ethanol. The rats were made type 2 diabetic by intraperitoneal injection of streptozotocin (90 mg/kg bw) to 48 hours old pups. Sucrose malabsorption was evaluated in twenty hours fasted type 2 diabetic rats by measuring the amount of sucrose remaining in six different parts of gastrointestinal tract after sucrose load (2.5 g/kg bw). Inhibition of glucose absorption in the gut was evaluated using *in situ* perfusion of small intestine. For evaluation of disaccharidase activity the extract was fed to 20 h fasted rats. After 60 min, rats were sacrificed and small intestine was isolated and homogenized. The homogenate (20 µl) was incubated with 40 mmol/l sucrose at 37 °C for 60 min. Disaccharidase activity was calculated by glucose converted from sucrose as µmol-mg glucose/protein/h. Glucose uptake and insulin action were evaluated in 3T3-L1 cells.

Results: When extract of *O sanctum* was administered simultaneously with the sucrose load, the residual sucrose content in the gastrointestinal tract was increased significantly ($p<0.01$), especially in the upper intestine at 30 min, in the whole intestine as well as cecum at 1 and 2 h. At 4 h sucrose was not detected in the gut in both groups. The intestinal glucose absorption was almost constant during 30 min of perfusion with glucose. When extract was supplemented with the glucose solution, the percentage absorption of glucose was decreased by 13 - 19% during whole perfusion period ($p<0.05$). It inhibited disaccharidase (sucrase) activity significantly ($p<0.05$) in diabetic rats compared to control. Extract significantly enhanced glucose transport compared to control (no insulin incubation, $p<0.05$). The enhancing effect of this extract was further increased by the presence of 10^{-9} M insulin ($p<0.01$). The extract significantly increased pancreatic insulin ($p<0.05$) and liver glycogen content ($p<0.05$) in type 2 diabetic compared to control group in 28 days feeding experiment.

Conclusion: The antihyperglycemic activities of *O sanctum* in type 2 diabetic rats are mediated at least partly via enhancing glucose uptake in adipocytes, storage of hepatic glycogen and delaying intestinal carbohydrate digestion and absorption.

[6] *School of Veterinary SciencesFirat University, Department of Animal Nutrition, Elazig, Turkey*

Background: Chromium is an essential element for carbohydrate, fat and protein metabolism. The therapeutic potential of chromium histidinate in the treatment of diabetes was elucidated.

Objective: The present study was conducted to investigate the effects of chromium histidinate (CrHis) on serum parameters of renal function and, oxidative stress markers [malondialdehyde (MDA) and 8-isoprostane], and heat shock proteins (Hsp60 and Hsp70) expression in rats.

Methods: The male Wistar rats (n=60, 8 w-old) were divided into four groups. Group I received a standard diet (12 % of calories as fat); Group II were fed standard diet and received CrHis; Group III received a HFD (40 % of calories as fat) for 2 weeks and then were injected with streptozotocin (STZ) on day 14 (STZ, 40 mg/kg i.p. HFD/STZ); Group IV were treated as group III (HFD/STZ+CH) but supplemented with 110 mcg CrHis/kg bw.d. Oxidative stress in kidney of diabetic rats was noted by an elevation in levels of MDA and 8-isoprostane. The protein concentrations of Hsp60 and Hsp70 in the renal tissue were determined by Western blot analyses.

Results: CrHis supplementation lowered kidney concentrations of MDA, 8-isoprostane levels, serum urea-N, creatinine, and reduced the severity of glomerular sclerosis ($P < 0.0001$) in STZ treated group (diabetes induced group). The expression of heat shock proteins, Hsp60 and Hsp70 was lower in STZ group that received CrHis than group that did not receive CrHis. No significant effect of CrHis supplementation on overall measured parameters was detected in Control group.

Conclusion: Chromium histidinate significantly decreased lipid peroxidation levels and heat shock proteins expression of kidneys in experimentally induced diabetes (Group IV) in rats. This study supports the efficacy of CrHis in reducing the renal risk factors and impairment due to diabetes.

Emblica officinalis improves glycemic status and oxidative stress in STZ induced type 2 diabetic model rats

R. Begum[1], A. Aneesa[2], R.D. Shukla[3], A. Sohel[3], H. Anwarul[2], A.K. Azad Khan[4], A. Liaquat[5]
[1] *BIRDEM, Department of Pharmacology, Dhaka, Bangladesh*
[2] *Islamic University, Dept of Biotechnology and Genetic Engineering, Kushtia, Bangladesh*
[3] *Jahangirnagar University, Dept of Biochemistry and Molecular Biology, Savar, Bangladesh*
[4] *BIRDEM, Dept of Gastroenterology, Dhaka, Bangladesh*
[5] *BIRDEM, Dept of Biochemistry and Cell Biology, Dhaka, Bangladesh*

Background and aims:. Emblica officinalis belonging to the family of Phyllanthaceae widely cultivated throughout Indian subcontinent. Fruits of this plant have been demonstrated to possess several medicinal values. Based on the mass use of the fruit, the study was undertaken to evaluate the antidiabetic & antioxidant activities of Emblica officinalis using normal & STZ induced diabetic rats.
Materials and method: Male Long-Evans rats bred at BIRDEM animal house were used. Type 2 diabetes was induced by a single ip injection of STZ to 48 hours old pups & 3 months later after confirming with an OGTT type 2 rats were selected for experiment. The rats were divided into four groups (n=6-8 in each group): i) Control group, normal rats receiving water (NWC) ii) Type 2 diabetic control receiving water (T2WC) iii) Type 2 diabetic treated with glibenclamide (T2GT) (5 mg/kg bw) iv) Type 2 diabetic treated with aqueous extract of fruit pulp of Emblica officinalis, (T2AE) at a dose of 1.25g/kg bw. The extract & glibenclamide were fed orally for 8 weeks with a single feeding. Blood was collected by cutting the tail tip on 0 & 28 days & by decapitation on 56 day. The parameters measured were: serum glucose (glucose-oxidase), serum insulin (ELISA), serum lipids (enzymatic-colorimetric), serum ALT (UV method) & serum creatinine by (colorimetric) methods. Packed red cells were used for the estimation of malondialdehyde (MDA) by thiobarbituric acid method & reduced gluthathion (GSH) by the method of Beutler et al.
Results: Four weeks administration of aqueous extract of *E. officinalis* improved oral glucose tolerance in Type 2 rats. Postprandial serum glucose rose by 62%, 122%, 148% & 64% in NWC, T2WC, T2GT & T2AE groups respectively. Oral consumption of *E. officinalis* for 8 weeks caused significant ($P<0.007$) reduction of fasting serum glucose (FSG) level compared to 0 day. FSG also reduced significantly ($P<0.002$) in T2GT group. No change was in total cholesterol but triglycerides level decreased 14% by feeding *E. officinalis.* Eight weeks treatment with *E. officinalis* did not improve serum insulin level (SIL) (serum insulin Mean$\pm$SD; ng/ml: 0.38$\pm$0.17 in T2AE vs 0.24$\pm$0.13 in T2WC group). SIL remained unchanged in NWC group. No significant change was noticed in serum ALT & creatinine level in any groups. Erythrocyte MDA level was significantly higher in T2WC compared with NWC group ($P=0.025$). Orally administrated aqueous extract of *E. officinalis* reduced erythrocyte MDA level although nonsignificantly ($P<0.07$). Erythrocyte GSH content was found to be increased significantly ($P<0.05$) upon *E. officinalis* treatment.
Conclusion: The study revealed that aqueous extract of *E. officinalis* improves glycemic status in type 2 diabetic rats, which is probably mediated by extrapancreatic action. It also has strong antioxidant activity that reduces the oxidative changes induced by STZ administration.

Hypolipidemic effect of Trigonella foenum-graecum in type 2 diabetic rats

K. Junaida[1], J.M.A. Hannan[1], M. Akhter[2], S.A.M. Khairul Bashar[1], L. Ali[2]
[1] *North South University, Pharmacy, Dhaka, Bangladesh*
[2] *BIRDEM, Pharmacology, Dhaka, Bangladesh*

Aims: *T foenum-graecum* seed has earlier been shown to have antihyperglycemic properties in type 2 diabetic rats. In the present work, we have investigated the chronic effects of the seed on serum fructosamine, non-esterified fatty acid (NEFA), serum lipids, platelet aggregation and total antioxidant status (TAS) in type 2 diabetic rats.
Methods: Type 2 diabetes was induced by single intraperitoneal injection of streptozotocin (90 mg/kg body weight) to 48 hours old pups. The soluble dietary fibre (SDF) fraction from the seed of *T foenum-graecum* was prepared by the Theander and Westerlund method. The rats (n=20) were fed with the extract (1.25 g/kg body weight/5 ml water) twice daily for 28 days. The control rats (n=20) were fed only with deionized water. Blood was collected at the beginning of the study period from tail tips and at the end from abdominal aorta. Serum fructosamine and NEFA were measured by colorimetric and lipids by enzymatic method. Platelet aggregation was measured by Platelet aggregometer. Serum insulin was measured by rat insulin kit.
Results: *T foenum graecum* extract significantly lowered Serum glucose ($p<0.01$) and fructosamine ($p<0.05$) levels. However, serum insulin did not differ significantly between the extract fed and control groups. Total antioxidant status (TAS) was increased by 1.4 fold compared to type 2 diabetic control group ($p<0.05$). In addition, atherogenic lipids (TG and total cholesterol) and NEFA levels were lowered 56%, 21% and 56% respectively compared to control ($p<0.01$). The level of HDL-cholesterol increased significantly ($p<0.05$). The extract showed a lowering tendency of platelet aggregation in type 2 diabetic rats after 28 d administration ($p=0.055$). It did not show any effect on the content of pancreatic insulin; however, it increased hepatic glycogen as compared to control.
Conclusion: the present study has demonstrated that extract of fenugreek has promising antihyperglycemic and hypolipidemic effects. It also has a tendency to reduce platelet aggregation in diabetic rats. Fenugreek therefore represents a possible dietary adjunct for the treatment of diabetes.

Effect of Chinese herbal medicine YuQuiQing on the upregulation of chemokines induced by AGEs

Z. Sun[1], Y. Yuan[1], L. Zhou[1]
[1] *Southeast University, Department of Endocrinology, Nanjing, China*

Aims: Previous work showed that advanced glycosylation end products (AGEs) increased the expression of chemokines in human renal mesangial cells (HRMCs). The aim of this study was to further investigate the effect of a Chinese traditional drug YuKuiQing on the upregulation of monocyte chemoattractant protein-1 (MCP-1) and fractalkine (FKN) induced by AGEs.
Methods: HRMC cultured in the serum-free medium was incubated with AGE-BSA in the presence or absence of neutralizing anti-MCP-1 and anti-FKN antibody (Ab). HRMC incubated with AGE-BSA was cultured in the medium containing rat serum or special YuKuiQing serum which prepared by using Chinese herbal medicine serum pharmacological approach. The capacity of monocytes transmigration to HRMC was detected with a transwell system. The expression of MCP-1 and FKN mRNA in HRMC were analyzed by RT-PCR, and the content of MCP-1 and FKN in the supernatant of HRMC was measured by ELISA.
Results: 1. The number of monocytes transmigration to HRMC treated with AGE-BSA was significantly higher than control group (17.8±2.04 vs 0.7±0.84, $P<0.01$). But that of anti-MCP-1 Ab (8.6±1.14, $P<0.01$) and anti-FKN Ab (2.2±1.10, $P<0.01$) group was lower than AGE-BSA group. 2. The number of monocytes transmigration to HRMC treated with AGE-BSA in the presence of different concentration of rat serum (0.313%, 0.625%, 1.25%) was increased dose dependently (19.6±0.89, 23.6±1.14, 27.2±0.84, $P<0.05$). But those of YuKuiQing serum groups (17.0±1.00, 14.8±0.84, 12.0±1.22, $P<0.01$) were decreased compare to similar concentration of serum. 3. The mRNA expression (FKN: 1.03±0.05 vs 0.22±0.05, MCP-1:0.74±0.05 vs 0.26±0.03, $P<0.01$) and the supernatant content (FKN: 289.49±9.77 vs 20.15±8.84 pg·L^{-1}, MCP-1: 33.47±3.14 vs 16.19±0.66 pg·L^{-1}, $P<0.01$) of MCP-1 and FKN in the HRMC treated with AGE-BSA was significantly higher compared to control group. 4. The mRNA expression (FKN: 0.950±0.051 vs 1.106±0.045, 0.885±0.041 vs 1.148±0.044, 0.833±0.040 vs 1.199±0.044,$P<0.01$. MCP-1: 0.724±0.043 vs 0.800±0.060, 0.663±0.031 vs 0.836±0.055, 0.604±0.028 vs 0.856±0.053,$P<0.01$) and the supernatant content (FKN: 280.19±9.31 vs 310.87±10.70, 268.41±9.77 vs 332.57±9.31, 251.98±9.80 vs 343.73±6.33 pg·L^{-1}, $P<0.01$. MCP-1: 27.49±2.16 vs 33.69±3.24, 26.77±2.13 vs 34.03±3.31, 26.06±1.65 vs 34.72±3.01 pg·L^{-1}, $P<0.01$) of MCP-1 and FKN in the HRMC treated with AGE-BSA in the presence of different concentration of YuKuiQing serum was lower than control serum.

Conclusions: 1. AGE-BSA enhance the capacity of MCP-1 and FKN to induce monocytes transmigration to HRMC, which are inhibited by anti-MCP-1 and anti-FKN antibody partially. 2. YuKuiQing markedly reduce the upregulation of MCP-1 and FKN induced by AGE-BSA, and attenuate the capacity of MCP-1 and FKN to induce monocytes transmigration to HRMC, These results indicate that YuKuiQing might play its role of reno-protection via inhibition of MCP-1 and FKN.

An audit of the risk factors of developing MRSA in diabetic foot patients in Kingsmill Hospital, Mansfield

N. Dhillon[1], D.J.S. Fernando[1], L. Chesterton[1], P. Kirby[1], E. Emmerson[1], A. Fisher[1], K. Makhdoomi[1], B. Fairbrother[1], D. Reid[1]

[1] Kingsmill Hospital, Diabetes and Endocrinology, Nottinghamshire, United Kingdom

Aim: To analyze risk factors for Methicillin resistant Staphylococus Aureus in diabetic foot ulcer (DFU) patients and reaudit after introducing remedial measures.
Method: A retrospective audit of 44 patients at Kingsmill Hospital, Mansfield. Using clinical coding and electronic discharge systems the duration of hospital stay, the number of hospital admissions, surgical procedures, vascular procedures and MRSA culture results of DFU patients admitted for surgical procedures between March and November 2008 and 22 patients between November 2008 and February 2009, after the introduction of a diabetic foot coordinator (DFC) and a multidisciplinary team meeting (MDT) were analyzed.
Results: From April to December 2008 there were 22 MRSA bacteraemias, 12 with DFU. The odds ratio for multiple procedures compared to single procedures being MRSA positive is 24 (95% confidence interval (CI) 4.20-137.27, p=0.000028).The duration of stay (p=0.5028) and the number of hospital admissions (p=0.424) increasing the likelihood of a patient becoming MRSA positive is not statistically significant. The odds ratio of patients having multiple procedures compared to single procedures and whether the patient had vascular procedures to improve peripheral circulation to their feet e.g. angioplasty is 5 (95% CI 0.99-25.22, mid-p=0.03). The odds ratio of having vascular procedures prior to surgery reducing the number of surgical procedures from multiple to single is 3 (95% CI 0.15-59.89, mid p=0.2857).
After the appointment of the DFC and introducing MDT there have been no further MRSA bacteraemias in DFU patients. From November 2008 to February 2009, 3 out of 22 patients were MRSA cultures positive. These interventions resulted in a reduction of patients requiring multiple procedures (from 31.8% before November to 18.2% after). The odds ratio of being MRSA positive after November was 4.38 (95% CI 1.12-17.05, Fisher exact value=0.0219). The odds ratio of having multiple procedures after November is 2.10 (95% CI 1.13-17.05).
Conclusions: Before November patients were initially managed by general surgeons who performed surgical intervention. Patients having multiple surgical procedures needed vascular procedures to improve peripheral limb circulation (OR=5). This emphasised the need of correct classification of the DFU (e.g. vascular or neuropathic). Early revascularisation prior to surgical interventions reduced the need of multiple procedures through expert vascular assessment prior to surgery permitting definitive earlier surgery rather than multiple procedures due to poor peripheral circulation. The introduction of a DFC enabled early involvement of vascular specialists and reducing MRSA and multiple procedures. The number of admissions and duration of stay did not increase risk of MRSA suggests that infection control procedures in the wards and diabetic foot clinic are working.

Risk factors, prevalence and quality of care of diabetic foot disorders in Egyptian subjects with diabetes mellitus

S.H. Assaad-Khalil[1], S. El Amrawy[2], A. Abdel Rehim[1], A. Zaky[3], M. Abou Seif[4], I.F. Darwish[2], G. Makboul[2], M.H. Megallaa[1], K. Hemeda[1], H. El Weshahy[2], N. Gaber[1], H. Gamal[1]

[1] University of Alexandria, Department of Internal Medicine (Unit of Diabetes), Alexandria, Egypt
[2] University of Alexandria, Department of Community Medicine, Alexandria, Egypt
[3] University of Alexandria, Department of Biostatistics, Alexandria, Egypt
[4] University of Alexandria, Department of Clinical Pathology, Alexandria, Egypt

Introduction: Podiatry services are almost absent in Egypt. A specific Centre initiated by an IDF-BRIDGES Grant provides foot care, patient's education and formation of Health Care Providers (HCPs).
Aim: The aim of the present work was to assess the magnitude of the problem by delineating the risk factors, prevalence, and quality of care of diabetic foot disorders (DFD) in Egyptian subjects with diabetes mellitus (DM).
Subjects: 1290 Egyptian subjects with DM were included in the study. The mean age was 57.6±10.3 years and 48.3% of them were males.
Methods: Examination included the overall conformation of feet & ankles and common deformities or callus; skin temperature, joint mobility, vascular status, ankle brachial index; neurological status including vibration perception threshold and 10g monofilament testing and screening for shoe-foot mismatches.
Results: The mean duration of DM was 12.5± 8.8 years in those with DFD vs. 9.6 ± 7 in the others (p=0.002); 16.2± 8.7 in those with ulcers vs. 10.7 ± 7.5 in the others (p<0.001); 14.9±9.3 in those with PAD vs. 10.9 ±7.7 in the others (p<0.001); 14.1± 8.6 in those with neuropathy vs. 9.7±7 in the others (p<0.001) and 18.3 ±10.3 in those with amputation vs. 10.9±7.6 in the others (p<0.001). History of foot ulcers was found in 9.8% of patients, 12% in males and 6.9% in females (p<0.001), 22.4% in illiterates vs. 3% in high school graduates (p<0.001). Active ulcers were detected in 5.3% of patients, 6.1% of males & 4.6% in females (p=0.36). Amputation was found in 4.4%, 6.1% & 2.9% respectively (p=0.007). Neuropathy in 34.8%, 35.9% & 33.9% respectively (p= 0.54). Fungal foot infection in 20.8%, 21.6% & 20.3% respectively (p=0.64). Foot deformities were found in 30.4%, 37.4% & 24.7% respectively (p<0.001). Callus was present in 28.7%, 29.2% & 28.3% respectively (p= 0.78). Limited mobility of the joints was detected in 26.7%, 31.7% & 22.6% respectively (p= 0.004). The crowding index did not show a significant impact on the prevalence of DFD. Only 4.8% of the screened cohort has been subjected to any therapeutic patient education (TPE) related to foot care. Besides, only 7.2% of them had their vascular status assessed, 7.2% their neurological system examined, and only 14% have ever been inspected for the state of their feet. Among male patients with DFD, 67.3% were smokers and/or ex-smokers vs. 32,6% non-smokers (p=0.029). Presence of IHD, hypertension or stroke did not affect significantly the prevalence of DFD. Inappropriate foot-wear was observed in 54.4% of the studied cohort, 38.2% of males & 67.7% of females (p<0.001). The glycemic control was worse in subjects with DFD (HbA1C 11.6±4.5%) than in the others (8.5±4.5%) (p<0.001).
Conclusion: From the present study one can deduce that a mosaic of factors is contributing in the high prevalence of DFD in our community. Most of these factors are manageable and need comprehensive preventive strategies, committed HCPs and patient's awareness and empowerment.

Foot care in Cameroon

J. Menang[1], E. Ntolo[1]

[1] Divine Providence Low Cost Clinic, Malingo Street, Buea South West Region, Cameroon

Background: With 10 years of working with renowned hospitals in Cameroon like the 2 major Baptist hospitals diabetes clinics and then local clinics as well as visiting other hospital settings, I have not come across a unit with special attention given to foot care and vascular assessment. There is no single podiatrist specialist, and diabetes as well as obesity trends are sharply increasing.
Method: Reviewing foot care and vascular needs of the diabetics in Cameroon. Retrospective study on cross section of care in relation to diabetes and foot care/vascular assessment interpreted.

Result: Few clinics give diabetes care and often run out of diabetes supplies. Muddy road networks often discourage diabetics in the hinterlands accounting for non compliance and poor sugar results and subsequently foot ulcers which are on the rise. There are no Centres where either diabetics' feet or vascular systems are assessed.
Conclusions: Carrying out amputations for limbs that can be salvaged through early counseling, education, empowerment, early vascular assessment, is inhuman. More effort in education, sensitization, proper counseling and empowerment are very vital, cheap and efficient tools that can be used with excellent result but the prevailing poverty is affecting both the health care professionals in effectively carrying out the programs. 35% Cameroonian now are overweight and 600,000 are diagnosed with diabetes (www.3four50.com) implying that this is time that Cameroonians need diabetes experts most.

Admission for diabetic foot ulceration in a specialized diabetes unit in sub-saharan africa: an 8-year trends study

C. Djouogo Tekogno[1], A. Kengne[2], Y. Dehayem[3], E. Sobngwi[3], A. Lekoubou Looti Alain[3], J.C. Mbanya[3]
[1] *Yaoundé Central Hospital, National obesity center, Yaounde, Cameroon*
[2] *University of Sydney, The George Institute for International Health, Sydney, Australia*
[3] *Yaoundé Central Hospital, National obesity center, Yaounde, Cameroon*

Aims: Diabetic foot disease, a common complication of diabetes is a real public health issue. The aim of this work was to study the evolution of admissions, hospital resources utilization and outcomes of diabetic patients with foot ulcer in Cameroon, and to depict the trends for the period 2000-2007.
Methods: Admission and discharge registers of the diabetes and endocrine unit of the Yaounde Central hospital, Cameroon were reviewed for the period 2000-2007. Data were collected on the status for diabetes, presence of foot ulcer, age, and sex, duration of hospitalization, amputation and deaths. Data were analyzed with the use of SPSS® v.9 and appropriate statistical techniques.
Results: 1841 patients were diabetics including 240 with foot ulcer, giving a prevalence rate of 13% [(95% CI): 11-15%]. This prevalence varied significantly by year of study. The proportion of men among those with foot ulcer was higher than that for women (67% vs. 33%, c^2=11.64). The average age of the population of diabetics was 57 years, with not significant difference by status for foot ulcer. The average age of the participants without ulcer varied significantly by year of study. Male sex was the only significant determinant of admission for foot ulcer: odd ratio, OR (95% CI): 1.68 (1.25 -2.27). The average duration of hospitalization for patients with foot ulcer was 19.36 days. It was significantly higher than that for diabetic patients without foot ulcer. The average duration of hospitalization decreased significantly according to the years of study in both groups. Diabetic patients with foot ulcer consumed 2.16 (95% CI: 1.85-2.45) times more hospital resources than those without. During the study period, 203 deaths were recorded in patients with diabetes in the service. The death rate was 5.8% (95% CI: 2.9-8.8%) in patients with foot ulcer and 11.8% (10.2-13.4%) in those without. The rate of amputation among patients with diabetic foot was of 16% (95% CI: 11-21%). This varied significantly by year of study.
Conclusions: This study suggests that the prevalence of the diabetic foot in hospital settings in our environment is rather high. Fuelled primarily by men, this complication is the leading cause of prolonged hospitalization and bed occupancy in patients with diabetes. Although it is associated with a lower death rate, at least one in every ten patients admitted for foot ulcer undergoes a lower extremity amputation during hospitalization.

The diabetic foot: patient & provider tools

B. Harpell[1], L. Harrigan[1]
[1] *Diabetes Care Program of Nova Scotia, NS Department of Health, Halifax, Canada*

Background: As a provincial program focused on improving the health of Nova Scotians living with diabetes (DM), the Diabetes Care Program of Nova Scotia (DCPNS) recognizes that foot problems are a major cause of morbidity and mortality for people with DM. NS data show evidence of high rate ratios for lower extremity amputation (LEA). In the age groups 29-39 and 40-49, people with DM are 34 and 73 times more likely than the non-diabetic population to have an LEA, respecitvely.
Aims: To address the growing burden of foot problems and related LEAs in persons with diabetes in Nova Scotia, through a province-wide initiative.
Methods: In May 2007, following roundtable discussions with foot care providers and stakeholders, the DCPNS released a discussion paper, The Diabetic Foot in Nova Scotia: Challenges and Opportunities. This document identifies issues and gaps in care that contribute to poor foot outcomes and outlines priority areas for improvement in 5 target areas: DM Centres; Physician and Other Healthcare Providers; Inpatient Care; Consumer Awareness and Education; and the Departments of Health and Community Services. A multidisciplinary Diabetic Foot Working Group was formed to address a number of recommendations from the foot document. Literature was reviewed, draft materials developed, and Advisory Council approval granted.
Results: A series of patient and provider foot care materials feature a traffic sign color/symbol identifying category of risk: Green-Low, Yellow-Moderate, and Red-High. The materials, including a Foot Care Questionnaire; Risk Assessment Form; Risk Stratification Form; Referral Algorithm; 3 Patient Risk Information Sheets; and Patient Decision Tree, were launched at the provincial Foot Forum in Spring 2009 targeting DM care providers (nurses, dietitians, foot care specialists, and others).
Discussion: The culmination of this work will lead to increased awareness of the diabetic foot, more standardized approach to the identification of the high/moderate risk foot, more streamlined referral, and consistent messaging to individuals with DM and among health care providers. Dissemination will focus across multiple health system sectors using a variety of media: professional newsletters, continuing medical education opportunities, and direct access through the DCPNS website. Work will continue on other recommendations from the foot document.

Younger females get foot problem in Egypt in comparison to the UK

M. Soliman[1,2], M.S. Rajbhandari[1], M.R. El-Kaseer[2], A.F. Arafa[2], G.S. Soliman[2], E. Salim[2]
[1] *Lancashire Teaching Hospitals, Medicine, Chorley, United Kingdom*
[2] *Zagazig University, Medicine, Zagazig, Egypt*

Background and aims: Diabetic foot problem is associated with significant morbidity and mortality but this is often neglected in developing countries like Egypt. Therefore a diabetic foot service was started in the Zagazig University Hospital of Egypt in April 2008. The aim of this study was to compare profile of subjects attending this clinic and established Foot Clinic of Lancashire Teaching Hospital, UK.
Method: Subjects attending foot clinic between April 2008 and August 2008 at both centers were studied retrospectively and characteristics of patients who presented with active problem (new onset ulcer or Charcot Neuroarthropathy) were compared.
Result: 199 patients attended foot clinic in Egypt and 281 in the UK of which 24 and 55 had active foot problems respectively (Charcot Neuroarthropathy in 2 cases at each site). There was higher proportion of female with active foot problem in Egypt (70.8% vs 45.5%; p=0.05). Egyptian patients with active foot problem were younger (55.8 +/- 9.8 years vs 68.5 +/- 13.6 years; p <0.001) but duration of diabetes was similar (13.1 +/- 7.8 years vs 11.0 +/- 8.3 years; p = 0.3). Although most had type 2 diabetes, higher proportion were on insulin treatment in Egypt (91.7% vs 23.6%; p = 0.006). There was no difference in cardiovascular complications (37.5 % vs 40%) and smoking status (8.3% vs 5.5%).
Conclusions: This study shows that more females develop foot problem in Egypt at a younger age. This may be due to survival advantage of diabetic females and further studies are needed.

Clinical characteristics on the patients with diabetic foot problem

M. Islam[1], Y. Talukder[2], M.A. Sayeed[3], B. Rokeya[4]
[1] *Dinajpur Medical College, Department of Surgery, Dinajpur, Bangladesh*
[2] *BNSB Eye Hospital, Department of Ophthalmology, Sirajganj, Bangladesh*
[3] *BIRDEM, Department of Biostatistics, Dhaka, Bangladesh*
[4] *BIRDEM, Department of Pharmacology, Dhaka, Bangladesh*

Background and aims: Diabetic foot problems are global burden and the consequences are major. There is an increase in amputation rates globally despite increased foot care education, research and prevention. This increasing trend has been attributed mainly to diabetes to failure of early detection of the risk group. The aim of this study was to express the prevalence of diabetic foot characteristics of diabetic patients that developed foot ulcer.
Materials and methods: This study was carried out in a district hospital, a secondary health care centre, which covers 270,7011 population. A total of 1875 diabetic subjects registered in the out patient department within a period of 35 months. Of these diabetic subjects 75 (M/F=46/29) presented with foot ulcer. We investigated the latter subjects for geographic location, family income, height, weight, mid-arm circumference (MAC), monofilament test, electrocardiogram (ECG), ophthalmoscopy, fasting blood glucose (FBG), fructosamine, lipids and micro-albumin creatinine ratio (ACR). Body mass index (BMI) was calculated as wt in kg/ht msq.
Results: The prevalence of foot ulcer among the diabetic population was 4%. Among them only 4% were from higher social class, whereas, 96% were either from lower middle or poor class. The urban subjects were only 40% and the rest 60% were either from rural or suburban communities. The mean (SD) of age was 52 (12)y, BMI 20.2 (3.8), and MAC 23.1 (2.7) cm. Their FBG and fructosamine levels were 12.4(6.0) mmol/l and 317 (118) micromol/l, respectively. A 10-g monofilament test could detect abnormal or absent sensation in 38.7% of the cases. Most importantly, the sensory impairment was found significantly associated with coronary heart disease ($p<0.04$) and retinopathy ($p<0.049$).
Conclusion: The study revealed that the prevalence of foot ulcer among the diabetes of Bangladesh is comparable to other countries. The prevalence was much higher in the low social class and in rural population. The monofilament test was found to be an important simple test for detecting early stage of impaired sensation related to foot ulcer.

D-0620

The prevalence of calcification of the pedal arteries in patients with disease of the foot in diabetes

A. Sharma[1], B. Scammell[2], J. Fairbairn[3], F. Game[1], W. Jeffcoate[1]
[1] *Nottingham City Hospital, Foot Ulcer Trials Unit, Nottingham, United Kingdom*
[2] *University of Nottingham, Accident and Orthopaedic Surgery, Nottingham, United Kingdom*
[3] *Nottingham City Hospital, Radiology, Nottingham, United Kingdom*

Aims: The mechanisms underlying the increased prevalence of medial calcification in diabetes are not understood. An association with distal symmetrical neuropathy has been reported in a number of small studies, and a particularly high prevalence was reported in two series of patients with Charcot's disease. The aim of this study was to attempt to confirm the high prevalences of calcification in Charcot's disease and to determine whether it is specific to that disorder by comparing the results with patients with other types of foot disease.
Methods: The prevalence of calcification was determined retrospectively in three groups of patients managed by a specialist diabetic foot service. Group A comprised those with an acute Charcot foot who were managed between 2002 and 2005, Group B comprised those managed in the foot service who had been diagnosed with osteomyelitis between 2002 and 2004, and Group C those who had had X-rays taken between 2002 and 2004 but who had neither osteomyelitis nor Charcot's disease. All X-rays were scored independently by three observers. All three observers were blinded as far as possible to the underlying diagnosis, with films from the three groups being mixed.
Results: There were 34 patients in Group A (Charcot), 53 in group B (osteomyelitis) and 35 in group C. There were no differences ($p>0.5$) in the mean age of the patients in the three groups (60, 72 and 68 years, respectively), the proportion of men (68%, 64% and 51%) and the prevalence of nephropathy (41%, 30% and 14%). The overall prevalences of calcification in the three groups were 53%, 66% and 54% ($p>0.05$). When all three groups were combined, the only factor associated with calcification on logistic regression analysis was duration of diabetes ($p=0.004$).
Discussion: The prevalence of arterial calcification in patients with foot disease was higher than the 40% previously reported in patients with neuropathy, but lower than that reported in other series of Charcot. As there was no difference in the prevalence of calcification between the three groups, it is concluded that the increase is not specific to Charcot's disease. It is possible that the increase in calcification in each of the three groups reflects the effect of preceding local inflammation, possibly by activation of the RANKL/OPG signalling system.

Practical thermal monitoring solutions: empowering diabetic foot care teams for prevention of lower extremity complications

M. Bharara[1], R. Fitzgerald[1], H.R. Rilo[1], D.G. Armstrong[1]
[1] *University of Arizona, Department of Surgery, Tucson, USA*

The purpose of this abstract is to summarize recent developments in thermometry and associated initiatives regarding prevention of lower extremity complications in diabetes mellitus. This information will facilitate adoption of thermometry related prevention strategies by diabetic foot care teams. Prevention of foot ulcers by identifying individuals at high risk and treating for lower extremity complications may reduce number of amputations by 85%. Inflammation is a potential marker of neuropathic complications leading to diabetic foot ulcers and can be easily identified by temperature assessments of the affected limbs. The authors' research group have reviewed various thermological techniques relevant to the diabetic foot disease and emphasize the importance of using thermometry for lower extremities as a tool for supplementary evidence of neuropathy. Additionally, the authors' research has shown that skin temperature monitoring at home reduces re-ulceration rates by 4 to 10fold. Currently, the authors' are investigating thermometry in dynamic state to model thermal changes during activity of daily living, develop prediction model for wound healing and combining thermography with other imaging modalities to futher understanding about diabetic foot infections.
In three independent clinical trials our group investigated the efficacy of the thermometry for lower extremities, with the intent to reduce recurrence of ulceration. Educating patients about self-monitoring and providing a hand-held digital thermometer achieved significant reductions in re-ulceration. In a recent study by our group involving a clinical thermometry test, it is shown for the first time, the evidence of poor recovery times for the diabetic foot with neuropathy when assessing the foot under load. Diabetics with neuropathy show the highest 'delta temperature' i.e. difference between the temperature after 10 minute recovery period and baseline temperatures measured independently. A temperature deficit (due to poor recovery to baseline temperature) suggests degeneration of thermoreceptors leading to diminished hypothalamus mediated activity in the diabetic neuropathic group.
There is a growing body of evidence emerging from our group's work in this area to build a knowledge base in thermal measurements. The long term goal of this research is to further the role of thermometry and thermography in clinical care for the diabetic foot. There are incremental benefits from a well equipped foot care team, that includes patient education or counselling for self monitoring of their condition which has been shown to be successful.

Diabetic foot problems in Mauritius

S. AhKion[1], V. Pauvaday[1], M. Kong[2], R. Jogia[2], I. Dumont[3]
[2] *University Hospitals of Leicester, Department of Diabetes, Leicester, United Kingdom*
[3] *Centre du Pied, Department of Diabetes, Ransart, Belgium*

Mauritius is an island in the Indian ocean and is a popular holiday destination. It has undergone rapid economic growth and as a consequence diabetes prevalence has increased by 40% between 1986 and 1997, and is still increasing, and affects close to 20% of the population over 30 years of age, and diabetic foot problems and lower limb amputations have increased.
Aim: To assess the scale of diabetic foot problems in Mauritius and the future impact of training health care professionals in the management of the diabetic foot.
Method: The Ministry of Health was successful in obtaining a grant from the World Diabetes Foundation and we[2,2,3] were invited to train health care professionals in diabetic foot care.

Results: Audit data showed that in 2007 there were 334 total amputations, 288 of which were diabetes-related and 139 of which were major amputations. 74% of the major amputations occurred in men. The average age for a major amputation was 63 years for males and 62 years for females. Data from 1995-1997 reported 5.8 major amputations per 100,000 population per year in Leicestershire compared to an estimated 10.7 major amputations per 100,000 population per year in Mauritius.
There are no established diabetes foot clinics on the island. Diabetics with foot ulcers are admitted under the general surgeons. There is only one vascular surgeon on the island who is a cardiac surgeon and there are no interventional radiologists involved in diabetes foot care. There is only one microbiologist and a podiatrist who had retired from Sheffield, UK, had recently been appointed. A patient who presented with a foot ulcer simply had the ulcer dressed and ointments such as iodine and gentian violet were sometimes used. Several ulcers assumed to be ischaemic or neuroischaemic were in fact entirely neuropathic with a good chance of healing with regular debridement and offloading. Offloading was not being offered and the health care professionals did not know how to do offloading casting. In addition the ideal material for the offloading cast is expensive and may not be a sustainable option. Cheaper options were discussed.
Discussion: During the week we spent in Mauritius we are glad to say that we managed to save some legs. We discussed the shortfalls with the Health Minister. There is a need for a dedicated diabetes foot team and the setting up of multidisciplinary diabetes foot clinics with close collaboration between the physicians and general and orthopaedic surgeons. There is an urgent need to recruit and train additional podiatrists. Radiologists could be trained to do lower limb angioplasties. Above all education and prevention of diabetic foot ulcers should be amongst the priorities. A foot clinic has now been set up and more feet have been saved. A re-audit of lower limb amputations is planned in 2010.

Comparative investigation of mortality in a population based study with type 2 diabetes in Germany (DIG) in comparison with the findings in ACCORD, ADVANCE and VATD

C. Koehler[1], P. Ott[1], J. Stelzer[1], I. Benke[1], M. Hanefeld[1]
[1] GWT-TUD GmbH, Center for Clinical Studies, Dresden, Germany

Background and aims: Patients with type 2 diabetes (T2DM) have a higher risk of mortality than normoglycemic subjects. Recently published results of three megatrials with intensified glucose lowering have shown no beneficial effect on all cause mortality. However the mortality rate was low in the three trials. The Diabetes in Germany (DIG) study is a population based prospective observational study of patients with T2DM with a HbA1C level of 7% at baseline. The focus of this report was to compare the overall mortality of the DIG population to the outcome of the international studies ACCORD, ADVANCE and VATD.
Materials and methods: Two hundred and thirty eight general practitioners and diabetologist practices that represent a cross section of daily practice in Germany took part as investigators in this study. Each center recruited 10-30 consecutive patients with T2DM. Medical history, cardiovascular medication, risk factor profile, clinical and laboratory parameters and all cause mortality were collected by a standardized questionnaire. Exclusion criteria were: major cardiac event in the last 3 months, neoplasia in the last 5 years, heart failure NYHA IV or chronic renal failure. The total population consisted of 4,020 patients aged 35-80 years.
Results: In the DIG study after an average follow-up time of 3.7 years we had available data of 2.959 patients. The mean glycated hemoglobin level was 7.0% (SD1.2) and the average age was 61.5 (7.9) years. In comparison in ACCORD, ADVANCE and VATD the range of HbA1C levels and age at entry were higher (8.3% / 62.2 yrs; 7.5% / 66 yrs; 9.4% / 60.5 yrs). The corresponding annual mortality rates were 1.28; 1.85; 1.96 and in DIG 1.48.
Conclusion: Compared with the large outcome studies the annual all cause mortality rate in the DIG study with an average HbA1C level of 7.0% was in the same range despite striking differences in glycated hemoglobin levels. It looks like that in these multimorbid patients other risk factors such as blood pressure and lipid control are of dominant importance.

Ethnicity and outcomes in a 20-week, randomized, controlled trial (TITRATE study)

L. Blonde[1], T. Gylvin[2], V. Karwe[2], P. Raskin[3]
[1] Ochsner Clinic Foundation, Department of Endocrinology Diabetes and Metabolic Diseases, New Orleans, USA
[2] Novo Nordisk Inc., Clinical Development Medical and Regulatory Affairs, Princeton, USA
[3] University of Texas Southwestern Medical Center at Dallas, Department of Endocrinology, Dallas, USA

Background and aims: Insulin titration is essential for the management of type 2 diabetes. Race/ethnicity has been claimed a factor in outcomes of some therapies. We sought any differences in efficacy and safety for self-titration of once-daily insulin detemir between self-identified Whites (n=177) and African Americans (n=36).
Methods: Data were analyzed from the TITRATE study, a 20-week, randomized controlled trial that examined two FPG targets (3.9-5.0 mmol/l and 4.4-6.1 mmol/l) for the self-titration of once-daily insulin detemir for the treatment of type 2 diabetes.
Results: The mean duration of diabetes for Whites and African Americans was 8.2 and 9.0 years, respectively. Mean baseline HbA1c values were significantly lower for Whites than for African Americans (7.9% and 8.2%, respectively, p=0.02), but there was no significant difference in mean HbA1c changes at end of study (-1.11% and -1.02% for Whites and African Americans, respectively, p=0.48).
The proportion of subjects who reached HbA1c levels <7% at 20 weeks did not differ significantly between Whites and African Americans (62.1% [110/177] and 47.2% [17/36], respectively, [p=0.37 for the odds ratio of White vs. African American]). Similarly, the proportion of subjects achieving HbA1c levels =6.5% at 20 weeks also did not differ significantly (37.3% [66/177] and 25.0% [9/36], for Whites and African Americans, respectively [p=0.45 for the odds ratio of White vs. African American]). Mean weight-adjusted insulin doses at 20 weeks were significantly greater for Whites compared to African Americans (0.57 U/kg vs. 0.39 U/kg, p=0.004).
Major and minor hypoglycemic events were low (4.50 and 2.79 events/patient-year for Whites and African Americans, respectively. One major hypoglycemic event occurred (White subject, 0.01 events/patient-year). There were no significant differences in rates of all hypoglycemic events (Exact rate ratio for White vs. African American = 1.65, 95% CI [0.87, 3.12], Poisson regression p=0.12). The rate of nocturnal hypoglycemic episodes was greater for Whites than for African Americans (Exact rate ratio = 5.46, 95% CI [1.14, 26.03], Poisson regression p=0.03).
Conclusion: Once-daily self-titration of insulin detemir was safe and effective in Whites and African Americans. Although baseline HbA1c levels were lower in Whites, both groups showed similar reductions in HbA1c at end of study, and there were no statistical differences in the proportion of subjects in either group achieving glycemic goals. However, African Americans used smaller doses of insulin by end of study and had fewer nocturnal hypoglycemic events, suggesting that successful diabetes management should take into consideration cultural, racial and ethnic differences. Finally, we note that the number of African Americans in this study was small compared to Whites, and therefore further study with larger subject populations is warranted.

[11] Centre Marc Sankale, Centre du diabete, Dakar, Senegal

Background: Weight control is an important aspect of diabetes mellitus (DM) management. Local data are important in the interpretation and use of patient's measurements. No region-wise information is available on indices of obesity in sub-Saharan Africa. The Diabcare project provided an opportunity to source comparative data from six sub-Saharan African (SSA) countries.
Aim: To analyze anthropometric measurements from African countries and critically evaluate and compare such data with recommended critical guidelines on anthropometric data for diagnosis of obesity.
Methods: The Diabcare Middle Africa project was conducted in 2008. The project consisted essentially of obtaining clinical data from patient records, interviewing the patient and performing an HbA_1c test. Among the records obtained from each patient were anthropometric measurements of height, weight, waist circumference (WC) and hip circumference. Information was obtained from 31 centres in six SSA countries. The anthropometric indices were analyzed by country and for the whole group with particular attention to body mass index (BMI), waist circumference, and waist hip ratio (WHR) using criteria suggested by IDF and/or World Health Organisation (WHO).
Results: Information on height and weight was available for 2643 patients while 1879 patients had measurements on waist and hip circumferences. The regional mean (SD) BMI was 27.3 (6.0) $kg/m^{2.}$ Individual country averages ranged from 27.7 to 29.0 kg/m^2. The mean WC of the 2302 patients with available data was 94.2(13.2) cm and a range of 35-182 cm. Mean country WC averages ranged from 91.6(12.7) cm to 97.2 (14.7). Mean WHR was 0.9 (0.1) with a regional range of 0.5-1.67. Using IDF WC cutoff for European men (<94) and women (<80) respectively as recommended for Africans, 46.8% and 90.1% had truncal or central obesity. Of the women the range of prevalence of central obesity by this criterion was particularly high at 86.0% to 91.8%.
Conclusion: The diagnostic criterion for the prevalence of obesity in African men using the IDF criteria appears to be within expected limits. However the criterion for women appears to excessively over diagnose central obesity. Urgent region-wide and local prospective studies are required to fill the gap.

The rate of patients achieving target levels for hyperglycemia, hypertension and hyperlipidemia in type 2 diabetes

M.K. Park[1], A.Y. Kang[1], S.R. Lee[1], Y. Han[1], H.J. Lee[2], D.K. Kim[1]

[1] School of Medicine Dong-A University, Internal Medicine, Busan, Korea
[2] School of Medicine Dong-A University, Pharmacology, Busan, Korea

In our study group, "3H care" was established since 2002. The meaning of "3H care" is attaining and maintaining adequate control of Hyperglycemia, Hypertension and Hyperlipidemia. We evaluated the rate of patients achieving target levels by American Diabetes Association (ADA) for hyperglycemia, hypertension and hyperlipidemia after 1 year "3H care" for type 2 diabetes. This was a cross-sectional retrospective study of 200 type 2 diabetic patients first visited at the diabetic clinic of Dong-A university hospital. Outcome data included HbA1C, blood pressure, total cholesterol, HDL-C, LDL-C, triglyceride and percentage of patients achieving HbA1c <7%, blood pressure <130/80 mmHg, LDL-C <100 mg/dL, HDL-C >40 (50 in women) mg/dL and triglyceride <150 mg/dL. Two hundred patients were enrolled (male 106 (53%) and female 94 (47%). The mean age was 56.0±11.3 years, BMI was 24.3±3.4 Kg/m^2, duration of diabetes was 6.2±8.2 years and initial level of HbA1C was 8.6±2.1%. The prevalence of hypertension, hyperlipidemia and both were 45%, 43% and 24% respectively. After 1 year " 3H care", the HbA1C level was reduced to 7.3±1.6% and the percentage of those <7% was 52%. The HbA1C levels among different treatment groups were 6.0±0.4% (diet alone), 6.8±2.2% (oral agents alone), 7.9±2.5% (insulin alone), and 8.3±4.1% (insulin and oral agents). Those who achieved HbA1C <7% showed a trend of shorter duration of diabetes and lower initial HbA1C levels, but statistically was not significant. The percentages for blood pressure were 58% (systolic blood pressure) and 64% (diastolic blood pressure). The percentages of achieving targets of hyperlipidemia were 63.5% (LDL-C), 67% (triglyceride), 59.4% (HDL-C in men) and 20.2% (in women). In conclusion, there is good evidence that multifactorial treatment of the risk factors will have a dramatic effect on diabetic end points. But overall rates of achieving targets need to be much improved. We should start more early these multi-factorial control and should also maintain it continuously to improve the achievement.

Achievement of therapeutic targets and use of cardioprotective medication in patients with type 2 diabetes mellitus: EuroAspire III Romania follow-up

A. Vlad[1], V. Serban[1], R. Timar[1], O. Albai[1], C. Avram[2], D. Stancila[3], M. Iurciuc[3], D. Gaita[3]

[1] University of Medicine and Pharmacy "Victor Babes", Diabetes Clinic, Timisoara, Romania
[2] Western University, Department of Rehabilitation, Timisoara, Romania
[3] University of Medicine and Pharmacy "Victor Babes", Clinic of Cardiovascular Rehabilitation, Timisoara, Romania

Aims: *EuroAspire III Romania Primary Care* investigated the achievement of therapeutic targets and the use of cardioprotective medication in accordance to the European guidelines of cardiovascular disease prevention in clinical practice 2007, in high-risk asymptomatic patients taken care of by their general practitioner (GP). *EuroAspire III Romania Follow-Up* evaluated the evolution of these parameters over a 1 year period. The aim of this work was to analyze the time trend of achievement of therapeutic targets and use of cardioprotective drugs in type 2 diabetes mellitus (T2DM) patients from the trial.
Methods: The study group comprised 43 patients with T2DM, 14 men (32.5%) and 29 women (67.5%), mean age±SD=59±8.6 years. The patients were submitted to clinical and biological evaluation at baseline and after 6 and 12 months. The main characteristics recorded were values of total cholesterol (TC), LDL cholesterol (LDLc), triglycerides (TG), fasting glycemia and glycated hemoglobin (HbA_1c) and use of cardioprotective medication (aspirin, statins and ACE inhibitors). GPs were advised to reinforce lifestyle changes and to optimize drug therapy in order to reach the targets mentioned in the guideline. The statistical methods used were chi-square test for trend and and Fisher's exact test. A value of $p < 0.05$ was considered statistical significant.
Results: The main results are shown in the table.
Table. Achievement of therapeutic targets and use of cardioprotective drugs in T2DM patients

Parameter	Number (%) of patients in target or receiving cardioprotective drugs			p
	Baseline	6 months	12 months	
TC <175 mg/dl	5 (11.6)	16 (37.2)	17 (39.5)	0.0045
LDLc <100 mg/dl	4 (9.3)	19 (44.1)	24 (55.8)	<0.0001
TG <150 mg/dl	19 (44.1)	22 (51.1)	20 (46.5)	0.82
Fasting glycemia <110 mg/dl	12 (27.9)	13 (30.2)	14 (32.5)	0.63
HbA_{1c} <6.5%	11 (25.5)	no data	23 (53.4)	0.0147
Aspirin	13 (30.2)	17 (39.5)	20 (46.5)	0.12
Statins	24 (55.8)	26 (60.4)	42 (97.6)	<0.0001
ACE inhibitors	21 (48.8)	26 (60.4)	29 (67.4)	0.0795

For all the parameters, the achievement of therapeutic targets and use of cardioprotective medication increased gradually in time. Statistical significant differences were recorded for TC (c^2=8.05, p=0.0045), LDLc (c^2=20.08, p <0.0001), HbA_{1c} (p=0.0147) and statin use (c^2=18.41, p <0.0001).

Conclusion: Preventive intervention, conducted by GPs, improved the lipid profile and glycemic control in T2DM patients, even though the guideline targets are far from being achieved. It also led to an important increase in the use of statins, but not of aspirin and ACE inhibitors. There is a strong need to continuously encourage GPs to apply current guidelines recommendations in T2DM patients.

Quality of care at a diabetes clinic in a predominantly rural population at General Hospital, Kandy, Sri Lanka

W.A.D.I. Lowe[1], S.D. Dharmaratne[2], D.J.S. Fernando[3]
[1] *General Hospital (Teaching) Kandy, Endocrinology & Diabetes Unit, Kandy, Sri Lanka*
[2] *Faculty of Medicine University of Peradeniya, Department of Community Medicine, Peradeniya, Sri Lanka*
[3] *KingsMill Hospital, Department of Diabetes and Endocrinology, Sutton in Ashfield Nottinghamshire, United Kingdom*

Objective: To determine the proportion of diabetic patients reaching target levels for blood glucose, blood pressure, serum lipids and body mass index and assess the quality and level of care of the study population.
Design: Cross sectional descriptive study.
Setting: Diabetes clinic, General Hospital, Kandy.
Patients: 685 diabetic patients attending diabetes clinic from September to December in 2007.
Measurements: Height, weight, Lipid levels, blood pressure, compliance with national guidelines regarding risk factor reduction, monitoring glycaemic control and screening for complications were recorded. Data collected by an interviewer administered structured questionnaire.
Results: Mean FBS & PPBS in the clinic population was 7.29mmol/l (± 2.65) [(131.4mg/dl (±47.8)] & 9.32mmol/l(±3.92) [167.9 mg/dl (± 70.7)]. Only 97(14.2%) patients had their HbA1c measured. Lipids were assessed in 376 (54.9%) patients. 114 (38.5%) received statin therapy, although 296 (78.7%) were above the target LDL. 58 (15.4%) patients achieved target LDL. 356(52%) patients received aspirin despite 641(93.6%) patients being over 40 years of age. 254(37.1%) patients were screened for retinopathy and 144(21%) had their feet examined. 299 (43.6%) patients reached target blood pressure. Mean systolic BP was 136 mmHg (SD=19). Mean Diastolic BP was 82 mmHg (SD=9).
538 (78.5%) patients reached AACE target level of BMI =27.
Conclusions: Non-availability of standard HbA1c measurement was a major deficiency in the assessment of glycaemic control. Screening for retinopathy, neuropathy & diabetic foot were sub-optimal. Management of lipids was unsatisfactory.
The AACE, BMI criteria of 27 was considered too high for ethnic Sri Lankans.
The difficulty in meeting targets showed that quality and level of care in the diabetes clinic was sub optimal. Excessive patient congestion at government diabetes clinics providing free service for all, is likely a major obstacle in the delivery of good quality services.

Compliance with clinical practice guidelines for type 2 diabetes in an urban area of Pondicherry: treatment gaps and opportunities for improvement

P. Mahajan[1], A. Purty[1], Z. Singh[1], Y. Sharma[1]
[1] *Pondicherry Institute of Medical Sciences, Community Medicine, Pondicherry, India*

Introduction: The number of people developing diabetes is very high in the union territory of Pondicherry (5.04%).
Aim of the study: This study aims to find out prevalence of risk factors and treatment gaps among type 2 diabetics and explore opportunities for improvement in Diabetes Care.
Methods: Community based study was carried out using a cross-sectional study design among 99 of 684 diabetics chosen randomly from the field practice area of urban health centre, Muthialpet, Pondicherry. Data were collected from laboratory test results(for previous 1 year)available with the patients, an interviewer-administered questionnaire and Standardized physical assessments(weight, height, and blood pressure)carried out during the study period between Feb and March 2009. Data was analyzed using means and proportions in SPSS software.
Results: Ninety nine patients(50 men, 49 women, mean age 58.91± 11.83 yrs)with type 2 diabetes were enrolled in the study.The patients had diabetes for a mean of 12 years.At the time of the interviews,9.1%,43.43%, 27.27% of the patients were smokers,overweight and physically inactive respectively.Clinical indicators were,on average, at or near the recommended clinical practice guideline targets;48.8%,39.39%,and 0% of patients were at target levels for glycemic,blood pressure,and lipid control,respectively. Patients were receiving oral antidiabetic agents (81.81% of patients), insulin alone (3.3%), antihypertensive agents (36.36%), and lipid-lowering agents (4.4%). Patients were receiving a variety of antihypertensive therapies,alone or in combination, most commonly calcium channel blockers (55.55%), beta-blockers (30.5%),angiotensin-converting enzyme inhibitors (8.3% of patients), and thiazides(2.7%).Statins were the most commonly prescribed lipid-lowering agents (100% i.e. 4 of these patients).Only 4(4.4%) of the 99 patients were taking aspirin.Important therapy gaps were observed in the pharmacologic management in all three clinical target areas for hyperglycemia, hypertension, and dyslipidemia.Of 48 patients who were not at the ADA practice guideline target for glycemic control (FBSL < 126 g%), 6.1% were receiving no therapy. Also, 6.6% of patients whose blood pressures were above the target level were not receiving any antihypertensive drugs.Of note, 90.9% of patients whose LDL levels were greater than 100 mg/dl were receiving no lipid-lowering therapy.
Conclusion: There is sufficient scope for improvement,in terms of achieving various clinical targets.

No conflict of interest

D-0630

Clinical characteristics according to a family history in type 2 diabetes patients

G. Koh[1], S.U. Jeong[1], D.H. Lee[1], H.J. Chin[2], D.M. Lim[3]
[1] *Jeju National University Hospital, Internal Medicine, Jeju, Korea*
[2] *Hankook General Hospital, Internal Medicine, Jeju, Korea*
[3] *Konyang University Hospital, Endocrinology & Metabolism, Daejeon, Korea*

Background and aims: Type 2 diabetes mellitus (T2DM) has a strong genetic component, and the prevalence is notably increased in their family members. However, there were few studies about a family history of T2DM. We carried out this study to assess influences of the family history on clinical characteristics in T2DM patients.
Methods: This is a cross-sectional study involving 660 T2DM patients from 2 university hospitals. History and physical examination were done and fasting blood and urine samples were taken. If any first degree relative was diabetic, a family history of diabetes was considered to be present. Metabolic syndrome was defined by IDF criteria.
Results: 31.2 percent of total subjects have a family history of diabetes. Patients with a family history had a younger age (55.4±14.4 vs 59.7±14.3 year-old, $p<0.01$), higher weight (65.5±13.4 vs 62.7±11.8 kg, $p<0.05$) and BMI (25.0±3.8 vs 24.2±4.1 kg/m^2, $p<0.05$), higher waist circumference (89.9±12.0 vs 87.7±11.7 cm, $p<0.05$), longer diabetes duration (10.4±8.6 vs 8.6±8.4 years, $p<0.05$), younger age at diagnosis (45.3±12.2 vs 51.3±14.7 year-old, $p<0.01$) and higher triglyceride (195.8±151.5 vs 176.8±162.9 mg/dL, $p<0.05$) than those without a family history. Metabolic syndrome was more prevalent in familial T2DM with a statistical significance (54.5 vs 44.3%, $p=0.03$). Sex, blood pressures, HbA1c, C-peptide, creatinine, microalbuminuria, total cholesterol, HDL and LDL cholesterols were not different between familial and non-familial T2DM. On multiple linear regressions, the T2DM family history remained significantly associated with body weight, waist circumference and triglyceride.
Conclusion: In T2DM patients with a family history, the disease developed earlier. Metabolic risk factors and metabolic syndrome are prevalent in familial T2DM more than non-familial T2DM. This result raises the necessities of earlier screening for diabetes in family members of T2DM and more active prevention against cardiovascular disease in T2DM patients with a family history.

Serum undercarboxylated osteocalcin (ucOC) levels in diabetic patients

K. Okayama[1], N. Hirose[1], Y. Kojima[1], M. Oono[1], M. Oritsu[2], J. Komatsu[2], M. Yoshitsugu[1], T. Hiyoshi[1], D. Nakazawa[3], M. Fujiwara[3], R. Kawamori[4]
[1] Japanese Red Cross Medical Center, Department of Diabetes and Endocrinology, Tokyo, Japan
[2] Japanese Red Cross Medical Center, Health care center, Tokyo, Japan
[3] Japanese Red Cross Medical Center, Department of Laboratory Medicine, Tokyo, Japan
[4] Juntendo University School of Medicine, Department of MedicineEndocrinology and Metabolism, Tokyo, Japan

Backgrounds and aims: Serum undercarboxylated osteocalcin(uc OC) is a bone-metabolism-related protein which reflects Vitamin K metabolism and increases in serum when synthesis of osteocalcin decreases by lack of Vitamin K. It is often reported that serum uc OC levels are increased in aged patients with Type 2 diabetes mellitus, but there are a few reports in younger diabetic patients. The aims are to study uc OC levels in the diabetic patients over a very wide age group in relation to diabetic control markers.
Subjects and methods: We examined serum uc OC, fasting blood glucose, glycohemoglobin, and glycoalbumin levels including renal function tests and other tests in the 554 diabetic patients (age: 27-93 years old; sex:330 men, 224 women). Serum uc OC was measured by ECLIA(Electro-chemiluminescence) method.
Results: The mean age of the subjects was 65.28±12.12 years old, mean HbA1c values were 7.04 ±1.11%, mean serum uc OC levels were 3.45±4.46ng/ml. When the value of serum uc OC exceeds 4.5 ng/ml, it defines as abnormal. In 554 patients, 91 patients(16.4%) were abnormal (41 patients of them were men (12.4%) and 50 patients women(22.3%), range of age was 30-89 years old). Women tend to have higher levels of serum uc OC than men. In the group under 50 years old, 8.6% patients showed abnormal high levels of uc OC. The mean age of the patients with higher uc OC values was higher than that of the patients with normal uc OC values. When we examined the relationship between serum uc OC levels and diabetic control marker. The mean HbA1c levels were 7.09±1.13% in the normal uc OC group and 6.77±0.92% in the higher uc OC group(p <0.005). There were 28 subjects who have renal dysfunction (Cre of more than 1.5mg/dl). 19 subjects of them were in higher uc OC group.The mean creatinin levels were 0.76±0.23mg/dl in the normal uc OC group and 1.48±1.74mg/dl in the higher group (p <0.0005).
Conclusion: This study shows that the frequency with the higher levels of serum uc OC is 16.8% in the patients with Type 2 diabetes mellitus. In relation to age, serum uc OC levels tend to be higher in older, female group than in younger group. It is suggested that serum uc OC levels reflect a decrease of bone mineral density with advancing age. However, the higher levels of uc OC were shown in young patients with slight glucose intolerance and renal impairment too. This may show that strict dieting in the diabetic patients contributes to deficiency of vitamin K intake.

[5] Faculty of Medicine and Biomedical Sciences University of Yaounde I, Biochemistry, yaounde, Cameroon
[6] Faculty of Medicine and Biomedical Sciences University of Yaounde I, Internal Medicine/Endocrinology, yaounde, Cameroon

Background: HIV-infected patients develop a group of metabolic abnormalities due to the action of the virus and/or to antiretroviral (ARV) drugs. There is a need for molecules that would be safe to use with ARV against these metabolic abnormalities. Spirulina, a widely used food supplement, improves the lipid profile and glycemic control in people with diabetes, suggesting that it could have some effects on insulin sensitivity (IS).
Method: We carried out a randomized double blind placebo controlled trial for 8 weeks at the National Obesity Centre of Cameroon to explore the effects of *Spirulina platensis* on HIV/HAART-associated insulin resistance and dyslipidemia. Soya bean was used as placebo to control for renutrition effect. We evaluated IS in 143 HIV-infected patients using the short insulin tolerance test(SITT) and found 44 with insulin resistance(IR), so eligible for the trial. 3 did not meet inclusion criteria while 8 refused to participate. 17 were randomized to spirulina and 15 to placebo. Each subject received an average of 18.6g of spirulina or placebo powder daily and were seen every 2weeks. 2subjects were discontinued treatment in the spirulina group due to acute intercurrent infection and 4 losses to follow up were registered in the spirulina group giving a follow-up rate of 82%. For each subject we collected clinical/anthropometric data, measured IS and fasting glucose and lipids at baseline and 8weeks from baseline. Physical activity and diet did not change over the study duration. Data was analyzed as per protocol.
Results: At baseline for the trial, treatment groups were comparable for insulin sensitivity (1.59±0.04 vs 1.58±0.04 %/minute), age(36±11 vs 39±7 years),sex distribution, HAART duration(22±14 vs 27±17months), BMI(23.8±3.2 vs 24.7±2.8kg/m^2),fat-free mass(38.2±11.5 vs 37.1±10.9Kg), total cholesterol(1.66±0.49 vs 1.79±0.43g/l), and triglycerides(0.72±0.53 vs 0.68±0.28g/l). After 8weeks, 100% (11) of HIV-infected subjects on spirulina versus 69% of the placebo group improved their IS (p=0.049). The rate of blood glucose decrement during SITT, reflecting IS was significantly greater in the spirulina group (-2.63 vs -1.68 g/l/minute, p=0.005). No significant difference in changes in BMI, FFM, TC, and TG was observed. On spirulina, there was a 1.45 increase in the chance of improving on IS compared to placebo (1.05<rr<2.02).
Conclusion: This preliminary study suggests that spirulina could be used in association with other approved methods to intensify the prevention of insulin resistance and dyslipidemia in HIV-infected patients, but appeal for validation in larger sample over a longer duration.

Emotional eating and risk of overweight among teenage girls.

L. Shainhouse[1], H. Saudny-Unterberger[1], S.J. Meltzer[2], G.M. Egeland[1]
[1] McGill University Macdonald Campus, School of Dietetics and Human Nutrition, Ste. Anne-de-Bellevue, Canada
[2] McGill University Health Centre, Obstetrics and Gynecology, Montreal, Canada

Aim: To determine differences in behavioural eating habits of overweight and normal adolescent girls; to differentiate between various habits such as emotional eating, self-control, food habits, and general health, and assess how these factors contribute to overweight risk.
Methods: A 15-year follow-up of mother-daughter pairs representing pregnancies affected and unaffected by glucose intolerance (GDM and IGT) resulting in singleton live births between 1989-1991 at the Royal Victoria Hospital in Montreal. As daughters of GDM cases were at greater risk of overweight than daughters of controls, the abstract explores the behavioural correlates of being overweight (BMI >85%ile) among teens. Chi-square test for differences in weight categories was evaluated by eating behaviour categories.
Results: Mean age of girls was 15.3 (±0.7) years, mean BMI percentile was 65.6 (±26.4), and mean waist circumference was 78.1 (±11.0) cm. Overall, 29.6% of teens had a BMI ≥85%ile. Overall, among those who regularly ate without feeling hungry, 58.3% were overweight compared to 21.9% overweight among those who ate when hungry (p=0.03). For those who experienced feelings of guilt and self-hatred after overeating, 75% were overweight, while 21.4% were overweight among those with guilt-free eating (p=0.00). Among those reporting minimal control on fighting urges to stop eating, 48% were overweight, while 25% were overweight among those that were able to cease eating when satiated (p=0.06). Among those who snacked regularly and often skipped meals, 35.3% were overweight, while 27% were overweight among those who consumed three meals and only occasionally snacked (p=0.27). Among those who were overwhelmed by thoughts of eating, 48.7% were overweight, while 22.6% were overweight among those who gave little thought to unwanted eating urges (p=0.009). Only 3 girls

reported vomiting to prevent weight gain, therefore, it was not an important determinant of BMI.

Discussion/conclusion: Girls who reported eating when not hungry and having less control over eating were more likely to be overweight than those having control over eating urges. The results are important for formulating public health messages aimed at reducing the epidemic in overweight and obesity among youth. Erratic eating behavioural habits have also been identified as risk factors for adult overweight and obesity.

Dietary conjugated linoleic acid isomers (cis-9, trans-11 and trans-10, cis-12) modulate insulin-dependent and independent skeletal muscle glucose transport in vitro

S. Mohankumar[1], C. Taylor[1], P. Zahradka[2]
[1] University of Manitoba, Human Nutritional Science, Winnipeg, Canada
[2] University of Manitoba, Physiology, Winnipeg, Canada

Impairments in the skeletal muscle insulin signaling cascades, glucose transport and GLUT4 translocation are the critical defects in insulin resistance and type 2 diabetes (T2D). Research into the molecules that could preserve, protect, repair or regenerate skeletal muscle glucose metabolism would be a major advance in the treatment and management of T2D. Conjugated linoleic acid (CLA) refers to a group of positional and geometric isomers of conjugated dienoic octadecadienoate (C18:2) that are abundant in dairy products, as well as ruminant and other meat products. CLA has been reported to have beneficial effects in both experimental animal models and in humans. However the activity of CLA has been questioned by some investigators. Although some studies indicate that CLA stimulates muscle glucose uptake in animal models, no study has yet elucidated the molecular pharmacological properties of CLA isomers on skeletal muscle. The current study investigated the effects of CLA isomers on skeletal muscle glucose transport with rat L6 skeletal muscle cells. Briefly, fully differentiated L6 myotubes were treated with or without CLA isomers (cis-9, trans-11and trans-10, cis-12; either alone or as a 50:50 mixture) in the presence or absence of insulin. Glucose uptake was evaluated using either isotope- or fluorescence-labeled 2-deoxyglucose. The results indicated that CLA isomers stimulated glucose uptake in the absence of insulin. Of these treatments, the CLA isomer mixture showed a significantly elevated glucose uptake compared to the individual isomers. Interestingly, insulin potentiated the stimulatory effect of c9, t11 CLA isomer on glucose uptake, inhibited the effect of the CLA mixture and had no effect on the actions of the c10, t12 CLA isomer. The additive effects of c9, t11 CLA isomer and insulin indicate that this isomer may stimulate a parallel glucose uptake pathway. In contrast, the fact that the combined actions of c10, t12 CLA isomer and insulin were not additive may be interpreted as showing that this isomer and insulin utilize the same pathways (at least terminally). In addition, the glucose uptake inhibitory effect of the CLA isomer mixture when combined with insulin may be due to the saturated activation of glucose transport by multiple pathways, thus leading to desensitization of insulin signaling. In summary, the present study for the first time demonstrates that CLA isomers have stimulatory effects on both insulin-dependent and independent skeletal muscle glucose transport *in vitro*. However further studies are required to understand the diverse, isomer specific mechanistic pathways of CLA on skeletal muscle glucose metabolism.

Multiminerals-enriched yeast alleviates oxidative stress, metabolic disorders and immune function impairment in streptozocin-induced diabetic mice

W. Bao[1], M. Jiang[1], S. Rong[1], F. Song[1], P. Yao[1], A. Nussler[2], L. Liu[1]
[1] Tongji Medical College of Huazhong University of Science & Technology, Department of Nutrition and Food Hygiene, Wuhan, China
[2] Technical University of Munich, Department of Traumatology, Munich, Germany

Aims: Chromium, selenium and zinc malnutrition has been implicated in the pathogenesis of diabetes mellitus. However, supplementation with these trace elements is always accompanied by side effects because of their potential toxic properties. Minerals-enriched yeast is considered to be an ideal novel form with higher bioavailability and lower toxicity for minerals supplementation, whereas evidence regarding its beneficial effects in diabetes mellitus is rare. The aim of this study was to investigate the effects of Multiminerals-enriched yeast (MMEY), which contained elevated levels of chromium, selenium and zinc together, on oxidative stress, lipid metabolism and cytokines expression in a diabetic animal model.

Methods: Streptozocin (STZ, 150 mg/kg b.w., i.p.) induced diabetic male Balb/c mice (n=80) were randomly divided into diabetes control group and three treatment groups, which were administrated by oral gavage with low, medium or high doses (1.6 g/kg b.w., 3.2 g/kg b.w. or 4.8 g/kg b.w.) of MMEY, respectively. At the same time, healthy adult male Balb/c mice (n=40) of the same body weight were randomly assigned into vehicle control group and high dose of MMEY control group. After 8 weeks duration of treatment, the animals were anesthetized and then sacrificed. Serum glucose, triglyceride (TG), total cholesterol (TC), low-density lipoprotein cholesterol (LDL-C), high-density lipoprotein cholesterol (HDL-C), superoxide dismutase (SOD), glutathione peroxidase (GPX), glutathione (GSH) and malondialdehyde (MDA) levels were determined. Liver and pancreatic islet tissues in each group were preserved for histopathological examination. Cytokines interleukin-2 (IL-2) and interleukin-2 (IL-4) expression in spleen lymphocytes were measured using flow cytometry.

Results: No adverse effects were observed in the high dose of MMEY control group. Treatment of diabetic mice with medium or high dose of MMEY supplementation significantly decreased serum glucose, TG, TC and LDL-C levels whereas it increased serum HDL-C level. Those two groups also showed a significant elevation in the serum SOD, GPX and GSH concentration, and a reduction in serum MDA concentration in STZ-induced diabetic mice. In addition, MMEY supplementation ameliorated beta-cell pathological damage in pancreatic islet, elevated the decreased thymus or spleen-body weight ratio and increased IL-2 and IL-4 expression in spleen lymphocytes.

Conclusions: Our results indicate that MMEY may have capacity for inhibiting hyperglycemia, abating oxidative stress, modulating lipid metabolic disorder and immune function impairment in diabetic mice, which suggests MMEY as a candidate for future studies in the prevention and treatment of diabetes mellitus. Further study for the detailed mechanism is needed.

The effects of the omega-3 polyunsaturated fatty acids supplements in the prevention of cardio-metabolic parameters in metabolic syndrome patients

A. Dragomir[1], G. Radulian[2], E. Rusu[1], S. Dragan[3], D. Cheta[4]
[1] Healthy Food Foundation, diabetes, Bucharest, Romania
[2] Institute of Diabetes Nutrition and Metabolic Diseases "NC Paulescu", diabetes, Bucharest, Romania
[3] UMF "Victor Babes", cardiology, Timisoara, Romania
[4] Institute of Diabetes Nutrition and Metabolic Diseases "NC Paulescu", diabetes, Bucharest, Romania

Aims: To test the functional effects of a diet containing omega-3 PUFA supplements vs. baseline diet recommended to patients with metabolic syndrome.

Methods: A total of 110 patients with metabolic syndrome (MS) according to IDF criteria, aged 58±6.7 years, were allocated to 2 groups, matched by sex and age: group A (56 patients) – diet according to ESC recommendations and individual needs; group B (54 patients) – the same diet + capsules of fish oil (1,0 g eicosapentanoic acid, 1,0 g docosahexanoic acid and 0,1 g a-tocopherol acetate). Body fat mass (BFM) and body fat percent (%BF) were measured by bioimpedance analysis (BIA) using InBody 3.0 Analyzer. Fasting plasma glucose, HbA1c, total cholesterol, LDL cholesterol, HDL cholesterol, triglycerides, plasma insulin, adiponectin and leptin were measured according to standard procedures. Insulin resistance was measured using HOMA-IR index. Oxidative stress was assessed using FormOx systems monitor on a blood drop. The duration of the study was 6 months.

Results: Baseline characteristics were similar between groups. After 6 months, omega-3 supplements determined a significant improvement of metabolic parameters: total cholesterol - 195 ± 18.4 mg/dl vs. 214 ± 20.5 mg/dl ($p<0.002$); HDL-cholesterol - 56 ± 12 mg/dl vs. 47 ± 15 mg/dl ($p<0.05$); triglycerides - 138 ± 53 mg/dl vs. 149 ± 69 mg/dl ($p=0.002$); fasting plasma glucose - 111 ± 12 mg/dl vs. 118 ± 19 ($p<0.0001$); HOMA-IR - 4.55 ± 2.3 vs. 4.64 ± 3.3 ($p=0.016$). Also, patients in group B experienced a significant decrease of oxidative stress (264 ± 78 Fort units vs. 320 ± 92 Fort units – $p<0.0001$) and a statistically significant increase in adiponectin levels (from 9.46 ± 2.76 to 10.86 ± 2.68). Mean BMI, mean %BF, mean BFM and mean waist-to-hip ratio (WHR) were significantly lower in group B vs. group A (BMI-31.12 kg/m^2 vs 29.1; %BF - 30.48 vs 27.48; BFM - 29.42 kg vs 26.78; WHR - 1.07 vs 1.02). BMI was statistically correlated with BFM ($p<0.0001$) and

%BF (p<0.0001). %BF (p<0.001) was correlated with WHR (p=0.016), leptin values (p<0.001), adiponectin values (p<0.05) and leptin/adiponectin ratio (p<0.001).

Conclusions: Omega-3 PUFA enriched diets bring metabolic parameters closer to target values, thus lowering cardiovascular risk of MS patients. Also, oxidative stress is decreased, underlying the role of omega-3 in the delay of endothelial cells damage.

Effect of oral administration of thiamine on serum markers of inflammation in type 2 diabetes patients

M.G. Ramos-Zavala[1], M. González-Ortiz[1], V. Ramírez-Ramírez[1], E. Martínez-Abundis[1], J.A. Robles-Cervantes[1]

[1] Medical Unit of High Specialty Specialties Hospital West National Medical Center Mexican Institute of Social Security, Medical Research Unit in Clinical Epidemiology, Guadalajara, Mexico

Aim: To evaluate the effect of oral administration of thiamine on serum markers of inflammation in type 2 diabetes patients.

Patients and methods: A randomized, double-blind, placebo-controlled clinical trial was carried out in 24 type 2 diabetes patients, aged between 30 to 60 years, BMI between 25.0 to 34.9 Kg/m^2, fasting glucose <205 mg/dl, A1C <8%, without pharmacological treatment. At beginning and at end of the study, BMI, waist circumference, a metabolic profile (fasting glucose, postprandial glucose, A1C and lipids), C-reactive protein, leptin, adiponectin, IL-6, TNFa concentrations were measured. The patients were randomly assigned to receive thiamine (150 mg/day), or placebo for a period of 30 days.

Results: In both groups decreased the BMI (29.4 ± 3.0 vs. 29.0 ± 3.2 kg/m^2, p = 0.028; and 29.7 ± 3.1 vs. 29.1 ± 2.7 kg/m^2, p = 0.016); and leptin (32.9 ± 13.3 vs. 26.9 ± 12.9 ng/ml, p = 0.023 and 32.9 ± 13.3 vs. 26.9 ± 12.9 ng/ml, p = 0.023); respectively thiamine and placebo groups. Thiamine administration decreased fasting glucose (123 ± 19 vs. 109 ± 16 mg/dl, p=0.013), postprandial glucose (197 ± 60 vs. 145 ± 38mg/dL, p = 0.047). Not showed modification in A1C (6.4 ± 0.4 vs. 6.4 ± 0.8%, p = 0.285), C-reactive protein (5.8 ± 2.9 vs. 5.0 ± 2.3, p = 0.128), adiponectin (73.2 ± 41.3 vs. 62.1 ± 31.9, p = 0.182), IL-6 (4.8 ± 1.0 vs. 4.4 ± 1.7, p = 0.423), and TNFa concentrations (14.4 ± 6.2 vs. 13.2 ± 9.1, p = 0.593).

Conclusion: One month administration of thiamine improves fasting glucose and postprandial glucose without modification in markers of inflammation.

Inulin increases postprandial serum short-chain fatty acids and reduces free fatty acids and ghrelin in healthy subjects: possible mechanisms by which dietary fibre reduces risk for type 2 diabetes.

J. Tarini[1], T.M.S. Wolever[2]

[1] St. Michael's Hospital, Centre for Diabetes and Osteoporosis, Toronto, Canada

[2] University of Toronto, Nutritional Sciences, Toronto, Canada

Diets high in dietary fibre have been associated with reduced risk for type 2 diabetes. This may be due, at least in part, to the ability of the short chain fatty acids (SCFA) produced during the colonic fermentation of fibre to influence circulating concentrations of free fatty acids (FFA) and gut hormones involved in insulin secretion and body weight regulation. Inulin, a prebiotic and fermentable soluble fibre, is being added to, or replacing, available carbohydrate in many new food products based on its perceived health benefit. We aimed to determine the acute effects of inulin on postprandial glucose, insulin, c-peptide, SCFA, and gut hormone responses (GLP-1, GIP and ghrelin) in normal subjects. Twelve overnight fasted, healthy subjects were studied for 6 hours after consuming 400mL drinks containing either 80g high fructose corn syrup (80HFCS), 56g HFCS plus 24g inulin (inulin), or 56g HFCS (56HFCS) using a randomized, single-blind, cross-over design. A standard lunch was served 4 hours after the test drink. The treatments were designed to distinguish between the effects of adding inulin to HFCS (56HFCS vs. Inulin) or partially substituting inulin for HFCS (80HFCS vs. Inulin). The addition or substitution of inulin did not alter glucose and insulin responses. Serum acetate, propionate and butyrate were significantly higher after Inulin than both 56HFCS and 80HFCS beginning at 4 hours. FFAs fell at a similar rate following all test drinks but Inulin resulted in significantly lower serum FFA at 4 hours compared to 56HFCS. Plasma GLP-1 was higher 30 minutes after inulin than 56HFCS, while plasma ghrelin was significantly lower 4, 4.5 and 6 hours after Inulin than 56HFCS and 80HFCS. The results of the study support the hypothesis that SCFA generated from the colonic fermentation of dietary fibre can influence serum FFA and certain gut hormones involved in the regulation of body weight. Therefore, they may provide a link between dietary fibre intake and prevention of type 2 diabetes through a SCFA-mediated reduction in insulin resistance, a reduction in food intake and/or obesity. This work was supported by the Canadian Institutes of Health Research.

Low-fat vegetarian diet improves oxidative stress markers in patients with type 2 diabetes

H. Kahleova[1], H. Malinska[1], T. Pelikanova[1]

[1] Institute of Clinical and Experimental Medicine, Diabetes Center, Prague, Czech Republic

Background and aims: In recent years attention is being paid to increased oxidative stress in diabetes. It has been shown that reactive oxygen species are able to induce insulin resistance in various tissues and in addition they increase the vascular risk. Clinical trials using vegetarian diets have shown greater improvements in blood glucose control and cardiovascular health than conventional hypocaloric diabetic diet. The aim of our study was to evaluate the effect of low-fat vegetarian diet compared to conventional diabetic diet with similar caloric restriction on plasma concentrations of oxidative stress markers in patients with type 2 diabetes after a 3-month-diet-intervention.

Materials and methods: Open, parallel randomized study. 70 patients with type 2 diabetes were randomly assigned to either experimental group (EG) following a low-fat vegetarian diet or the control group (CG) following conventional diabetic diet with similar caloric restriction (-500 kcal/day). We measured all common anthropometric and laboratory parameters including oxidative stress markers. All procedures were done at start (0) and after 12 weeks.

Results: Average weight loss was greater in the EG than in the CG (6.41±4.23 vs. 3.47±4.07 kg; p<0.01). Diabetes medication was reduced according to the study protocol in 15 subjects from the EG (42.86%) vs. in 2 subjects from the CG (6.45%). We observed a trend to a greater reduction of plasma HbA1c, cholesterol, free fatty acids and fasting glucose in the EG, but the differences were not statistically significant. There were significant differences in plasma concentrations of oxidative stress markers between the groups: Vitamin C increased significantly in the EG, whereas it decreased in the CG ($p \leq 0.01$), the same with superoxidedismutase (p<0.01); this trend is also evident in glutathionperoxidase and glutathion, but the differences did not reach statistical significance. Plasma concentrations of thiobarbituric acid reactive substances decreased in the EG but increased in the CG (p<0.01)

Conclusion: Our results indicate that low-fat vegetarian diet leads more effectively to reduction of diabetes medication and improvement of oxidative stress markers than the conventional diabetic diet and it could be a more convenient alternative in treatment of type 2 diabetes.

A comparative study of knowledge, attitudes and practices of complications of type 2 diabetes and associated risk factors among patients with type 2 diabetes in Dar es Salaam, Tanzania and New Hampshire, USA

G. Lyatuu[1], M. Bakari[2], H. Semu[3]

[1] Muhimbili University of Health and Allied Sciences, Medical Student, Dar Es Salaam, Tanzania

[2] Muhimbili University of Health and Allied Sciences, Internal Medicine, Dar Es Salaam, Tanzania

[3] Tanzania Food and Nutrition Centre, Community Health and Nutrition, Dar Es Salaam, Tanzania

Background: An analytical, cross-sectional study was done to compare the differences in Knowledge, Attitudes and Practices of complications of type-2 diabetes and associated risk factors, among patients with type 2 diabetes in Tanzania and USA.

Methods: Swahili and English structured questionnaires were administered to 86 diabetic patients attending clinics in 3 hospitals in Dar es Salaam, Tanzania and 77 patients attending at Dartmouth Hitchcock Medical Centre (DHMC) in New Hampshire, USA respectively. Study participants were selected by simple random sampling over a period of 6 weeks in each country. Data from both study areas were analyzed using SPSS data analysis tool.
Results: This study revealed no significant difference in proportion of patients knowledgeable of complications of diabetes and associated risk factors in the two communities with both communities 84.9% in Dar es Salaam and 92.2% in New Hampshire scoring high on knowledge, P = 0.15. There was also no significant difference in attitude towards diabetes whereby majority had a positive health promoting attitude towards the disease, i.e. only 9.3% in Dar es Salaam and 5.2% in New Hampshire considered regular physical exercise to have little influence on diabetes management, P = 0.29, and 5.8% in Dar es Salaam and 5.2% in New Hampshire considered weight management to have little influence on the management of their Diabetes, P = 0.86.
There were however significant differences in practice whereby; only 11% of study participants in Dar es Salaam compared to 93.9% in New Hampshire reported to be doing blood glucose check-ups at least once a week, P < 0.001; only 63% of study participants in Dar es Salaam compared to all in New Hampshire reported to weigh themselves at least once a month, P < 0.001; and 48% in Dar es Salaam compared to 69.4% in New Hampshire reported to be doing physical exercise at least 4 to 6 times a week for at least 15 minutes, P = 0.02.
Conclusions: In conclusion, although knowledge on Diabetes Mellitus was high in both settings, and attitude positive, significant differences in practice were noted with Dar es Salaam scoring poorer compared to New Hampshire.
More elaborate studies assessing multi-factorial of issues that influence positive health attitudes and behaviors towards Diabetes Mellitus should be conducted, especially in less developed countries. Furthermore efforts should be done to further expand the diabetes health education being provided at the health care facilities in Dar es Salaam so as to reach out to more diabetes patients in other health facilities in the country.

Patients' perspectives on factors that influence diabetes care and treatment compliance: voices from Iran

E. Shakibazadeh[1], D. Shojaeezadeh[1], B. Larijani[2], A. Rashidian[3], M.H. Forouzanfar[4], L.K. Bartholomew[5]
[1] *Tehran University of Medical sciences, Health Education and Promotion, Tehran, Iran*
[2] *Tehran University of Medical sciences, Endocrine and Metabolism Research Center, Tehran, Iran*
[3] *Tehran University of Medical sciences, Health Management and Economics, Tehran, Iran*
[4] *Tehran University of Medical sciences, Biostatistics and Epidemiology, Tehran, Iran*
[5] *University of Texas, Center for Health Promotion and Prevention Research, Texas, USA*

Aims: Although Diabetes mellitus is of high concern in Iran, and the level of control is unacceptable, few qualitative studies have been carried out to reflect experiences and perceptions of patients on the barriers and motivators to self-care.The aim of this study was to explore a culturally based experience of Iranian diabetic patients regarding the personal and environmental barriers to and facilitating factors for diabetes self-care.
Methods: Six focus groups were conducted among type 2 diabetic patients in the Charity Foundation for the Special Disease's diabetes clinic, which is a large team-focused clinic. Purposeful sampling was used. People with confirmed type 2 diabetes were included. Newly diagnosed patients (less than six months) and all type 1 diabetic patients were excluded. Because of cultural issues we had 3 focus groups for each sex in order to encourage free and honest expression. Participants included 22 women and 21 men(n=43). Framework analysis was used to extract the themes from the data.
Results: The data showed five main barriers: physical barriers (physical effects of diabetes, long-term health conditions, physical effects of treatment, and no symptom cues); psychological barriers (health beliefs, cognitive barriers, perceptions of time required, negative perceptions of Iranian medicine, and stigma); educational barriers (lack of knowledge about diabetes, health services life-style requirements, and alternative therapies); social barriers (group pressure and lack of family support, lack of public awareness of diabetes, unsupportive macro-environment, and various difficultiesin the social system, (such as high inflation rate), lack of appropriate programs in media, and lack of standard resources to educate people); and care system barriers (service availability, acceptability, and accessibility). Along with the barriers, there were some motivators that the participants mentioned as a stimuli to control their diabetes. They included beliefs about diabetes, perceived responsibility for family, religious beliefs, and the views of significant others.
Conclusion: Public health education and culturally based interventions are needed to improve diabetes management in Iran. In addition to personal factors, diabetes health educators should pay attention to the environmental factors when they develop programs.

Myths and misconception about diabetes mellitus: Bangladesh perspective

B. Bhowmik[1], A. Khan[2]
[1] *Bangladesh Diabetic Somity, Executive Diabetes care unit, Dhaka, Bangladesh*
[2] *BIRDEM Bangladesh Diabetic Somity, Department of Gastroenterology, Dhaka, Bangladesh*

Aims: To determine the level of myths and misconception regarding DM in the health professional (HP) and non-health professional (NHP) in Bangladeshi populations.
Methods: Cross sectional study was conducted between January-April, 2008. Recruitment of subjects to the study populations was by convenience sampling. A pre-set self-administered questionnaire was distributed across urban and suburban communities, and all levels care services. Data was analyzed using SPSS.
Results: Three thousand and fifty eight HP and NHP respondents returned a completed questionnaire. Of them, 20.5% were general physicians, 3.0% diabetic practitioners, 10.5% general nurses, 8.3% nurses with diabetes training, 2.0% nutritionists, 55.7% general population (service holder, businessman, teacher and students). Female, illiterate and low socioeconomic class had more misconceptions about the diabetes. (p<0.0001). Forty nine percent reported that diabetics should eat special diabetic diets and they have restriction on diet also, 33.5% subjects reported that sour and bitter food act like insulin and tablet, 31.6% believes that there is no restriction for the diabetes patients to use corn plaster for the treatment of corn of leg, 27.7% had misconception on those who have diabetes but no complication need not go to doctor so frequently. The general physician and nurse reported myths more as compared to physicians and nurse who have trained on diabetes management (p<0.0001).
Conclusion: Education is an important factor that might have reversed misconception. So efforts should be made to promote health education and awareness special emphasis

Social support, treatment adherence and metabolic control of type 2 diabetes mellitus patients: a perspective for care

A. Pace[1], L.C. Gomes[1], M.C. Foss-Freitas[2], M.C. Foss[2]
[1] *University of São Paulo at Ribeirão Preto College of Nursing, General and Specialized Nursing, Ribeirão Preto - SP, Brazil*
[2] *University of São Paulo at Ribeirão Preto Medical School, Clinical Medicine Department, Ribeirão Preto - SP, Brazil*

Introduction: Social support has been related with a person's good adaptation to a chronic disease and is highlighted among the factors favoring treatment adherence and the development of perceived self-efficacy.
Method: cross-sectional study with a quantitative approach. The aim was to analyze the relation between perceived social support, adherence to self-care activities, adherence to medication treatment, metabolic and clinical control of 162 type 2 Diabetes Mellitus patients, without severe complications, under outpatient follow-up, between May and November 2008, after approval by the Research Ethics Committee. For data collection, the Social Support Network Inventory, the Diabetes Self-care Activities Questionnaire and the Treatment Adherence Measure were used.
Results: 58% of participants were women, with an average age of 59 years (SE=8) and mean education 5.4 (SE=3.9) years; 41.4% were retired or

pensioners; mean diagnosis time was 15 (SE=14.8) years; 54.3% were obese and 35.8% overweight; 64.2% were under combined insulin and oral anti-diabetic treatment; mean systolic blood pressure was 140 mmHg (SE=22) and diastolic 78mmHg (SE=12); mean glycated hemoglobin was 9.1% (SE=1.8); total cholesterol 182 mg/dl (SE=47.7); HDL 42 mg/dl(SE=9.3), triglycerides 215 mg/dl (SE=237.3) and creatinine 1.1% (SE=0.5). High perceived social support was observed and the main source were relatives, followed by health professionals. Adherence to self-care was low in 69.1% of the participants and high for medication treatment (95.7%). At p=0.05, social support was directly correlated with age (0.2), self-care adherence (0.2) and medication adherence (0.2); and inversely related with education level (-0.24). Adherence to self-care was directly correlated with medication adherence (0.2), and inversely with education level (-0.2); medication adherence was directly correlated with self-care adherence (0.2), with daily insulin application (0.2), with daily oral anti-diabetic agent intake (0.3) and inversely related with diastolic pressure (-0.15).
Conclusions: Data suggest that education level is a variable that should be considered in diabetes mellitus education and can be a barrier for self-care, while social support can be a facilitator to obtain adherence to treatment and self-care. Other methodological approaches should be used to broaden studies on the relation between these variables.

Diabetes knowledge among the general public in Brunei

S. Bosseri[1], M. Ahmad[1]
[1] Suri Seri Begawan Hospital, Dept of Medicine, Kuala Belait, Brunei

Introduction: World wide the number of people with diabetes is in continuing rise and nowadays we are seeing type 2 diabetes at increasingly younger age this most likely due to the change in the eating habits and physical activity. With the accumulation of the national wealth, diabetes stands to be one of the most important health problems in Brunei.
The aim of this study is to explore the general public knowledge about diabetes, that is to identify the needs for future awareness programs.
Methods: B5 Diabetes knowledge Questionnaire (Southeast Chicago Diabetes Community Action Coalition) was used in this study. It is 23 item questionnaire to test the individual's understanding of prevention and management of diabetes and its complications (scores 0-23).
The investigators went around the main fast food restaurants in the city Kuala Belait and asked the customers to answer the questionnaire while they were waiting for their meals
Data was coded and entered into Excel and subsequently analyzed in SPSS.
Results: 1065 persons answered the questionnaire. 57% of them were females. There ethnic origin was; Malay 59%, Chinese 22%, Indigenous 11%, Others 8%. Their age distribution; 25% < 18, 52% 18-44, 21% 45-64 & 2% ≥ 65 y. Their level of education; primary 10%, secondary 70% & higher education 20%. Diabetes was present in 7% of the subjects and in the families of 30% of them.
Their mean diabetes knowledge score was low (8±5.3).
Better knowledge about diabetes was found in the subjects with previous diagnosis of diabetes in them or in their families, and those who believe for some other reason that they are at high risk of diabetes ; mean±SD: 11.3±6.0, 9.8±4.9, 8.6+5.3 compared to the subject who are not diabetic and believe they are not at diabetes risk; mean 7.4±4.3 (P <0.0001).
There was a positive correlation of the diabetes knowledge with the level of education; university 9.8±5.9 vs. secondary 7.8±5.0 vs. primary 5.7±3.8 (P < 0.0001).
The 45-64 age group scored the best (10.6±5.5) followed by the age group 18-44 (8.8±4.7) and the worst was those under 18 (5.9±3.1) and those aged 65 and above (5.9±2). P <0.0001.
Females and Males appeared to have same knowledge level 8.6±5.3 vs. 8.0±5.0 (P 0.219). The ethnic origin was not found to be a predictor of diabetes knowledge; the score for Malay, Chinese, Indigenous and other groups was 8.0±4.7, 8.5±4.8, 9.4±5.0, 8.9±5.0 respectively.
Discussion: Diabetes knowledge is poor amongst the general public.
The diabetes education should not only be offered to people with diabetes and healthcare professionals but also mandatory.
That everybody in the society get proper understanding of diabetes and be empowered to adopt healthy lifestyle to prevent diabetes and its consequences.

Insulin dosage blunders due to mismathch between vial strength and syringe specifications are common; the need for intensive patient education

P.G. Talwalkar[1]
[1] Talwalkar Diabetes Clinic, Diabetes, Mumbai, India

In India U\40 and U\100 insulin vials are available. Syringes are available in two types, U\40 and U\100, to suit specific insulin vial. Occasionally, either due to lack of training or because of carelessness of the patient, mistakes in insulin injection procedure leading to hypoglycaemia or hyperglycaemia which can sometimes be life threatening, are created. Some of the mistakes the author has come across are described below.

1. A 34 year old patient was on premixed insulin, [U\40], 40 units twice a day and his blood glucose was poorly controlled, thus he was advised 50 units twice a day. Since capacity of U\40 syringe is only 40 units, he was advised to use U\100 Syringe so that "you can take up to 50 units mark". Thus he actually took 20 units twice a day.
2. A 34 year old male on premixed insulin, 48 units before breakfast and 34 units before dinner was investigated for poor control. From the cost of vial we derived that he was taking U\40 insulin. When asked, "How long the bottle lasts?", we found that it was lasting two and half times the expected period. Thus he was taking U\40 Insulin with U\100 syringe [40% of the prescribed dose].
3. A 45 year old female patient was put on premixed insulin, 8 units before breakfast and dinner. She approached a trainee nurse in her village and forced her to administer insulin. Under pressure, the nurse injected entire vial containing 400 units through 10 ml multi purpose syringe. Patient walked 1.5 km to reach home and subsequently developed hypoglycemia. She was shifted to a nursing home immediately and observed for 48 hours under constant intravenous glucose infusion and dire emergency was avoided.
4. A 56 year old patient was prescribed 10 units of premixed insulin,[U\40] before dinner. She was doing well with appropriate syringes and vials purchased from the market, till she received a vial of premixed insulin [U\100], free of cost from her employer. For few days she used U\40 syringe to inject insulin from U\100 vials till the family doctor noticed that he was drawing U\100 insulin in U\40 syringe. He decided to draw up to 25 units mark to account for the difference.[He should have drawn up to 4 units mark] Thus he injected 62.5 units subcutaneously.
5. A 43 year old female patient was on premixed insulin, 20 units before breakfast and dinner. After some time she decided to do cost cutting by purchasing premixed insulin, U\40 vial from the market and by refilling empty cartridges via syringe filled with insulin drawn from U\40 vial. Soon her blood glucose rose significantly [the cartridge contains 100 units per ml, U\40 insulin from vial contains 40 units per ml.].

Conclusion: Insulin dosage blunders due to mismatch between vial strength and syringe specifications are common, thus the need for intensive patient, nurse and family physician education.

Diabetes Education in India: From Concept to Operational Reality

S. Gadok[1]
[1] Project HOPE, Global Health, Delhi, India

Background: With around 40.9 Million people living with Diabetes, India is the highest Case Burden country in the World. Approach to management is doctor centric, limited number of Endocrinologists and GP's are struggling to treat this huge patient cohort. Hence, there is urgent need to expand base of healthcare providers appropriately trained in Diabetes Education to empower patients with knowledge and skills to better manage their disease and improve treatment outcomes. Oposed to this compelling need, there is no formally recognized National Curriculum for Diabetes Education for allied health professionals in India. Few of the estimated 500,000 nurses, dieticians, etc. have any professional education in Diabetes.
Assessment: A multi disciplinary team comprising members from the International Diabetes Federation, Project HOPE, Duke University and Industry Partners identified a critical deficiency in qualified nurses, dieticians, etc. necessary to effectively empower patients living with diabetes. A method to

impart diabetes management knowledge and skills broadly and rapidly was devised and the first Pan India project on Diabetes Education was designed.

Program design/delivery: The Curriculum is based on the IDF DECS guidelines. Indian experts were engaged to ensure extensive cultural adaptation and referencing against existing Indian medical standards and practices. A 6-month distance learning program with reinforcement at regional training centers was selected to reach the greatest number of allied health care workers most cost effectively and with the greatest flexibility. Project HOPE is partnering with 7 centers of excellence across the country and has trained 16 of their best professionals as Master Trainers (MT) by experts from IDF and India. The MT's are training 9 batches in these centers with around 200 nurses, dieticians, etc. on the program. Scaling is underway and around 50 MT's from 12 Centers will be trained to ensure sustainability. Over the next 2 years these MT's will train over 3,000 allied health professionals. Evaluation will include clinical outcomes such as QOL, HbA1c and diabetes-related complications.

Challenges/solutions: Included finalizing the design and mode of implementation. Forming public-private partnerships was also critical to ensure greater regional expansion, higher quality services and greater acceptance. The challenge of uniformity of trainings and materials was addressed by utilizing a CD-ROM with standardized materials.

Conclusions: Project HOPE is creating an enabling environment for Diabetes Education in India by developing the first national curriculum and a program that offers standardized training across the country. The large cadre of healthcare professionals trained in Diabetes Education, will serve patient population improving treatment outcomes.

Low adherence to educational program in women with a history of gestational diabetes

A. Rivas[1], C. Guerra[1], J. Gonzalez[1], M. Guevara[1], S. Davila[1]
[1] University of Carabobo, Diabetes and Pregnancy Unit, Valencia, Venezuela

Women with Gestational Diabetes Mellitus (GDM) show a high risk of developing diabetes; therefore, emphasis has been made on post-partum follow-up in applying educational and clinical strategies aimed at preventing and diagnosing early this condition in a relatively young population.

Objectives: To know the progression to diabetes of women with GDM enrolled in a post-partum follow-up program within a ten year period.

Methods: 139 women with previous GDM attending the Postpartum Follow-up Program at the Diabetes and Pregnancy Unit, University of Carabobo, "Dr. Enrique Tejera" Hospital, Valencia, Venezuela were assessed, from a total of 248 referred to the program from September 1998 to September 2008. Under the program, the women were screened for diabetes 2-4 months postpartum and then annually. They were also called to basic theoretical-practical educational activities, aimed at promoting lifestyle changes, once a week during the first month. Socio-demographic data, attendance at educational sessions and previous screening results were registered. 47 (34.53%) tested positive for diabetes during screenings. The remaining 92 were tested with a 75g - oral glucose tolerance test. Plasma glucose levels were measured by the enzymatic method with an automated analyzer (Cienvar Kit). The Graffar method for socio-economic stratification was used. Student's t, Fisher exact test and x^2 were used for variable association.

Results: The average age was 34.9 years $\pm$ 6.44 and 4.04 years $\pm$ 2.68, postpartum period. 41.01% completed high school and/or university studies and 93.73% was placed in socio-economic strata II, III, IV (I-V). 44.6% did not attend any of the basic educational program sessions and only 17.98% attended all the scheduled sessions. 5.75% were diagnosed with diabetes, 21.6% with impaired glucose tolerance and 7.9% with impaired fasting glucose. Progression to diabetes, which overall increased to 39.6%, was more frequent in women with higher post-partum periods ($p<0.002$) and lower socio-economic level ($p<0.03$).

Conclusions: More than half of the women with GDM history attended the scheduled diabetes screenings during postpartum but showed very low compliance to the educational sessions. The progression rate to diabetes and prediabetes is high, showing the need for further research on social determinants of poor adherence to preventive programs.

-1123 G/C mutation of PTPN22 gene is associated with latent autoimmune diabetes in adults of Shanghai Han ethnics

F. Liu[1], J. Liu[1], T. Zheng[2], X. Pan[2], W. Jia[3]
[1] Shanghai Jiaotong University Affiliated 6th People's HospitalShanghai Diabetes, Endocrinology and Metabolism, Shanghai, China
[2] Shanghai Institute for Diabetes, Endocrinology and Metabolism, Shanghai, China
[3] Shanghai Jiaotong University Affiliated 6th People's HospitalShanghai Institute for Diabetes, Endocrinology and Metabolism, Shanghai, China

Objective: Protein tyrosine phosphatase non receptor 22 (PTPN22) gene locates in chromosome 1p13.3-13.1, which encodes a lymphoid protein tyrosine phosphatase (LYP). The recent study showed that the 1858T variation in PTPN22 was associated with T1DM. This study is to explore the relevance between the polymorphism of LYP/PTPN22 gene and latent autoimmune diabetes in adults(LADA) in Shanghai Chinese.

Methods: 229 unrelated LADA patients of Han Ethnics with positive autoantibodies to glutamic acid decarboxylase (DM group) and 100 healthy volunteers (control group) were recruited. Subjects of two groups were divided into male subgroup (n=100 vs 36) and female subgroup (n=129 vs 69). The genotypes of -1123G/C and +1858C/T polymorphism of PTPN22 were determined by PCR-restriction fragment length polymorphism (PCR-RFLP), the genotypic, allelic frequencies and the clinical characteristics were compared between two groups.

Results: Three genotypes, GG GC and CC, were detected for -1123G/T polymorphism of PTPN22 gene in Shanghai Han ethics. The most frequent genotype and allele of the PTPN22 -1123 were GC and C. Two genotypes, CC and CT, were detected, while no TT were detected for +1858C/T polymorphism. There was no significant difference in +1858C/T genotypic (CC, CT) and allelic frequencies(C,T) between control group and DM group($P>0.05$). However, significant difference of -1123G/C polymorphism of PTPN22 gene was observed between two groups (odds ratio[OR]=1.99, 95% CI=1.24-3.2, P=0.001). There were significant differences in -1123G/C genotypic(GG,GC,CC) between the male or female subgroups in DM and control group, and the G/C, C/C genotype is more likely in DM-male subgroup than in control-males(OR =1.65, 95% CI=1.21-2.26, P=0.005).

Conclusions: There is -1123G/C PTPN22 genotypic polymorphism in LADA patients of Shanghai Hans. The promoter -1123G/C SNP of PTPN22 gene, but not the +1858C/T variant, is associated with LADA in Han ethnics.

Functional characterization of the rs1990760 SNP in IFIH1, a genetic locus associated with type 1 diabetes

H. Zouk[1], C. Polychronakos[2]
[1] Montreal Children's Hospital, Human Genetics, Montreal, Canada
[2] Montreal Children's Hospital, Human Genetics and Pediatrics, Montreal, Canada

Background: Currently, over 177 million people worldwide are affected by diabetes. About 10% of the people with diabetes have type 1 diabetes (T1D), resulting from an auto-immune destruction of pancreatic insulin producing ß cells, due to the loss of immune tolerance. It has been established that T1D is a disease of complex etiology, due to both genetic and environmental factors involving genetic variation among individuals at several loci. One of these loci involves the association of T1D with rs1990760, a non-synonymous single nucleotide polymorphism (nsSNP) causing an Ala946Thr change in the interferon induced helicase gene (IFIH1). This gene is involved in antiviral innate immunity, and encodes an interferon-inducing protein with a helicase-C domain which binds viral double-stranded RNA and consequently induces a type I interferon (IFN) response. Given the autoimmune nature of T1D, possibly partially triggered by viral infections, IFIH1 is an interesting candidate for protein studies exploring allelic effects of this SNP on protein function, particularly IFN response.

Aim: We hypothesized that the T1D-predisposing Ala allele at the IFIH1 Ala949Thr polymorphism is associated with an enhanced cytokine response to dsRNA and we aimed to test this hypothesis in human lymphocytes.
Methods: 18 lymphoblastoid cell lines (LCLs) homozygous for the major predisposing genotype (Ala/Ala) and 6 LCLs homozygous for the minor protective genotype (Thr/Thr) were transfected by electroporation with polyI:C, a mimic of viral dsRNA, in three separate, independent experiments. Media was collected 24 hours later and subsequently measured for IFN-a production by sandwich ELISA.
Results: We found that the basal IFN response is minimal in mock-transfected cells from both genotypes and increases by about 8 fold in cells treated with polyI:C. Our results show that LCLs with the Thr/Thr genotype have slightly higher IFN-a levels than their Ala/Ala counterparts (66.56±9.44 vs. 61.24±17.34); however, this did not reach statistical significance. This suggests that there is no differential affinity for polyI:C between the two alleles.
Conclusion: We conclude that although the rs1990760 SNP does not seem to affect IFN response to polyI:C, this does not rule out the possibility of differential viral dsRNA recognition. Thus, the mechanism of the observed association of this SNP with T1D remains to be determined.

Identification of the ENPP1 three-allele risk haplotype and its possible contribution to the development of obesity and insulin resistance in 8–18 year old learners in communities of the Western Cape, South Africa

M. Hoffmann[1], Y. Yako[2], B. Fanape[3], T. Matsha[3], R.T. Erasmus[1]
[1] *National Health Laboratory Services (NHLS) and the University of Stellenbosch, Chemical Pathology, Cape Town, South Africa*
[2] *University of Stellenbosch, Chemical Pathology, Cape Town, South Africa*
[3] *Cape Peninsula University of Technology, Biomedical Sciences, Cape Town, South Africa*

Background: The ENPP1 (nucleotide pyrophosphatase/phosphodiesterase-1) gene encodes a membrane-bound glycoprotein that inhibits the insulin receptor tyrosine kinase activity, resulting in reduced insulin sensitivity. There has been strong evidence from several previous studies that a common coding variant of ENPP1 (K121Q) and a three-marker haplotype (Q121, IVS20delT-11 and G + 1044TGA) are associated with a higher risk of glucose intolerance and type 2 diabetes as well as childhood obesity. Many different studies attempted to confirm the association in different population groups, but results have been controversial.
Aims: The aim of this study was to determine the role of the ENPP1 genetic variants in obesity and increased fasting plasma glucose in children from the Western Cape, South Africa.
Materials and methods: The study population consisted of 1,683 learners aged 8 – 18 years recruited randomly from public and government funded schools in the target areas within the Western Cape, South Africa. Anthropometric variables, blood pressure, fasting blood glucose and lipids were performed on all learners. From this group, all obese individuals (n = 110, 6.5% of total group) together with an age, gender and ethnic matched normal-weight control group were selected. We genotyped the three previously associated polymorphisms (K121Q, IVS20delT-11 and A/G + 1044TGA) for association analysis in these two groups.
Results: We identified a significantly increased risk of obesity in children carrying the G+1044TGA variant compared with the normal weight control group (p=0,011). The other variants showed no association with increased body mass index (BMI) with $p > 0,05$. No individual with the three-marker haplotype was identified in our study group. There were also no individual SNP or haplotype associations of the ENPP1 variation with increased fasting blood glucose in either the case or control group ($p > 0,05$).
Conclusion: Our study failed to replicate the association of variation of ENPP1 with impaired fasting glucose and obesity in children from the Western Cape, South Africa.

Impact of coronary artery calcification as measure of subclinical atherosclerosis on validated genetic variants for type 2 diabetes mellitus – Results of the prospective Heinz Nixdorf Recall study

S. Pechlivanis[1], A. Scherag[1], T.W. Mühleisen[2], S. Möhlenkamp[3], B. Horsthemke[4], M. Bröcker-Preuss[5], K. Mann[5], R. Erbel[3], K.H. Jöckel[1], M.M. Nöthen[2], S. Moebus[1]
[1] *University Hospital of Essen, Institute for Medical Informatics Biometry and Epidemiology University Duisburg-Essen, Essen, Germany*
[2] *Life & Brain Center, Department of Genomics University of Bonn, Bonn, Germany*
[3] *West German Heart Centre University Hospital of Essen, Clinic of Cardiology University Duisburg-Essen, Essen, Germany*
[4] *University Hospital of Essen, Institute of Human Genetics University Duisburg-Essen, Essen, Germany*
[5] *University Hospital of Essen, Department of Endocrinology and Division of Laboratory Research University Duisburg-Essen, Essen, Germany*

Aims/hypothesis: Type 2 diabetes mellitus (T2D) is associated with a high risk of atherosclerosis and cardiovascular disease. Subsequently a higher burden of coronary artery calcification (CAC), a specific marker of coronary atherosclerosis, has been found in individuals with T2D. Recently, several genome-wide association (GWA) studies have robustly identified novel single nucleotide polymorphisms (SNP) related to T2D. Here we investigated the combined effect of the T2D SNPs and CAC for prevalent T2D cases in comparison with T2D-free controls in an unselected population-based cohort from Germany.
Methods: We genotyped 13 T2D SNPs in eight T2D candidate genes, including up- and downstream flanking sequences, using 4,459 participants (aged = 45-75 years; 610 (13.68%) with T2D; males n=2225 (49.90%) with 389 (17.48%) T2D; females n=2234 (50.10%) with 221 (9.89%) T2D) of the Heinz Nixdorf Recall Study. Odds ratios (ORs) were assessed by logistic regression models, adjusted for age, sex and in addition CAC.
Results: We observed an association between four SNPs and T2D, in particular SNPs in insulin-like growth factor 2 mRNA binding protein 2 (IGF2BP2), transcription factor 7-like 2 (TCF7L2), CDK5 regulatory subunit associated protein 1-like 1 (CDKAL1) and solute carrier family 30 (zinc transporter) (SLC30A8). ORs and p values for these associated SNPs ranged between ORs 1.16 to 1.30 ($p = 0.00011$ to 0.03). However, after adjusting for multiple testing by calculating false discovery rate, only SNPs in IGF2BP2 and TCF7L2 remained significant. Interestingly, when stratified for sex, we observed these effects only in males.
Conclusions: We confirm that genetic variants in *IGF2BP2* and *TCF7L2* are associated with T2D in our population-based cohort. Furthermore, the estimators for the genetic effects for T2D risk with involvement of CAC hardly changes, implying that these genetic variants are largely independent of the existence of subclinical atherosclerosis.

Multifactor-dimensionality reduction shows a four-locus interaction associated with type 2 diabetes mellitus

R. Bagarolli[1], M.J.A. Saad[1], S.T.O. Saad[1]
[1] *Universidade Estadual de Campinas, Clinica Medica, Campinas, Brazil*

Background: The toll-like receptor 4 (TLR4) and inducible nitric oxide synthase (iNOS) are proteins from the innate immune system that, when activated, can induce insulin resistance. Polymorphisms in these genes could affect the immune response, as well as the prevalence of type 2 diabetes (T2DM).
Objective: The aim of the present study was to investigate the contribution, isolated or together, of four polymorphisms (Asp299Gly and Thr399Ile from *TLR4*; deletion (D)/ insertion (I) AAAT and (CCTTT)n from *NOS2*) to susceptibility to T2DM in a southeastern Brazilian population.
Design: A total of 211 patients with T2DM and 200 unrelated controls were genotyped for the Asp299Gly and Thr399Ile polymorphisms of the *TLR4* gene and for the deletion (D) / insertion (I) AAAT and (CCTTT)n polymorphisms of the *NOS2* promoter gene. Besides conventional statistics analysis, the data was also analyzed for gene-to-gene interactions among the four polymorphic loci using the multifactor-dimensionality reduction (MDR) method.
Results: With regard to the *NOS2* promoter region, data showed that the I allele of the deletion (D) / insertion (I) AAAT polymorphism was more prevalent

in the T2DM group (p= 0.039, OR= 1.7, 95% CI 1.02-2.86). Similarly, the L/L genotype of the (CCTTT)n polymorphism was more frequent in the T2DM group (p= 0.047, OR = 1.51, 95% CI 1.01–2.28). In contrast, the 299Gly allele and the 399Ile allele from the Asp299Gly and Thr399Ile *TLR4* gene polymorphisms, respectively, were associated with protection against T2DM (Asp299Gly: p= 0.023, OR= 0.45, 95% CI 0.19–0.99; Thr399Ile: p= 0.03, OR=0.25, 95% CI 0.07–0.9). The MDR analysis showed a significant gene-to-gene interaction between the four polymorphisms studied (p= 0.0048). Moreover, the combination of the *NOS2* deletion (D)/ insertion (I) AAAT D/I heterozygote, the *NOS2* (CCTTT)n (stratified in short and long forms) S/L heterozygote and the *TLR4* Asp299Gly Asp/Asp or Thr399Ile Thr/Thr, homozygotes was associated with an increased risk of T2DM. Additionally, the genotype combination of the *NOS2* deletion (D) / insertion (I) AAAT D/D homozygote, the *NOS2* (CCTTT)n (stratified in short and long forms) S/L heterozygote and the *TLR4* Asp299Gly Asp/Gly or Thr399Ile Thr/Ile, heterozygotes was associated with protection from T2DM.

Conclusions: Genetic variations in the *NOS2* gene promoter and *TLR4* coding sequence, when analyzed together or isolated, may lead to deleterious and protective effects, respectively, arising from altered function of the innate immune system in patients with T2DM.

Molecular scanning of mtDNA gene in early onset maternal diabetic pedigrees

W. Wang[1], Y. Ren[1], Y. Long[2], H. Tian[2]

[1] *West China Hospital of Sichuan University, Division of Endocrinology and Metabolism, Chengdu, China*

[2] *West China Hospital of Sichuan University, Laboratory of Endocrinology and Metabolism, Chengdu, China*

Aims: To search for new potential diabetogenic mtDNA defects, we scanned the mtDNA genome in two early onset maternal diabetic pedigrees.

Methods: We screened early onset diabetic patients from in-patient and out-patient departments of Endocrinology and Metabolism from 2006. The whole mtDNA genome except D-loop were detected by direct sequencing in probands of suspected mtDNA mutated diabetic pedigrees. Novel mutation was identified by direct sequencing and then was screened in 200 non-diabetic controls and 100 early-onset diabetic patients.

Results: Two maternal diabetic pedigrees were recruited from 180 early-onset diabetes. These two families both had a maternal history, the probands were characterized by severely impaired ß cell function, sensory neuronal deafness, and low BMI. Affected family members all had relatively higher lactic acid concentrations and low insulin secretion. But we didn't find any pathogenic mutation by direct sequencing in No.1 family. In No.2 family, we found nt14319T/C mutation in the region of ND6 subunit. This mutation was heteroplasmic and has been not reported previously. The proband of this family characterized by severely impaired ß cell function and epileptic seizures. His affected mother had sensory neuronal hearing loss. Three members in the family had relatively higher lactic acid concentrations. The proband's mother and brother who were diabetics both carried this mutation. The frequencies of 14319T/C substitution in early-onset diabetes and control subjects were 6% and 5%, there were no significant differences between these two groups(P>0.05).

Conclusion: We didn't find pathogenic mutation in No.1 family by direct sequencing, this may because of heteroplasmic of mtDNA. Furthermore, we found a novel mutation 14319T/C in No.2 family, this mutation causes amino acid change (N to D). All three diabetic patients in this family harboured 14319T/C mutation, so we think it may be the major pathogenic mutation for this family.

MODY diabetes in type-1 diabetic children

C. Martinez Lopez[1], X.M. Boldo[1], S. Cano[1], J.L. Cortez-Peñaloza[1], R. Díaz-Martinez[1]

[1] *Universidad Juárez Autónoma de Tabasco México, Centro de Investigación de la División Academica Ciencias de la Salud, Tabasco, Mexico*

MODY-type diabetes has been identified as type-2 diabetes, with early onset in young subjects, and affects 5-10% of type-2 diabetic subjects (Fajans, 2001). Mutations in HNF1A/MODY3 and HNF4A/MODY1 have been reported in both Latins and PIMAS indigenes in the 6-16 age range (Ríos Burrows et al., 1998a, 1998b). In Mexico, MODY has been studied in type-2 diabetic subjects in the 20-40 age range with an incidence of 1.5% (Aguilar-Salinas et al., 2001). These researchers consider the MODY genes are not the main cause of type-2 diabetes with early onset (Dominguez-Lopez et al., 2005). The objective of this work was to determine the incidence of MODY-type diabetes in children diagnosed with type-1 diabetes in the Hospital del Niño "Dr. Rodolfo Nieto Padron". 20 out of 40 children diagnosed with type-1 diabetes in 2006 were chosen from the department of endocrinology in the Hospital del Niño "Dr. Rodolfo Nieto Padron". Three genes were reviewed (HNF-1a, HNF-4a and GCK). Informed consent was given by the children's parents. The analysis of the genes was carried out in the molecular-diagnosis laboratories of the University. DNA was isolated from leucocytes in peripheral blood (Wizard® Genomic DNA kit, Promega, U.S.A). DNA concentration was verified by densitometry. 2 exons of each gene were amplified by PCR (Supermix, Promega U.S.A.). The primers were previously designed (Aguilar-Salinas, 2001). The amplified exons were purified from the 2%-agarose gel (kit Gene Clean, BIO-100), sequenced in an ABI Prism BigDye Mod. 3100, and analysed in BioEdit v.7.05.3 and GENBANK (http://www.ncbi.nlm.nih.gov/blast/Blast.cgi). Mutations were corroborated with a second anti-sense sequence. From the HNF1A/exon 7 gene, a sense mutation was identified (L456L) C/A allele. This mutation was found in 5 children with an incidence of 25%. A missense mutation with G/A allele in this exon was also localized in three children; one of these children was observed with two alleles. This mutation has not been associated with functional alterations of beta cells (Rissanen, 2000). A missense mutation (R254H) from the HNF4A/exon 4 gene was identified. This mutation has not been reported ever before with G/A allele in two children aged 2 and 6. This polymorphism is localized in the alpha helix 7, site of adhesion recognized as conserved domain of the hormone receptor (Ryffel, 2001). No mutations in the exons of the KCG/MODY2 gene were identified. In conclusion, only 10% of the children subjects could have MODY-type diabetes and the other mutations could be considered as markers of diabetes in the type-1 diabetic population (Domínguez-López et al., 2005).

Backgound: The prevalence of uni-polar depression (DEP) is twice as high among people with Type 1 and Type 2 diabetes relative to the general population, affecting approximately 10-20% of the patients. DEP is associated with suffering, poor clinical outcomes and high costs. It is unclear to what extent DEP is related to high diabetes-specific distress (DSD) and if anti-depressant treatment should address DSD. In the context of the cross-national DAWN MIND (Monitoring of Individual Needs in Diabetes) study, patients are screened for DEP and DSD using validated self-report measures as part of ongoing diabetes care, along with socio-demographic and clinical parameters.

Aims: To explore the relationship between DEP and DSD and differentiate between different subgroups on the basis of the existence or absence of DEP and/or DSD. Such differentiation may help to clarify the relevance of perceived diabetes-specific burden in the etiology and management of DEP in people with diabetes.
Methods: Cross-sectional data were collected in 1131 diabetes patients from diabetes care centres in 9 countries. Frequencies of DEP and DSD were tested using established cut-off scores of the World Health Organisation-5 item Well-being Index (WHO-5 score <29) and the Problem Areas In Diabetes (PAID score > 39) scale, as measures of DEP and DSD respectively. Group differences on demographic and clinical variables were tested for 4 sub-groups: a) No DEP and No DSD, b) DEP, no DSD, c) DEP and DSD, and d) No DEP, DSD.
Results: Correlation between WHO-5 and PAID was -.443 ($p<0.01$), confirming they are related but not interchangeable. Both measures showed weak but significant associations (*r* -.077 and .122 resp.) with HbA1c, in the expected direction. Over 1/4 (26.2%, n=296) of the patients reported to be depressed and/or distressed. 15.6% had DSD but no DEP; 5.5.% had DEP alone (n=62), 5.1% combined DEP with DSD (n=58). Comparing DEP with and without DSD revealed that the combined DEP/DSD group comprised more females, but no other striking differences. DEP/DSD had poorest glycemic control of all groups and significantly worse than those with no DEP nor DSD (8.6% ± 2.1 vs. 7.9%± 1.5, $p<.05$).
Discussion/conclusion: Approximately 1: 4 diabetes patients has serious psychological issues that warrant clinical attention. Questionnaires such as WHO-5 and PAID can help clinicians distinguish between those affected by depression or diabetes-related distress only, and those with a combined problem. Those affected by depresion and diabetes distress had the worst glycemic control, suggesting they have the greatest difficulty self-managing their diabetes. Addressing diabetes distress in treating their depression would seem essential. Our findings underscore the importance of assessing patients' individual needs to help tailor psychological services in the context of diabetes care.

Background: Emotional distress is common in diabetes patients but poorly recognized by health care professionals and undertreated. The DAWN MIND (Monitoring of Individual Needs in Diabetes) study is a cross-national implementation project, promoting systematic evaluation of the psychological status of patients in diabetes clinics and improvement of psychosocial care.
Aim: There is a need for short, valid instruments that can be used in busy diabetes clinics by non-mental health specialists to screen patients for psychological distress. We sought to develop and validate a 5-item short form of the 20-item Problem Areas In Diabetes (PAID) scale, a widely used and well-validated measure of diabetes-related emotional distress.
Methods: Data from 1153 participants of the DAWN MIND study were available on the PAID questionnaire and WHO-5 (World Health Organisation 5 item Well-being Index) along with socio-demographic and biomedical characteristics. Mean age 53.8 years (SD 14.7), 52.1% female, 63.2% Type 2 diabetes; 54.9% reported no complications, 20.4% 2 or more complications. Two random sub-samples were created (sample 1: n=589 and sample 2: n=564) for psychometric testing, including descriptive statistics, Principal Components Factor Analysis (PCA), Explorative Factor Analysis (EFA), tests of internal consistency and validity. Receiver Operator Characteristics (ROC) analysis was performed to test for diagnostic accuracy.
Results: Based on PCA in sample 1, 10 items from the full PAID were identified constituting a negative emotions scale, from which 5 were retained after reliability analysis (alpha .86, 95% CI=.84-.88). Average score 6.07 (SD 5.09, 0-20). Convergent and construct validity of PAID-5 were confirmed with WHO-5 ($r=-.47, p<.001$) and females reporting higher PAID-5 scores then males ($p<.001$). Patients with complications tend to report more distress than those without complications. These data were confirmed in sample 2. Diagnostic accuracy was tested by ROC analysis, showing 94% sensitivity and 89% specificity for using as cut-off PAID-5 score of >7 against established criterion score for high distress of full PAID.
Conclusion: We have identified a brief, user friendly and reliable measure of diabetes-specific emotional distress, that should prove useful in busy practices, taking 1 minute maximum to complete and offering a clear cut-off score for clinically relevant levels of diabetes distress. The PAID-5 is an excellent candidate for systematic screening in ongoing diabetes care as recommended by the ADA and IDF, either alone or combined with a measure of general well-being such as the WHO-5.

Three Canadian provinces participated in a pilot project to field test the initial version of the CANRISK survey (July 2007). CANRISK is a risk-scoring questionnaire based on Finland's FINRISK which is being further evaluated in other Canadian provinces by the Public Health Agency of Canada. The pilot included 997 participants in New Brunswick (NB), Prince Edward Island (PE) and Saskatchewan (SK) with undiagnosed diabetes over the age of 40 (only 3% of the participants were under 40). All participants completed both the CANRISK survey and 75-g oral glucose tolerance test (OGTT). There were 204 participants (20.5%) with abnormal fasting plasma glucose (FPG) or OGTT results, according to Canadian Diabetes Association (CDA) definitions. Prediabetes and diabetes was diagnosed in 154 participants (15.5%) and 50 participants (5.0%) respectively.
The CDA 2008 Clinical Practice Guidelines recommends screening for diabetes using FPG over age 40. A 2-hour plasma glucose (2hPG) in a 75-g OGTT is indicated when FPG is 6.1-6.9 mmol/L (impaired fasting glucose (IFG)) and may be indicated when the FPG is 5.6-6.0 mmol/L and risk factors for type 2 diabetes are present.
Had FPG been the only screening performed in this study population, IFG would have been diagnosed in 63 cases. 91 participants with isolated impaired glucose tolerance (IGT) would not have been recognized, representing 59% of those with prediabetes. FPG alone would have recognized 26 cases of diabetes; however, 24 participants with diabetes (48%) would not have been diagnosed. If OGTTs were conducted on the 76 participants with FPG between 6.1-6.9 mmol/L, 41 participants would have been recognized with isolated IFG, 26 with both IFG and IGT and 9 new diagnosis of diabetes would have been made. An OGTT for those with IFG increases prediabetes and diabetes case detection to 59 (38%) and 35 (70%), respectively.
CDA guidelines suggest OGTT if FPG is 5.6-6.0 mmol/L with risk factors. Given that a majority of participants were over the age of 40 with multiple risk factors, all were assumed to be at risk. Following the guidelines, 112 additional OGTTs would have been performed resulting in 28 additional cases of prediabetes (isolated IGT) and 8 additional cases of diabetes. These recommendations improved prediabetes and diabetes case detection to 87 (56%) and 43 (86%), respectively.
Even strict adherence to the CDA screening guidelines missed 63 (44%) of prediabetes and 7 (14%) of diabetes cases. 70 participants (7%) with either prediabetes or diabetes had FPG values $\leq$ 5.5 mmol/L.

Four questions from CANRISK (waist circumference, age, history of abnormal blood sugar, and history of high blood pressure) were sensitive (73%) and specific (67%) using a pre-determined scoring system to identify prediabetes and diabetes, and may be helpful in determining those people who would benefit from OGTT.

[2] Ebi Clinic, Internal Medicine, Hino, Japan

Aims: Fetuin-A is a hepatic secretory protein that induces insulin resistance in vitro, and several studies reported higher Fetuin-A levels were associated with insulin resistance and incident diabetes in human. So, we presumed that Fetuin-A could be a good predictor to detect impaired glucose tolerance (IGT).
Methods: We conducted medical examination of 1033 inhabitants in resident of rural area in Japanese population (Kofu-town, Tottori, Japan). The 75g oral glucose tolerance test (75g-OGTT) was applied to 251 high risk participants (age:68.2, M/F:91/160) with FPG>=95mg/dl (5.3mmol/l), or with FPG<95mg/dl and having any other following criteria, HbA_{1C}>=5.3%, BMI=>25 kg/m^2, TG>=150 mg/dl (1.7mmol/l), and Hypertension treatment in 2006. 74 IGT subjects and 7 diabetes subjects, total 81 patients (32%) were detected with glucose intolerance in 251 high risk participants. In this study, we retrospectively measured Fetuin-A level in preload serum among 251 participants applied OGTT.
Results: The optimal cut-off value of Fetuin-A to detect IGT was 230µg/ml using ROC curve (sensitivity 74%, specificity 42%). From logistic analysis, participants with Fetuin-A>=230µg/ml had a significantly higher risk of incident IGT compared with participants with Fetuin-A<230µg/ml in models adjusted for age, gender, and whether having FPG=95mg/dl, HbA_{1C}>=5.3%, BMI>=25 kg/m^2, TG>=150 mg/dl, and Hypertension treatment (adjusted hazard ratio, 2.68; 95% confidence interval, 1.17-6.16; P=0.02)(Table1). According to multi-regression analysis, Fetuin-A level is reversely correlated with age.
Discussion/conclusion: We speculate the high Fetuin-A level in elderly could be the marker to predict the latent IGT. In elderly people of Japan, IGT is one of important metabolic risk factors for cardiovascular events. It is necessary to find the efficient and economical way to detect IGT in early phase. Our results indicate that Fetuin-A is a good predictor to detect IGT in elderly residents in Japanese population.

NGT/IGT/DM=Total (75gOGTT is applied)	hazard ratio of High Fetuin-A (>=230µg/ml) for IGT	95% CI
170/74/7=251	2.68 (P=0.02)	1.17-6.16

[3] University of Buenos Aires, Statistics, Buenos Aires, Argentina

[4] Durand Hhospital, Pediatrics, Buenos Aires, Argentina

Background: There is growing interest in understanding the role that lifestyle behaviors play in relation to children's weight status.
Objective: To determine the association between children's waist circumference (WC), health behaviors, and components of the metabolic syndrome.
Methods: 1065 students (535M) aged 9.54 ± 2.08 years from 6 suburban elementary schools, were examined between April 2007and March 2008. Mothers were asked about their children's lifestyle. A simple 5-level index ranked participants' daily consumption of vegetables or fruits portions, glasses of milk, sweetened beverages, blocks walked, breakfast intake, and TV viewing. We assigned a score of 0 for unhealthy and 1 for healthy (above or below median level). Thus the healthy behavior score for the 6 components had a range from 0 (unhealthy) to 6 (healthy). Data also included parental education levels socioeconomic status, children's BMI, WC, blood pressure (BP), Tanner stage, fasting lipids, insulin, and glucose. We also created two groups for WC $\geq$ or < 90t^h percentile.
Results: All families were in the low socio-economic class: 77.8 % of parents had an elementary education or less, 7.8% of the families did not have a refrigerator and 4.1% had a dirt floor. One hundred and sixty five (15.5%) of children were obese (OB) (BMI$\geq$95%ile per CDC norms), and 152 (14.3%) overweight (OW) (BMI>85<95%ile). The prevalence of WC$\geq$90th percentile was 24.6% (262). 58.4% of the children were at Tanner 1. The median daily intake of sweet beverages was 4, of fruit and vegetables 2, and of milk 2. The median number of blocks walked daily was 10 and the median hours of TV watched daily was 3. Children with WC$\geq$90 showed significantly lower scores for healthy habits than children with WC<90 (Chi-Square 16.04; p= 0.014). Mean values of triglycerides (91.37 vs 69.79 mg/dL), systolic BP (98.35 vs 90.71mm Hg), diastolic BP(59.93 vs 55.40) and HOMA-IR (1.44 vs 0.75) were significantly higher while HDL-C (46.49 vs 52.85) and healthy score (2.55 vs 2.80) were significantly lower in the group of children with WC$\geq$90 than in the other group. Multiple regression analysis showed a positive association between children's WC, HOMA-IR (B=5.36; p<0.01), sex (B=3.04; p<0.01) and Tanner (B=4.13; p<0.001), and a negative association with healthy lifestyle's score (B=-0.69; p=0.016) (R^2 0.38).
Conclusions: Our results suggest that insulin-resistance, sex and puberty are positively associated with childhood central OB while healthy habits are inversely associated. Most of these behaviors can be modified, suggesting opportunities for preventive intervention during childhood to avoid the development of metabolic disease.

Screening glucose challenge test in pregnancy: impact of family history of diabetes on the likelihood of a false-negative result

N. Yakubovich[1], Y. Qi[1], M. Sermer[2], P.W. Connelly[3], A.J.G. Hanley[1], B. Zinman[1], R. Retnakaran[1]

[1] Mt. Sinai Hospital, Leadership Sinai Centre for Diabetes, Toronto, Canada

[2] Mt. Sinai Hospital, Division of Obstetrics and Gynecology, Toronto, Canada

[3] Li Ka Shing Knowledge Institute of St. Michael's Hospital, Keenan Research Centre, Toronto, Canada

Introduction: The glucose challenge test (GCT) is commonly used as a screening test for gestational diabetes mellitus (GDM). Women with a 1-hour plasma glucose of > or =7.8 mmol/l after a 50-g oral glucose load (positive test) proceed to an oral glucose tolerance test (OGTT) for definitive diagnosis. Women with a normal GCT do not undergo further metabolic testing; however, some of these women subsequently develop GDM or gestational impaired glucose tolerance (GIGT). These women are typically not identified in clinical practice. The aim of this study was, therefore, to identify clinical characteristics of women with a false-negative GCT that might be predictive of an increased risk of the later development of GIGT or GDM.
Methods: In a prospective longitudinal cohort study, 124 women with a normal GCT screening test subsequently underwent a diagnostic three-hour 100g OGTT in pregnancy and a 75 g OGTT at 3 months postpartum. These women were stratified into two groups based on the OGTT results in pregnancy: (i) those who maintained normal glucose tolerance (NGT, n=93) and (ii) those who were diagnosed with GIGT or GDM (i.e. false-negative screening GCT, n=31).
Results: At the time of GCT screening, age, ethnicity, pre-pregnancy BMI and GCT 1-hour glucose values were not significantly different between the two groups. However, women with a false-negative GCT were more likely to have a family history of diabetes than were women with NGT in pregnancy (64.5% versus 41.9%, p=0.03). At the OGTT at 3 months postpartum, the false-negative GCT group also exhibited significantly higher fasting and 2-hour glucose values, lower insulin sensitivity and poorer beta-cell function compared to women with NGT. Furthermore, 12.9% of women with a false-negative GCT were found to have pre-diabetes on postpartum testing compared to 3.2% in the NGT group (p=0.06). Amongst clinical characteristics at the time of the GCT, the GCT 1-hour glucose value was not significantly associated with subsequent GIGT/GDM (odds ratio (OR) 1.45, 95% confidence interval (CI) 0.95-2.22, p=0.08), whereas family history of diabetes was a significant

predictor of glucose intolerance in pregnancy (OR 2.37, 95% CI 1.01-5.57, p=0.048). Indeed, for identifying women at risk of GIGT/GDM, the GCT was informative in women with no family history of diabetes (area-under-the-receiver-operating-characteristic-curve (AROC) 0.71), but it was of limited value in women with a family history of diabetes mellitus (AROC 0.54).
Conclusion: A normal GCT screening test may be falsely negative in women with a family history of diabetes. Further metabolic testing in pregnancy should be considered in these women.

Autoimmunity against REG family antigens in Japanese diabetes patients

N.J. Shervani[1], K. Nata[1], N. Noguchi[2], I. Takahashi[1], T. Ikeda[2], A. Yamauchi[3], T. Yoshikawa[2], A. Uruno[2], S. Takasawa[3], H. Okamoto[2], A. Sugawara[2]
[1] *Iwate Medical University School of Pharmacy, Department of Medical Biochemistry, Yahaba, Japan*
[2] *Tohoku University Graduate School of Medicine, Department of Advanced Biological Sciences for Regeneration, Sendai, Japan*
[3] *Nara Medical University, Department of Biochemistry, Kashihara, Japan*

Aims: ß-cell regeneration is induced by Reg, via an autocrine/paracrine mechanism. Recombinant REG was shown to ameliorate diabetes in 90% depancreatised rats and non-obese diabetes mice. Human *REG* family is comprised of five genes (viz; *REG Iα*, *REG Iß*, *REG III*, *HIP/PAP* and *REG IV*). The gene structure consisting of 6 exons and 5 introns, is common in all five members, that encodes homologous 158-175 amino acids secretory proteins expressed during tissue injury and regeneration. Previously we identified antibodies to REG Iα in Japanese Type 1 and Type 2 diabetes patients showing significant correlation with the duration of diabetes and ages of patients at the onset of the disease. The existing sequence homology and similarity in expression pattern between the REG family members draws much interest in identifying autoimmunity against other REG family proteins, and to understand their association with autoimmune diseases, if any. Presently, we analysed the presence of autoimmunity to REG Iß, REG III, HIP/PAP and REG IV and their correlation with diabetes in Japanese sera.
Methods: Sera from 300 diabetes subjects and 75 healthy controls were drawn at Tohoku University Hospital (Sendai, Japan) after obtaining their consent for purpose of study. The cDNA of each *REG* gene was cloned into pTriEX-4 multiple expression system vector with conjugated S-tag sequence at N-terminal to facilitate one-step affinity purification on S-Protein agarose (Novagen®). Autoantibodies to REG proteins were screened by Western Analysis. Each purified REG protein was electrophoresed on SDS-polyacrylamide gel, electrotransferred to PVDF membrane and blocked with milk solution before incubating with patient sera as primary antibody. HRP conjugated anti-human monoclonal IgG (American Qualex) was used as secondary antibody. Signal was detected by ECL Plus Western Blotting System (GE Healthcare). Signal intensity from each patient serum was analysed by densitometry, using ImageJ software. Statistical significance of the occurence of anti-REG autoimmunity in patient sera and its correlation with the general characteristics of diabetes patients was analysed by Chi-squared test, Student's *t*-test, simple regression analyses and ANOVA analyses.
Results: We found autoimmunity against REG Iß in 10% of Type 1, 32% of Type 2, and 2.7% of non-diabetes controls ($P = 0.001$), and against REG III in 15% of Type 1, 20% of Type 2, and 1.4% of non-diabetes controls ($P = 0.0001$). There was significant difference between anti-REG Iß positive (39.8 ± 1.6) and negative (33.5 ± 1.0) groups in age at onset of disease ($P = 0.0024$). No autoantibodies were detected against HIP/PAP and REG IV in diabetes patient sera.
Conclusion: These results suggest that autoimmunity against REG family proteins may be associated with diabetes, thus REG family members may serve as separate biomarkers.

[5] *Cree Board of Health and Social Services of James Bay, Chisasibi, Canada*
[6] *Laval University, Diabetes Research Unit, Québec, Canada*
[7] *Laval University, Department of Food Science and Nutrition and Institute of Nutraceuticals and Functional Foods (INAF), Québec, Canada*

Type 2 diabetes (T2D) reaches epidemic proportions in many of Canada's First Nations and Indian Cree populations. Nevertheless, Inuit from Nunavik show a low prevalence of T2D. Gestational diabetes (GDM) has been proposed as a predictor of T2D in various populations particularly among Cree from James Bay region. Moreover, GDM is highly prevalent among Indian Cree population; yet, the impacts of GDM on T2D among Canada's First Nations population are poorly investigated.
Aims: To identify the impact of a history of GDM on the suboptimal glucose metabolism among Canadian First Nations women.
Methods: Study participants were recruited during two different health surveys conducted between 2004-2008 in the Nunavik and James Bay regions (Québec, Canada). Participants included in the current analysis comprised 419 Inuit and 176 Cree adult women (18-74 years) who previously gave birth. History of GDM and T2D was obtained from medical records for each participant. Women with either T2D or impaired fasting glucose (obtained from blood fasting glucose measurements at the time of recruitment) were classified as having a postpartum suboptimal glucose metabolism. Comparisons between the two ethnic groups were performed by Ancova and the influence of GDM on suboptimal glucose was determined by logistic regression analyses.
Results: Among all participants, 6.5% had a history of GDM; this proportion was not statistically different between ethnic groups (Inuit: 6.7% vs. Cree: 5.9% ; p=0.73). Women with prior GDM showed higher plasma total-cholesterol, LDL-cholesterol and triglycerides concentrations ($p<0.05$). The prevalence of a suboptimal glucose metabolism among participants was 13.2% and this proportion was significantly higher among Cree(30.1% vs. 7.1%, $p<0.0001$). Cree women also showed a metabolic profile that is more deteriorated, as they show higher waist circumference (110 vs. 91 cm, $p<0.0001$), higher plasma triglycerides levels (1.5 *vs.* 1.0 mmol/L,$p<0.0001$), lower plasma HDL-cholesterol levels (1.3 *vs.* 1.8 mmol/L, $p<0.0001$) and higher systolic blood pressure (120 *vs.* 114 mmHg, $p<0.0001$) compared to Inuit women. Adjusted logistic regression revealed that a GDM history predicted significantly the likelihood of having a suboptimal glucose metabolism (OR: 3.9 [1.5-9.8]). This association was markedly seen among Inuit women (OR: 7.7 [2.6-22.2]).
Conclusion: Among Canadian Cree and Inuit women, GDM history is associated with a suboptimal glucose metabolism as previously shown in other populations at risk. Moreover, our results suggest that among a population such as the Cree, showing a high prevalence of T2D and associated metabolic diseases, GDM history has less impact on suboptimal glucose metabolism.

Derivation of BMI and waist circumference cut-off values for Sri Lankan adults

P. Katulanda[1], M. Jayawardena[1], D. Lamabadusuriya[1], M.H.R. Sheriff[1], D.R. Matthews[2]
[1] *University of Colombo, Diabetes Research Unit Department of Clinical Medicine, Colombo, Sri Lanka*
[2] *University of Oxford, Oxford Centre for Diabetes Endocrinology and Metabolism, Oxford, United Kingdom*

Introduction: Anthropometric cut-off values derived for Caucasians would be less sensitive to define obesity in Non-Caucasians. We aimed to derive BMI and WC cut-offs for Sri Lankan adults.
Methods: Data were from a nationally representative sample of 4276 subjects without known diabetes. Presence of = 2 of dysglycaemia (fasting glucose =5.6mmol/l; 2-hr post OGTT glucose =7.8mmol/l), elevated blood pressure

(=130/85mmHg/antihypertensive therapy), low HDLC (males <1.03mmol/l; females <1.3mmol/l) and elevated triglycerides (>1.7mmol/l) was considered as having high cardiovascular disease (CVD) risk. Receiver operating characteristic (ROC) curve analysis was performed using SPSS to identify BMI and WC cut-offs with optimal sensitivity and specificity to predict high CVD risk.

Results: The mean age, BMI and WC were 45.2 years, 21.8kg/m^2 and 77.7cm. The area under the curve (AUC) for BMI for both males (M) and females (F) were 0.71 (P<0.001). AUC for WC were M: 0.71, F: 0.72 (p<0.001). The BMI cut-off for all adults was 21.5kg/m^2 and that for males and females were 20.7 kg/m^2 and 22.0 kg/m^2 respectively. The WC cut-off for men and women were 76.5cm and 76.3cm respectively. The sensitivity for the new BMI cut-off in predicting high CVD risk was 66% compared to 34% for the cut-off for overweight (25kg/m^2) for Caucasians. The sensitivities for newly derived WC cut-offs were 76% for males and 72% for females compared to the recommended cut-off values by the International Diabetes Federation for Asians (male: 90cm - sensitivity 27%, female: 80cm - sensitivity 57%)

Conclusions: Population specific anthropometric cut-offs are more sensitive in identifying those with higher CVD risk in Sri Lankans compared to those derived for Caucasians.

Making it Work - addressing program implementation challenges in Indigenous communities

S. Lynch[1], R. Carriere[1], J. Ramsay[1], P.T. McGowan[1], T. Cayer[1], M.V. Davies[1], K. Hannah[1]

[1] University of Victoria, Centre on Aging, Delta, Canada

Aims: While there is evidence demonstrating the effectiveness of diabetes self-management programs in Indigenous populations, there are also implementation challenges, notably: remote locations with small populations, cultural and ethnic diversity, and complex issues of poverty. The aim of this research was to identify and understand these specific challenges, and develop strategies for successful implementation of community self-management programs.

Methods: Between 2005 and 2009 a team from University of Victoria conducted four sequential studies examining this challenge in First Nations communities in British Columbia, Canada. Using qualitative methodology, the 2005 study elicited perspectives on program processes and materials, training, and implementation processes from community leaders. The 2006 study focused on the use of information and skills in the communities following program implementation, and ways to make the materials more culturally appropriate. The focus for the 2007 study was to examine the effectiveness of various support strategies to enhance program implementation. Lastly, the 2008 study addressed issues of program sustainability.

Results: Following program implementation, participants reported using the information and skills in a variety of ways. They learned skills of action planning and goal setting which could be used beyond the management of diabetes and other chronic conditions. Participants provided suggestions relating to program format and content, acceptability of training community members as Leaders, and language and cultural considerations. An Aboriginal Liaison Coordinator was hired with a focus on building relationships with communities and volunteer leaders. The findings led to modifications in training materials, including the addition of artwork and colours in the manuals and charts, resource examples from First Nations communities, and the development of a First Nations brochure and poster. To ensure sustainability, participants identified the need to provide adequate funding for transportation, rooms and promotion.

Conclusion: Self-management programs for persons living with diabetes in First Nations communities can be delivered in a culturally acceptable way.

Role of Ox-LDL immunocomplexes in diabetic retinopathy

M. Wu[1], Y. Chen[1], S.A. Abdel-samie[2], K. Wilson[1], M.E. Boulton[3], J.X. Ma[1], G. Virella[2], M.F. Lopes-Virella[2], T.J. Lyons[1]

[2] Medical University of South Carolina, Medicine/Endocrinology, Charleston, USA

[3] University of Florida, Anatomy and Cell Biology, Gainesville, USA

Extravasated and oxidized low-density lipoprotein (LDL) have been identified in the retina in diabetes, and implicated in diabetic retinopathy (DR) in our recent cell culture and immunohistochemical studies. Oxidized LDL may be immunogenic, resulting in the formation of ox-LDL immunocomplexes (LDL-IC) containing IgG/M – and such complexes have recently been implicated in atherogenesis. In the current study, we investigated whether LDL-IC are associated with the initiation and progression of DR. Immunostaining of ox-LDL and IgG/M was performed in retinal sections from four different groups of human subjects: non-diabetic; (Type 2) diabetic without clinical retinopathy; diabetic with moderate non-proliferative diabetic retinopathy (NPDR); diabetic with proliferative diabetic retinopathy (PDR). Ox-LDL and IgG/M was absent in non-diabetic subjects but present in all three diabetic groups, increasing with severity of DR. Merged images revealed co-localization of ox-LDL and IgG/M. In cell culture studies, induction of apoptosis by human LDL-IC in human retinal capillary pericytes (HRCP) was assessed. Human LDL-IC (50 mg/L) significantly attenuated viability in HRCP at 6 and 24 hrs. In contrast, rabbit LDL-IC and ox-LDL (50 mg/L) did not induce this effect (however ox-LDL also triggered apoptosis, but at higher concentrations). The apoptotic mechanisms were related to PARP pathways and caspase cascade activation. The data suggest a potentially important role for LDL-IC, formed after extravasation and oxidation of LDL in the retina, in promoting an early feature of DR, pericyte loss by apoptosis.

[2] University of Florida, Department of Anatomy and Cell Biology, Gainesville, USA

[3] Oklahoma Medical Research Foundation, Free Radical Biology and Aging Program, Oklahoma City, USA

[4] University of Oklahoma Health Sciences Center, Department of Medicine, Oklahoma City, USA

Loss of retinal pericytes due to apoptosis plays a central role in the development of diabetic retinopathy (DR). Our previous studies have demonstrated that intra-retinal highly oxidized-glycated LDL (HOG-LDL), formed from LDL extravasated through a leaking inner blood retinal barrier, may be important in promoting apoptosis of human retinal capillary pericytes (HRCP). In this study, we investigated potential mechanisms by which HOG-LDL induces apoptosis in HRCP. In cultured cells, HOG-LDL (200 mg/L) increased levels of intracellular reactive oxygen species (P<0.01, n=3) and 3-nitrotyrosine (P<0.05, n=3), and decreased glutathione peroxidase-1 (P<0.05, n=3). Also, HOG-LDL reduced the activity of proteasome (P<0.05, n=3) (which is responsible for degrading activated pro-apoptotic Bcl-2 proteins), enhanced Bax translocation to mitochondria as detected by a reduced level of Bax in cytosol (P<0.05, n=3) and an enhanced level of Bax in membrane (P<0.05, n=3). Further, HOG-LDL increased cytosolic cytochrome c (P<0.05, n=3), and apoptosis-inducing factor (P<0.05, n=3). In contrast, treatment with N-LDL (200 mg/L) did not induce any of these changes. In *ex-vivo* studies, co-staining of oxidized LDL and Bax was demonstrated in the ganglion cell and the inner and outer nuclear layers in retinae from human diabetic subjects with non-proliferative diabetic

retinopathy, but was absent in retinae from non-diabetic subjects. We conclude that in the development of DR, HOG-LDL may mediate pericyte loss through enhanced oxidative stress, proteasome inhibition, and mitochondrial-mediated apoptosis.

Declining prevalence of visual impairment among people with diabetes in the United States, 1997–2007

N.R. Burrows[1], I. Hora[1], J. Saaddine[1], L.S. Geiss[1]
[1] Centers for Disease Control and Prevention, Division of Diabetes Translation, Atlanta, USA

Aim: Diabetes can lead to impaired vision and blindness. We examined trends in the prevalence of visual impairment (VI) among adults with diabetes in the United States.
Methods: Using 1997-2007 data from the National Health Interview Survey, we calculated the prevalence of VI among people aged 18 years or older with self-reported diabetes. VI was defined as having trouble seeing even when wearing glasses or contact lenses. Data were analyzed by age, sex, and race or ethnicity using single years of data. The race groups included people of both Hispanic and non-Hispanic origin; people of Hispanic origin may be of any race. Rates were age-adjusted based on the 2000 U.S. standard population. We examined trends using joinpoint regression analysis and each trend in the final model was described by an annual percentage change (APC).
Results: Among people with self-reported diabetes, VI increased from 2.6 million in 1997 to 3.2 million in 2007. However, throughout the period, crude and age-adjusted VI prevalence decreased significantly among people with diabetes, with the age-adjusted prevalence dropping from 23.9% to 18.3% (APC = -3.3%, p<0.001). The declines in crude and age-adjusted prevalence were similar, suggesting that the aging of the population had little effect on trends. Between 1997 and 2007, although not always significant, VI prevalence decreased steadily across the demographic groups examined.
Prevalence of VI among adults with self-reported diabetes and APC, by age, sex, and race or ethnicity, United States, 1997–2007

	Percentage		Trend		
	1997	2007	APC	95% CI*	p value
Age					
18–44	21.0	17.7	-3.4	(-7.0, 0.3)	0.07
45–64	25.6	18.3	-3.4	(-4.8, -2.0)	<0.001
65–74	26.4	19.0	-1.9	(-4.2, 0.6)	0.12
>=75	33.2	21.6	-2.5	(-4.7, -0.3)	0.03
Age-adjusted					
Men	22.2	16.4	-2.7	(-4.8, -0.5)	0.02
Women	25.3	20.1	-3.8	(-5.4, -2.0)	<0.001
White	22.8	19.2	-2.7	(-4.1, -1.3)	0.002
Black	27.4	18.6	-3.4	(-7.0, 0.3)	0.07
Hispanic	24.7	14.5	-2.6	(-5.5, 0.4)	0.08

*CI=confidence interval

Conclusion: Between 1997 and 2007, the prevalence of VI among people with diabetes declined. This encouraging trend was likely due in part to a reduction in VI risk factors, improved detection and treatment of eye problems, and other factors. Continued efforts are needed to improve and sustain the decline.

Elevated glucose activates the P38 MAP kinase pathway in cultured human retinal pigment epithelial cells

P.C. Kothary[1], D. Prieur[1], M.A. Del Monte[1]
[1] University of Michigan, Ophthalmology, Ann Arbor Michigan, USA

Purpose: Proliferative diabetic retinopathy (PDR) is a serious complication of diabetes that can result in blindness. Elevated glucose, as seen in diabetes mellitus, activates the p38 mitogen-activated protein kinase (P38) pathway in various kinds of cells. Since retinal pigment epithelial cells (hRPE) have been implicated in the pathogenesis of PDR, we examined the production of P38 in cultured hRPE cells under high glucose conditions.
Methods: hRPE cells were isolated and cultured from three human eyes. The hRPE were exposed to fetal bovine serum (FBS) (0-10%) and FBS (10%) supplemented with 20mM glucose for 48 hours with or without SB203580, an inhibitor of P38. Some experimental hRPE cells were labeled with 14C-methionine to assess P38 production by immunoprecipitation of 14C-methionine p38 (14C-P38) with anti-P38. hRPE viability and proliferation were evaluated by trypan blue exclusion method (T) and 3H-thymidine (3H-thy) incorporation respectively. Light microscopy was done to assess cell phenotype. Data were analyzed by student t-test. $p < 0.05$ was considered as significant difference.
Results: hRPE cells studied in FBS (0-10%) with or without high (20mM) glucose showed similar epitheloid phenotype and remained viable as determined by T. Increasing concentrations of FBS stimulated hRPE proliferation in a dose dependent manner as determined by 3H-thy. Increasing concentration of FBS also stimulated 14C-P38 production in a dose dependent manner. FBS (10%)+ high glucose (20 mM) stimulated significantly greater 14C-P38 production compared to FBS (10%) alone (2106.40±107.12 vs. 1127.00±400.43, CPM±SEM, n=4, p=0.01). FBS (10%)+glucose (20 mM)+SB203580 (20μM) stimulated 14C-P38 even greater production compared to FBS (10%)+glucose (20 mM) alone (2654.69±333.88 vs. 2198.36±226.23, CPM±SEM, n=4, p=0.02). In addition, exposure of hRPE cells to high glucose stimulated increased proliferation, as measured by 3H-thy incorporation, in parallel with the increased 14C-P38 production.
Conclusion: Exposure of hRPE cells to elevated glucose stimulates increased proliferation as well as increased P38 production. This activation of the P38 MAP Kinase pathway may play a role in the pathogenesis of PDR.

MicroRNA 146a in diabetic retinopathy

B. Feng[1], S. Chen[1], Y. Wu[1], S. Chakrabarti[1]
[1] The University of Western Ontario, Pathology, London, Canada

Aims: Glucose induced multiple signalling mechanisms may cause tissue damage in diabetic retinopathy (DR). Endothelial cells (ECs) play an important role in the pathogensis of DR. We have previously demonstrated glucose induced alteration of transcription factors, fibronectin (FN) and endothelin-1 (ET-1) in ECs and in the retina in diabetes. At the nuclear level, microRNAs (miRNAs), through transcriptional regulation, influence a large number of cellular processes and may influence the pathogenesis of several disease processes. However, exact role of miRNAs in diabetic complications such as DR have not been studied. We investigated glucose induced miRNAs alteration and their downstream effects in ECs and in DR.
Methods: miRNAs microchip arrays was used to examine alteration of miRNAs expression in human umbilical vein endothelial cells (HUVEC), exposed to glucose. Specific miRNA expression (miR146a), identified on the array analysis, was validated by TaqMan™ PCR. Real time PCR was used to determine mRNA expression of selected targets, FN and ET-1, in glucose exposed cells with or without miR mimic transfection. ERK1/2, another target of miR146a, was analysed. Retinas from the STZ induced diabetic rats were also analysed for miR146a alteration.
Results: Array analysis demonstrated glucose induced alterations of 231 miRNAs (out of a total of 733 miRNAs) in HUVECS exposed to 25mM glucose (HG) for 24 hours. Three were upregulated and 228 were downregulated. Twenty five mM glucose (HG) caused significant decrease in miR146a expression compared to 5mM glucose (LG). Simultaneously, HG caused increased ERK1/2 protein levels, ERK phosphorylation and augmented mRNA expression of FN and ET-1. Retinas from the STZ-induced diabetic rats also showed decreased miR146a and other changes similar to ECs. Transfection with miR146a mimics increased miR146a levels. Furthermore, all aforesaid mRNA and protein alterations were prevented by such transfection.
Discussion/conclusion: Data from these studies demonstrate a novel glucose-induced molecular mechanism in which miRNAs may participate in the transcriptional circuitry regulating downstream gene expressions in diabetes. It is important to identify such mechanisms that may lead to potential novel RNA based treatment target for DR and other diabetic complications.

Expression of RAX and microRNA 29b in the Retina of Diabetic Rats: Implications for Apoptosis of Retinal Neurons

V.A.O. Silva[1], T.A. Sousa[1], N. Delgado-André[1], R.I. Reis[1], V.M.A. Corrêa[1], A. PolessKaya[2], A. Harel-Bellan[2], F.L. De Lucca[1]
[1] School of Medicine University of São Paulo Ribeirão Preto SP Brazil, Biochemistry and Immunology, Ribeirão Preto - SP, Brazil
[2] Institut of André Lwoff, University Paris-Sud XI, Villejuif, France

Diabetic retinopathy is one of the most common complications of diabetes, but the molecular mechanisms underlying this ocular pathology are only partly understood. Accumulating evidence indicates that apoptosis of retinal neurons precede the microvascular alterations in retina in both diabetic patients and streptozotocin-induced diabetic retinopathy. It is known that RAX, an activator of the RNA-dependent protein kinase (PKR), is up-regulated during stress and activation of PKR signaling pathway leads to apoptosis. We hypothesized that the up-regulation of RAX is involved in the apoptosis of retinal neurons of diabetic rats. Recently, it has been demonstrated that microRNAs play a pivotal role in regulation of gene expression and our computational analysis predicted that RAX is regulated by *miR-29b*. Here, we investigate the expression of RAX and *miR-29b* and their cellular localization in retina of diabetic rats. Retinas were obtained from normal and streptozotocin-induced diabetic rats (45mg/kg bogy weight). We found that *miR-29b* expression evaluated by real time RT-PCR was up-regulated (>3-fold) at 28 and 35 days after injection of streptozotocin. We also observed that the expression of RAX monitored by Western blot was down-regulated at 28 and 35 days which is consistent with the prediction that RAX mRNA is a target of *miR-29b*. The analysis by *in situ* hybridization showed that *miR-29b* is highly expressed in ganglionar neurons of retina of diabetic rats. Interestingly, RAX assessed by immunofluorescence displays the same cellular localization of *miR-29b*. We also found that RAX was up-regulated at 6, 15 and 22 days in retinal ganglionar neurons of diabetic rats which could activate the pro-apoptotic PKR signaling pathway. These findings are relevant since apoptosis of ganglionar neurons is observed in diabetic retinopathy. Our data suggest that RAX is negatively regulated by *miR-29b* which may contribute to develop a new strategy for the treatment of diabetic retinopathy by intravitreal injection of *miR-29b*.

Incidence of diabetic retinopathy amongst type 2 diabetic patients in a Tertiary Care Hospital in Bangladesh

K.R. Ahmed[1], L. Ali[2], A. Hussain[1], S.H. Habib[3]
[1] Institute of General Practice and Community Medicine, Department of International Health University of Oslo, Oslo, Norway
[2] Bangladesh Institute of Research and Rehabilitation for Diabetes Endocrine & Metabolic Disorders, Department of Biochemistry and Cell Biology, Dhaka, Bangladesh
[3] BADAS, Department of Health Economics Unit, Dhaka, Bangladesh

Background and aims: Diabetic retinopathy (DR) refers to damage of blood vessels in the retina, is one of the most common micro vascular complications of diabetes. DR may affect up to 80% of all patients who have had diabetes for 10 years or more but can potentially be prevented. Considering the projected exponential rise of diabetes in South Asian subjects by 2030, the significance of the DR for the identification and prevention is of paramount importance. The aim of the present study was to investigate the 5, 10 and 15 years of incidence rate of diabetic retinopathy in Bangladeshi type 2 diabetic patients.
Materials and methods: A random sample of 977 newly diagnosed type 2 diabetic subjects were recruited and followed since 1993 to 2008. The subjects were attending the out patient department, BIRDEM. Diabetic Retinopathy was graded using the Early Treatment Diabetic Retinopathy Study. All patients were examined by an ophthalmologist and were reconfirmed by a senior ophthalmologist.
Results: Of the 977 subjects investigated, 468 were male and 509 were female (mean±SD, age 56±8 years). The incidence rates of DR and (95% CI) were 23.54 (19.61-28.26), 17.52 (14.93-20.55) and 21.47 (18.86-24.44) per 1000 person-years at 5, 10 and 15 years respectively. Incidence of DR increased with increasing age, but this was more prominent in female subjects. Non Proliferative DR (NPDR) was found in 115 patients (11.8%) at 5 years, while this was 13,9% at 10 years and 11,4% at 15 years of follow-ups. Severity of DR increased with the duration of diabetes. Most of the moderate to severe NPDR cases were identified at 15 years control.
Conclusions: Higher rate of DR and NPDR were observed in this population. The severity of the condition intensified with the duration of diabetes. Therefore, necessary strategies are needed to cope with the increasing challenge of diabetes epidemics in Asian subjects. Allowing for avoiding a life long entrenched condition of blindness, prevention in the first place is only likely measure to be successful, for which improved coordination between physician and ophthalmologist are needed along with necessary policy developments.

Diabetic retinopathy: associated risk factors and prevalence in a diabetic population at Yaounde Central Hospital

H. Hakapoka Ouoham[1], J.C. Mbanya[2], E. Sobngwi[2], L. Bella Hiag Assumpta[3]
[1] District Hospital of Mifi, Internal Medicine, Bafoussam, Cameroon
[2] Yaounde Central Hospital, Endocrinology, Yaounde, Cameroon
[3] Yaounde Central Hospital, Ophthalmology, Yaounde, Cameroon

Objective: Available data suggest that application of management of diabetes as recommended by United Kingdom Prospective Diabetes Study and Diabetes Control and Complications Trial Research Group reduces the onset of chronic complications such as diabetic retinopathy (DR). Our objective was to study the prevalence and associated risk factors of DR in diabetic patients in Cameroon, following the recommendations of UKPDS and DCCT.
Method: We carried out a descriptive and analytical study on 186 consecutive diabetic patients aged 7 to 79 with respectively 11 type 1 diabetic patients and 175 type 2 diabetic patients. We carried out a fasting blood sugar test, followed by a post prandial glycaemia after a meal of an energetic value of 300 calories. A clinical examination was then done during which anthropometric parameters were collected. An examination of their feet was done in search of neuropathies using tuning fork and monofilament test. An electrocardiogram was done at rest in search of electrical signs of myocardial ischemia. On the blood and urine samples taken during fasting, we proceeded by measuring the levels of glycated hemoglobin, total cholesterol, HDL cholesterol, triglycerides, plasmatic creatinine, uricemia and urinary level of albumin. We determined the LDL cholesterol and calculated the creatinine clearance according to Cockcroft and Gault and we carried out digital retinographies whereby the films were interpreted by 2 ophthalmologists.
Results: We got a prevalence of DR of 23.7% with respectively 21% for patients with non proliferative DR (NPDR) and 2.7% for patients with proliferative DR (PDR). The average duration of evolution of diabetes was 12(1-24) years for patients with NPDR and 15(7-20) for those with PDR. Those without DR had diabetes which had evolved since 6(1-24) years (P<0.01). Glycated hemoglobin showed a value of 9.9±2.6% for patients with NPDR and 9.2±3.1% for those with PDR. Those without DR had a glycated hemoglobin of 7.7±2.3% (ANOVA F=12.0; P<0.01). Concerning the association with cardiovascular risk factors, the systolic blood pressure was 150±23mmHg and 167±26mmHg in patients with NPDR and PDR respectively. For those without DR it was 139±25mmHg (P<0.01). Diastolic blood pressure was 87±12mmHg and 93±21mmHg in patients with NPDR and PDR respectively. For those without DR it was 82±12mmHg that's a difference of 5mmHg. LDL cholesterol had a value of 1.34±0.66g/l in patients with NPDR and 92±53g/l in those with PDR (P=0.02). We found also a relationship between chronic renal disease and DR (P=0.01).
Conclusion: African subjects don't develop chronic complications of diabetes faster than Caucasian subject if their management applies recommendations of UKPDS and DCCT studies.

Effect of glycaemia levels on mortality rate in patients with type 2 diabetes and prior myocardial infarction

M. Dundua[1], N.G. Asatiani[1], R.B. Kurashvili[1], M.G. Khelashvili[1], L.R. Tsutskiridze[1], E.L. Shelestova[1]
[1] Georgian Diabetes Center, Georgian Diabetes Center, Tbilisi, Georgia

Aim: It is now abundantly clear that effective control of blood glucose, as well as control of hypertension and dyslipidemia, is associated with significant benefits for development of vascular complications in type 2 diabetes (T2DM). The aim of the present work was to reveal correlation between glycemia levels and mortality rate in patients (pts) with T2DM and prior myocardial infarction (MI).
Materials: Totally, 131 T2DM pts with prior MI were enrolled in the study (mean age-57.2±3.1 yrs.; diabetes duration-6.5±2.8 yrs). Pts were supervised for 6 months. According to their glycemia control pts were divided into 2 groups (Gr.): Gr.1(study group) – n=72, pts performing home-blood glucose monitoring (five-point profiles, 3 profile days per week). In 53 of these pts oral hypoglycemic agents (OHAs) were administered, and 19 pts were treated with insulins and OHAs. Gr.2 (control groups) –n=59, blood glucose was controlled scarcely (2-3 times per month); 49 pts were treated with OHAs and 10 pts with insulin and OHAs.
Results: Data at entry revealed that glycemia and HbA1c levels were practically identical in both groups: HbA_{1c} (Gr.1 – 7.9±0.4%; Gr.2 –8.1±0.6%, P=0.024), fasting glycemia (FG) – (Gr.1 - 140.5±39.15mg/dl; Gr.2 – 139.3±36.1mg/dl, P=0.857), postprandial glycemia (PG) – (Gr.1 - 162.5±32.43mg/dl; Gr.2 – 169.1±28.6mg/dl, P=0.197) There was no statistically evident difference between the groups. Repeated examination at month 6 revealed: HbA_{1c} (Gr.1 – 6.0± 0.3%; Gr.2 –7.5± 0.7%, P= 0.000), FG – (Gr.1 - 101.5±39.15mg/dl; Gr.2 – 131.1±17.8mg/dl, P=0.000), PG – (Gr.1 -124.7±20.8mg/dl; Gr.2 – 158.1±28.6mg/dl, P= 0.000). Totally, during the 6-month follow-up period five Gr.1. (6.9%) patients died, all of them having repeated MI. In Gr.2 - 7 out of 10 death (16.9%) were caused by repeated MI.
Conclusion: T2DM patients with prior MI, having postprandial glycemia <130 mg/dl showed lower mortality rate (6.9%), than those with postprandial glycemia > 150 mg/dl (mortality rate -16.9%). According to our data 30 mg/dl decrease in fasting glycemia, 30-40 mg/dl decrease in postprandial glycemia and 1.5% drop in HbA1c levels result in 10% decline in mortality rates in these patients.

The CREDIT Study (Cardiovascular Risk Evaluation in People with Type 2 Diabetes on Insulin Therapy): French baseline data

S. Picard[1], A. Bekherraz[2], M. Marre[3]
[1] Point Médical, Point Médical, Dijon, France
[2] Cabinet Médical, Cabinet Médical, Boulogne Billancourt, France
[3] Bichat - Claude Bernard Group, Endocrinology Diabetology Nutrition, Paris, France

Objective: This 4-year non-interventional study aims at observing cardiovascular risk factors (CVRF) and events (CVE) among type 2 diabetic patients (T2D) treated with insulin in a real-life clinical setting.
Methods: GPs and diabetologists enrolled T2D patients who had been recently initiated on insulin therapy. Baseline HbA1c was obtained as the most recent value within 1 year before and 1 month after insulin initiation and divided into 3 categories: <8.5%, [8.5-10.1%] and >10.1%.
Results:
***Population*:** 88 French centers included 432 patients between December 2006 and April 2008. 426 patients (98.6%) were considered eligible (50.5% female). At the time of insulin initiation, mean age (±SD) was 63.3±11.7 years (43.9% being >65 years) and diabetes duration 12.6±9.4 years (>10 years for 50.1% of the subjects). Mean BMI was 30.3±6.3 kg/m^2 (46.6% being > 30 kg/m^2). The prevalence of CVRF was respectively: high blood pressure: 68.5%, family history of premature CVE: 15.5%, current smoker 11.1%. The mean HbA1c was 9.1±1.8%, (> 8% for 77.4% patients).
Microvascular and macrovascular complications were present in roughly 2/3 and 1/3 of the patients respectively, and also present in patients with HbA1c <8.5%:

Prevalence of complications at baseline	HbA1c <8.5% N=161 (39%)	8.5-10.1% N=143 (35%)	HbA1c > 10.1% N= 108 (26%)
Microvascular			
1 or more	67.7%	73.9%	63.6%
Nephropathy	53.5%	53.5%	48.6%
Renal failure	35.4%	28.0%	29.9%
Retinopathy	9.4%	17.5%	14.8%,
Peripheral neuropathy	16.8%	16.8%	24.3%
Macrovascular			
1 or more	28.6%	32.2%	25.5%
Myocardial infarction	12.4%	7.0%	3.8%
Heart failure	4.3%	4.9%	5.7%
Myocardial revascularization	11.2%	11.9%	9.4%
Stroke	1.9%	2.1%	0.9%
Peripheral vascular disease	11.2%	11.9%	9.4%

In a real life setting, insulin was initiated with basal insulin alone, or [+ prandial], for 80.1% [4.3%], 84.6% [4.2%] and 71.3% [10.2%] of the patients in the 3 HbA1c categories respectively. The daily dose of basal insulin was respectively 13.0±6.3, 14.2±7.8, 16.6±9.1 UI. Nearly all patients (97.6%) had only 1 injection daily either at breakfast (22.2%), lunch (2.1%), dinner (35.3%) or bedtime (40.4%). When prandial insulin was combined with basal insulin, 44% of patients had 2 injections of rapid insulin and 52% 3 injections. Premix insulin was used in 10.8%, prandial insulin alone in 1% and another regimen in 3.3% of patients. The daily insulin dose used in subjects on premix was 30.1±20.6 UI divided in 1 (39.1%), 2 (56.5%) or 3 (4.3%) injections. Basal + prandial insulins or premix regimen were initiated among patients with the highest HbA1c levels.
Conclusion: In this population, insulin was initiated, in a real life setting, in T2D patients with a long history of diabetes and high levels of HbA1c. A high prevalence of micro and/or macrovascular complications was present across all HbA1c levels.

Predictors of mortality in patients with type 2 diabetes mellitus

A. Kofinis[1], L. Milika[1], A. Thanopoulou[1], M. Noutsou[1], E. Spanou[1], E. Dimaki[1], B. Karamanos[1], A. Archimandritis[1]
[1] National University of Athens, Diabetes Centre 2nd Department of Internal Medicine, Athens, Greece

Aims: To assess mortality and factors related with it, in patients with type 2 diabetes.
Methods: We followed 1211 consecutive patients who were examined for the first time at the outpatient clinic between 1996 and 2002. In 1001 of them, 5-year data was available, while 210 could not be reached, however comparison for 15 baseline anthropometrical and biochemical parameters between the groups showed no difference, thus the sample studied is considered representative of the total. Mortality and causes of death were recorded from patient records or from close relatives. Baseline parameters were compared after appropriate adjustments between the groups of the deceased (n=100) and the group of the survivors (n=901).
Results: The group of the deceased compared to the survivors had older age, 65.2 vs 55.3, p<0.001, greater duration of diabetes, 11.9 vs 8.0 years, p<0.001, higher systolic blood pressure, 141.8 vs 136.7 mmHg, p<0.05, higher serum creatinine, 1.2 vs 1.1 mg%, p<0.01, lower GFR, 66.1 vs 72.2 ml/min, p<0.05, higher albumin concentration in the urine, 50.5 vs 28.9 mg/L, p<0.01 and higher serum urea 48.8 vs 36.8 mg%, p<0.001. HbA1c, total, HDL, LDL and non-HDL cholesterol as well as triglyceride levels did not differ between the two groups. The indices of total or abdominal obesity did not also differ between the two groups. The prevalence of cardiovascular disease (myocardial infarction, coronary by-pass surgery, PTCA, stroke or abnormal ECG indicative of coronary heart disease according to the Minnesota Code) was higher in the group of the deceased compared to the survivors, 49.0 vs 27.0%, p<0.001.
Discussion: In diabetic patients cross-sectional assessment of the glycemic control and lipid profile have no predictive value for mortality. On the other hand, renal function indices and the presence of cardiovascular disease are strongly related with mortality.

Screening strategy for asymptomatic coronary heart disease in Japanese patients with diabetes mellitus

Y. Kawasaki[1], S. Honjo[1], Y. Hamamoto[1], H. Ikeda[1], K. Nomura[1], Y. Wada[1], R. Nohara[2], H. Koshiyama[1]

[1] *The Tazuke Kofukai Foundation Medical Research Institute Kitano Hospital, Center for Diabetes and Endocrinology, Osaka, Japan*

[2] *The Tazuke Kofukai Foundation Medical Research Institute Kitano Hospital, Division of Cardiology, Osaka, Japan*

Background and aim: It has been considered that Japanese patients with diabetes are less frequently associated with cardiovascular disease (CVD) than Caucasians, but they have recently been indicated to be complicated with CVD, especially coronary heart disease (CHD). However, screening strategy to detect asymptomatic CHD in diabetes mellitus is not established, yet, in Japan. We investigated effectiveness of our screening strategy for asymptomatic CHD during the past five years.

Subjects and methods: The study included a total of 1180 Japanese patients with diabetes who were admitted to our hospital during five years. Among them, all subjects without previous history of CHD or any symptom suggesting CHD were checked with electrocardiography (ECG) at rest. Treadmill tolerance test (TTT) was performed in all patients unless they have any contraindication for TTT. The patients with abnormal TTT findings were further examined with thallium 201 cardiac scanning (TCS), and the subjects with abnormal TCS findings were examined with coronary angiography (CAG) in order to make a final diagnosis of CHD.

Results: Among 1180 patients, a total of asymptomatic 418 subjects were checked with both ECG at rest and TTT, of whom, a total of 60 subjects had positive TTT, and 53 patients of them received TCS. Among those 53 patients, 22 (41.5%; 1.9% of total patients with diabetes) had positive TCS. There were no significant differences of basal clinical parameters between the TCS-positive group and negative group, except for female dominance in the negative group. Among TCS-positive patients, 17 subjects received CAG, and 11 subjects (64.7%) were finally indicated to have CHD; three cases received percutaneous coronary intervention (PCI), two cases received coronary artery bypass surgery (CABG), and two cases of the remaining six cases received PCI and CABG, respectively, after one-year follow-up with medication.

Conclusion: As a screening strategy for asymptomatic CHD in Japanese patients with diabetes, it seems rational to use TTT, TCS and finally CAG.

People with diabetes in France: a 3.95% prevalence rate in 2007 and a 32% hospitalisation rate

A. Weill[1], O. Kusnik-Joinville[1], D. Simon[2], P. Tuppin[1], P. Ricordeau[1]

[1] *Cnamts, Dses, Paris Cedex 20, France*

[2] *Groupe hospitalier salpétrière, diabétologie, Paris 13, France*

Aims: To update data on treated diabetes prevalence and to compare age and gender-adjusted hospitalization rates and their motives between people with or without treated diabetes

Methods: Study conducted using claims data on the 56.5 million people insured by the general healthcare scheme (84% of the population). Our database contains individualized, anonymous and exhaustive data on all healthcare consumption covered by national insurance: GP and specialist consultations and visits, all drugs dispensed with their ATC, diagnostic procedures, medical devices. Our data also includes individual level information on hospital diagnostics (ICD codes), technical and surgical procedures, length of stay and the patient's French DRG. People with claims for at least 3 deliveries of oral hypoglycaemic agents (OHA) or insulin in 2007 were considered as diabetics (2,062,092 individuals).Comparisons between diabetic and non-diabetic individuals were adjusted for age and gender.

Results: In 2007, the prevalence rate of people treated for diabetes was 3.95%. (mean age 64.8 years (SD 13.8). Prevalence rates by age group indicated huge differences: 0-44 years old: 0.4%; 45-64 years old: 5.8%; 65-74 years old: 13.3%; 75 years and older: 13.4%. Overall prevalence was higher for men (4.7 %) than for women (3,3 %). In 2007, 31.9% of people treated for diabetes were hospitalized (13.0% had a stay under 24hours and 24.1% had a stay above 24 hours). The annual hospitalization rate was higher for under 20 years-olds (54%) and for over 80 years-olds (42%). After adjustments, people treated for diabetes were more often hospitalized [Relative Risk = 1.57 (1,56-1,59)] than those without diabetes and more specifically for cataract [2.58% annual hospitalization rate, RR = 1.46 (1.41-1.53)], stroke [0.63%, RR = 1.64 (1.50-1.80)], myocardial infarction [0.32%, RR = 2.3 (2.0-2.,6)], amputation [0.16%, RR = 6.1], kidney transplantation [0.02%, RR = 4.9]. Dialysis sessions (553 823) concerned 0.29% of diabetics [RR = 3.1 (2.6-3.6)]. For chemotherapy and / or radiotherapy (1.02%) and major orthopedic surgery (1.12%), there was no significant difference between diabetics and patients without diabetes. Hospitalization was less frequent for digestive endoscopy amongst diabetics [3.38%, RR = 0.88 (0.86-0.91)].

Conclusion: As in other countries, the diabetes epidemic is still expanding rapidly in France, at rates above what experts had predicted. The high prevalence in individuals aged over 60 years and the increasing number of geographic disparities have to be taken into account in public health policies. A better knowledge of the links between healthcare spending and hospitalisation rates may contribute to a better follow-up of complications likely to lead to hospitalisations of persons treated for diabetes.

Predicting microvascular complications in people with type 2 diabetes: utility of estimated global cardiovascular risk

P. Gouking[1], A.P. Kengne[2], E. Wawo[3], M. Dehayem[4], E. Sobngwi[4], J.C. Mbanya[4]

[1] *Endocrine unit and National Obesity Centre Yaoundé Central Hospital, internal medicine/Endocrinology, yaounde, Cameroon*

[2] *University of Sydney, internal medicine/Endocrinology, Sydney, Australia*

[3] *Faculty of Medicine and Biomedical Science, internal medicine, Yaounde, Cameroon*

[4] *Endocrine unit and National Obesity Centre Yaoundé Central Hospital, internal medicine/Endocrinology, Yaounde, Cameroon*

Background and purpose: Chronic complications are associated with increased morbidity and mortality in people with diabetes. Effective treatments for preventing or slowing their progression are well known. In resource-poor settings however, reliable methods are needed to select those more likely to benefit from such treatment or further investigations. The aim of this study was to assess the performance of two global cardiovascular risk equations in predicting the presence of diabetic microvascular complications, in a Cameroonian type 2 diabetic population.

Methods: The study population included 213 (41% women) individuals with diabetes, aged 32 to 78 years, consecutively recruited at the National Obesity Center (Yaounde-Cameroon), between August and December 2008. Anamnestic, clinical and paraclinical data were used to assess the presence of the following complications: any peripheral neuropathy, any diabetic retinopathy and any nephropathy. The projected 10-year absolute coronary risk was estimated with the UKPDS coronary risk engine and one recent Framingham risk equation. Discrimination and calibration of these equations to predict the presence of microvascular complication were evaluated using the Area Under the Curve (AUC) and the Hosmer & Lemeshow khi square test respectively. Data analysis used the computer software SPSS® 12.0, and the p-value < 0.05 was considered significant.

Results: The distribution of microvascular complications was as follows: at least one complication (61%), retinopathy (25%), nephropathy (11%), and neuropathy (54%). The median (25-75th percentile) of absolute cardiovascular risk was 18.3% [8.1-26.4] with the Framingham's equation, and 17.7 [6.2-24.3] with UKPDS coronary risk's equation. The two equations had a statistically significant discrimination for diabetic retinopathy with an AUC (95% confidence interval) of 0.593 (0.504-0.682) for Framingham's equation, and 0.603 (0.518-0.688) for the UKPDS one. Both equations had no significant discrimination to detect neuropathy and nephropathy. The calibration of the two equations was good, with a good agreement within deciles of calculated risk, between the estimated retinopathy prevalence using equations and the observed prevalence within the population. However, the prevalence within lower deciles was not appreciably different to the one within upper deciles.

Conclusions: The UKPDS and Framingham's coronary risk equations have a low or no discriminative power for screening microvascular complications of diabetes. Therefore, these models may not be appropriate for the selection of patients for costly diagnostic investigations for microvascular complications. Cohort data are needed to develop reliable screening tools for our population.

Comparing the power of metabolic syndrome and type 2 diabetes for discrimination of those who develop cardiovascular outcomes: results from a 7.5-year population based cohort study in Iran

H. Harati[1], F. Hadaegh[1], A. Zabetian[1], F. Azizi[1]
[1] *Research Institute for Endocrine Sciences, Prevention of Metabolic Disorders Research Center, Tehran, Iran*

Aims: To compare the discriminatory power of metabolic syndrome and Type 2 diabetes for developing cardiovascular outcomes in a population based setting.
Methods: A total number of 6547 subjects aged=30 years and free of cardiovascular disease (CVD) at baseline were followed for a median duration of 7.5±1.2 years. The measured outcome was fatal and non-fatal coronary heart disease and stroke. Metabolic syndrome (MS) was defined according to the ATP III and IDF definitions. Type 2 Diabetes (T2DM) was defined as fasting plasma glucose =126 mg/dl and/or 2-hour plasma glucose (standard OGTT) =200 mg/dl and/or taking of anti-diabetic medications. Cox regression was used to calculate the relative risk (RR) of the outcome in different groups. Area under the receiving operating characteristic (ROC) curve (AUC) was used to calculate the discriminatory power of Cox models.
Results: A total number of 396 outcomes were ascertained during the follow-up. The RR (95%CI) of developing CVD in those with MS based on the ATP III and IDF definitions after adjustment for age, sex, smoking and family history of premature CVD were 2.3(1.9-2.9) and 2.1(1.6-2.6) respectively. The Corresponding RR for T2DM compared to normoglycemic subjects was 3.3(2.6-4.2). The AUC (95%CI) of multivariate models that contained the ATP III definition, the IDF definition and T2DM were 0.79(0.77-0.81), 0.78(76-0.80) and 0.80(0.78-0.82) respectively. T2DM had significantly higher discriminatory power than the IDF definition (P=0.006) but had comparable power to that of the ATP III (P=0.2). Addition of either the ATP III or the IDF definition to a model that already contained T2DM did not significantly increase its discriminatory power [AUC of 0.80(0.78-0.82) after addition of either definition].
Conclusion: For prediction of future cardiovascular outcomes, T2DM has comparable discriminatory power to that of the ATP III definition of MS and is superior to the IDF definition in this regard. There seems to be little benefit from adding MS to T2DM if improvement in prediction of cardiovascular outcomes is desired.

Chronic diseases among teachers in South Africa - should we be concerned?

N. Phaswana-Mafuya[1], N. Zungu[2], K. Zuma[3]
[1] *Human Sciences Research Council, Social Aspects of HIV/AIDS and Health, Port Elizabeth, South Africa*
[2] *Human Sciences Research Council, Social Aspects of HIV/AIDS and Health, Cape Town, South Africa*
[3] *Human Sciences Research Council, Social Aspects of HIV/AIDS and Health, Pretoria, South Africa*

Aims: In developing countries, there is a dual burden of both infectious and chronic diseases due in part to the epidemiological transition. Chronic diseases are usually associated with socioeconomic status, lifestyle factors and age. However, in South Africa it is unclear which groups should be targeted for chronic disease prevention as research is limited in this area. The objectives of this study were to: (1) to determine the prevalence of chronic diseases (hypertension, diabetes, heart disease, HIV) among South African teachers; and (2) to examine the association of chronic diseases in regards to health status, hospitalization and frequent mental distress.
Methods: A survey was conducted among South African public school teachers to examine HIV in 2004. In addition to HIV questions, several questions related to chronic diseases such as hypertension, diabetes and heart disease were included. The survey employed cluster sampling in order to be representative of teachers in South Africa. Teachers were selected from districts in all nine provinces. A total of 21,626 teachers were interviewed from 1,766 randomly chosen schools. Data analysis included univariate and bivariate analyses using STATA version 9 that accounted for the complex sample design of the survey.
Results: The prevalence of self-reported diabetes was 4.7%, hypertension 15.9%, heart disease 2.0%, and HIV 12.8%. There were some teachers with both HIV and heart disease (0.3%), diabetes (0.4%) or hypertension (2.0%). Overall, the majority of teachers (69.8%) had no chronic disease, 26.0% had one, 3.7% had two and 0.5% had three. The prevalence of chronic diseases differed by socio-demographic variables. Teachers with two or more chronic diseases when compared to those with no chronic diseases were more likely to have been hospitalized in the past 12 months (unadjusted odds ratio {UA OR} = 2.79, [2.24-3.48]), reported their health status as fair or poor (UAOR = 5.78, [4.79-6.97]) and experienced frequent mental distress (UAOR = 1.56 [1.05-2.31]). Similar results were observed for teachers with only 1 chronic disease when compared to those with none.
Conclusions: In South Africa, teachers are a group to target for chronic disease treatment and prevention. Quality of life may also be affected as teachers with chronic diseases did not view their health status favorably and were more likely to have frequent mental distress, a proxy for depression.

Diabetes and vascular complications in Botswana

C. Onen[1]
[1] *Centre for Chronic Diseases, Medicine, Gaborone, Botswana*

Introduction: The role of diabetes as a cardiovascular risk factor in populations undergoing rapid epidemiological transition remains unclear. In the West, macrovascular complications (MAC) are the leading causes of morbidity and mortality whereas in Sub-Saharan Africa, microvascular complications (MIC) dominate. There are no data on the prevalence of vascular complications of diabetes in Botswana, a middle-income country in Southern Africa. It was hypothesized that MAC would be the major vascular disease in adult diabetics in Botswana.
Objectives: To determine the prevalence of MAC and MIC in diabetics aged 20-74 yrs at a tertiary hospital in Gaborone, Botswana.
Methods: Setting: Diabetes Clinic, Princess Marina Hospital. Participants were recruited through systematic sampling based on a finite population of 500 diabetics with 95% confidence interval and 80% power. Each diabetic was evaluated for CVD risk factors; coronary heart disease (CHD), cerebrovascular disease (CBVD) and peripheral arterial disease (PAD); diabetic retinopathy, neuropathy and nephropathy. Statistical significance ($p<0.05$) was estimated using Chi square tests or Fisher's exact test with 2-tailed p-value.
Results: Of the 258 diabetics, mean age 50.2 ± 10.8 yrs enrolled into the study, the majority were females (55.4%), Batswana (89.9%), married and employed, with secondary or tertiary education. Diabetes was diagnosed after the age of 30 years in 90% of patients; mean duration of known diabetes 6.2 ± 6.0 years; 53.1% were diagnosed >5 years before enrolment. MAC singly or in combinations affected 25% of diabetics with PAD in 19%, CBVD in 5.4% and CHD in 4.3%. Two-thirds of patients with CBVD suffered thrombotic stroke; 28.6% had amaurosis fugax and one patient had transient ischaemic attack. The major risk factors for CHD were age >55 years, duration of diabetes >10 years and elevated LDL-cholesterol; while age >60 years and blood pressure >160/>85 mm Hg were strongly associated with CBVD. Tobacco, age >50 years and systolic blood pressure >140 mm Hg predisposed to PAD. MIC was twice (46.8 %) more common than MAC (peripheral neuropathy 30%, retinopathy 20%, nephropathy 7.8%). The odds risk of MAC in a diabetic with impaired pin prick sensation was 2.30 (95% CI 1.26-4.13; p=0.005). Absent ankle jerk was strongly associated with PAD (OR 2.61; 95% CI 1.22-5.62; p=0.01).
Conclusions: Contrary to the hypothesis, MIC was more prevalent than MAC in Botswana despite high prevalence of CVD risk factors. Three risk factors (hypertension, advanced age and longer duration of diabetes) were strongly associated with both MAC and MIC. Unprecedented opportunities exist for primary prevention of MAC in Botswana.

Ambulatory blood pressure monitoring, arterial stiffness index and erythrocyte electron transfer in type 1 diabetes families

E. Matteucci[1], C. Consani[1], M.C. Masoni[1], O. Giampietro[1]
[1] *University of Pisa, Internal Medicime, Pisa, Italy*

Aims: Oxidative damage is increased in type 1 diabetes (T1D) families and normotensive non-diabetic relatives of T1D subjects have an abnormal blood pressure response to exercise testing that is associated with indices of metabolic syndrome and oxidative damage. We evaluated the pattern of 24-h ambulatory

blood pressure monitoring (ABPM) and ambulatory arterial stiffness index (AASI) in T1D families in relation with clinical parameters, autonomic function and oxidative biomarkers.

Methods: A cross-sectional study was conducted in 25 control subjects (46±12 y), 20 T1D patients (46±10) and 20 siblings (45±10) using an oscillometric device (Takeda TM2430). In addition to routine laboratory investigations and clinical testing of autonomic function, we measured the rate of oxidant-induced erythrocyte electron transfer to extracellular ferricyanide (RBC vfcy). This redox system supplies electrons (from intracellular electron donors) to reduce extracellular oxidants.

Results: Systolic BP (SBP) MESOR and pulse pressure (PP) were higher in T1D subjects and correlated positively with the duration of diabetes. Their siblings were insulin resistant (lower HOMA-IS than controls) and had larger SBP amplitude than controls; daytime SBP was positively associated with BMI and RBC vfcy. AASI was higher in members of T1D families. It was significantly associated with expiration/inspiration ratio at deep breathing and disease duration in T1D patients, whereas with fasting plasma glucose among non-diabetic people.

Conclusion: Siblings of T1D probands show signs of insulin resistance, larger circadian SBP amplitude and higher AASI. Circadian SBP amplitude was significantly associated with RBC vfcy, thus confirming the role of transplasma membrane electron transport systems in vascular pathobiology. Increased arterial stiffness in siblings was partially explained by plasma glycaemia.

Endothelial cells isolated from newborns with a family history of type 2 diabetes mellitus show reduced synthesis of NO and ROS, and diminished metabolic and cellular activity

N. Alvarado[1], E. Zapata[2], S. Alcazar[3], F. Massó[4], L.F. Montaño[5]

[1] *National Institute of Respiratory Diseases "Ismael Cosío Villegas", Biochemistry, México D.F., Mexico*

[2] *National Institute of Cardiology "Ignacio Chavez", Cell Biology, México D.F., Mexico*

[3] *Institute of Scientific Research "Hans Selye", Gerontology, Querétaro Qro. Mexico., Mexico*

[4] *National Institute of Cardiology "Ignacio Chavéz", Cell Biology, Mexico D.F., Mexico*

[5] *Faculty of Medicine UNAM, Lab. Immunobiology, Mexico D.F., Mexico*

The efficacy of endothelial cell metabolism is currently evaluated by its adequate function. The increased risk to develop early cardiovascular damage in individuals with a family history of type 2 diabetes mellitus (FH-DM2) has been associated with an inadequate endothelial function. In this work, we evaluated glucose uptake, lactate synthesis, cell proliferation, mitochondrial activity, as well as the synthesis of nitric oxide (NO) and reactive oxygen species (ROS), in Human Umbilical Vein Endothelial Cells (HUVECs) obtained from healthy newborns with and without a FH-DM2. Cell cultures were incubated with supraphysiological glucose concentrations (15 or 30 mmol/L) before adding or not CCCP, a mitochondrial uncoupler, cytochalasin B (inhibitor of glucose transport), thiamine pyrophosphate (PPT, coenzyme of the pyruvate dehydrogenase complex) and DPI (inhibitor of NADPH-oxidase). eNOS and GLUT1 transcripts were determined by RT-PCR. Results obtained after 24 or 48 hours of cell culture showed an increase in glucose uptake, lactate synthesis, cell proliferation and mitochondrial activity in control HUVECs in comparison with FH-DM2 HUVECs. PPT diminished the uptake of glucose in control HUVECs, while FH-DM2 HUVECs didn´t show significant changes. We also found two different cell populations in control HUVECs, but only one of them was important for NO and ROS synthesis. In contrast, only one cell population which showed a reduced synthesis of NO and ROS ($P<0.05$) was observed in FH-DM2 HUVECs. Control HUVECs showed a significant inhibition of ROS synthesis in the presence of CCCP, DPI or cytochalasin B. We also found diminished expression of eNOS transcripts, and enhanced expression of GLUT1 transcripts in FH-DM2 HUVECs vs control HUVECs ($P<0.05$).

Conclusions: our results support the presence of relevant metabolic differences in HUVECs with and without FH-DM2; they also suggest that mitochondria and NAD(P)H-oxidase from FH-DM2 HUVECs have an impaired response in the presence of high glucose concentrations. The inadequate mitochondrial activity of FH-DM2 HUVECs is probably associated with an impaired synthesis of NO. This inherent deficient energy metabolism might be the cause of the early endothelial dysfunction observed in individuals with a strong FH-DM2.

Immediate and long-term clinical outcome after spinal cord stimulation for refractory angina pectoris in diabetics and non-diabetics

S. Eckert[1], A. Dongas[2], W. Quester[3], F.H. Gueldner[4], D. Horstkotte[1]

[1] *Heart and Diabetes Center North Rhine-Westphalia Ruhr University Bochum, Department of Cardiology, Bad Oeynhausen, Germany*

[2] *Heart and Diabetes Center North Rhine-Westphalia Ruhr University Bochum, Institute of Anesthesiology, Bad Oeynhausen, Germany*

[3] *Heart and Diabetes Center North Rhine-Westphalia Ruhr University Bochum, Department of Diabetology, Bad Oeynhausen, Germany*

[4] *Heart and Diabetes Center North Rhine-Westphalia Ruhr University Bochum, Department of Thoracic and Cardiovascular Surgery, Bad Oeynhausen, Germany*

Introduction: Neuromodulation (Spinal Cord Stimulation, SCS) has become an established therapeutic alternative for patients with therapy-refractory angina pectoris not suitable for percutaneous or surgical revascularisation. In Germany this therapy has encountered considerably less acceptance to date than in other countries (e.g. Sweden and Italy). How effective is neuromodulation in patients with diabetes mellitus?

We compared the medium and long-term clinical improvements in diabetics to non-diabetics, as well as the reduction in hospitalization rates.

Methods: Since January 2001, we performed SCS in 141 patients (pts.) (103 men, 38 women, age 65±8 years, bmi 27±9 kg/qm). 29 percent had known type 2 diabetes mellitus. All pts. had severe angina pectoris (III to IV [79/62] according to Canadian Cardiovascular Society [CCS]) under considered medication due to angiographically documented end-stage coronary artery disease (CAD), which could not be treated interventionally (mean intervention: CABG 1.3±0.8, PCI 1.4±1.3).

Results: We have analysed 20 pts. with known diabetes and compared the results to 20 matched non-diabetics. In the 1-24-month follow-up angina pectoris and nitrate consumption could be significantly reduced. With SCS, the amount of time spent in hospital due to angina pectoris or other complaints associated with coronary artery disease was significantly reduced (diabetics compared to non diabetics): 28±19 / 26±17 days within 12 months before SCS to 1±2 / 2±3 days after SCS; medical consultations from 11±6 / 12±7 days before to 6±3 / 7±3 days after.

SCS in diabetics	before (n=20)	after 12 months (n=20)	after 24 months (n=17)
angina (class/es)	III/13, IV/7	0/9, I/3, II/6, III/2	0/8, I/4, II/3, III/2
nitrates (per week/s)	> 7/15, 3-7/3,>3/2	>7/0, 3-7/3, <3/4, 0/12	>7/0, 3-7/2, <3/4, 0/11
SCS in non diabetics	**before (n=20)**	**after 12 months (n=20)**	**after 24 months (n=18)**
angina (class/es)	III/12, IV/8	0/10, I/5, II/3, III/2	0/9, I/4, II/4, III/1
nitrates (per week/s)	> 7/14, 3-7/3,>3/3	>7/0, 3-7/2, <3/5, 0/13	>7/0, 3-7/2, <3/5, 0/11

Conclusion: Neuromudolation is a safe and effective symptomatic treatment for therapy-refractory angina pectoris in conjunction with end-stage coronary artery disease in diabetic and non diabetic patients.

Nitrate consumption and in-patient time spent in hospital can both be significantly reduced.

SCS leads to a significant reduction in therapy costs.

Cross-sectional association of lung function with insulin resistance and metabolic disorders in Japanese subjects

S. Jimba[1], T. Nakagami[1], J. Oya[1], S. Fukushima[1], Y. Yamamoto[1], M. Hasegawa[1], T. Wasada[2], Y. Endo[3], Y. Iwamoto[1]

[1] *Tokyo Women's Medical University, Diabetes Center, Tokyo, Japan*

[2] *Totsuka Royal Clinic, Internal Medicine, Tokyo, Japan*

[3] *Saitama-ken Saiseikai Kurihashi Hospital, Internal Medicine, Saitama-ken, Japan*

Background: Recently, it has been reported that lung dysfunction, as measured by declined forced vital capacity (FVC) or forced expiratory volume in one second (FEV1), is independently associated with cardiovascular events, insulin resistance (IR) and diabetes (DM). These associations are partly explained by lung-related inflammatory mediators and their effects on insulin signaling, and by adverse early life exposures, which affect lung growth and development. However, very few studies have analyzed the relation between

lung function with IR and metabolic disorders in Japan. The aim of our study is to examine whether lung dysfunction is independently associated with IR and several metabolic disorders in Japanese.

Subjects and methods: Subjects included 2,048 men and 1,065 women who did not have previous DM, cancer, endocrine, respiratory or congestive heart disease, and were not under pharmacological treatment for hypertension or dyslipidemia in a general health examination. FVC and FEV1 were measured by spirometer. Before analysis, crude data on FVC and FEV1 were divided by predicted FVC and FEV1, respectively, to yield FVC (% predicted) and FEV1 (% predicted). Smoking status and physical activity were assessed by questionnaires. The homeostasis model assessment (HOMA) was calculated as: fasting immunoreactive insulin (F-IRI)(μU/ml) x fasting plasma glucose (FPG)(mmol/l) / 22.5 among those with FPG < 6.10 mmol/l. IR was defined as the highest quartile of F-IRI or HOMA in subjects with FPG < 6.10 mmol/l. Multivariate linear regression models were used to evaluate whether FVC or FEV1 is independently associated with metabolic variables, F-IRI and HOMA.

Results: FVC % predicted and FEV1 % predicted were significantly correlated with baseline values for age, BMI, waist circumference (Wc), HbA1c, triglyceride (TG), HDL-C, blood pressure (BP), F-IRI and HOMA. The multiple linear regression analysis showed that FVC % predicted was significantly associated with FPG (ß= -0.032, p=0.025), HbA1c (ß= -0.002, p<0.000), TG (ß= -0.237, p=0.007), systolic BP (SBP)(ß= -0.049, p=0.013), HDL-C (ß=0.066, p<0.000), F-IRI (ß= -0.031, p<0.000) and HOMA (ß= -0.008, p<0.000) after adjusting for age, sex, BMI, Wc, pack-years of cigarette and physical activity. Further additional analysis adjusting for F-IRI showed that these relations were not changed in HbA1c and HDL-C. FEV1 % predicted was also associated with HbA1c (ß= -0.002, p<0.000), SBP (ß= -0.059, p=0.004), HDL-C (ß=0.094, p<0.000), F-IRI (ß= -0.024, p<0.000) and HOMA (ß= -0.006, p<0.000) after adjusting for those confounders. These associations were not changed in HbA1c, SBP and HDL-C, even after additional adjusting for F-IRI.

Conclusion: Decline in FVC and FEV1 were related with a deterioration of BP and lipids and glucose metabolism, independently of IR. This may suggest that hypoxia and inflammation induced by lung dysfunction cause multiple metabolic disorders with or without mediation by IR.

Albuminuria levels are independently associated with peripheral arterial disease in type 2 diabetes without advanced chronic kidney disease

J.Y. Shin[1], Y.G. Shin[1], C.H. Chung[1]

[1] Yonsei University Wonju College of Medicine, Internal medicine, Wonju, Korea

Aims: Chronic kidney disease (CKD) is associated with the elevated risk of cardiovascular disease (CVD). Also, the presence of microalbuminuria in type 2 diabetes is known as a risk factor for CVD. The ankle-brachial index (ABI) has been used to assess peripheral arterial disease (PAD). We evaluated the associations of markers for renal impairment with ABI in type 2 diabetic patients without advanced CKD.

Methods: We enrolled 284 type 2 diabetic patients (mean age 57.8±9.8 years; body mass index (BMI) 25.2±3.2 kg/m^2; male 57.4%; diabetes duration 6.5±6.1 years; HbA1C 7.8±2.1%). Patients with serum creatinine (Cr)>1.4 mg/dl and estimated glomerular filtration rate (eGFR)<60 ml/min per 1.73 m^2 were excluded. Clinical and biochemical metabolic parameters were measured. Markers of renal impairment including serum Cr, serum cystatin C (CC), 24 hour (h) urine albumin (Alb), and eGFR were measured. PAD was diagnosed based on an ABI<0.9.

Results: Patients with PAD were 7.4%. Patients with microalbuminuria and macroalbuminuria were 26.1% and 6.3%, respectively. According to the severity of albuminuria, systolic blood pressure (BP), diabetes duration, fasting blood glucose, and HbA1C levels were significantly increased, but ABI was decreased (p<0.05). Patients with macroalbuminuria had higher CC and uric acid levels than those without albuminuria. Age, smoking, hypertension, 24 h urine Alb, Cr, CC levels were positively correlated with the presence of PAD, but diastolic BP was negatively correlated (p<0.05). In multivariate regression analysis, 24 h urine Alb, smoking, and diastolic BP were significantly associated with the presence of PAD. The odds ratio (OR) for the presence of PAD according to the severity of albuminuria was significantly increased in patients with macroalbuminuria after adjustment for age, sex, diastolic BP, and smoking [OR (95% CI); 5.30 (1.15-24.35)].

Conclusion: Our finding suggested that 24 h urine Alb levels were independently associated with PAD in type 2 diabetes without advanced CKD.

Postprandial endothelial dysfunction in prediabetic first degree relatives of patients with type 2 diabetes mellitus

S.V. Madhu[1], B. Sinha[2], S. Dwivedi[3], G. Mehrotra[4]

[1] University College of Medical Sciences, Department of Medicine Division of Endocrinology and Metabolism, Delhi, India

[2] University College of Medical Sciences, Department of Medicine Division of Endocrinology and Metabolism, Delhi, India

[3] University College of Medical Sciences, Department of Medicine, Delhi, India

[4] University College of Medical Sciences, Department of Radiodiagnosis, Delhi, India

Aim: To compare postprandial endothelial dysfunction after oral fat challenge in prediabetic (IGT±IFG) subjects and healthy individuals with normal glucose tolerance (NGT), and to evaluate the role of familial predisposition on postprandial endothelial dysfunction in them.

Methods: Oral Glucose tolerance tests (OGTT) were performed in 39 apparently healthy, obese individuals without previous history of Diabetes Mellitus. Study subjects were divided on the basis of family history of type 2 Diabetes(T2DM) and OGTT results using standard WHO criteria into three groups – prediabetes (IGT±IFG) with positive family history of T2DM, prediabetes (IGT±IFG) with no family history of T2DM, and NGT with no family history of T2DM. Fasting and postprandial lipids were estimated at 0,2,4,6 and 8 hours after the fat meal. Endothelial function was studied in all subjects after 4 hours of standard oral fat challenge by non-invasive brachial flow mediated vasodilation (FMD), and comparisons made between the three study groups.

Results: There was a progressive and highly significant worsening of postprandial FMD endothelial function as we moved from NGT to family history negative prediabetic subjects (p=0.000) to family history positive prediabetic subjects (p=0.000), which showed significant correlation to postprandial plasma glucose (r= -0.598) HOMA IR (r=-0.382) and post prandial serum triglyceride levels at 6 hours (r=-0.323) and 8 hours (r= -0.371) but not to fasting plasma glucose (FPG), glycosylated hemoglobin, other postprandial lipemic parameters (LDL, TC, HDL) and markers of insulin resistance.

Conclusion: Prediabetic subjects, particularly those with familial predisposition to diabetes, respond to oral fat challenge with greater endothelial dysfunction which correlates with postprandial glucose and triglyceride levels and insulin resistance.

Relationship between left ventricular diastolic dysfunction and insulin resistance in non-diabetic Korean subjects

J.H. Jee[1], M.R. Kang[1], J.D. Sung[1], Y.C. Hwang[2], J.H. Chung[3], Y.K. Min[3], M.S. Lee[3], K.W. Kim[3], M.K. Lee[3]

[1] Samsung Medical Center, Center for Health Promotion, Seoul, Korea

[2] Kyung Hee East-West Neo Medical Center, Division of Endocrinology and Metabolism Department of Medicine, Seoul, Korea

[3] Samsung Medical Center, Division of Endocrinology and Metabolism Department of Medicine, Seoul, Korea

Aims: Mild left ventricular diastolic dysfunction is frequently detected in elderly or hypertensive subjects without severe heart disease, and in subjects with impaired fasting glucose or impaired glucose tolerance without cardiovascular disease. Insulin resistance has been suggested to be associated with the left ventricular diastolic dysfunction in IGT or diabetes. The purpose of this study was to examine the relationship between the insulin resistance and left ventricular diastolic dysfunction in non-diabetic subjects.

Methods: Using the health database of 1,826 non-diabetic subjects (1,536 men and 290 women), aged 25 ~ 85 years, in two other medical centers, we evaluated the relationship between left ventricular diastolic dysfunction and HOMA-IR.

Results: The higher quartile of insulin or HOMA-IR, the higher the prevalence of left ventricular diastolic dysfunction and the higher the age-, gender-, and BMI-adjusted OR of the left ventricular diastolic dysfunction were significantly in logistic regression (p < 0.01). The prevalence of left ventricular diastolic dysfunction was increased significantly with increased metabolic score, too (p < 0.01). Gender, and BMI-adjusted ORs for the left ventricular diastolic dysfuction were exponentially increased according to increased age group (p < 0.01). Among the diagnostic components of the metabolic syndrome, obesity of BMI more than 25 kg/m2, and hypertension were associated with the prevalence of left ventricular diastolic dysfunction (OR 1.87, p < 0.01 and OR 1.32, p < 0.05). Among the indices of tissue Doppler imaging, the Ea (peak early diastolic mitral annual velocity) was negatively associated with the HOMA-IR quartile

($p < 0.01$) and showed the more negative linear correlation with HOMA-IR than E/A ratio, E/Ea ratio, DT (deceleration time) after adjustment for age and gender ($r = -0.27$, $p < 0.01$).

***Conclusion*:** Insulin resistance is suggested to be significantly associated with the left ventricular diastolic dysfunction independently of the BMI in non-diabetic Korean subjects without heart disease.

Acceleration of carotid artery atherosclerosis is associated with impaired glucose metabolism and related changes of adipocytokines: a cross-sectional study in an elderly Chinese population

Q.F. Ding[1], M.Q. Hu[2], A.X. Jiang[1], F. Luo[1], Y.L. Zhang[1], L. Cao[1], X.L. Huang[1]

[1] *West China Hospital of Sichuan University, Department of Geriatrics, Chengdu, China*

[2] *The 3rd Affiliated Hospital of Chengdu University of Traditional Chinese Medicine, Department of Endocrinology, Chengdu, China*

Objective:To investigate the relationships among acceleration of carotid artery atherosclerosis, impaired glucose metabolism, metabolic syndrome and related changes of adipocytokines in elderly Chinese population.

Method: A cross-sectional study was carried out in 305 elderly subjects (age, 77.48±7.98 years). Anthropometric parameters, blood pressure, blood lipid profiles, fasting glucose and insulin levels were carefully measured. Serum concentrations of tumor necrosis factor (TNFa), interleukin-6 (IL-6), adiponectin, and leptin were measured by ELISA method. OGTT were applied in all subjects without established diabetes mellitus. The diagnoses of NGT, IGT, T2DM were based on WHO criteria, and metabolic syndrome(MS) were based on NCEP ATPIII criteria. Subjects were divided into four groups according to different glucose tolerance and presence or absence of metabolic syndrome. Ultrasonography was used to measure intima-media thickness (IMT) and plaques in carotid arteries.

Results: Compared with NGT group, IGT group had significantly higher levels of waist WC, TG, fibrinogen and lower level of HDL-C. T2DM/MS(+)group had the highest level of WC. T2DM/MS(-) and T2DM/MS(+) group had higher levels of fasting glucose, insulin and HbA1C than other two groups. Both IMT and carotid artery plaque scores in IGT group and T2DM with or without MS groups were higher than NGT group. IMT, plaque incidence, and plaque scores were revealed to be higher in IGT and T2DM groups with and without MS, and significantly positively correspondent with TG, and fasting glucose. TNF-a, IL-6, leptin and leptin/adiponectin ratio increased in T2DM/MS(-) and T2DM/MS(+) group. Adiponectin level tended to decrease associated with exacerbation of glucose metabolism and combination metabolic syndrome.

Conclusions: Impaired glucose metabolism is closely associated with acceleration of atherosclerosis, even in the stage of IGT. Changes of adipocytokines may play an important role in this situation. Accumulations of other metabolic disorders defined by MS seemed not to be more important in our studied elderly population.

[4] *Universite Paris 7, Diabetes Endocrinology and Metabolism, Paris, France*

[5] *Aarhus University Hospital, Diabetes & Endocrinology, Aarhus, Denmark*

[6] *PLA General Hospital, Endocrinology, Beijing, China*

Background: The results of recent large-scale trials have raised questions about the benefits of intensive glucose control in patients with type 2 diabetes. We investigated the relationship between glycaemic exposure and the risks of vascular complications and death in a contemporaneous cohort of 11,140 patients with long standing type 2 diabetes included in one of these trials.

Methods: All patients randomised in the ADVANCE trial to receive either intensive or standard glucose control were included in analyses examining risks of all major macrovascular and microvascular complications, all-cause death, cardiovascular death, new or worsening nephropathy, new or worsening retinopathy and hospitalisation. Glycaemic exposure was measured as baseline haemoglobin A1c (HbA1c) or over time as the mean HbA1c of annual measurements during follow up and prior to the first event. Adjusted risks for each 1% increase in HbA1c were estimated using Cox proportional hazards models. Differences in the slope of the association between HbA1c and risks at different HbA1c levels were tested using linear spline models.

Results: There was a positive and independent log-linear relationship between the risk of all major macrovascular or microvascular events and glycaemic exposure when assessed by baseline or mean HbA1c over time. For every 1% lower level in mean HbA1c over time, there was a 22% lower risk of a macrovascular event, 26% lower risk of a microvascular event, 22% lower risk of all-cause death, 25% lower risk of cardiovascular death, 19% lower risk of new or worsening nephropathy, 31% lower risk of new or worsening retinopathy and 15% lower risk of hospitalisation (all $p<0.01$). Within the range of HbA1c studied (about 5.5 -10.5%), there was no evidence of any "threshold" below which lower levels of HbA1c were not associated with lower risks of major microvascular events. However, there was some evidence of a "threshold" effect for risks of major macrovascular events and death at a mean HbA1c level of less than 6.5%.

Conclusions: While the risks of major microvascular events are progressively lower down to HbA1c levels of 5.5%, the risks of major macrovascular events and death are only significantly lower down to levels of 6.5%. This reinforces current guidelines which recommend lowering HbA1c to levels below 7.0% and as low as 6.5%.

D-0691

Improvement of glucose control in type 1 diabetes mellitus during last 15 years in Crete Island (Greece)

I. Koympa[1], P. Matalliotaki[2], E. Kirlaki[3], M. Sfakianaki[3], N. Kefalogiannis[3], A.C. Pappas[3]

[1] *Venizelion Hospital, Department of Internal Medicine, Heraklion Crete, Greece*

[2] *University Hospital, Department of Radiology, Heraklion Crete, Greece*

[3] *Venizelion Hospital, Diabetic Clinic, Heraklion Crete, Greece*

Type 1 DM (T1DM) is a rare disease in Greece. Major changes in therapeutic approaches for T1DM occurred during last 2 decades but data for the impact of these on glucose control in our country is scarce.

Aim: The estimation of the improvement of glucose control as reflected in HbA1c changes in T1DM patients in Crete, during last 15 years
Methods: We retrospectively studied the records of the Diabetic Clinic of Venizelion Hospital, the major diabetic clinic in Heraklion (Crete, Greece) during the period 1988-2009.
We compared the Hba1c values of 3 different five-year periods: 1994-1998, 1999-2003 and 2004-2008. A patient was considered T1DM according to following criteria: age at onset <40 years old, prone to ketosis and need of continuous insulin treatment within 24 months from initial diagnosis. Low c- peptide was available as criterion for ambiguous cases. All patients were permanent citizens of Crete Island.
We excluded Hba1c values of T1DM patients in the first 2 years from the diagnosis of the disease.
HbA1c was estimated by DCA 2000 Analyser (Bayer) throughout all the follow up period.
Statistical analysis was carried out, as appropriate, using commercial available software (SPSS statistics, 17.0).
Results: Hba1c values from 238 eligible patients (Men 52,3%, Women 47,7%) were included.
A total of 2076 measurements of HbA1c recorded.

Table 1: summarizes our results for every five year-period.

A statistical significant reduction of Hba1c values for the whole population and for both sexes between the 3 five-year periods (t-test, p<0,001 in all cases) was recorded. In parallel a significant increase in the percent of values within the treatment targets is observed (x^2, p<0,01). There was no statistical significant difference in mean values of HbA1c between male & female in any of the 3 five-year periods. Also no statistical significance was observed between the 3 five-year periods for mean duration of diabetes per Hba1c value (t-test).
Conclusion: Our results reflect the improvement of glucose control during the last 13 years, possibly due to the intensification of the treatment (general use of MDI or pumps with frequent SMBG,) and to the use of high technology products (new insulins etc). Still the majority of Hba1c records, even during the last 5 years, are far from the treatment targets. Further efforts are required to help patients reach current targets of glucose control.

IFCC HbA1c, fructosamine, random venous plasma glucose and estimated average glucose (eAG): relationships in diabetes

S.E. Manley[1], R.A. Round[1], J.D. Carr-Smith[2], P.G. Nightingale[3], J.A. McKnight[4], R. Cramb[1], I.M. Stratton[5], J.M. Smith[1], S.C.L. Gough[6]

[4] *Western General Hospital, Department of Diabetes, Edinburgh, United Kingdom*
[5] *Gloucestershire Hospitals NHS Foundation Trust, English National Diabetic Retinopathy Screening Programme, Cheltenham, United Kingdom*
[6] *University of Birmingham, Division of Medical Sciences, Birmingham, United Kingdom*

Introduction: Recent international guidance recommends reporting of HbA_{1c} in both IFCC (International Federation of Clinical Chemistry and Laboratory Medicine) units mmol/mol and DCCT percentages, and also as estimated average glucose (eAG) mmol/L or mg/dL. eAG is derived from measured HbA_{1c} using formulae produced by a research study involving self-monitoring of glucose by patients and continuous blood glucose monitoring over 4 months. In addition, statements are awaited from the World Health Organisation and international, professional diabetes organisations on use of HbA_{1c} for the diagnosis of diabetes.
Aim: To describe the relationships of random venous plasma glucose (RPG), fructosamine and HbA_{1c} expressed in IFCC units and also as eAG in patients with diabetes recruited from a hospital diabetes clinic and also to compare them in patients with other co-existing illnesses.
Methods: HbA_{1c} was measured by IE HPLC on Tosoh G8 analysers (IFCC reference interval 20-42mmol/mol; DCCT 4-6%) along with glucose, fructosamine (200-285umol/L) and other related haematological (reticulocyte reference interval 20-80x10^9/L) or biochemical factors. All variables are quoted as median (IQ range).
Results: 96 (64 male) white Caucasian patients, 29 having type 1 diabetes were aged 61(51-71) years with BMI 31.5(26.8-35.6)kg/m^2.

Markers of glycaemic control	Results (n=96)
IFCC HbA_{1c} mmol/mol	60(53 – 69)
DCCT HbA_{1c} %	7.6(7.0 – 8.5)
eAG mmol/L	9.5(8.5 – 10.9)
Random venous plasma glucose (RPG) mmol/L	7.3(5.0 – 10.8)
Fructosamine µmol/L	310(268 - 355)
Other factors	
Hb g/dL	13.9(12.6 – 15.2)
Reticulocytes x10^9/L (n=65)	45.5(37.8 – 64.5)
Serum albumin g/L	46(44 – 47)
Albumin creatinine ratio (ACR) g/mol (n=71)	1.1(0.7 – 3.8)
Serum creatinine µmol/L	101(87 – 113)

There was significant correlation between RPG and IFCC HbA_{1c} (Pearson coefficient r=0.52) and RPG with fructosamine (r=0.46), both p<0.001. Individual patients were identified from other clinics whose indices of glycaemic control fell outside 2SD of the linear regression lines describing these relationships. They included patients with haematological disorders such as polycythaemia rubra vera (reticulocytes 140x10^9/L) or variant haemoglobin trait Hofu, and others with severe renal (ACR >500g/L) or liver disease.
Conclusions: Graphical representation of the relationships between these markers of glycaemic control will assist health care professionals when IFCC HbA_{1c} reporting is introduced. Care should be taken interpreting such markers when patients have co-existing illnesses.

accuracy in the hypoglycemic range may provide the opportunity for patients to obtain and maintain intensive control with limited hypoglycemia.
The primary objective of this feasibility study was to determine the performance of a new Continuous Glucose Monitor (CGM), specifically in the hypoglycemic glucose range.
14 subjects with type 1 or 2 diabetes underwent glucose clamp procedures. The evening before the clamp procedure 1 CGM sensor was inserted on each side of the abdomen in each subject (2/subject). The order of the glucose plateau periods and target glucose levels were: hypoglycemic (50 mg/dL), hyperglycemic (250 mg/dL), second hypoglycemic (50 mg/dL) and euglycemic (target glucose level of 90 mg/dL). The transition period between glucose plateaus was targeted at a 2 mg/dL per minute rate of glucose change.
Sensor insertion was successful on the first attempt for 25 of 28 sensors (89.3%). During the clamp procedures the investigational devices provided raw current results only. Results were converted to sensor interstitial fluid (ISF) glucose after the study was completed using an algorithm provided before the study began. The algorithm was designed to skip or abort data transmission under pre-defined circumstances. The total percent of minutes lost due to algorithm skips or aborts was 8.9%, the majority of which were due to two sensor aborts.
Plasma venous glucose measurements (using the Yellow Springs Instrument [YSI] glucose analyzer) were used for calibration. Plasma venous results for reference (comparison to CGM glucose) were measured at 5-minute intervals and Mean Absolute Percent Difference (MAPD) was determined. The smallest MAPD, 12.78%, was observed during the hypoglycemic plateaus (95% CI, 11.72 – 13.84) and the largest, 18.46%, during the euglycemic plateau (95% CI, 15.65 – 21.27). During the plateau and transition periods combined, mean absolute difference (MAD) for samples with YSI glucose levels < 75 mg/dL = 8.7 mg/dL and MAPD for samples with YSI glucose levels ≥ 75 mg/dL = 17.9%. Parkes Error Grid Analyses for the four plateaus (n = 873 paired data sets) showed that 86.8% of results were in Zone A, 12.2% in Zone B and 1% in Zone C.
A new CGM device and its attendant algorithm had a high degree of accuracy and reliability during a glucose clamp study with euglycemic, hypoglycemic and hyperglycemic plateaus. These results provide promise for future clinical application of this device.

Characteristics of 24 hour glycaemic excursions revealed by continuous glucose monitoring in subjects with impaired glucose tolerance

M. Yu[1], J. Xia[1], J. Zhou[2], M. Li[2], X. Yu[1], C. Zhu[1]
[1] *The Central Hospital of Putou District in Shanghai, Endocrinology, Shanghai, China*
[2] *Sixth People Hospital, Endocrinology, Shanghai, China*

Aims: To reveal the characteristics of 24 hour glycemic excursions in subjects with impaired glucose tolerance (IGT).
Methods: The glycemic excursions and tendency of 37 newly diagnosed IGT subjects (aged 59(38~80)yrs, 16M/21F) and 41 normal glucose tolerance (NGT) subjects (aged 42(25~69)yrs,21M/20F) were measured by continuous glucose monitoring system (CGMS) for 3 days. The CGMS took the glycemic measurements for a total of 288 values every 24 hours.
Results: IGT group in comparison with NGT group exhibited significantly higher values (means ± SEM) of body mass index [(25.4±0.6) kg/m2 vs (22.8±0.4) kg/m2], systolic blood pressure [(131±3) mmHg vs (119±2)mmHg], HbA1c [(5.97±0.08)% vs (5.53±0.09)%] and triglyceride [(1.62±0.13)mmol/L vs (1.15±0.13)mmol/L] (all P<0.01). The profiles of the CGMS showed: There were significant differences in the average glycemic level [(5.31±0.08)mmol/L vs (6.26±0.11) mmol/L], the standard deviation of 24hour glycemic excursions [(0.88±0.04) mmol/L vs (1.34±0.08) mmol/L], and the difference between the maximal and minimal glucose values [(3.91±0.25) mmol/L vs (6.62±0.41) mmol/L] between NGT group and IGT group (P <0.01). 62.2% diurnal glycemic peaks occurred in 6am~10am period, but no glycemic peaks were observed during 9pm~5am period in IGT group. The values of postprandial glycemic peaks, time to postprandial glycemic peaks, the postprandial amplitude of glycemic excursions and the area under the curve (AUC) of postprandial glucose in IGT group were (9.68±0.33) mmol/L, (72.6±4.8) min, (3.77±0.32) mmol/L, (0.24±0.03) mmol/L·24h in breakfast; (8.51±0.22) mmol/L, (81.5±5.0) min, (3.20±0.26) mmol/L, (0.33±0.03) mmol/L·24h in lunch; (8.70±0.29) mmol/L, (86.9±5.1) min, (3.13±0.29) mmol/L, (0.33±0.03)mmol/L·24h in supper; respectively, which were all significantly higher than those in NGT group (all P<0.01). The glycemic peak of post-breakfast was higher than those of post-lunch and supper, but the AUC of post-breakfast was not higher than those of post-lunch and supper.
Discussion: Continuous glucose monitoring provided the greater details about the glycemic excursions and tendency throughout the day in IGT subjects. The glycemic profiles from the CGMS have a valuable role in identifying the characteristics of glycemic excursions and making the optimal treatment decisions in IGT.

The impact of a national specialized center on glycemic control in youth with type 1 diabetes mellitus

V. Serban[1], A. Lacatusu[2], L. Barna[2], A. Sima[1], A. Vald[1]
[1] *University of Medicine and Pharmacy, Diabetes Clinic, Timisoara, Romania*
[2] *Clinical Medical Center Cristian Serban, Clinical Medical Center Cristian Serban, Buzias, Romania*

Background and aims: As cure for type 1 diabetes (T1DM) is still unavailable, the achievement of an optimal glycemic control represents the main therapeutic goal that will delay or prevent the development of chronic complications. The aim of the paper is to assess the impact on glycemic control in youth with T1 DM of a national center specialized in evaluation, treatment and diabetes education. In Romania this role is played by Clinical Medical Center Cristian Serban for Evaluation and Treatment for Children and Youth (CCS) from Buzias, nearby Timisoara, where young people with DM from all over the country are admitted. Through its profile, CCS is unique in Romania.
Material and method: Between 1999 and 2008, 580 T1DM patients aged between 19 and 30 years were admitted at least once in the CCS, for an average of 12 days; 269 patients were admitted once (A1), 192 twice (A2) and 119 three times (A3), at intervals between 6 months and 5 years. In all patients we performed: physical examination, frequent daily glucose monitoring (on average 5 times/day), glycemic profile (twice during admission), HbA1c (immunoturbidimetric method, normal range 4.5-5.7%), eye exam and albuminuria (immunoturbidimetric method). In 516 patients during A1 we measured fructosamine twice, in the first and last day of admission (normal range 205-285 mmol/L). Diabetes education consisted in 8 theoretical (on all aspects of T1DM) and 8 practical lessons (insulin injections, self-monitoring, dose adjustments, food weighing, etc.) with duration of 2x 45 minutes each. Insulin therapy used both human and analog insulin. We computed mean HbA1c and the percentage distribution of patients on HbA1c intervals for each admission (<7%; 7-7.9%; 8-8.9%; =9%), as well as mean fructosamine at admission and discharge.
Results: For the whole group, mean HbA1c was 9.37±2.39% (A1); 8.47±1.73% (A2) and 8.34±1.57% (A3). Differences were statistically significant between A1 vs A2 and A1 vs A3 (p<0.001), but not for A2 vs A3. Mean HbA1c was below 7% in 13.7% (A1), 19.46% (A2) and 18% (A3) patients; between 7 and 7.9% in 17.3% (A1), 23.5% (A2) and 25.2% (A3) patients; between 8 and 8.9% in 19.1% (A1), 22.3% (A2), 27.1% (A3) patients and =9% in 49.8% (A1), 34.6% (A2), 29.5% (A3) subjects. Mean fructosamine decreased from 435±96 mmol/L at admission to 387±85 mmol/L at discharge (p<0.001). Results are similar for all types of insulin used.
Conclusions: DM management in a national specialized hospital, where therapy is strictly monitored and intensive diabetes education is provided, leads, after repeated admissions, to a significant decrease of mean HbA1c, an increase in the proportion of patients with HbA1c below 7 % and between 7 and 7.9%, and the decreases of patients with HbA1c greater than 9%. The effectiveness of CCS is also shown by the decrease of fructosamine during hospital stay.

D-0696

The efficacy of lowering HbA1c with a gliclazide modified release-based intensive glucose lowering regimen in the ADVANCE trial

M. Marre[1], J. Chalmers[2], S. Zoungas[2], B. de Galan[2], P. Hamet[3], B. Neal[2], N. Poulter[4], A. Patel[2]

[1] *Universite Paris 7, Diabetes Endocrinology and Metabolism, Paris, France*

[2] *The George Institute for International Health, Cardiovascular, Sydney, Australia*

[3] *University of Montreal, Medicine, Montreal, Canada*

[4] *Imperial College, Preventive Cardiovascular Medicine, London, United Kingdom*

Background: The ADVANCE trial (Action in Diabetes and Vascular disease: Preterax and Diamicron Modified Release Controlled Evaluation) has demonstrated that intensive glucose control with a gliclazide modified release (MR)-based intensive glucose lowering regimen in people with type 2 diabetes reduced the risk of combined microvascular and macrovascular events, primarily through reductions in the risk of diabetic nephropathy. In these analyses we examine the efficacy of this regimen in achieving good glycaemic control as reflected in the level of glycated haemoglobin (HbA1c).

Methods: All 11,140 patients randomised to receive either intensive (n= 5,571) or standard glucose control (n=5,569) were included in analyses assessing treatment efficacy as either the absolute HbA1c reduction, the HbA1c level achieved or the percentage of patients reaching various HbA1c targets (<=7.0%, <=6.5% and <6.0%) at the end of follow-up (median 5 years). Treatment efficacy was also examined in those receiving intensive glucose control according to subgroups defined by age, duration of diabetes, body mass index (BMI), HbA1c level and glucose lowering treatment at study entry (diet alone, monotherapy, or combination therapy with 2 or more oral hypoglycaemic drugs) using simple linear and multiple regression models.

Results: At the end of follow-up, in those patients assigned to intensive glucose control, HbA1c was reduced to a mean of 6.5%, with 81, 65 and 21% achieving HbA1c levels of <=7.0%, <=6.5% and <6.0% respectively, and 70% of patients receiving the maximum dose of gliclazide MR of 120mg. In contrast, in those assigned to standard control, HbA1c was reduced to7.3%, with only 50, 29 and 8% achieving comparable HbA1c levels. With intensive glucose treatment, substantial reductions in HbA1c were observed across all subgroups defined by baseline age, duration of diabetes, BMI, HbA1c or glucose lowering treatment at study entry (all p<0.0001). Moreover, at the end of follow up, HbA1c was reduced to 6.1% in those receiving gliclazide MR alone, 6.4% in those on other oral regimens including gliclazide MR, and 6.8% in those also requiring insulin. In a model including all these variables, the only independent predictors of reduction in HbA1c were baseline HbA1c and BMI (p<0.001). There was no weight gain in the intensive glucose control group and while severe hypoglycaemia was more frequent than in the standard care group, it was uncommon overall (0.7 vs. 0.4 episodes per 100 patient years).

Conclusions: Intensive glucose control with a gliclazide MR-based regimen was effective in lowering HbA1c, irrespective of age, duration of diabetes, BMI or HbA1c at entry, and irrespective of initial glucose lowering treatment. The decrease in HbA1c was more marked in those with higher HbA1c levels and lower BMI at baseline. The regimen was well tolerated without weight gain and with acceptable rates of severe hypoglycaemia.

Average Daily Risk Range (ADRR), an index of glycaemic variability, correlates with oxidative stress in type 2 diabetic patients

S.A. Park[1], S.H. Lee[1], S.Y. Kim[1], J.W. Son[1], J.A. Shin[1], S.H. Ko[1], H.S. Kwon[1], K.H. Song[1], Y.B. Ahn[1]

[1] *The Catholic University of Korea, Department of Internal medicine, Seoul, Korea*

Aims: Recent studies suggest that glycemic variability and consequent oxidative stress causes diabetic vascular complication in type 2 diabetes. The aim of this study was to evaluate the association between Average Daily Risk Range (ADRR), an index of glycemic variability, and the degree of oxidative stress.

Methods: We conducted a cross-sectional study in 71 type 2 diabetic patients being treated with either oral hypoglycemic agents (OHA, n = 41) or insulin (n = 30). The mean age and duration of diabetes in study subjects were 54.1 ± 12.7 and 5.4 ± 7.1 years, respectively. As a measure of glycemic variability, ADRR was calculated from self monitoring blood glucose (SMBG) data recorded over fourteen consecutive days. Subjects were categorized into non-fluctuation (ADRR < 20) and fluctuation (ADRR = 20) group. Plasma nitrotyrosine was measured by ELISA as a marker of oxidative stress.

Results: 39 (54.9%) and 32 (45.1%) patients were allocated into non-fluctuation and fluctuation group, respectively. Fluctuation group was characterized by longer duration of diabetes (7.8 ± 8.6 vs 3.4 ± 4.9 years), higher prevalence of diabetic retinopathy (34.4 vs 12.8%) and higher levels of HbA1c (9.6 ± 2.0 vs 7.8 ± 2.2%), fructosamine (364 ± 65 vs 294 ± 88 μmol/L), fasting plasma glucose (181 ± 53 vs 150 ± 54 mg/dL), postprandial plasma glucose (312 ± 102 vs 242 ± 80 mg/dL), serum creatinine (0.9 ± 0.3 vs 0.8 ± 0.2 mg/dL), high-sensitive C-reactive protein (0.9 ± 1.7 vs 0.3 ± 0.4 mg/dL) and nitrotyrosine (32.1 ± 17.0 vs 17.7 ± 10.3 nM) compared with non-fluctuation group. ADRR showed positive correlation with nitrotyrosine ($r = 0.490$, $P < 0.001$) and their significant relationship was established independent of glycemic control status (HbA1c < 8%: $r = 0.528$, HbA1c = 8%: $r = 0.401$) or treatment modality (OHA: $r = 0.440$, insulin: $r = 0.501$). The independent variables showing statistically significant associations with ADRR were duration of diabetes (ß = 0.313, $P = 0.001$), HbA1c (ß = 0.313, $P = 0.001$), $HOMA_{IR}$ (ß = 0.259, $P = 0.004$) and nitrotyrosine (ß = 0.462, $P < 0.0001$). Fasting and postprandial plasma glucose, serum creatinine and fructosamine also correlated with ADRR, although the significance was lost after multivariate adjustment.

Conclusion: ADRR, an index of glycemic variability based on SMBG data, was significantly correlated with levels of nitrotyrosine. This suggests that ADRR could reflect the degree of oxidative stress in type 2 diabetic patients. Glycemic control should be focused not only on the level of HbA1c but also on the degree of glycemic variability.

[10] *Lagos State University Teaching Hospital, Department of Medicine, Lagos, Nigeria*

[11] *Centre Marc Sankale, Centre du diabete, Dakar, Senegal*

Background: It is well established that glycaemic control is of utmost importance in the management of diabetes mellitus (DM). The gold standard for assessing glycaemic control is taken to be glycated haemoglobin, also referred to as HbA_1c. Reports of control levels using HbA_1c are few from Africa. The Diabcare project recently conducted a survey of the status of diabetes in six sub-Saharan countries, including measurement of HbA_1c levels.

Aim: To assess the status of glycaemic control in sub-Saharan African persons with DM using the Diabcare data methods.

Methods: Novo-Nordisk Diabcare survey was conducted in six sub-Saharan countries - Cameroun, Ghana, Kenya, Nigeria, Senegal, and Tanzania in 2008. Each patient completing the Diabcare questionnaire has his/her HbA_1c determined at the time of interview, in addition to obtaining basic clinical data recorded in the data collection form. HbA_1c level was determined using blood obtained by finger prick, with the result being available within ten minutes of blood collection.

Results: The frequency of HbA_1c testing varied widely between countries, with a regional range of 0-6 times per year and a mean rate of testing of about one

annually. In the cross-sectional testing, the mean HbA_1c was 8.5 (2.5)% with a regional range of 4.0-14.8%. The country means ranged from 7.5% to 9.0%. Using the IDF criterion of <6. 5% as good glycaemic control, only 26.6 % of the patients were in good control. Generally, there was a trend towards increasing frequency of chronic complications as the mean HbA_1c increased.
Conclusion: HbA_1c testing is infrequently performed in most African countries. Of those tested, satisfactory glycaemic control using the IDF criterion occurs only in a small proportion of patients. The level of testing and the outcome suggest that quality of diabetes care in sub-Saharan Africa leaves much to be desired. There is urgent need to improve the quality of care, which is essential to preventing or delaying long-term diabetic complications and improving the quality of life of Africans with diabetes mellitus.

National Initiative for Quality Assurance in Diabetes Care

J. Kroll[1], S. Khan[2]
[1] *Canadian Diabetes Association, Diabetes Educator Section, Toronto, Canada*
[2] *Canadian Diabetes Association, Research Professional Education and Government Affairs, Toronto, Canada*

Background: The Diabetes Educator Section (DES), a professional section of the Canadian Diabetes Association, developed the Standards Recognition Program (SRP) in 1996, and revised it in 2004. The SRP program provides diabetes education centers with the opportunity to undertake a self-assessment process to achieve national recognition for programs that successfully meet the Standards for Diabetes Education in Canada. The process includes a committee of certified diabetes educators who review submissions, provide recommendations for improvements, and confirm recognitions. The Association formally acknowledges the diabetes education center with certification for a five-year period.
Aim: The purpose of the SRP program is to assess the quality of care and services in diabetes education across Canada, and ultimately improve the care and treatment for people with, or at risk of diabetes.
Method: The SRP program focuses on individuals with diabetes, their families and/or communities and is articulated in three categories: outcomes, processes and structures.
The outcome standard demonstrates both behavioral changes and client knowledge. The process standard measures how education is provided, while the third standard, structure, is the organization and support services in providing care.
Additionally, these three categories have multiple standards, with examples of indicators for each standard. Indicators are verifiable examples of how a standard is met. Diabetes education centers may have other indicators illustrating how a standard is met, and should submit supporting documents to incorporate these indicators for each standard.
Results: Evaluating the performance and effectiveness of diabetes education centers and/or programs against national standards for diabetes care provides several opportunities for quality assurance. These include *improvements to the quality of care and services* currently provided in diabetes education. The *identification of Centers or Programs as a best practice site*, while giving *constructive feedback* and *positive reinforcement* provided to clients and staff for improvement. Lastly, the opportunity for diabetes education centers to earn public and professional recognition as a center providing *Excellence of Care*.
Conclusion: The Diabetes Educator Section (DES) of the Canadian Diabetes Association supports the work of diabetes educators who are dedicated to benefiting people living with diabetes. The SRP process assists program sites to evaluate their current practice while exploring new avenues to improve both processes and outcomes of diabetes care.

Enabling health care providers to deal with therapeutic education: the experience in the Cuban Diabetes Education Program

R.S. Suarez[1], R.G. Garcia[1]
[1] *National Institute of Endocrinology, Education and Social Work, Ciudad de la Habana, Cuba*

Enabling Health Care Providers to develop patient's understanding, abilities and self confidence to cope with daily self-care is a difficult task not solving by clinic knowledge or skills. The **purpose of this paper** is to show the evolution of this subject in the Cuban Diabetes Education Programme.
Methods: Capability covers Health Care Providers countrywide taking into account that every member of the team needs to develop educational skills.
Results: Activities have evolved according to the Program development. At the beginning of the Program (1980-1985) Psycho pedagogic Courses were held on the traditional classes and conferences but the results on educating people with diabetes have not improved. Since 1986, workshops were organized all over the country, as well as training in Diabetes Care Centre. Health Care Providers learnt in the same interactive methodology, they later will introduce in education activities with people with diabetes. Participants in these activities have shown better results on educating patients. In 2000, another activity was added: a Diploma on Diabetes Care and Education, certificated by the different Medicine Schools of the country, is developed twice a year in the different provinces for Health Professionals at the Primary Health Care Level. Participants have improved the quality of therapeutic education in the diabetes services and have gotten a better comprehension and treatment adherence in people with diabetes.
Conclusion: Continuous capability of Health Care Providers has increased abilities to deal with therapeutic education task, improving quality of services and patient's comprehension, skills and behaviors on treatment requirements.

Role-play for Certified Diabetes Educator (CDE) for developing communication skills, knowledge and attitude in clinical settings

H. Kitazato[1], M. Kishimoto[2], Y. Kaneko[1], K. Ohashi[3]
[1] *The Institute for Adult Disease Asahi Life Foundation, Department of Endocrinology and Metabolism, Tokyo, Japan*
[2] *International Medical Center of Japan, Department of Diabetes and Metabolic Medicine, Tokyo, Japan*
[3] *University of Tokyo Hospital, Department of Metabolic Diseases, Tokyo, Japan*

Aims: A certified diabetes educator (CDE) is a health care professional who has undergone specialized training and is certified to instruct diabetic patients on the management of their condition. We used the role-play method to assess CDEs, especially those who had only recently acquired the certification, on their communication skills, knowledge, and attitude in dealing with diabetic patients in clinical settings. We also attempted to explore the effects of these role-play sessions and the inadequacies of this model of training.
Methods: The role-play training sessions were held 10 times a year. The participants included 137 CDEs or those wishing to obtain this certification, who belonged to 19 medical facilities. They were mainly nurses, and some were dieticians or pharmacists. The participants were oriented to the role-play method and were divided into small groups. In each group, one member (either a participant or an instructor) played the role of the patient and was provided with a description of his/her role, while the other (e.g. another participant) played the role of a CDE and was given a specific topic of instruction. The participants exchanged their roles and received feedback from the other members of the groups and the instructors. Themes for role-play were subjects of high interest to the CDE, such as conducting a medical interview with a diabetic patient, introducing self-monitoring of blood glucose level, explaining the process of administering insulin injection. The skills of the participants were assessed by the instructors by using a rating form. After the session, all participants were encouraged to give their impression of the session and complete the questionnaires administered to them.
Results: Of the total number of participants, 78% completed the questionnaire, and almost all participants found the sessions helpful. The aspects that were viewed as advantageous included first-hand experience in dealing with patients; feedback, including constructive criticism; and understanding of the patient's point of view. The assessment of the communication skills, knowledge,

and attitude of the participants by the staff doctors tended to be viewed as a relatively subjective, but still effective, form of personal feedback.
Discussion: The role-play method of training was received well by the CDEs in Japan. However, since actual diabetic patients are diverse in nature, the CDEs may often be unable to associate the situations created during role-play with real-life situations encountered. To enhance the effectiveness of role-play sessions, we should create challenging cases that closely reflect actual situations. In addition, it is essential that we construct a structured assessment form such that impartial and better feedback is obtained from all the participants.

Diabetes education: train-the-trainer programme on insulin therapy & administration

B. Lim[1], N. Othman[1], E. Tan[1], A. Husain[1], C.W. Ooi[1], R. Pagi[1]
[1] Association of Diabetes Educators (Singapore), Singapore

Aim: The lack of trained diabetes educators and standardised diabetes (DM) care and education to train Healthcare Professionals (HPS) has been an issue impeding the delivery of high-quality DM education and care for people on insulin therapy. The non-profitable Association of Diabetes Educators (Singapore)(ADES) aims to provide HPS who are from institutions that lack DM care and education, with training through International Diabetes Federation (IDF) curriculum.
Methods: The ADES adopted part of the module in curriculum of the International Diabetes Federation (IDF) on insulin therapy. A one-day DM education programme on Insulin Therapy and Administration was conducted by ADES in May 08. Institutions (IS) that do not have full-time DM educators were invited to nominate staff nurses (SN) to attend Train-the-Trainer (TT) programme. A post-course learning action was set for SN to provide pass-it-on DM care and education sessions to at least 5 nurses in their institutions within 3 months using the given teaching slides in CD-Rom and paper-based resource booklets. Variables including ethnic, years of experience in nursing, contact of patients with DM, place of work, duration of last update in DM education, and numbers of completed post course forms endorsed by SN supervisors, were collected for analysis.
Results: Twenty-two SN attended the workshop. 54% of the SN nominated had more than fifteen years of nursing experience. In terms of involvement in patient care, 90 % of SN involved in some level of routine diabetes education and care for patients and 10 % of SN from training & education department. In term of ethnicity, 83 % of them were Chinese. 50% of nurses were from Community Hospital, 40% from Nursing Homes/Services, and 10% from teaching institutions. 77% of SN from private and non profitable IS were not updated on DM education in the last 12 months in their nursing practice. 90% of the SN completed post course action within 3 months.
Conclusion: The IDF Curriculum resources allow diabetes educators in ADES to provide consistent, evidence-based research and information to promote diabetes care and education amongst the healthcare professionals.

Evaluating the effectiveness of using a Diabetes Needs Assessment Tool on health professionals' knowledge of diabetes and self-reported changes in clinical practice: a randomised controlled trial

T. Kellner[1], D. Owens[2], D. Jenkins[3], S. Schroter[4], K. Walsh[5], C. Probert[6], G. Arnhofer[7]
[1] MSD RBSC GmbH, CME, Haar, Germany
[2] University Hospital Llandough, Diabetes Research Unit, Penarth, United Kingdom
[3] Cardiff University, Cardiff Medicentre, Cardiff, United Kingdom
[4] BMJ Publishing Group, BMJ Editorial Office, London, United Kingdom
[5] BMJ Publishing Group, BMJ Learning, London, United Kingdom
[6] Cardiff Medicentre, BMJ OnExamination, Cardiff, United Kingdom
[7] MSD RBSC GmbH, Education Solutions, Paris, France

Aims: The medical profession has a tradition of self-directed learning based on the individual's identified priorities for learning. However, there is evidence that this ability to self-assess is limited, and that the least competent are also the least able to self-assess. It may therefore be of benefit to have some form of external assessment. Whilst many diabetes educational programmes have been explored, few have been assessed in a systematic manner. As diabetes is an increasingly prevalent disease, effective methods for the dissemination and understanding of clinical guidelines need to be explored. This paper describes a randomised controlled trial to evaluate the effectiveness of using an online Diabetes Needs Assessment Tool (DNAT) to improve health professionals' knowledge of how to manage diabetes; to evaluate the acceptability of this process of learning and self-reported changes in clinical practice as a result of this educational process.
Methods: *Design*: Multi-centred randomised controlled trial.
Outcome measures: Primary - diabetes knowledge at 4 months and secondary - self-reported changes in clinical practice and acceptability of learning materials.
Sampling: Health professionals, both doctors and nurses managing diabetes patients, were recruited from the UK and Germany.
Process: The DNAT is a computerised test that adapts to the knowledge level of the learner and is comprised of clinically rich case problems developed by a group of diabetologists/educationalists.
After giving consent, eligible registered participants were given an online baseline diabetes knowledge test and then randomised to one of two groups using a stratified minimisation method. The control group were only given access to online diabetes learning modules whereas the intervention group were also given the DNAT for a 4 month period. After this time, both groups were administered a second diabetes knowledge test and a questionnaire assessing the acceptability of the learning materials. One month later, all participants were asked to complete a questionnaire measuring self reported changes in clinical practice. On completion of the DNAT, a personalised learning report was created for each participant identifying needs alongside individualised recommendations of the most appropriate modules to meet those requirements.
Results: To date, 1286 participants have enrolled in the study (951 English language and 335 German language). The results of this study will be presented.

Continuing education program for practical abilities of diabetes care nurses in Japan

N. Seto[1], Y. Shimizu[1], H. Ishii[2], H. Masaki[3]
[1] Osaka University, Health Sciences, Osaka, Japan
[2] Nagoya University, Education and Human Development, Nagoya, Japan
[3] Chiba University, Nursing, Chiba, Japan

Aims: The purpose of this study was to develop the continuing education program in the diabetes care field in Japan. This time we plan to report a part of this study from the viewpoint of clinical knowledge of interpersonal relationship in Japanese nursing.
Methods: 1. The nurse managers and researchers involved in continuing education for diabetes care nurses by our evaluation index (We have developed "Evaluation index for nurturing practical ability of diabetes care nurses" in 2007) were interviewed regarding "the present conditions and issues concerning the evaluation" and data were analyzed. 2. Item of the evaluation index were on the basis of interview refined by 3 expert groups of certified diabetes care nurses in Japanese Nursing Association. 3. The continuing education program was created, which reflects the attributes of diabetes care nurses in Japan.
Results: 1. Practical roles include [role of providing patient with nursing assistance], [role of collaborating with medical professionals], [role of improving staff's assistance skill], [role of working in an organization], and [role of striving for self-education and self-study]. 2. The continuing education program for practical abilities from the viewpoint of clinical knowledge of interpersonal relationship include (1) three items, such as "Attitude as a specialist toward patient," and "understanding patient and Construction of a relation," and "Care of the using a nursing process Attitude toward their practice," refined base on their thoughts, (2) four items, such as "Adjustment of medical treatment and learning environment of patient" and "Information gathering required for nursing assistance," and "Providing of assistance skill," and "Care in the emergency," refined base on their actions, and (3) five items, such as "Developing interpersonal relationships" and "Patient satisfaction," and "Self-control action," and "Acceptance and decision-making of a patient of medical treatment action," and "An improvement of a patient's body condition," refined base on the results of their actions.
Conclusions: The result revealed the present conditions and issues concerning the evaluation, and many suggestions regarding continuing education by

nurse managers were received in Japan. As a result of verifying the validity and reliability of an evaluation index, the continuing education program from the viewpoint of clinical knowledge of interpersonal relationship in Japanese nursing, which consists of 12 items for diabetes nurses, were completed.

Diabetes related knowledge among residents and nurses: a multicenter study in Karachi, Pakistan

A. Ahmed[1], A. Jabbar[1], L. Zubairi[1], K. Shamim[1], K. Muhammad[1]
[1] The Aga Khan University Hospital, Endocrine And Diabetes, Karachi, Pakistan

Objective: To evaluate and compare the knowledge related to the management of diabetes among nurses and trainee residents of internal medicine, family medicine and surgery at tertiary care hospitals of Karachi, Pakistan.
Methods: It was a Cross sectional study. A validated questionnaire consisting of 20 questions related to diabetes awareness was acquired through a study done at Thomas Jefferson University Hospital with the permission of primary author. The questionnaire was administered at 5 tertiary care hospitals in Karachi, Pakistan to residents and nurses in wards or after regular meetings after taking their informed consent. Statistical analysis was performed using SPSS software version 16. Statistical significance was considered to correspond to a *P* value =0.05.
Results: 169 internal medicine residents (IMR), 27 family medicine residents (FMR), 86 surgery residents (SR) and 99 nurses (RN) participated. The survey had a good reliability coefficient(Cronbach a of 0.81).The overall mean correct percentage was 50%.There was no difference in total scores of IMR & FMR(64% vs. 60%, p= 0.47).The total scores of SR and RN were quite low (39% & 31% respectively).Although FMR scored higher than IMR on items regarding outpatient management of diabetes, that difference was not statistically significant(p=0.128).For inpatient diabetes care the scores of IMR were higher than FMR but not statistically significant either (p-value 0.175).SR and RN had profound deficit in both inpatient and outpatient management. Surprisingly, despite the fact that RN are actively involved in in-patient management of diabetes, they didn't answer correctly on most of the items regarding in-patient management of diabetes (Mean score 40%).
Conclusion: Since the prevalence of diabetes has been rapidly rising, it has become one of the major public health problems. Pakistan is also one of those countries estimated to have the highest number of people with diabetes. To be able to face this enormous number of diabetes cases, health care providers need to have adequate knowledge to deliver optimal care to these patients. There are several studies that have examined the diabetes knowledge of nurses, but the data assessing the knowledge of diabetes among trainee residents' especially surgical residents is lacking. This study is of paramount importance because to date, we didn't find any published study evaluating diabetes related knowledge of trainee residents and nurses in Pakistan. Based on these results, there are significant gaps in diabetes knowledge among residents and nurses. Due to high burden of disease and considering the fact that our residents and nurses are actively involved in diabetes management, this raises important concerns and needs to be addressed.

A model of education project for health care professional - a partnership between a scientific society and a laypeople association

D.R. Franco[1], G.M.C. Camara[2], S. Grossi[3], R. Rezende[2], M. Merino[4], F.C. Branco[5], S.D. Castilho[6], B. Rodriguez[7], R. Garcia[8], A.C. Forti[9]
[1] Juvenile Diabetes Association, diabetes Education, São Paulo, Brazil
[2] Juvenile Diabetes Association, Diabetes Education, SÃo Paulo, Brazil
[3] Brazilian Diabetes Society, Nursing, SÃo Paulo, Brazil
[4] Brazilian Diabetes Society, Nutrition, SÃo Paulo, Brazil
[5] Juvenile Diabetes Association, Nutrition, SÃo Paulo, Brazil
[6] Juvenile Diabetes Association, Physical activity, SÃo Paulo, Brazil
[7] IDF - SACA, Diabetes Education, Atlanta, USA
[8] IDF - SACA, Diabetes Education, SÃo Paulo, Brazil
[9] Brazilian Diabetes Society, Diabetes Education, SÃo Paulo, Brazil

There is a lack of diabetes educators in Brazil. In order to develop a training course to educators, a laypeople association, Juvenile Diabetes Association (ADJ) joined with a medical society - Brazilian Diabetes Society (SBD). Together they adapted all their way of working and developed a diabetes education course based on IDF curriculum.
The main objective of the course was to training the professionals to develop diabetes education considering the needs, goals, and life experiences of the patients. This comprehensive way to educate can support informed decision-making, self-care behaviors, problem solving, and active collaboration with health care team, and improve clinical outcomes, health status, and quality of life.
Material and Method: A scientific council was created from both groups (SBD and ADJ) to review the IDF curriculum and to develop a program based on Brazil necessities focus on Diabetes Education in a interdisciplinary way. A group of psychologist, pedagogy, nurse, dietitian, physician, physical educator joined for 6 months to develop the program.
Program design: The program was divided in theoretical interactive exposition and workshops. The theoretical review consisted of Physiopathology, Epidemiology, and treatment of type 1, type 2 and gestational diabetes and their complications were presented as clinical cases with endocrinologist and members of the staff interacting during the presentation as an example of an interdisciplinary work. The fundamental concepts on health education were presented in a way to prepare the participant to develop an educational project at the end of the course. The workshops were designed to have at least 3 different working stations at the same time, being conducted by members of the staff, a nurse, or a dietitian. The workshop program included glycemia control, insulin and medication therapy, diabetic foot, carbo-counting therapy and nutritional aspect of diabetic disease.
It was planned to have 6 sessions in different regions of Brazil. For each session 6 -8 persons from the scientific council and a IDF-SACA diabetes educator were present, and 2 professional, from the next city where the course would be done were trained in advance for the next course to join the original group. It was 40 hours course for 60 health care professional working in diabetes education. All the participants were submitted to an initial test, and in the end of the course for the final certification they should have to develop an Educational Project to be analyzed by the scientific board.
Results: From May 2008 untill March 2009, 4 sessions were done (southeast, central and northeast of Brazil). We have trained 235 persons that now are qualified to train other diabetes educators as a team to improve the quality of life of diabetic patient.

Partnering for success: developing a training programme for joint teams of lay and health care professional educators delivering DESMOND structured group education in diabetes

H. Daly[1], L. Martin-Stacey[1], C. Taylor[2], M. Carey[1], R. Hale[3], S. Heller[4], K. Khunti[5], M. Panna[1], J. Phillips[6], M. Stone[5], M.J. Davies[7]
[1] University Hospitals of Leicester NHS Trust, Department of Diabetes Research, Leicester, United Kingdom
[2] NHS Cumbria, NHS Cumbria provider services, Cumbria, United Kingdom
[3] Diabetes UK, Fareham Group, Hampshire, United Kingdom
[4] University of Sheffield, Department of Medicine, Sheffield, United Kingdom
[5] University of Leicester, Department of Health Sciences, Leicester, United Kingdom
[6] Expert Patients Programme, CIC, London, United Kingdom
[7] University of Leicester, Department of Cardiovascular Sciences, Leicester, United Kingdom

Aims: To enable lay educators to successfully deliver structured group education in diabetes by: a) attaining an appropriate level of diabetes knowledge, b) fostering a positive team dynamic and c) developing effective group facilitation skills.
Method: A task group drawn from the DESMOND Lay Educator Study investigators, developed a training framework for lay educators. The group drew on findings from an action research project conducted by Leicester University which identified key obstacles for potential lay educators including: a) lack of diabetes knowledge; b) impact of learning for self-knowledge at the same time as learning for the role of educator; c) lack of sufficient experience in group work. The task group planned an iterative cycle of training and feedback beginning with an initial package of preparation, training and support carried out through centralised training days, specific DESMOND educator training and on-site practice delivering group education in local teams. A total of 12 lay educators (LEs) and 12 health care professional educators (HCPEs) working in 6 teams of 4 (2 LEs and 2 HCPs) took part in a 1-day preparation course. The

purpose of this day was to promote team work, introduce people to the study and prepare LEs for formal DESMOND educator training. Lay educators then attended the standard 2-day DESMOND educator training together with other prospective educators from around the UK.
In each of the 6 study sites, LEs delivered DESMOND in teams of 3 (1 HCPE & 2 LEs). The teams then came together for a formal feedback day to share their experiences and to highlight outstanding needs as individuals and as teams.
Results: As intended, the initial package had partly met the stated aims of the training. However, the feedback process was successful in identifying generic, team and individual training and mentoring needs. For the LEs, the generic needs were further opportunities for practice and developing diabetes knowledge. For HCP educators generic needs were around developing mentoring and feedback skills. Some teams recognised a need for team mentoring via an experienced trainer, and individuals expressed a variety of needs, generally focussed around delivery of the education programme.
Conclusion: In creating a successful training framework for any group it is crucial to use an iterative cycle of development for incorporating the feedback and experience of all participants. Training must also recognise that individuals develop at different rates and to be successful, must address specific individual needs in addition to those that are generic.

Combined effects of atorvastatin and metformin on post glucose-loading changes in inflammatory process in patients with diabetes mellitus type 2

K. Koniari[1], D. Tousoulis[1], C. Antoniades[1], A. Nikolopoulou[1], K. Makris[1], M. Noutsou[2], N. Papageorgiou[1], K. Marinou[1], E. Voltirakis[1], C. Stefanadis[1]
[1] *Hippocratio Hospital University of Athens, Cardiology, Athens, Greece*
[2] *Hippocratio Hospital University of Athens, Diabetes Center, Athens, Greece*

Aims: Statin treatment has been suggested to improve survival in patients with atherosclerosis, but their effects on the glucose-induced variations of inflammatory markers are unknown. We examined the effect of atorvastatin when administered on top of conventional anti-diabetic treatment or diet, on glucose-induced variations of inflammatory molecules in patients with newly diagnosed diabetes mellitus type 2 (DM).
Methods: Seventy subjects with newly diagnosed DM were randomised to receive metformin 850mg/d (M, n=17), metformin 850mg/d+atorvastatin 10mg (M+A, n=16), atorvastatin 10mg/d with dietary instructions (A+D, n=18) or diet only (D, n=19). All subjects underwent glucose loading (75g oral glucose) at baseline and after 12 weeks of treatment. Blood samples were obtained at baseline and 3 hours post-loading, while serum tumor necrosis factor alpha (TNF-a) and soluble E-selectin (sE-sel) were determined at baseline and at 3h.
Results: Serum TNF-a remained unchanged after loading at baseline in D (1.38±0.17 to 1.33±0.18 pg/ml p=NS) and it was reduced after 12 weeks (1.70±0.23 to 1.32±0.14 pg/ml p<0.05). TNF-a remained unchanged in M at baseline (1.36±0.18 to 1.47±0.21 pg/ml p=NS) and after treatment (1.44±0.71 to 1.31±0.17 pg/ml p=NS) and were reduced in M +A (2.0±0.309 to 2.0±0.38 pg/ml p=NS at baseline and 1.87±0.12 to 1.74±0.12 pg/ml p<0.05 after treament) as well as in A (from 1.37±0.17 to 1.17±0.12 pg/ml p=NS at baseline and from 1.18±0.09 to 1.06±0.0087 pg/ml p<0.05 after treatment).
Serum sE-sel remained unchanged after loading at baseline in D (42.5±2.6ng/ml to 48.5±4.5 ng/ml p=NS) and was reduced after 12 weeks (44.6±2.8 to 40.3±3.0 ng/ml p<0.01). sE-sel remained unchanged in M at baseline (53.0±4.9ng/ml to 49.7±5.3 ng/ml p=NS) and after treatment (44.5±3.4 to 43.3±3.9 ng/ml p=NS after treatment), and were reduced in M+A (44.2±5.6 to 40.5±6.2 ng/ml p=NS at baseline, and 40.8±5.4 to 36.8±5.1 ng/ml p<0.05 after treatment), but not in A (39.7±6.6 to 35.5±6.1 ng/ml p=NS at baseline to 35.6±5.8 to 33.6±6.5 ng/ml p=NS after treatment).
Discussion/conclusions: Treatment with atorvastatin alone is unable to reduce inflammatory process induced by hyperglycemia in patients with newly-diagnosed diabetes mellitus. However, atorvastatin treatment reduces the post-glucose loading levels of sE-selectin and TNF-a, only when administered on top of metformin treatment in these patients.

A selective impairment of hepatic versus adipocyte insulin action such that increased lactate flux from adipocytes, fuels excessive hepatic gluconeogenesis in programmed insulin resistance

M.J. Holness[1], M.G. Zariwala[1], M.C. Sugden[1]
[1] *Cell & Molecular Science, Diabetes and Metabolic Medicine, London, United Kingdom*

Background and aims: Lactate release from white adipose tissue is quantitatively important, generally accounting for 5-15% of total glucose uptake by small adipocytes and up to 35-40% of total glucose uptake by large adipocytes. Net lactate production per adipocyte is increased in first degree relatives of individuals with type 2 diabetes, whose fat cells are enlarged compared with controls. Insulin resistance and diabetes can be "programmed" in early life by e.g. poor nutrition. We aimed to establish whether programmed insulin resistance could reflect increased hepatic gluconeogenesis due to increased flux of lactate as gluconeogenic precursor from adipose to liver.
Materials and methods: Maternal protein restriction during pregnancy and lactation (Maternal Low Protein, MLP) was used as a model of early life programming of diabetes and insulin resistance. As MLP programming augments basal and insulin-stimulated glucose uptake, yet adipocytes are small, we examined whether MLP affected lactate production by isolated adipocytes. We studied adipocytes from young male offspring at 8 weeks of age in the prediabetic phase.
Results: Adipocytes from MLP offspring had 33% higher basal lactate production than control (Con) offspring. On increasing the glucose concentration, Con adipocytes responded with 54% increase in lactate production, whereas MLP adipocytes responded with a 2.2 fold increase in lactate production. Insulin was added to media containing 20 mM glucose to minimize any possibility that glucose availability might limit lactate production. While insulin addition only modestly increased lactate production with adipocytes from Con offspring (30%), insulin stimulation of MLP adipocytes led to a much greater stimulation of lactate production.
Conclusion: Hepatic gluconeogenesis is inappropriately increased in type 2 diabetes and insulin resistance. Our data demonstrate that adipocytes in a model of early life programming of insulin resistance have a predilection for lactate production. Epidemiological studies have suggested a link between basal lactate release and adipocyte insulin resistance; however, in the present research, MLP adipocytes were more insulin responsive as the stimulation of lactate release observed in response to insulin was greater than observed with Con adipocytes. Thus a selective impairment of hepatic versus adipocyte insulin action, allowing increased lactate production from glucose by adipocytes under hyperinsulinaemic conditions, would be predicted to allow a greater rate of hepatic gluconeogenesis when hepatic insulin action is compromised.

TFE3 acts as a transcriptional activator in hepatic glucokinase gene expression

M. Kim[1], T. Kim[1], J. Bae[1], J. Park[2], Y. Ahn[1]
[1] *Yonsei University College of Medicine Dept. of Biochemistry and Molecular Biology, Center for Chronic Metabolic Disease Research, Seoul, Korea*
[2] *Yonsei University College of Medicine Brain Korea 21 Project for Medical Sciences, Center for Chronic Metabolic Disease Research, Seoul, Korea*

Background: TFE3 (transcription factor E3) is a bHLH protein that was first identified and characterized in enhancer element in the immunoglobulin heavy-chain and T cell receptor gene. E-boxes, the *cis*-elements for bHLH protein binding, are located in the promoters of numerous genes involved in metabolism. Previously it was reported that TFE3 activates hepatic IRS-2, an important component of insulin signaling.
In this study, we demonstrate that glucokinase (Gck) gene, which is a key regulator of glycolysis in liver is upregulated by TFE3 at the transcriptional level.
Methods: Transcriptional activity of hGck promoter by TFE3 was measured by luciferase assay in HepG2 cells. Transient highly expressed TFE3 nuclear extract of HepG2 cell protein was used in EMSA to show the binding of TFE3 in hGck gene promoter. Chromatin immunoprecipitation (ChIP) was performed to show the binding of TFE3 to hGck promoter *in vivo*. Messenger RNA level of Gck was measured by real time PCR in the primary cultured rat hepatocyte which is infected with TFE3 adenovirus.
Results: *In silico* search suggested that there are several E-boxes in the human Gck (hGck) promoter. Luciferase assay showed that TFE3 activates the hGck

promoter activity by 20 fold. Introduction of mutation at the E-boxes resulted in the decrease of the transcriptional activity. EMSA and ChIP assay showed that TFE3 binds directly to hGck promoter. Infection of TFE3-adenovirus to primary cultured hepatocytes increased endogeneous hGck mRNA level. The transcriptional activation of hGck by TFE3 was greater in hepatocytes maintained in high glucose media than in low glucose media.

Conclusion: We demonstrated that TFE3 activates the gene expression of Gck by direct binding on Gck promoter.

S6 ribosomal protein kinase 1 (S6K1) level in skeletal muscle cells is sensitive to nutritional manipulation

O. Adegooke[1], H. Samimi-Seisan[1]
[1] York University, Kinesiology and Health Science, Toronto, Canada

Obesity, a result of disequilibrium between energy intake and expenditure, is the major predisposing condition for type 2 diabetes and cardiovascular disease. Insulin resistance can result from, and/ or worsen, the obese state. Hence understanding the molecular mechanisms of insulin resistance is critical to control of obesity and its consequences. The mTOR/S6K1 is a signalling pathway that is critical for insulin action and nutrient utilization. Upon stimulation by insulin or amino acids, mTOR is activated, leading to the activation of S6K1. This protein then promotes protein synthesis and growth by phosphorylating its effectors, including ribosomal protein S6 and the translation initiation factor eIF4B. However, over-activation of S6K1 is implicated in insulin resistance. Thus, while the functions of the kinase are essential, its over-activation is undesirable. It is crucial therefore to identify mechanisms regulating S6K1 functions. Its activity can be controlled by phosphorylation, but it is unknown if other mechanisms of regulation exist.

Aim and methods: To determine whether S6K1 levels are altered by nutritional manipulations, rat skeletal muscle cells (L6 myoblasts) were grown in a complete medium (AMEM, supplemented with 10% FBS), or in a medium that contained 11 mM glucose but lacked amino acids and growth factors for up to 24 h. Another group of starved cells was re-fed for 1-4 h in the complete medium. S6K1 levels were then detected by immunoblotting.

Results and discussion: We observed starvation-induced, time-dependent attenuation of S6K1 protein level: at 6 and 24 hours, starved cells had, respectively, 25 and 50% decrease in S6K1 compared to control ($P<0.05$). In parallel, phosphorylated S6 and eIF4B (measures of S6K1 functions) were barely detected in starved cells, compared to control or re-fed group. We then examined mechanisms behind this regulation. Ubiquitination is a post-translational modification that regulates protein function and degradation. Remarkably, elevated ubiquitination of S6K1 was observed in both the control and the starved-refed groups; little ubiquitination was seen in the starved group. However, when starved cells were incubated in the presence of MG132, an inhibitor of the proteasome, increased ubiquitinated S6K1 was detected, suggesting the involvement of the ubiquitin proteolytic system in regulating the kinase.

Conclusion: Our data point to novel mechanisms of regulating S6K1 activity that may prove critical in controlling the functions of this kinase especially in conditions such as obesity and insulin resistance.

Amino acids stimulate protein anabolism and attenuate fed-state glucose uptake in healthy young men

S. Chevalier[1], O. Adegoke[1], S. Lalonde[1], R. Gougeon[1], J.A. Morais[1], E.B. Marliss[1]
[1] Mc Gill University, Nutrition and Food Science Centre, Montreal, Canada

We have shown a greater increase in protein anabolism, associated with lower glucose infusion and utilization rates, in a fed steady-state clamp (Hyper-3: insulin 798±74 pM, glycemia 7.9±0.0 mM, branched-chain amino acids [BCAA] 740±10 μM, n=9). These differences occurred when compared with a Hyper-1 clamp (insulin 450±22 pM, glycemia 5.5±0.0 mM, and BCAA 359±8 μM, n=10). Since endogenous insulin contributed to the higher than Hyper-1 postprandial hyperinsulinemia in Hyper-3 (C-peptide increased 5 fold), we performed a Hyper-3PC (pancreatic clamp) with octreotide and exogenous insulin, glucagon and growth hormone infusions. This suppressed C-peptide 46%, achieved insulinemia of 524 pM, with identical hyperglycemia and BCAA (n=9). Comparisons were made among these protocols in the three groups of men of similar age (26±1 yr), BMI (22±1 kg/m^2) and fat-free mass (FFM, 60±1 kg). Protein turnover (in μmol/kgFFM•min) was estimated by primed-continuous infusion of ^{13}C-leucine and that of glucose (in mg/kg•min) by ^{3}H-glucose. Amino acid infusion rates were identical in Hyper-3PC (130±4) and Hyper-3 (142±9), and greater than in Hyper-1 (49±2 mg/min, $P<0.01$). Suppression of leucine endogenous Ra (protein breakdown) was -0.86±0.05, -0.64±0.11 and -0.43±0.06 respectively (Hyper-3PC > Hyper-1, $P<0.001$). Stimulation of nonoxidative Rd (synthesis) was 0.40±0.05, 0.78±0.06 and 0.39±0.07 (Hyper-3PC and Hyper-1 < Hyper-3, $P<0.05$). Increase in net balance (anabolism) was 1.26±0.06, 1.42±0.09 and 0.82±0.03 (both $P<0.001$ vs. Hyper-1). Leucine oxidation was markedly increased to 1.5±0.1 and 1.6±0.1 vs. 0.6±0.03, ($P<0.001$). Glucose infusion rate was 5.4±0.3, 7.1±0.6 and 8.3±6 (Hyper-3PC $P<0.05$ vs. both). Endogenous production was inhibited similarly, but utilization increased to only 5.6±0.3, vs. 7.0±0.5 and 8.0±5 ($P<0.05$), such that M (Rd/insulin) was 0.82±0.07 and 0.65±0.10, vs. 1.25±0.10 (mg/min•pM, $p<0.01$). Therefore, with the postprandial hyperinsulinemia of Hyper-3PC, similar marked stimulation of anabolism occurred as with Hyper-3 clamps, though by somewhat different effects on synthesis vs. breakdown, perhaps related to different portal insulinemia. Postprandial hyperaminoacidemia to levels that exceed the maximum capacity for incorporation into protein synthesis results in their oxidation, that could be responsible for a physiological (not necessarily an insulin resistance-mediated) attenuation of the increased glucose uptake. As these findings were found in healthy, young, insulin-sensitive subjects, they may represent normal physiological mechanisms to maintain glucose and amino acid homeostasis, when provided in excess of immediate needs.

Quercetin decreases inflammatory response and increases insulin action in skeletal muscle of ob/ob mice and in palmitate- and TNF-alpha-treated L6 myotubes: possible role for the negative regulation of JNK phosphorylation and NF-kappaB activity

G.F. Anhe[1], M.M. Okamoto[1], G.A. Lima[1], S.M. Hirabara[1], T.S. Yamanaka[1], F.F. Anhe[1], S. Bordin[1], U.F. Machado[1]
[1] Institute of Biomedical Sciences, Physiology and Biophysics, São Paulo, Brazil

Quercetin, the most abundant flavonoid present in plants, is a potent anti-inflammatory that has been described to increase insulin sensitivity in obese rats through an unknown mechanism. In the present study we demonstrate that long-term intraperitoneal quercetin treatment increased whole-body insulin sensitivity in ob/ob mice, as assessed by insulin tolerance test (204%). In skeletal muscle of ob/ob mice, quercetin decreased JNK phosphorylation and IL-6 and IL-1 expression (respectively to 62%, 85% and 24%) and increased GLUT4 expression (151%). In vitro treatment of L6 myotubes with TNFa and palmitate decreased, as expected, insulin-induced glucose uptake (respectively to 28% and 50% vs. untreated cells). Previous addition of quercetin (48 hours) abolished this diabetogenic effect of TNFa and palmitate on L6 myotubes. In parallel, TNFa and palmitate reduced insulin-induced Akt serine phosphorylation (respectively to 45% and 42% vs. untreated cells) and increased JNK phosphorylation in myotubes (respectively to 195% and 215% vs. untreated cells). Quercetin effectively prevented the increase of JNK phosphorylation induced by TNFa and palmitate and the downregulation of Akt phosphorylation induced by TNFa. However, quercetin had no effect on the downregulation of Akt phosphorylation induced by palmitate. Additionally, palmitate increased nuclear accumulation of NF-kappaB proteins (580% for c-Rel, 172% for p50 and 340% for p52 vs. untreated cells) and binding to the GLUT4 promoter (125% vs. CTL) in myotubes. This effect was accompanied by downregulation GLUT4 content (56% vs CTL). Quercetin also suppressed palmitate-induced iNOS and TNFa expression in L6 myotubes. In conclusion, our results show that quercetin reduces insulin resistance in obese mice by suppressing the inflammatory response and enhancing GLUT4 expression in skeletal muscle. This quercetin property probably involves inhibition of TNFa and palmitate effects upon inflammatory pathway, as observed in L6 myotubes. These are the first results describing the quercetin improvement of insulin action in skeletal muscle, and highlights this flavonoid as a candidate for prevention and/or treatment of obesity-related insulin resistance.

Toll-like Receptor 2 (TLR2) improves cellular inflammation induced by diet-induced obesity, but worsens glucose tolerance

A. Caricilli[1], P.K. Picardi[1], L.L.F. De Abreu[1], B.M. Carvalho[1], M. Ueno[1], E.R. Ropelle[1], J.B. Carvalheira[1], L.A. Velloso[1], M.J.A. Saad[1]
[1] Universidade Estadual de Campinas, Internal Medicine, Campinas, Brazil

There are convincing evidences that the activation of JNK, IKK and iNOS are associated with insulin resistance, but only recently it has been demonstrated that those pathways can be connected to the insulin resistance by membrane receptors, such as Toll-like Receptors (TLRs). Studies from our laboratory demonstrated that mice with an inactivating mutation of TLR4 are protected from diet-induced obesity (DIO), IKKß and JNK activation, and insulin resistance. However, none of these studies have characterized the role of TLR2 in animal models of insulin resistance. Therefore, the goal of the present study was to investigate the role of TLR2 in DIO and insulin resistance. We investigated the weight gain, the sensitiv and signaling of insulin in liver, muscle, hypothalamus and white adipose tissue of TLR2 knockout (KO) mice fed a standard chow or a high-fat diet (HF). The insulin sensitivity was investigated by euglycemic-hyperinsulinemic clamp, the cell signaling was studied by Western Blotting and the serum insulin was determined by ELISA. Mice fed a standard chow, the TLR2 KO mice and their controls, were similar concerning the weight gain and the insulin resistance, but the TLR2 KO mice fed a HF presented similar degree of insulin resistance and higher weight gain than their controls fed a HF. The investigation of inflammatory pathways, such as JNK, IKK and tissue expression of IL-6, indicates that TLR2 KO mice fed a HF showed a decrease of the activation of the inflammatory pathways, such as JNK and IKK, and a decreased tissue expression of IL-6, indicating a reduced subclinical inflammation. Nevertheless, TLR2 KO mice fed a HF had higher fasting blood glucose than their controls, as they do with blood glucose during GTT, in parallel with a lower level of serum insulin in 30 minutes after the glucose infusion of GTT. Therefore, the results show that TLR2 KO mice fed a HF present, compared with their controls: 1. higher weight gain; 2. less evident subclinical inflammatory process; 3. decreased insulin secretion and worsening of glucose tolerance. In conclusion, the results of our study suggest that TLR2 protects from DIO subclinical inflammation in liver, muscle, white adipose tissue and hypothalamus, but worsens insulin secretion and glucose tolerance.

Macrophage secreted factors inhibit cdk2 activity in preadipocytes

J. Ide[1], A. Gagnon[1], A. Sorisky[1]
[1] University of Ottawa Ottawa Hospital Research Institute, Biochemistry Microbiology and Immunology Chronic Disease Program, Ottawa, Canada

Background and rationale: Macrophage infiltration in adipose tissue may contribute to adipose tissue dysfunction by inhibiting adipogenesis, leading to hypertrophied, inflamed, and insulin-resistant adipocytes. Our laboratory has previously reported that macrophage-conditioned medium (MacCM) from murine J774 and human THP-1 macrophages inhibits the adipogenic response of murine 3T3-L1 and human preadipocytes in culture (1). We have reported that early exposure (first 48 hrs of the 8 day protocol) of 3T3-L1 preadipocytes to J774-MacCM is required for the anti-adipogenic effect (2). This early phase of adipogenesis is characterized by mitotic clonal expansion that involves phosphorylation of the Retinoblastoma protein (Rb). The J774-MacCM severely inhibited mitotic clonal expansion as well as Rb phosphorylation.
Aim: Determine if cdk2, an upstream kinase that phosphorylates Rb, is inhibited by MacCM.
Methods: J774 macrophages were grown to ~90% confluence, then placed in fresh growth medium (DMEM containing 10%FBS and antibiotics) for 24 hrs. J774-MacCM, as well as control medium not exposed to macrophages, were collected and used to induce differentiation of confluent 3T3-L1 preadipocytes. To evaluate differentiation, J774-MacCM and control medium were supplemented with 0.25 µM dexamethasone and 0.5 mM isobutylmethylxanthine for the first 2 days, and 1 µM insulin for the first 4 days. Non-differentiated preadipocytes were kept in corresponding medium without adipogenic inducers. On day 8, the extent of the adipogenic response was visualized and quantified by triacylglycerol accumulation. Cdk2 expression was assessed by immunoblot analysis. Cdk2 activity was determined in cdk2 immunoprecipates, by measuring the incorporation of radiolabelled phosphate into histone H1 by autoradiography.
Results: The inhibition of adipogenesis by J774-MacCM was confirmed, shown by the 87% reduction in triacylglycerol accumulation ($p<0.05$; n=3). There were no apparent changes in cdk2 expression over the first 48 hrs following addition of adipogenic inducers, in the absence or presence of J774-MacCM. Activity of cdk2 was measured at 20 hrs following induction of differentiation. Under standard differentiating conditions, cdk2 activity increased 5-fold ($p<0.01$; n=3) from control (non-diffferentiating). In the presence of J774-MacCM, the increase in cdk2 activity was strongly inhibited by 83% ($p< 0.01$; n=3).
Conclusion: J774-MacCM inhibits the increase in cdk2 activity and Rb phosphorylation that normally occurs in response to adipogenic inducers.

Forecasting future diabetes incidence in Canada using FINDRISC

C. Robinson[1], H. Morrison[1], M. Abdel-Motagally[1], Y. Shi[1], L. Vardy[1]
[1] Public Health Agency of Canada, Centre for Chronic Disease Prevention and Control, Ottawa, Canada

Aims: To describe the distribution of type 2 diabetes risk within the general Canadian population at large using risk scores from Finland's FINDRISC questionnaire.
Methods: This analysis is based on self-reported data from PHAC's 2009 National Prediabetes Survey, a stratified random digit dialled (RDD) phone survey of the general population between ages 30 to 75 (n=1755). This analysis was restricted to ages 40 years and over without diagnosed diabetes, and then weighted by age, sex and province. Information for 8 self-reported questions were assigned scores based on the FINDRISC diabetes questionnaire, and then summed to estimate the total risk score for each respondent. These scores were derived from the cohort experience in the Finnish Diabetes Study.
Results: The total cumulative incidence of type 2 diabetes in Canada over the next 8 to 10 years is estimated at 1.4 million cases, for those currently age 40 years and over. The distribution of diabetes risk is concentrated in a relatively small portion of the adult population: roughly half of all incident cases will derive from only 11% of the population, those comprising the moderate/high risk cases with FINDRISC scores above 14. Low risk cases with FINDRISC scores under 7 comprise over one-third of the total target population, yet will only contribute 5% of new incident cases over the next 8 to 10 years.
Discussion/Conclusion: Current screening recommendations suggest regular screening for all asymptomatic adults over 40 years of age every three years, or more often in the presence of various risk factors. This analysis suggests that diabetes risk is concentrated in a relatively small portion of the population, who could be identified using inexpensive risk scoring questionnaires, such as FINDRISC, as an initial pre-screen in order to improve the efficiency and effectiveness of overall screening efforts.

Ethnic disparities in some type 2 diabetes intermediate outcomes are shown to be diminished by 5 years of primary health care intervention based on annual reviews

R.B.W. Smith[1], M. Hullah[2], J.D. Krebs[1], L. McBain[3], M. Shapleski[4]
[1] Wellington Regional Diabetes Trust and Capital Coast District Health Board, Medicine, Wellington, New Zealand
[2] Wellington Regional Diabetes Trust, Trust, Wellington, New Zealand
[3] University of Otago Wellington, Primary Care and General Practice, Wellington, New Zealand
[4] Wellington Regional Diabetes Trust, Information Technology, Wellington, New Zealand

Aim: To observe the impact of 5 years of primary care annual review examinations on ethnic disparities in intermediate outcomes of Type 2 diabetes care.
Methods: Within the New Zealand community Maori and Pacific persons have had lower uptake of, and poorer results from, diabetes care. In 2000, a

government-sponsored nationwide programme of free-to-the-patient annual review of their diabetes was instituted. Payments to primary care were made on completion of a defined clinical and laboratory dataset returned from the areas served by Capital and Coast, Hutt Valley, and Wairarapa District Health Boards (approximately 10% of the 4 million population of New Zealand) to the database coordinator at the Wellington Regional Diabetes Trust. From the database of 49,965 annual reviews on 19,054 persons with diabetes, to the end of 2006, those with Type 2 diabetes who had had five or more completed annual reviews were selected and analysed here.

Results: The cohort comprised 2967, males 50.8%, ethnicity Asian 10.2%, European 69.5%, Maori 10.0%, Pacific 8.6%, median age at latest review 69 years.

Weight was strikingly different between ethnic groups, averages being respectively (in alphabetic order) initially 68.7, 84.6, 94.0, 94.5 and by year 5 had reduced little 68.6, 83.5, 92.7, 92.8.

HbA1c initial means 7.48, 7.12, 8.00, 8.32 by year 5 were 7.44, 7.26, 7.98, 8.24.

Cholesterol total initial means 5.51, 5.44, 5.68, 5.56 fell spectacularly to 4.63, 4.60, 4.61, 4.65 mmol/l concomitant with Statin use rising from 15, 23, 18, 7 to 61, 61, 67, 54 %. Triglyceride mean levels reduced from 1.95, 1.96, 2.77, 2.05 to 1.71, 1.75, 2.04, 1.72 mmol/l.

HDL cholesterol initial means 1.28, 1.27, 1.20, 1.24 rose to 1.46, 1.44, 1.33, 1.40 mmol/l.

Systolic BP initial means 135.4, 142.5, 139.0, 139.5 fell to 133.8, 140.1, 136.6, 135.9 mm Hg and diastolic BP 78.9, 79.1, 83.0, 83.2 fell to 76.1, 76.0, 79.1, 79.3 concomitant with ACE inhibitor use rising from 35, 46, 55, 48 to 51, 63, 75, 72%.

Urinary albumin/creatinine median values 1.4, 1.0, 2.7, 3.5 became 1.4, 1.2, 1.7, 3.1mg/mmol.

Current smoking 4.5, 8.5, 27.5, 15.7 reduced a little to 4.2, 8.0, 21.8, 12.2 %. The changes were linear over the five years of annual reviews except for urinary albumin/creatinine ratio which tended to fall a little then rise.

Conclusions: The closing of the ethnic differences in serum lipids and the fairly uniform BP response to intervention establish that ethnic differences can be reduced and even abolished. That these successes depend on pharmacotherapy rather than life style change raises the need for better ways of addressing the unresolved differences in weight, and smoking in particular, but also in glycaemic control where both more lifestyle coaching and more intense pharmacotherapy may be required.

D-0718

The association of fat distribution and components of the metabolic syndrome in the mixed ancestry population of South Africa

T. Matsha[1], F. Abrahams[1], J.D. Soita[2], M.S. Hassan[2], R.T. Erasmus[3]

[1] *Cape Peninsula University of Technology, Biomedical Sciences, Cape Town, South Africa*

[2] *Cape Peninsula University of Technology, Nursing and Radiography, Cape Town, South Africa*

[3] *University of Stellenbosch, Chemical Pathology, Cape Town, South Africa*

Background: The metabolic syndrome (MS) is currently one of the major challenges facing public health globally. The consensus risk factors are raised triglyceride levels, increased blood pressure, raised plasma fasting glucose or reduced high-density lipoprotein (HDL) levels. The waist circumference and/or waist-to-hip (WHR) ratio are commonly used as indicators of fat distribution and are consequently a measurement for the risk of MS. However, differences in body structure of various ethnic groups have been observed. For example, in Caucasians a larger hip circumference is dissociated with MS. The unique Mixed Ancestry population of South Africa is a combination of European settlers and the indigenous Africans and may therefore have different associations altogether. The objective of this study was to investigate the association of fat distribution as measured by waist circumference, hip circumference, Body Mass Index (BMI), and skinfold thickness with various components of MS such as blood pressure and lipid levels.

Methods: The Bellville South Study is a cross-sectional and prospective study of the Mixed Ancestry population of South Africa. In this study we analyzed the risk factors for MS in 600 randomly selected Mixed Ancestry individuals. The waist circumference, hip circumference, BMI, blood pressure and lipid levels of the participants were determined. Linear logistic regression analysis was used to study association of fat distribution with lipid levels and blood pressure.

Results: The serum cholesterol, low-density lipoproteins (LDL) and HDL levels were significantly higher in females than in males ($P = 0.01$). Lipid levels increased with age except for the HDL levels in males which were similar for all age groups. In a logistic regression model with BMI, waist circumference, hip circumference and WHR as continuous variables, the waist circumference was associated with higher triglyceride levels ($P < 0.01$) while the hip circumference showed an opposite effect ($P = 0.01$). The reverse was observed with regards to HDL-cholesterol. Waist circumference was negatively associated with HDL-cholesterol ($P = 0.007$) whilst the hip circumference was positively associated ($P = 0.020$). Waist circumference, BMI and supra-iliac were positively associated with systolic and diastolic blood pressure ($P < 0.05$), whilst the hip circumference and triceps were negatively associated ($P < 0.05$).

Conclusion: As reported in Caucasian and other ethnic groups a larger hip circumference had a protective effect on some components of the metabolic syndrome. The present results suggest that the hip circumference be included in the assessment of the risk for metabolic syndrome in this population.

Increasing incidence and prevalence with limited survival gains among rural Albertans with diabetes: a retrospective cohort study, 1995 - 2006

J.A. Johnson[1], S.U. Balko[1], G. Hugel[1], C. Low[2], L.W. Svenson[3]

[1] *University of Alberta, School of Public Health, Edmonton, Canada*

[2] *University of Alberta, Faculty of Medicine and Dentistry, Edmonton, Canada*

[3] *Alberta Health and Wellness, Surveillance and Environmental Health Branch, Edmonton, Canada*

Aims: To compare recent trends of diabetes prevalence, incidence and mortality between men and women living in urban and rural Alberta, Canada.

Methods: We tracked population trends in diabetes in adults based on diagnostic codes from provincial administrative health records from 1995 to 2006. Location of residence was defined by registered postal codes. Sex-stratified logistic regression with interaction terms were used to compare increases in rates over the past decade by location of residence, adjusting for age. Status Aboriginals were excluded from these analyses.

Results: Men living in rural residences had the greatest increases in prevalence, at 61%, from 3.6 per 100 in 1995 to 5.8 per 100 in 2006, compared to a 55% increase in urban men, from 3.9 per 100 in 1995 to 6.0 per 100 in 2006 ($p<0.001$). Prevalence among women increased by 50%, regardless of location. Diabetes incidence in rural men increased 61% while urban men had a similar increase of 59% ($p=0.177$). Incidence was lower in women in both urban and rural locations, at 5.6 and 5.3 per 1000 in 2006, representing increases of 51% and 49%, respectively. Overall mortality rates decreased by 34% for urban men and 8% for rural men with diabetes ($p=0.006$). Women with diabetes living in rural areas had no decline in overall mortality, compared to a 28% reduction in urban women ($p<0.001$).

Conclusions: Diabetes prevalence remains highest in men, with the greatest increases seen in men living in rural residences. While mortality rates have declined substantially over the past decade for those with diabetes living in urban settings, declines in mortality in rural areas have been much more modest (for men) and non-existent (for women). Our results suggest the need for improved health promotion and access to appropriate treatment for the growing number of people living with diabetes in rural areas.

Agreement between the Canadian community health survey and the national diabetes surveillance system for identifying diabetes patients in Newfoundland and Labrador, Canada

M. Murphy[1], J. Dowden[1]

[1] *Newfoundland and Labrador Centre, Research and Evaluation, St. John's, Canada*

Aims: The specific objectives of this study are to

1. estimate the accuracy of the Canadian Community Health Survey in identifying diabetes cases as compared with the National Diabetes Surveillance System for the population aged ≥ 25 years,
2. assess sensitivity, specificity, positive predictive value, and negative predictive value of the Canadian Community Health Survey using the

National Diabetes Surveillance System as the gold standard for the population aged ≥ 25 years.

Methods: This study linked the National Diabetes Surveillance System (1998-2005) to the 2001, 2003, and 2005 Canadian Community Health Survey share files via health care number. The sample included individuals aged 25 years and older. The prevalence of diabetes from the National Diabetes Surveillance System and the Canadian Community Health Survey were compared and the sensitivity, specificity, positive predictive value, and negative predictive value of the Canadian Community Health Survey using the National Diabetes Surveillance System as the gold standard were determined.

Results: Among people aged 25 years and older, overall agreement between the Canadian Community Health Survey and the National Diabetes Surveillance System was substantial (Kappa = 0.71). Self-reporting of diabetes in the Canadian Community Health Survey was 72% sensitive and showed 98% specificity. Positive predictive value was 77% and negative predictive value was 97%.

Discussion/conclusion: This study highlights the importance of having correct estimate of diabetes prevalence for surveillance, research and planning purposes. These findings can support public health decision-making related to diabetes prevention and management.

Monitoring diabetes outcomes across Europe, and beyond: the EU DG SANCO funded EUBIROD project

F. Carinci[1], M. Massi Benedetti[1], EUBIROD Consortium[3]
[1] Serectrix, Health Systems Research, Pescara, Italy
[2] University of Perugia, Internal Medicine, Perugia, Italy
[3] European Commission, DG-SANCO, Brussels, Belgium

Aim: The EUBIROD project, co-funded by the European Commission, started in September 2008 to implement a sustainable European Diabetes Register through the coordination of existing national/regional frameworks and the systematic use of the BIRO technology. A total of 22 participants from 20 European states, plus the Dasman Institute from Kuwait, will be connected through a system that will safely collect aggregated data and produce systematic EU reports for diabetes indicators, to be used for decision support in public health.

Methods: The workplan includes the following tasks: secure and privacy-safe data collection; development of epidemiological techniques to compute standardized diabetes indicators; development of a customized toolbox to facilitate the connection process and the transfer of technology; dissemination and training through the activity of BIRO Academy, which will establish an e-learning platform and residential training courses; evaluation, made by international experts, of completeness and information content of the statistical reports.

Results: By August 2011 the project will ensure the establishment of a stable network for data exchange at the international level and the creation of a common framework for standardized measurements whose users will be specifically trained. The main result arising from the project will be the annual production of the European Diabetes Report, consisting of an analysis of quality of care and outcomes in diabetes using standardized criteria on top of a database of over 500,000 subjects. The report will include a discussion of the results, targeted at providing valuable input for European policy makers, health care and scientific organizations, citizens.

Conclusion: The EUBIROD project further develops the platform established by BIRO and EUCID, whose results have raised the interest of the European Commission. The project will progress the construction of a unique diabetes information system that can be used in Europe and beyond, realizing a possible model for the automatic production of global IDF reports. Using administrative data to define diabetes cases in children and youth

E. Cummings[1], L. Dodds[1], C. Cooke[2], Y. Wang[2], A. Spencer[3], M. Dunbar[4], Z. Karlovic[4], N. MacDonald[1], G. Kephart[2]
[1] IWK Health Centre, Pediatrics, Halifax, Canada
[2] Dalhousie University, Community Health and Epidemiology, Halifax, Canada
[3] IWK Health Centre, Perinatal Epidemiology Research Unit, Halifax, Canada
[4] DOH, Diabetes Care Programme of NS, Halifax, Canada

Background: Analysis of administrative data to monitor trends in diabetes (DM) prevalence and outcomes is an important tool used to inform practice and policy. The National Diabetes Surveillance System (NDSS) is a network of regional DM surveillance systems that compiles person-level administrative healthcare data for DM in Canada. The case definition, requiring that an individual have either 1 hospitalization or 2 medical claims coded as DM within 2 years, may not function optimally in populations with lower DM prevalence, such as those <20 yrs of age, where the impact of false positives will be amplified.

Aims: The objective of this project is to explore and validate DM case definitions in those <20 years in the province of Nova Scotia(NS) Canada.

Methods: The administrative database consists of provincial physician billing and hospital discharge files, containing comprehensive information about insured health services delivered to residents of NS since 1989. Health care in the province is publicly funded. Case definitions studied in this dataset were compared with provincial Registry data, considered the gold standard. The Diabetes Care Program of NS maintains a centralized Registry of individuals attending Diabetes Centres in NS. Incident DM cases for the < 19 years population are validated annually and capture is near complete in this age group (n=1235 for 1996-05). Datasets for 1996-2005 were linked using encrypted unique identifiers. Various algorithms were examined to determine the optimal case definition, including varying the number of DM codes required, time period, age, and number of diagnostic fields used to optimize sensitivity, specificity, positive and negative predictive value of the case definitions.

Results: The optimal case definition was 1 hospitalization or 2 MD visits in 1 year with exclusion of infants <4 months of age, using 3 diagnosis fields for hospitalization and 1 for MD visits with a sensitivity of 87.31% and specificity 99.92%. Given an estimated population prevalence of 0.0033, the positive and negative predictive values are 78.69% and 99.96% respectively. Extension of the time period to 2 or 3 years increased false positives without improving sensitivity. Addition of diagnosis fields was not beneficial. False negative ($p<0.05$) and false positive ($p<0.001$) cases were strongly associated with age group 16-20 years.

Conclusions: DM case definitions for individuals <20 years are adversely affected by accumulation of false positives. Even our optimal case definition only had a positive predictive value of 79%, making this method of finding cases in administrative data prone to unacceptable levels of error. All case definitions performed especially poorly in the 15-19 year age group. Registries will provide the most reliable source of identification of DM cases in this age group.

D-0723

Do geographical disparities affect the pattern of medication use in diabetic patients?

S. Asghari[1], J. Courteau[1], C. Drouin[1], M.G. Orzanco[1], A. Vanasse[1]
[1] University of Sherbrooke, Family Medicine, Sherbrooke, Canada

Aims: The purpose of this study was to describe and understand the geographic variations in anti-diabetic medication use in the diabetic population in Quebec as recommended by national diabetes guidelines.

Methods: An exhaustive cohort of diabetics between 1997 and 2002 was constructed using the Quebec provincial health service database. Diabetes cases were determined using the Canadian National Diabetes Surveillance System's definition for administrative data. Patients were included if they were 20 years or older, living in Quebec and covered by the public drug insurance. Patients who were hospitalized or died during the one-year follow-up and patients who had gestational diabetes were excluded. The level of anti-diabetic medication use was measured using medication possession ratio (MPR) and categorized into: Regular users, for patients who filled prescriptions for a period of time covering at least 292 days (80% of the time); irregular users, for patients who filled at least one prescription but for a period of time less than

292 days; and non-users, for patients with no prescription filled. The level of anti-diabetic medication use was computed and mapped by age, sex and living area (Statistics Canada definition). Multinomial logistic regression was used to show variables associated with drug use categories.

Results: Among the 155,646 diabetic patients (mean age: 63 years ± 13) covered by public drug insurance, 34% never claimed an anti-diabetic prescription during the study period, 44% regularly claimed diabetes medications. Multinomial logistic regression showed that regular use of medications was positively associated with increasing age (P<0.0001) and living in a rural area (P<0.0001). Regular users were more likely to live in rural areas compared to irregular users (OR 1.26; 95% CI: 1.22-1.30) and compared to non-users (OR 1.10; 95% CI: 1.06-1.12).

Conclusion: Despite similar insurance coverage and drug benefits, geographic variations in the medication use among diabetic patients exist. After controlling for age and gender, diabetic patients living in urban regions were less likely than those in rural regions to use regular drug treatment for diabetes. However, these disparities may not be related to variations in the quality of available care and should be interpreted with caution.

D-0724

Populations in transition: how to measure the dietary component ?

E. Counil[1], M.L. Château-Degat[1], A. Ferland[1], E. Suhas[2], R. Teyssou[2], E. Dewailly[1]

[1] CHUL- Research Centre Laval University, Population Health and Environment, Québec, Canada

[2] Institut Louis Malardé, ILM, Papeete, French Polynesia

Aims: The «dietary transition» that accompanies rapid social change has been related to increased prevalence of obesity and type 2 diabetes worldwide, and in particular among aboriginal populations. Instead of using individual food/nutrient consumptions or complex dietary patterns as a measure of dietary changes over time, age and space, we propose a simple score developed in the framework of the «Dietary and health transition in French Polynesia» study.

Methods: Austral-born, Maohi participants aged 12-88 years (n=232) answered a 24-groups FFQ and one 24h-recall with 30% of replicates. We measured the fatty acid profile of red blood cell (RBC) membrane phospholipids as a surrogate for individual intakes of PUFA and trans-fatty acids. We calculated a «dietary transition score» (DTS) based on the sum of food frequency scores: local foods scored positively while store-bought-foods scored negatively. We compared scores across three age groups (12-17 years, 18-49 years, 50 years+) and two communities (urban-Papeete and rural-Tubuai) in order to assess generational as well as urban-rural gradients. We also measured fasting plasma glucose (FPG) and insulin (FPI), whole blood selenium, body composition, and urinary sodium and iodine.

Results: DTS varied greatly according to age: from -61.0±58.8 in teenagers to 12.3±52.9 in elders (p<0.0001), and community: -5.33±63.0 in rural-Tubuai and -33.9±62.7 in urban-Papeete (p=0.0006). There was a positive linear trend from teenagers in Papeete to elders in Tubuai. Total energy, carbohydrates, total fat, cholesterol as well as sodium intakes were higher in the 1st as compared to the 3rd DTS tertile. Moreover, DTS correlated positively with urinary iodine, whole blood selenium, marine omega-3 fatty acids in RBC, and negatively with omega-6 and trans-fatty acids as well as urinary sodium. Concomitantly, DTS correlated negatively with FPI, even after adjustment on age. As a negative score is indicative of a greater importance of «store-bought» as compared to «local» foods in the diet, this suggests that Maohi teenagers and those living in a urban environment are at a more advanced stage of dietary transition, which we found corresponds to generally less favorable nutrient intakes and higher FPI levels.

Conclusion: The simple dietary transition score we propose captures generational and geographical differences in food consumption patterns that may be relevant to the study of the ongoing health transition, in particular regarding early stages of insulin resistance and diabetes, in French Polynesian Maohi and other populations facing social change. This is of particular interest if at-risk groups are to be identified in order to propose relevant primary prevention programs regarding obesity and type 2 diabetes.

[2] Eli Lilly and Co, Global Health Outcomes, Indianapolis, USA

[3] MRC Biostatistics Unit, University of Cambridge, Cambridge, United Kingdom

[4] Atlanta Diabetes Associates, Atlanta, Georgia, USA

[5] Endocrine Associates, Dallas, Texas, USA

Aims: Recent advances in anti-CD3 monoclonal antibody therapies offer the prospect of the amelioration of type 1 diabetes (T1DM). The present study was designed to understand the preferences of people with T1DM regarding different profiles of infusion therapy. A discrete choice experiment (DCE) was used in a survey of T1DM patients in the UK.

Methods: The optimal dosing schedules and likely benefits of infusion therapies in T1DM are currently being established in clinical trials. The current survey was designed to capture the preferences of people with T1DM regarding the length of infusion cycles, frequency of cycles, duration of benefit and nature of benefit. Levels for each attribute were based on current expert opinion and were combined into choice sets using fraction orthogonal design which had been folded over. Pairs of choice sets were presented to adults with T1DM who indicated which they preferred. Data were analysed using the conditional logit procedure.

Results: The results are expressed as odds ratios for ease of interpretation. Participants (*N*=49) preferred shorter and less frequent treatment cycles, longer duration of treatment benefit and preferred no insulin at all to a reduction in either basal or prandial dosing alone.

Conclusion: This survey shows the value that people place on a therapy that can reduce or eliminate the need for insulin therapy. This was a powerful driver of participants' choices even when treatment involved lengthy cycles of therapy on a frequent basis. The results indicate we believe that people understood the issues related to infusion therapy in diabetes despite never having experienced it.

Prevalence of diabetes in a population based survey: preliminary results

N. Phaswana-Mafuya[1], K. Peltzer[2], M. Schneider[3], M. Makiwane[3], K. Zuma[2], C. Tabane[2], A. Davids[1], M. Mbelle[2], G. Matseke[2], S. Ramlagan[2], K. Phaweni[2]

[1] *Human Sciences Research Council, Social Aspects of HIV/AIDS and Health, Port Elizabeth, South Africa*

[2] *Human Sciences Research Council, Social Aspects of HIV/AIDS and Health, Pretoria, South Africa*

[3] *Human Sciences Research Council, Child Youth Family and Social Development, Pretoria, South Africa*

Aim: To assess the prevalence of diabetes by self-report (SR), percentage on current (past 2 weeks) therapy (CTx) and recent (last 12 months) therapy (RTx) by selected demographic characteristics using a portion of the preliminary results of the first ever national survey on ageing and health (SAGE) in South Africa.

Methods: A population-based representative household face-to-face survey was conducted in South Africa involving 4897 individuals from 4083 households. The survey instruments were based on the World Health Survey, with substantial revisions and additions based on a review of other major large ageing surveys, cognitive testing of a draft survey instrument and recommendations from a group of experts. The instruments include a standardized questionnaire including self-reported and objective health measures such as performance tests, anthropometry and biomarkers.

Results: Diabetes was reported by 6.72% of men (87.80% on CTx and 83.75% on RTx) and 10.57% of women (84.25% on CTx and 82.98% on RTx). In terms of age group, self-reported prevalence was 3.08% (75% on CTx and 75% on RTx) for participants aged 18-49 years, 7.73% (81.31% on CTx and 79.05% on RTx) for those aged 50-59 years, 11.72% (87.83% on CTx and 86.09% on RTx) for those aged 60-69 and 12.09% (87.95% on CTx and 85.54% on RTx) for those aged 70+ years. Self-reported prevalence was 11.84% in urban areas (85.35% on CTx and 82.80% on RTx) and 4.74% in rural areas (84.72% CTx; 81.95% RTx). In terms of marital status, self-reported prevalence for never married was 7.28% (90.48% CTx; 88.10 RTx), for currently married was 9.30 (84.55% CTx; 80.99% RTx), for cohabiting was 4.07% (75% CTx; 75% RTx), for separated/divorced was 6.20% (88.24% CTx; 82.35% RTx) and for widowed was 12.27% (84.13% CTx; 84.13% RTx)

Discussion and conclusion: Self-reported diabetes prevalence is high among women. Diabetes prevalence increases with increasing age, is high in urban and is lowest among individuals who are co-habiting. These self-reported results will be compared with subsequent HbA1c test results (not reported here). Although these preliminary results are only based on self-reported information, they indicate the need to develop health promotion programmes that take into consideration gender, age, place of residence and marital status. These findings have implications for health service delivery.

Projecting the long-term outcomes in previously insulin-naïve patients with type 2 diabetes after insulin initiation with biphasic insulin aspart 30/70: a subgroup analysis of the IMPROVE™ study

J.G. Gumprecht[1], T.E.C. Christensen[2], T.L. Thomsen[2], M. Benroubi[3]

[1] *Medical University of Silesia, Department of Internal Medicine Diabetology and Nephrology, Zabrze, Poland*

[2] *Novo Nordisk A/S, Global Marketing, Virum, Denmark*

[3] *Athens Polyclinic General Hospital, Diabetes, Athens, Greece*

Aims: The IMPROVE™ study documented significant improvements in clinical endpoints after 26 weeks of biphasic insulin aspart 30/70 (BIAsp 30) treatment in a routine care setting. Based on data from the IMPROVE™ study the objective of the present analysis was to project the long-term clinical outcomes in type 2 diabetes patients previously only treated with oral antidiabetic agents (OADs), when initiated with BIAsp 30.

Methods: The IMPROVE™ study evaluated clinical outcomes in 52,419 patients after 26 weeks of treatment with BIAsp 30. Background and treatment data from 33,797 insulin-naïve patients previously treated with OADs were used in the present analysis. A validated computer simulation model of diabetes epidemiology (the CORE Diabetes Model) was used to make long-term projections of clinical outcomes based on patient characteristics (mean age 55.9 years, duration of diabetes 7.4 years, HbA_{1c} 9.2%, BMI 26.3 kg/m^2). In the model, patients were assumed to either continue on OADs or obtain the treatment effects of BIAsp 30 (HbA_{1c} improvement of 2.1 percentage points and 0.1 kg weight loss) observed in the IMPROVE™ study.

Results: The improved glycemic control with BIAsp 30 led to a projected delay in the onset of any diabetes-related complications of 0.7 years (2.1 vs. 1.4 years for BIAsp 30 and OAD respectively), e.g. the projected delay of myocardial infarction and stroke were 1.8 and 1.5 years, respectively. The cumulative incidence of complications was projected to decrease with BIAsp 30 in the majority of parameters studied, e.g. the cumulative incidence of severe vision loss was projected to decrease by 10.9% (1.1 %-point absolute risk reduction) and stroke by 6.2% (0.7 %-point absolute risk reduction). The average life expectancy was projected to increase by 1.5 years.

Conclusion: The long-term health outcome projections based on surrogate endpoints reported in the IMPROVE™ study, indicate that initiating treatment with BIAsp 30 in patients with type 2 diabetes rather than continuing on OADs will improve life expectancy, delay the onset of diabetes-related complications, and reduce their cumulative incidence over patient lifetimes.

Low compliance to statins in Kerala rural population(DIABSCREEN KERALA-14)

J. Kesavadev[1], J. Shamsudeen[1], G. Dinkar[1], S. Jothydev[1], A. Shankar[1]

[1] *Jothydev's Diabetes and Research Center, Diabetes, Trivandrum, India*

Cardiovascular factors rank first as major cause of mortality in diabetes. Intensive glycemic management has not yet proven clear benefits in preventing macrovascular complications of diabetes as seen in UKPDS, ACCORD etc., Diabetes is a coronary risk equivalent and there is undisputed evidence that dyslipidemia of any form should be aggressively managed. However widespread use of statins, despite scores of published supporting scientific data, is limited due to various factors. WHO estimates that 60% of the world's cardiac patients will be Indians by 2010. Nearly 50% of CVD-related deaths in India occur below the age of 70, compared with 22% in the West.

Diabscreen Kerala is a major project of P Kesavadev trust operating among the rural & urban population of Kerala. It includes free diabetes screening, interactive education and treatment with special focus on lifestyle modifications. The Diabscreen team consists of doctors, nurses, dieticians and other trained healthcare professionals. Apart from anthropometric measurements, blood is drawn for lab tests.

Of the 2877 participants from selected Diabscreen camps conducted in rural Kerala, 73% were found to be known diabetes subjects. Of these 28% had cholesterol > 220 mg% and were already prescribed statins at one time or the other by their treating physicians. Among these only 2.4 % were on steady medications while others discontinued.

Our Diabetes Care Team decided to analyze the non compliance by carrying out patient interviews with open-ended questions. The qualitative analysis of interview excerpts showed a mixed response.

Unnecessarily on an extra drug with no existing symptoms	46%
Misconception on adverse affects on kidney & liver function	28%
Took for 2-3-months and discontinued	17%
Cost of Statins	13%
Miscellaneous causes.	6%

Even among the educated patients, some kept away from ideal compliance due to the escalating cost of statins. Other aspects were patient negligence towards treatment as the disease was asymptomatic; the patient felt 'why take an additional drug unnecessarily'; misconceptions on the long term adverse effects of the drug such as damage to 'liver and kidney'; discontinuation of drugs when they found that lipids are in the normal range.

Over 80% of CVD deaths take place in low- and middle-income countries. By 2015, almost 20 million will die from CVDs, mainly from heart disease and stroke. These are projected to remain the single leading causes of death.

It is important that conventional risk factors for CVD like hypertension, smoking, sedentary life styles etc., have to be addressed. However in diabetes, statins are mandatory considering the economics of prevention of CVD.The poor compliance to statins calls for urgent intervention through structured, aggressive educational activities and free drug distribution whenever possible.

The relationship between diabetes mellitus and health-related quality of life in Korean adults: the Korea National Health and Nutrition Examination Surveys 2007

D.J. Kim[1], H.J. Kim[1], S.J. Han[1], Y.S. Chung[1], K.W. Lee[1]
[1] Ajou University School of Medicine, Endocrinology and Metabolism, Suwon, Korea

Aims: This study examines the relationship between diabetes mellitus and health-related quality of life (HRQL) in Korean adults and investigates the associated factors for decreasing HRQL in Korean diabetic patients.
Methods: A total of 2,644 participants (1,101 men, 1,543 women) aged 30 years or over in the 2007 KNHANES survey were included. HRQL was measured by the EQ-5D and EuroQol visual analogue scale (EQ-VAS). Mean age was 53.1±14.7 years and the prevalence of known diabetes was 8.0% (n=211). The EQ-5D utility scores were calculated by assigning utility scores to each of the health states in Korean adults.
Results: Mean EQ-VAS was 70.03±18.43 and mean EQ-5D score was 0.90±0.15 of total subjects. Compared to non-diabetic subjects, diabetic patients had a lower HRQL according to the EQ-5D (0.80±0.21 vs. 0.91±0.14, p<0.001) and EQ-VAS (60.5±21.8 vs. 70.9±17.9, p<0.001) after controlling for other related factors of age, sex, household income, and educational level. Among known diabetic patients, the associated factors for decreasing EQ-VAS were household income (beta=0.186, p=0.010) and sex (beta=-0.164, p=0.023), and the associated factors for decreasing EQ-5D were age (beta=-0.367, p<0.001) and sex (beta=-0.196, p=0.003).
Conclusion: Diabetes mellitus is associated with a lower HRQL, even after controlling for major associated factors of age, sex, household income, and educational level.

Diabetes: the stubborn friend

M. Ahmad Adel[1]
[1] ECHEM, Investment, Cairo, Egypt

You might have been confused once you've read the title, I am sure a query like a new bad experience with Diabetes will be read, but I can consistently assure you that, after having this long relationship with Diabetes, I entirely believe that Diabetes was and will remain my lifetime best friend.
It was in 1992, when Diabetes first knocked my door and I was 9 years old, my family were extremely shocked, worried, and afraid! But they were sure that GOD Almighty tests us through this new comer. It was definitely not impressive receiving this Diabetes stranger who has just landed suddenly, without any prior notice or alert.
I returned back to school, shocked, in denial and loaded with vials of insulin and syringes, but over the years diabetes has gone from uninvited guest to just a part of who I am. For over the years, in moving from denial to acceptance, I learned how to live with it, and I do that well now.
Fortunately, during my early relationship with Diabetes, I was treated by a doctor who knows how to deal PSYCHOLOGICALLY with his patients, knows how to kick out any fear of Diabetes from the patient's family. He was one of the vital reasons that made Diabetes my Best Friend
If I am always going to be serious about taking good care of my Diabetes friend, this will let me live very pleasantly and quietly without causing any problems or hazards for me or my family. On the other hand, if I will lose interest about caring well for my Diabetes friend, it will hit back! And will never let me live well because I will always be paying too much to keep myself as well as my Diabetes friend surviving.
My Family helps me in converting my relationship with Diabetes from being an unfavorable guest to be my best friend. This came by encouraging and supporting me for being healthier, and having a better life style. If it was not for my Diabetes friend, I believe I would have never thought of organizing my life, nor living healthily.
Also, having an excellent and helpful group of people makes me feeling better and better in controlling my Diabetes friend. I usually like to spread my experience with Diabetes to people who have no idea about it, so I've found an association which aims at introducing Diabetes to all people with a mix of scientific and social way. Last year, I did register with Diabetes Youth Care Association (DYCA). I've found an excellent group of people, who are working hard to inform the society with definition of Diabetes and definition of a Diabetic person.
DYCA had helped me to spread out my experience positively. I did record a TV short speech talking about my experience with Diabetes and how to deal and live as any healthy person.This TV speech was broadcast on the World Diabetes Day Celebration in Cairo.

Diabetes & tourism

M. Mounir[1]
[1] Travel Ways, Tourism, Cairo, Egypt

Throughout my study in the faculty of Tourism, I was not paying attention to medical issues such as Diabetes mellitus. For example when I open my T.V. watching medical program discussing diabetes mellitus types, symptoms, how to control I was easily able to switch to another channel. I was just feel pity when I heard about that type which begin at young age, wondering how these young people can cope with their illness.
They inject themselves everyday, they can't go out having fast food & desserts they like to have.They are all the time expecting complications.
But, it took me few minutes to think about this then back again to my life.
Then I had graduated & started my work in the field of tourism & get engaged.
After that an event happened in my life which changed a lot of my plans that I had to travel abroad & stay a long period of time away from my country, family, friends, fiancée.
I traveled already against my will, but I had to do this for the sake of our care together, that put me in very stressful condition I suffered a lot & I decided to get back to my country again.
When I get back I discovered that I had high blood glucose level & I had type I as my doctor told me afterwards.
I was shocked took me sometimes denying that I had this problem, then with help of my family I started to think how I am going to cope with this.
I started to follow my doctor instructions, learning new procedures which was new for me such as injecting myself insulin, diet instructions.
I started to read, search in the internet information about it.
More over my information about diabetes mellitus started to be reflected on my work as tour operator, I started to think about remedies & ideas that can help my tourists to enjoy their trips while they are controlling Diabetes well.
As tour operator, I am responsible of arranging tours programs including accommodations, tour sight seeing visiting, etc…
I started to ask our travel agents which I deal abroad to notify me about there is diabetic patients among the groups coming to us to arrange with the hotels for special requirements in diet for them.
In addition, I talked with one the hotel duty manger about the possibility of specifying corner in the dining room that fit with diabetic patients.
Before sight seeing tours I tried to give them full information about details of that day for the importance of good diabetic control because it require an extra effort.
I made suggestion to my boss about giving our tour leaders emergency course to how to deal with medical emergency that could happen during the trip esp. Diabetic coma.
My interest in this subject had emerged from my personal experience in that so I doing my best to know better about my disease and lower my customers suffering helping them to enjoy more with good health.

Coping processes in people living with Diabetes Mellitus: experiences and challenges

L. Ledon-Llanes[1]
[1] National Institute of Endocrinology, Psychology, Ciudad de la Habana, Cuba

Aims: Coping processes are important to consider in the context of health care services of people living with Diabetes Mellitus, because they are related to other categories and dimensions related to psychological stability and the way of living of individuals and groups. Besides, it expresses the active role of the human being in its quotidian life, and it can even palliate the adverse effects of distress over health. This work intends to show how this field has been approached and the multiple dimensions are related to them, particularizing over socio-cultural aspects and sharing our research and assistance experience.
Methods: Scientific review about the field integrated to studies carried out by the author and to assistant experiences with people living with Diabetes Mellitus in psycho-social field.

Results: The work points out over the relevance of social support as one of the most important coping strategies in the process of living with Diabetes, mainly when this social support comes from family, health providers and other people living with Diabetes. According to the author's experience, there appeared some "problematic" moments during the process of living with Diabetes: the debut of the illness, the metabolic instability, and the presence of "complications". The more difficult aspects to cope with in the process of living with Diabetes are how to modify life styles, how to "accept" living with Diabetes and when needing to use insulin.

Discussion/conclusions: The work ends sharing comments and recommendations considered important to enhance active coping processes that promote wellbeing and quality of life in people living with Diabetes.

Type 1 diabetes impairs muscle growth and absolute force production in developing skeletal muscle

C.S. Gordon[1], M.P. Krause[1], E. Cafarelli[1], T.J. Hawke[1], M.C. Riddell[1]
[1] York University, Kinesiology and Health Science, Toronto, Canada

Background: Type 1 diabetes mellitus (T1DM) is often diagnosed in childhood, a time of growth and development. Studies into the effect of T1DM on growing skeletal muscle are limited, and those that have been performed have largely used the streptozotocin model. Unfortunately, streptozotocin itself directly causes myopathy independent of hypoinsulinemia/hyperglycemia.
Purpose: Thus, the purpose of this study was to utilize a non-pharmacological, partial pancreatectomy (Px) model to investigate the effects of T1DM on the properties of young skeletal muscle.
Methods: Male Sprague Dawley rats (5 weeks old) were randomly assigned to Px or Sham-surgery groups. At 4 or 8 weeks rats underwent *in situ* muscle stimulation to assess skeletal muscle force production and fatigue rates, and tissues were collected for further analyses.
Result: Px rats with significant elevations in glycemia (fasting >20mM) had lower body mass at the time of sacrifice vs Sham (4wk: 270±9 vs 341±7g; 8wk: 349±21 vs 484±10g, both p<0.05). Gastrocnemius-plantaris-soleus (GPS) mass was also reduced with T1DM at 4 and 8 wks compared to Sham (4wk: 1.2±0.06 vs 1.9±0.03g; 8wk: 1.8±0.1 vs 3.3±0.1g; both p<0.01). While Sham muscle grew 46% between 4 and 8 weeks, Px muscle growth was significantly attenuated during this time (only 27%, p<0.05 vs Sham). The reduced mass of T1DM muscle resulted in reduced absolute maximal force (F_{max}) production (4wk: 10±0.8 vs 15±1.6 N; 8wk: 23±1.8 vs 12±1.3N, both p<0.05). Stimulation of the GPS at ~50% F_{max} (2 min, of 3 sec stimulation, 3 sec rest) demonstrated a reduced rate of force decline in Px compared to Shams at both 4 and 8 wks (4wk: 61±4.5 vs 75±4.5%; 8wk: 53±3.4 vs 70±7.2% respectively; both p<0.05). Morphometric analysis demonstrated that Sham increased fiber size more than Px in both type IIa (69% vs 26%) and IIb/d (59% vs 15%) fibers, but not type I fibers (36% vs 21%).
Conclusion: Taken together, these data suggest that sustained hyperglycemia/hypoinsulinemia in young skeletal muscle significantly impairs growth and force production, primarily as a result of attenuated growth of type II fibers. This impairment may help to explain the functional defects including low aerobic capacity frequently observed in youth with poorly controlled T1DM.
This research was funded by NSERC.

Association of C242T polymorphism of NADPH oxidase p22phox and I/D polymorphism of angiotensin converting enzyme with diabetes complications and cardiovascular risk in patients with type 1 diabetes

R.A. Cobas[1], I. Palermo[1], M.B. Gomes[1], M.T. Marques[2], L.C. Porto[2], R. Neves[3], D. Crispim[4], L.H. Canani[5]
[1] State University of Rio de Janeiro-UERJ, Diabetes Unit, Rio de janeiro, Brazil
[2] State University of Rio de Janeiro-UERJ, HLA laboratory, Rio de janeiro, Brazil
[3] State University of Rio de Janeiro-UERJ, Ophthalmology division, Rio de janeiro, Brazil
[4] Federal University of Rio Grande do Sul, Genetic Department, Porto Alegre, Brazil
[5] Federal University of Rio Grande do Sul, Endocrinology Division, Porto Alegre, Brazil

Background and aims: Patients with type 1 diabetes (T1DM) present high morbidity due to its chronic complications, and genetic factors may lead to a higher individual susceptibility. In this cross-sectional study we aimed to investigate the association between C242T p22phox from NADPH oxidase and I/D angiotensin converting enzyme (ACE) polymorphisms, and the presence of microvascular diabetic complications and cardiovascular risk factors in patients with T1DM, and to compare genotype distributions between non diabetic subjects (controls) and diabetic patients.
Methods: Patients were evaluated for diabetic nephropathy and retinopathy, arterial hypertension, overweight/obesity, lipid levels, glycemic control, levels of C-reactive protein (CRP). DNA was isolated from lymphocytes from patients (n=128 for ACE analysis and n=93 for p22phox analysis) and controls (n=202 for ACE analysis and n=163 for p22phox analysis) using standard extraction technique. Genotype analysis was performed using Polymerase Chain Reaction for ACE I/D, followed by specific Rsa I restriction for p22 phox C242T polymorphism. P<0.05 was considered statistically significant. Data are shown as mean ± SD.
Results: Patients with T1DM were 28± 11.4 years old, 51.6% females, with duration of diabetes of 11.2 ± 8.2 years. The relative frequencies of the I/D ACE and C242T p22phox alleles were not different between controls and patients (II 15.3 *vs* 13.3 % ; DI 47.5 *vs* 51.5% ; DD 37.2 *vs* 35.%; p=0.751 and CC 50.3 *vs* 46.3% ; CT 36.8 *vs* 48.4%; TT 12.9 *vs* 5.3%; p=0.066).
Diabetic retinopathy and overweight/obesity were significantly more frequent in patients with DD genotype compared to those with II/DI genotype (33.3 *vs* 13.2%; p=0.009 and 32.6 *vs* 13.2%, p=0.034, respectively). The presence of the I allele (II/DI *vs* DD genotypes) was associated with lower levels of diastolic blood pressure (69.7 ± 12.3 *vs* 74.6± 13.1 mmHg, p=0.04). Diabetic incipient and overt nephropathy were not statistically different between patients with DD genotype compared to II/DI genotype (20 *vs* 33.3%, p=0.07). The presence of the C allele (CT/CC *vs* TT) was associated with higher levels of HDL cholesterol (50.1± 12.9 *vs* 38.2 ± 10.3 mg/dl, p=0.046). There was no association between ACE I/D or C242T p22phox polymorphisms and glycemic control, CRP levels, presence of dyslipidemia or hypertension. C242T p22phox polymorphism was not associated with the presence of diabetic retinopathy or nephropathy.
Conclusion: In our population composed of patients with T1DM the ACE I/D, but not C242T p22phox polymorphism, was associated with the presence of diabetic retinopathy and overweight/obesity as well as levels of diastolic blood pressure. This analysis may help to identify patients at higher risk for diabetes complications.

The association between basal and change of serum C-peptide levels and vascular complications in Korean T2DM patients

C. Jung[1], B. Kim[1], M. Roh[1], M. Song[2], Y. Kim[2], H. Park[3], J. Mok[1], C. Kim[1], S. Kim[2], D. Byun[3], K. Suh[3], M. Yoo[3]
[1] Soonchunhyang University Hospital Bucheon, Endocrinology and Metabolism, Bucheon, Korea
[2] Soonchunhyang University Hospital, Endocrinology and Metabolism, Cheonan, Korea
[3] Soonchunhyang University Hospital, Endocrinology and Metabolism, Seoul, Korea

Aims: C-peptide has been widely accepted as the most appropriate measure of endogenous beta cell function because it is secreted on a basis equimolar to insulin. People with type 1 diabetes and higher fasting C-peptide values had lower prevalence of microvascular complications independently of duration of diabetes, A1C, and other risk factors. But there are only a few studies regarding the association between C-peptide and vascular complications in T2DM. Therefore, the purpose of our study is to assess the association between basal and change of serum C-peptide levels and vascular complications in Korean T2DM patients.
Methods: Out of 2010 T2DM patients cared for at the diabetes clinics at Soonchunhyang Hospital in Bucheon, Korea, we recruited patients being followed up at least two years during the period 2001-2006 (n=1351). For all patients, we retrospectively reviewed the clinical records about microvascular (retinopathy, neuropathy, nephropathy) and macrovascular (CVA, CAD) complications.
Results: The mean age, duration of DM, A1C and BMI in the 1351 patients were 57 years, 6.4 years, 8.4% and 24.7±3.8 kg/m2. Mean basal fasting and stimulated c-peptide levels were 2.58±1.83 ng/ml and 6.31±4.84 ng/ml. Fasting c-peptide levels were shown significantly negative correlation with age, HbA1C, duration of DM and HDL-C and positive correlation with BP, total cholesterol, triglyceride, LDL-C and hsCRP. Patients with microvascular complication showed significantly lower levels of basal stimulated and stimulated c-peptide levels and significantly higher levels of age, HbA1C, FBS, DM duration, systolic BP and creatinine levels. The prevalence of microvascular complications were significantly higher in those in the lowest quartile of basal fasting c-peptide (retinopathy, p=0.005, neuropathy, p=0.006, nephropathy, p=0.01) but no associations were evident with macrovascular complications. Differences between baseline and last c-peptide levels were not significant correlation with microvascular and macrovascular complications.

Conclusions: Our study shows association of plasma C-peptide levels with microvascular complications not macrovascular complications in T2DM patients.

Hyperglycaemia: Effects on expression of genes affecting epithelial differentiation and vascularisation

G. Sujoy[1], A. Kolb[1], A. Collier[1], I. Malik[1]
[1] The Ayr Hospital, Diabetes Day Centre, Ayr, United Kingdom

Background: : Wound healing is impaired in patients with diabetes. It would seem sensible that good glycaemic control should improve wound healing.
Aims and objectives: To determine if there is any difference in gene expression in skin of patients with diabetes and determine whether there was any difference between good and poor glycaemic control
Materials and methods: Skin biopsies of 2 cm^2 were obtained from forearm of 3 groups of male volunteers (20-45yrs): 5 patients in each group
(i) Healthy non-diabetics (control)
(ii) Type 1 Diabetics with poor glycaemic control (HbA1c >9.5): poor control group
(iii) Type 1 Diabetics with good glycaemic control (HbA1c < 7.5): good control group
Samples were frozen immediately in liquid nitrogen and transported on dry ice. RNA was isolated and analysed by Affymetrix micro-arrays.
3 groups of genes were analysed:
1. Markers of epithelial differentiation - trichohyalin, keratin 25, keratin 27.
2. Markers of vascular endothelial smooth muscle cells - alpha actin, myosin heavy chain and tropomyosin
3. Markers of neuronal cells - Purkinje cell protein 4 and somatopodin.

Results: The genes of all 3 groups were expressed at a much higher level in healthy subjects as compared to those with diabetes with poor glycaemic control. With good glycaemic control the level of gene expression was similar to healthy controls.
Conclusions: Poor glycaemic control possibly leads to poor wound healing as a result of alteration of expression of genes responsible for epithelial differentiation and vascular smooth muscle formation.

D-0737

Vitamin D deficiency among adults with and without diagnosed diabetes, U.S., 2001-2006

G.L. Beckles[1], E.F. Tierney[1], B.L. Gunnels[1]
[1] Centers for Disease Control and Prevention, Division of Diabetes Translation National Center for Chronic Disease Prevention and Health Promotion, Atlanta, USA

The U.S. National Health and Nutrition Examination Surveys (NHANES, 1988-94) found that adults with diabetes and people from racial/ethnic groups at high risk for type 2 diabetes (t2DM) have lower levels of serum vitamin D, measured as serum 25-hydroxyvitamin D [25-(OH)D], compared to those without diabetes and non Hispanic whites. Few data exist about the prevalence of vitamin D deficiency (VitD Def).
Aims: We used recent national data to examine the association between diagnosed diabetes and VitD Def and to estimate the prevalence of VitD Def among adults with and without diabetes.
Methods: We used data from surveys of representative samples of U.S. adults (≥18 years) who participated in NHANES, 2001-2002 and 2005-2006. (No values were available for NHANES 2003-2004). Serum 25-(OH)D values were available for 15,994 participants. VitD Def was defined by criteria based on 1) studies of bone health, 25(OH)D =11ng/mL; 2) studies of non-skeletal health, 25(OH)D <20 ng/mL. Persons with diagnosed diabetes were self-identified (n=1,468). Logistic regression was used to estimate odds ratios (95% confidence intervals [CI]) for the association between diabetes and Vit Def, controlling for age, sex, race/ethnicity, education, income and body mass index (kg/m^2). The models provided adjusted predictive marginal probabilities of Vit Def. Differences were considered significant at P-values <0.05
Results: Persons with diagnosed diabetes had a nearly 2-fold higher odds of having VitD Def than those without: for serum 25(OH)D =11 ng/mL, unadjusted OR=1.88 (95% CI, 1.53-2.31), adjusted OR = 1.37 (95% CI, 1.13-1.66)(p<0.01 for both). For serum 25(OH)D <20ng/mL, ORs were of similar magnitude (p<0.01 for both). After adjustment, prevalence estimates for VitD Def among persons with and without diagnosed diabetes were: 9% vs. 7% overall, 6% vs. 3% for nonHispanic whites and 17% vs. 11% for Mexican Americans (P<0.01 for each). Prevalence was highest among nonHispanic blacks (28% vs. 31%) but did not differ by diabetic status (p>0.05). Prevalence was higher using 25(OH)D <20ng/mL but showed similar patterning.
Conclusions: Regardless of how defined, diagnosed diabetes was positively associated with increased risk of VitD Def among non Hispanic whites and Mexican Americans but not among African Americans. The implications of these findings for the health of people with diabetes require further investigation.

Expression of mitochondrial Hsp60 in blood monocytes isolated from type 2 diabetes mellitus patients

R. Martinus[1], J. Wu[2], A. Johnstone[2], P. Dunn[2]
[1] University of Waikato, Biological Sciences, Hamilton, New Zealand
[2] Waikato Hospital, Waikato Regional Diabetes Service, Hamilton, New Zealand

Aims: The objective of this study was to assess if long-term exposure to Metformin results in significant changes to the expression and secretion of Hsp60 (a mitochondrial specific stress protein) from blood Monocyte cells.
Methods: Peripheral blood mononuclear cells (PBMC) were isolated from Type 2 Diabetes Mellitus patients attending the Waikato Regional Diabetes Clinic. A total of ten patients were selected. Five were being treated on Metformin (500mg) and five patients were being managed on diet and exercise. All patients had been diagnosed within the past 2 years and were selected on the following criteria: non-smokers, not subjected to treatment by Statins, anti-inflammatory drugs or calcium beta-blockers.
Monocyte cells were isolated by percoll gradient centrifugation and checked for purity by morphological criteria and surface expression of CD14 by immuno cytochemical analysis.
Expression of Hsp60 was determined by RT-PCR and normalised to the house keeping gene GAPDH
Results: We show for the first time that at mRNA level the expression of mitochondrial Hsp60 is significantly higher in primary monocyte cells from Type 2 DM patients being treated on Metformin (500mg) compared to patients being managed on diet and exercise. The HbA1c levels (range 5.9% to 8.4%) at time of blood collection for the Monocyte assays were similar for both cohorts, indicating that the levels of Hsp60 expression seen in Monocyte cells was unlikely to be related to changes in glucose homeostasis.
Conclusions: Metformin is known to be an inhibitor of complex 1 of the mitochondrial respiratory chain. Since the expression of Hsp60 is an indicator of mitochondria stress, our results suggest that long-term use of Metformin (via Hsp60 expression) may indeed exacerbate mitochondrial related processes already compromised in diabetic patients.

Decreased blood level of glyoxalase I activity and diabetic complications

M. Hamoudane[1], M. Bennani[1], M. Nhiri[1]
[1] Faculty of Sciences and Techniques of Tangier Abdelmalek Essaâdi University, Department of Biology, Tangier, Morocco

Background: The formation of advanced glycation endproducts (AGEs) has been recognized as an important pathophysiological mechanism in the development of diabetic complications. Production of methylglyoxal (MG), a cytotoxic and crosslinking aldehyde, is elevated among patients with T2DM and is a precursor to (AGEs). The ubiquitous glyoxalase system is one of several defense systems designed to metabolise MG and to protect against the production of AGEs. It is composed of two enzymes, glyoxalase I (GloI) and glyoxalase II (GloII) and reduced glutathione (GSH) as an essential cofactor. GloI catalyzes the conversion of MG to D-S-lactoylglutathione by a GSH-dependent reaction and GloII catalyzes the hydrolysis of D-lactoylglutathione into D-lactate. A dysfunction of the glyoxalase system will result in accumulation of the highly reactive MG.
Aims: The present study was conducted to explore the hypothesis that the reduction of GloI activity may be associated with diabetic complications.
Methods: The activity of the GloI and the content of GSH were measured in blood samples of 150 controls and 172 subjects with T2DM from the North of

Morocco (35 with nephropathy, 25 with retinopathy, 18 with neuropathy, 33 with arteritis of lower limbs, 5 with cerebral vascular accident, 20 with cardiac complications and 36 uncomplicated). The GloI protein level was also examined by electrophoresis and western blot analyses. We evaluated the relationships between these levels and the pathogenesis of micro- and macrovascular complications of diabetes.

Results: There were significant decreases in the activity of GloI and GSH level between diabetic patients and controls. The reduction was more pronounced in diabetic patients with complications than the uncomplicated subjects. The GloI protein level, assessed in blood extract by electrophoresis and western blot analyses, was markedly lower in a diabetic patient with nephropathy and another with retinopathy than that observed in an uncomplicated patient and a normal subject.

Conclusions: This study provides evidence for elevated concentrations of MG and AGEs in T2DM which might have pathogenic significance and reflected the lower detoxification level of the glyoxalase system in subjects with chronic complications of T2DM.

Diltiazem inhibits apoptosis of vascular smooth muscle cells (VSMC) exposed to high glucose concentration through lectin-like oxidized low density lipoprotein receptor-1 (lox-1) pathway

A.R. Cholil[1], A. Tjokroprawiro[2], D.W. Soeatmadji[1], A. Widodo[1]
[1] RS Saiful Anwar Malang, Internist, Malang, Indonesia
[2] RS Sutomo Surabaya, Internist, Surabaya, Indonesia

Objectives: To know the effect of diltiazem on the apoptosis of VSMC exposed to high glucose through inhibition of LOX-1 expression.

Method: The research approved by Ethical Commission of Faculty of Medicine, informed consent was assigned by the subjects. We performed experimental study on the primary culture of VSMCs. The arterial VSMCs isolated from the umbilical cord, prepared based on the method of Maasch in 18 well-plate. After confluence in the sixth subculture VSMCs in the first 6 wells were incubated in the media + 5 mM glucose, in the second 6 wells incubated in the media + 25 mM glucose, both for 6 days, and in the third 6 wells VSMCs were pretreated with diltiazem 10μM for 30 minutes, before incubation in the media + 25 mM glucose + diltiazem (10μM final concentration) for 6 days. Intracellular Ca^{++} concentration measured by Fluo-3 staining observed with an argon confocal microscope (Olympus FV-1000). The intensity of fluorescence were observed in the region of interest (ROI). Fluorescent signal from samples quantified by FV10-ASW 1.7 software embedded on Olympus FV-1000. Expression LOX-1, and Caspase-3 activity (a key regulatory protease at which many signaling pathways merge for the execution of apoptosis) was measured by Elisa. Data were expressed as mean ± SEM. The statistical significance was assessed by one-way analysis of variance (ANOVA) followed by post hoc analysis by Tuckey test. $p < 0.05$ was considered statistically significant.

Results: Several studies proved the role of LOX-1 in cell apoptosis in high glucose environment. Chronic exposure to high glucose concentration (25 mM), increases cytosolic Ca^{++} concentration (3127 ± 413.89 v/s 2011.81 ± 410.93 unit/cell, $p < 0.01$), expression of LOX-1 ((506.80 ± 10.47 v/s 458.40 ± 36.49 ng/ml, $p < 0.05$), and caspase-3 activity (129.98 ± 5.97 v/s 114.73 ± 10.84 %, $p < 0.05$) in VSMCs, compared with exposure to 5mM glucose concentration. LOX-1 was related to caspase-3 activity, pre-treated with inhibitor LOX-1 activity, k-carragenan before exposed to glucose 25 mM, prevents the increasing of caspase-3 activity (96.41 ± 5.11 v/s 129.98 ± 5.98 %, $p < 0.01$). Pre incubation with 10μM of diltiazem before exposure to 25 mM glucose concentration significantly inhibits the elevation of cytosolic Ca^{++} concentration (2149.61 ± 339.49 v/s 3127 ± 413.89 unit/cell, $p <0.01$), and LOX-1 expression (468,60 ± 14.44 v/s 506.80 ± 10.47 ng/ml, $p < 0.05$), and caspase-3 activity (82.50 ± 9.90 v/s 129.98 ± 5.97%, $p < 0.01$).

Conclusion: The results demonstrate that high glucose induces VSMCs apoptosis through LOX-1 and caspase-3 pathway. This effect appears to be inhibited by diltiazem through the decreases of cytosolic Ca^{++} concentration, LOX-1 expression and caspase-3 activity.

Blood serum nucleic acids level increased in diabetes mellitus

A. Tashmanova[1], A. Alieva[1], F. Mukhamedova[1], Z. Shamansurova[1]
[1] Endocrinology, Diabetology, Tashkent, Uzbekistan

Aims: Diabetes mellitus (DM) are complex disease and involve many parts of tissue damage in pathogenesis. The nucleic acids in blood serum (SNA) are detected in very small amount in healthy subjects and are increased in some disorders. The aim of this study was an investigation of the level of SNA in DM2 patients and its relationship with glycemic control.

Materials and methods: In 32 DM2 patients and 9 healthy subjects SNA level, fasting (FG) and 2 hour after breakfast (2HG) glycemia, HbA1c, serum nitrites and nitrates (NN) level, CRP, erythrocytes sialidase activity (ESA) were measured and HOMA were calculated as (FG x fasting insulin): 22.5.

Results: Data analysis showed that in DM2 patients FG and 2HG were significantly increased in 1.9 and 2.1 time and HbA1c level was increased in 1.7 time, HOMA was increased in 2.7 time and indicated the poor glycemic control and insulin resistance in observed patients. ESA was increased in 9.1 time and indicate cell plasma membrane destabilization, and CRP level was increased in 1.6 times which suggest presenting of tissue damage and inflammation. NN levels were decreased in 2.1 time and indicated endothelium dysfunction in observed patients. In DM2 patients SNA level were increased in 2.3 time ($P<0.05$) than in healthy subjects. Increasing the SNA level shown positive correlation with FG ($r=0.4$) and 2HG ($r=0.48$), HbA1c ($r=0.3$) level and had linkage with HOMA, ESA, NN.

Conclusion: SNA levels are increased in patients with DM2 and shown positive correlation with glycemia indexes and had linkage with HOMA, NN, ESA and reflected tissue damage degree.

Effect of Diabetes Mellitus on ovarian reproductive hormones and the enzymes required for their synthesis

C. Mitchell[1], E. Uche-Nwachi[1]
[1] University of the West Indies, Pre-Clinical Sciences, St. Augustine, Trinidad and Tobago

Aims: Diabetes has been reported to reduce fertility in females. However, the association between reduced fertility, reproductive hormones (progesterone, testosterone, estradiol) and steroidogenic enzymes (3b-hydroxysteroid dehydrogenase {3b-HSD}, 17ß-hydroxysteroid dehydrogenase {17b-HSD}, Aromatase {P450arom}) has not been exhaustively investigated. The aim of this study is to determine how diabetes affects these ovarian hormones and the enzymes required for their synthesis.

Materials and methods: Sixty female Sprague Dawley rats (250-300g) were selected from the Animal House, Faculty of Medical Sciences, University of the West Indies, Trinidad. Animal care was in accordance with the guidelines of the Laboratory Animal Committee of the Faculty. Diabetes was induced by a single intraperitoneal injection of streptozotocin (65mg/kg body weight) dissolved in sodium citrate buffer (pH 4.5). Control rats received physiological saline intraperitoneally. Rats with blood glucose levels of 250-600 mg/dl were considered diabetic. Humulin R (0.3I.U./kg body weight) was administered when necessary to maintain this diabetic glucose range for two months.

Ten animals in each group (control and diabetic) were anesthesized with diethyl ether. Their thoracic and abdominal cavities were exposed. Blood was aspirated intracardially from each rat for hormonal assay and the ovaries were dissected out for histochemical investigations.

Serum concentrations of progesterone, testosterone and estradiol were estimated using the *VITROS Eci* immunodiagnostic system (Ortho-clinical Diagnostics). Histochemical staining for the activities of 3b-HSD, 17ß-HSD and P450arom was carried out on the ovarian tissues.

The mean hormonal values of the experimental and control rats were calculated. The staining intensities of the enzymes were determined using Image J software. The statistical analyses of the respective means were determined using the paired T-test (Minitab 15), and their P-values determined at 95% confidence intervals.

Results: Results showed that the mean serum progesterone, testosterone and estradiol concentrations of 2-month-diabetic animals were 49.3%, 54.1%, and 49.0% respectively, when compared with the controls. The P-values for these hormones were 0.000, 0.003, and 0.000 respectively. The staining intensities for 3b-HSD, 17ß-HSD, and P450arom of experimental animals were 82.7%,

79.9%, and 89.7% respectively, when compared with controls. The P-values for the staining intensities for these enzymes were 0.014, 0.001 and 0.011 respectively.

Conclusion: We conclude that diabetes mellitus decreased the serum concentration of progesterone, testosterone and estradiol and that this was mediated through decreased activities of ovarian steroidogenic enzymes.

Caspase-3 inhibition augments cardiac triglyceride accumulation after diabetes

M. Kim[1], B. Rodrigues[1]
[1] University of British Columbia, Pharmaceutical Science, Vancouver, Canada

Impairment of cardiac glucose utilization after diabetes rapidly shifts heart metabolism to consumption of more fatty acid (FA), which can be provided by lipoprotein lipase (LPL). Protein kinase D (PKD) is a key element involved in increasing cardiac LPL after diabetes. We determined the mechanisms by which PKD is regulated in heart and adipose tissue following diabetes. STZ (100 mg/kg) was used to induce diabetes whereas Z-DEVD-fmk was employed to lower caspase-3 activity. In severely diabetic rats, in the presence of augmented circulating FA, cardiac LPL remained unchanged and was likely a consequence of caspase-3 cleavage of PKD. Nevertheless, hearts from these rats demonstrated higher plasma membrane CD36 (FA transporter), FA oxidation and triglyceride (TG) accumulation. Treating diabetic rats with Z-DEVD effectively lowered caspase-3 activity, prevented PKD cleavage and increased LPL vesicle formation and translocation to the vascular lumen. The increase in cardiac luminal LPL was associated with a striking accumulation of cardiac TG which was almost 2-fold higher than that in the untreated diabetic animals. This effect was unrelated to a further increase in CD36 but was correlated to a greater association between the lipid droplet and OXPAT, a lipid droplet binding protein. Adipose tissue from untreated diabetic rats had lower PKD phosphorylation, and treatment with Z-DEVD-fmk prevented this effect. Our data suggest that although caspase-3 inhibition in diabetes may increase TG accumulation in adipose tissue, when caspase-3 is inhibited in the heart, a potentially destructive lipid accumulation may induce heart dysfunction.

The impairment of cerebrovascular reactivity in patients with diabetes mellitus

I. Saienko[1], A. Kovalenko[2], I. Kondratska[1], B. Mankovsky[1]
[1] Institute of endocrinology and metabolism of AMS, Prof. diabetology, Kiev, Ukraine
[2] Center of radiology, Functional diagnostics, Kiev, Ukraine

Aims: Diabetes mellitus is associated with significantly increased risk of stroke and vascular dementia compared to the general population, independently of the classic risk factors. The impairment of cerebrovascular reactivity could be one of the underlying factors of such association. In this study we assessed cerebrovascular reactivity in patients with diabetes mellitus compared to healthy subjects.

Methods: We studied 20 patients with diabetes mellitus – 10 with type 1 (aged 32.6±3.8 years) and 10 with type 2 (aged 53.3±2.0 years) and 10 healthy subjects as controls (aged 41.4±3.3 years). The patients studied did not have a history of cerebrovascular diseases, occlusion of extracranial carotid arteries and did not take any medications affecting the cerebrovascular reactivity. The mean cerebral blood flow velocity by the medial cerebral artery was measured by transcranial dopplerography, and cerebrovascular reactivity was assessed using the breath-holding test (for 30 sec) and the cold test (application of the ice for 5 sec). The cerebrovascular reactivity was calculated by the difference of blood flow velocity before and immediately after the test expressed in percentage of the basal level.

Results: We found that an increase of cerebral blood flow velocity during breath-holding or cold tests was significantly attenuated in patients with diabetes (either type 1 or type 2) compared to the control group. The mean cerebral blood flow by the right medial cerebral artery after the breath-holding test was increased by 11.4±2.2%, 9.8±2.3% and 28.2±3.9% and by the left medial cerebral artery by 10.8±2.6%, 6.2±4.6% and 23.5±3.9% in patients with type 1, type 2 diabetes and healthy controls, respectively, $p<0.05$ for comparisons between subjects with and without diabetes. The cold test led to an increased blood flow by the right medial cerebral artery by 9.4±2.5%, 12.8±4.2% and 25.9±3.3% and by the left medial cerebral artery by 8.3±3.6%, 13.1±4.2% and 21.4±3.5% in those with type 1, type 2 diabetes and controls, respectively, $p<0.05$.

Conclusions: We may conclude that the cerebrovascular reactivity is significantly impaired in patients with diabetes mellitus, which could be one of the predisposing factors for stroke in these subjects.

Role of intracellular zinc ion in diabetic cardiomyopathy

A. Bilginoglu[1], E. Tuncay[1], A. Seymen[1], B. Turan[1]
[1] faculty of medicine, Biophysics, Ankara, Turkey

Several Ca^{2+} binding proteins in cardiomyocytes bind Zn^{2+} suggesting that Zn^{2+} can modulate the structure and function of many proteins, which play important role in excitation-contraction coupling. It was also demonstrated that Ca^{2+} dependence of ryanodine binding to the sarcoplasmic reticulum of cardiac muscle is greatly affected by Zn^{2+}. Additionally, it was shown that transverse striations for high $[Zn^{2+}]_i$ localized and coincided with the I-band of cardiomyocytes. Evidence from animal models suggests that reactive oxygen species (ROS) play an important role in development of diabetic cardiomyopathy. Since free Zn^{2+} is altering function of numerous cellular proteins, its mobilization by ROS in diabetic heart can be likely to cause significant effects. It is highly likely that any mechanism that alters the concentration and distribution of intracellular free Zn^{2+} ($[Zn^{2+}]_i$) in cardiomyocytes will cause profound functional effects.

Therefore, in the present study, we focused first on the quantization of STZ-induced alterations of $[Zn^{2+}]_i$ in cardiomyocytes by using fura-2 and the metallothionein (MT) level of heart tissue. We also measured oxidation levels (levels of lipid peroxidation and nitric oxide products) as well as levels of antioxidants (superoxide dismutase, glutathione reductase, and glutathione peroxidase) of the heart tissue of STZ-induced diabetic rats. Second, a beneficial effect of selenium on diabetes-induced altered parameters of the heart was demonstrated. Diabetic rats were treated with sodium selenate (15 mmol/kg body weight/day) for 4-week. Our data showed that diabetes caused significant increases in basal $[Zn^{2+}]_i$ as well as basal $[Ca^{2+}]_i$ of cardiomyocytes, and also a significant increase in oxidized glutathione of the heart while decreasing the level of reduced glutathione, significantly. We also found that sodium selenite treatment of the diabetics markedly restored these altered parameters. Our data indicate that an oxidant shift of cellular thiolic pools can modulate $[Zn^{2+}]_i$ in diabetic heart.

Left ventricular diastolic function in type 2 diabetic patients with and without metabolic syndrome

M. Harada[1], A. Sato[1], T. Kunugi[1], K. Sakai[1], Y. Iwamoto[1]
[1] Tokyo women's medical university, Diabetes center, Tokyo, Japan

Aim: Diabetes mellitus and hypertension are risk factors for left ventricular (LV) diastolic dysfunction. Metabolic syndrome (MetS) is associated with the increased LV mass which induced LV diastolic dysfunction. There are few studies of the association between MetS and LV diastolic function without LV mass effects. The aim of our study is to evaluate the influence of MetS on LV diastolic function in type 2 diabetic patients.

Methods: Echocardiography was performed in 26 type 2 diabetic patients with MetS(14 men, age 53±11 yr, (mean±SD)) and compared with 26 type 2 diabetic patients without MetS (15 men, 53±10 yr) matched for age and sex. LV internal diameter was measured by M-mode echocardiography, and fractional shortening (FS) and LV mass were also calculated. LV mass was indexed by body surface area (LVMI) and body height to the power of 2.7. LV systolic function was assessed by FS, and LV diastolic function was assessed by the ratio between the peak diastolic velocity and the peak atrial systolic velocity (E/A) on the mitral inflow pulsed wave with doppler examination. MetS was defined, according to the Japanese criteria of 2005, as a waist circumference level >85 cm in men and >90 cm in women and two or three of the following

three risk factors: hypertension (a blood pressure level >130/85mmHg), dyslipidemia (an HDL cholesterol level <40 mg/dl or a TG level >150 mg/dl), and glucose intolerance (a fasting glucose level >110 mg/dl). Subjects taking medications for any of the three components were also considered to have the corresponding risk factor. In addition, we also measured visceral, subcutaneous and total fat areas at the umbilicus level using computed tomography. Fasting plasma glucose, HbA_{1c}, serum total cholesterol, triglycerides, HDL-cholesterol (HDL-C) and LDL-cholesterol were determined. Adipocytokines such as leptin, adiponectin, t-PAI-1 and IL-6 were measured. Insulin resistance was measured by fasting insulin. Atherosclerosis was evaluated through pulse wave velocity (PWV) and ankle-brachial index (ABI).

Results: E/A was significantly decreased in patients with MetS as compared to patients without MetS (0.91±0.21 vs. 1.10±0.35, p<0.05). Patients with MetS had elevated BMI (p<0.001), elevated BP (p<0.05), higher TG and HDL-C (p<0.01), increased LVMI (p<0.005), LVMI $^{2.7}$ (p<0.001), increased t-PAI-1 and leptin(p<0.01), and decreased adiponectin(p<0.005) as compared with patients without MetS. In type 2 diabetic patients with MetS, increased HbA1c, TG, BPs and PWV, and decreased adiponectin were independent risk factors for decreased E/A (p<0.05), after adjusted by LVMI.

Conclusions: MetS was associated with the decreased LV diastolic function in type 2 diabetic patients. Both factors of MetS and atherosclerosis may lead to LV diastolic dysfunction without the effect of LV hypertrophy in type 2 diabetic patients.

[3] Piedmont Medical Center, Diabetes Resource Center, Atlanta, USA

[4] Gluctec, Senior Vice President Research and Development, Greenville, USA

[5] Gluctec, Marketing Sales and Training, Greenville, USA

The optimal target range for blood glucose in critically ill patients is not known. Tight glycemic control has been supported by numerous randomized and observational studies. Recent studies, however, have reported excessive rates of severe hypoglycemia and increased mortality. The initial response from the ADA/AACE/Endocrine Society is to compromise by accepting levels that previously were associated with increased complications.

Glucommander™ is a computerized system for advising insulin dosing to achieve any desired BG target with very limited hypoglycemia. When BG does drop insulin is phased out while nutrition continues and carbohydrate intake is augmented with D50.

The experience shows that out of 6323 runs in 17 hospitals the incidence of BG below normal range was:

	n	Patients with 1 or more BG's<=40 mg/dl	Patients with 1 or more BG's<=60 mg/dl	Mean ± sd
NICE-SUGAR	3034	6.8%		115±18 mg/dl
Glucommander				
Version 4	3095	0.3%	7.5%	121±31 mg/dl
Surg ICU	238	zero	7.7%	103±19 mg/dl
Med ICU	79	2.9%	42.0%	102±26mg/dl
G+	2911	2.0%	15.7%	107±13mg/dl
All Glucommander	6323	1.1%	11.7%	

Version 4 Glucommander--Version used since 1992

Surg ICU: CV Surgery study by authors.

Med ICU: Multicenter medical ICU study.

G+: A commercial version of Glucommander. Data from 11 hospitals not supervised or coached by inventors.

The rate of severe hypoglycemia with the Glucommander is significantly lower that those reported by Leuven SICU (5.2%) and MICU (18%), NICE-SUGAR (6.8%), VISEP (17%), and Arabi (28.6%).

A computer controlled algorithm for managing IV insulin with: 1) alarms for prompting BG measurement at varying intervals, 2) the ability to calculate insulin adjustments to prevent excursions outside the target range, and 3) a system to dictate controlled glucose correction, is mandatory to stabilize glucose levels in a optimal safe range.

Now is the time to implement tight glycemic control in any institution. We propose that near normoglycemia in ICU setting be performed with a more effective and safe computer controlled system.

Glycemic control, antiplatelet therapy and blood coagulation activity in diabetes

I. Uchimura[1], Y. Hayashi[2], Y. Shiga[3], M. Kaibara[4]

[1] Tokyo Medical and Dental University, Endocrinology and Metabolism, Tokyo, Japan

[2] Sony Corporation, Advanced Material Laboratories, Tokyo, Japan

[3] Meiji University, Graduated School of Science and Engineering, Ikuta, Japan

[4] RIKEN, Institute of Physical and Chemical Research, Wako, Japan

Background and aims: Macroangiopathy (MA) such as cerebral infarction, myocardial infarction is a common cause of death in diabetes. These complications are thought due to increased coagulation activity. To evaluate an accurate blood coagulation activity which responds to treatments, we measured blood coagulation in diabetes using free oscillation rheometer.

Materials and methods: Blood was obtained from human adult volunteers including normal (N: n=52) and diabetic patients (DM n=56). Blood coagulation was measured by free oscillation rheometer (FOR). Blood was taken from healthy volunteers using 3.8% tri-sodium citrate solution as an anticoagulant. The blood was immediately transferred into a polypropylene tube which is attached to a torsion wire. The cup was initially rotated about its longitudinal axis and released. Change in logarithmic damping factor (LDF) was monitored after adding 0.085mL $CaCl_2$ solution to anti-coagulated blood sample. This LDF value is closely related to the viscosity and viscoelasticity of blood sample in the vascular model tube. The onset time of coagulation (Ti) and the slope of coagulation curve (SCC) were determined. Plasma glucose(PG), HbA1c, LDL-cholesterol(C), triglyceride, hematocrit, platelet count, s-creatinine, plasma fibrinogen and urine protein were measured at the same time.

Results: Ti from N or DM group were 34.6±9.0 (min: mean±SD) and 43.2±22.3, respectively. This rheometer detected erythrocyte sedimentation phenomenon (ES) from 23 DM patients. The Ti showed significant negative correlation with HbA1c levels (r=-.359, p<0.01) or LDL-C levels (r=-.313, p<0.05). The SCC showed significant negative correlation with Ti (r=-.302, p<0.05), and showed positive correlation with PG (r=0.381, p=0.005) or HbA1c (r=0.269, p<0.05). Table1 shows SCC, PG, HbA1c, LDL-C and Fibrinogen levels in each groups.

Table 1.

Ti and ES	SCC	PG(mg/dL)	HbA1c(%)	LDL-C (mg/dL)	Fibrinogen (mg/dL)
Shortened with ES+	.0049±.0031	236±87	9.6±2.6	150±58	478±92
Prolonged with ES+	.0037±.0014	195±104	7.5±1.4	111±29	348±111
Shortened with ES-	.0037±.0030	220±151	8.6±2.5	134±29	334±73
Prolonged with ES-	.0022±.0011	140±54	7.3±1.9	118±44	345±97

Twelve patients took antiplatelet drug. Table 2 shows Ti, SCC, PG, HbA1c and LDL-C in diabetics with or without antiplatelet therapy.

Table 2.

	Ti(min)	SCC	PG(mg/dL)	HbA1c(%)	LDL-C(mg/dL)
Antiplatelet therapy+	59.62±2.9	.0033±.0013	171±113	7.1±0.88	108±32
Antiplatelet therapy-	39.9±21.6	.0039±.0025	208±106	8.4±2.1	125±39

Conclusion: Free oscillation rheometer revealed the deterioration of whole blood coagulation and erythrocyte sedimentation phenomenon, and also the contribution of platelets to coagulation which responds to treatments. These observations show that rheological technique may have a significant impact on the assessment of coagulation parameters, such as Ti and SCC, and glycemic control is important on blood coagulation in diabetes.

Effects of oxidized or glycated LDL on mitochondrial respiration chain activity and enzymes in arterial endothelial cells

G. Sangle[1], S. Roy Chowdhury[1], X. Xie[1], G. Shen[1]
[1] University of Manitoba, Internal Medicine, Winnipeg, Canada

Elevated low density lipoprotein (LDL) is a classical risk factor for atherosclerotic cardiovascular disease. Increased levels of oxidized LDL (ox-LDL) and glycated LDL (gly-LDL) were detected in diabetic patients. Our previous studies demonstrated that ox-LDL and gly-LDL increased the generation of reactive oxygen species (ROS) in vascular endothelial cells (EC). ROS is implicated in endothelial dysfunction and diabetic vascular complications. Mitochondria are an important source of ROS in the body. We hypothesize that ox-LDL or gly-LDL might affect the activity of mitochondrial respiratory chain. We evaluated the activities of mitochondrial respiratory chain complexes in porcine aortic EC (PAEC) using oxygraphy. The oxygen consumption in Complex I, II and IV of PAEC was significantly decreased by 12 or 24 h of incubation with ox-LDL or gly-LDL compared to control cultures. Ratio of NAD+/NADH (Complex I) and the activities of succinate-ubiquinone oxidoreductase (Complex II), ubiquinone cytochrome c oxidoreductase (Complex III) and cytochrome C oxidase (Complex IV) in EC were significantly reduced by treatment with ox-LDL or gly-LDL. Increased ROS in EC induced by ox-LDL or gly-LDL was associated with mitochondrial marker in EC. The findings suggest that attenuated mitochondrial activity in vascular EC may contribute to ROS generation induced by atherogenic lipoproteins.

Gene therapy is a promising strategy being explored to correct blood glucose concentrations in patients with Type 1 diabetes. One approach is delivery of beta cell transcription factors to the liver to induce the generation of insulin-producing cells. In the current study, we used a bicistronic retroviral vector to deliver either the human insulin gene alone or the human insulin gene and the rat *NeuroD1* gene to the rat liver cell line H4IIE to determine if storage of insulin and pancreatic transdifferentiation occurred. Stable clones were selected and expanded into cell lines: H4IIEins cells (insulin gene alone), H4IIE/ND (*NeuroD1* gene alone) and H4IIEins/ND (insulin and *NeuroD1* genes). The H4IIEins/ND cells (10^7) were subsequently transplanted subcutaneously into diabetic NOD/Scid mice to examine if the cells could reverse diabetes.
Radioimmunoassay of acid/ethanol cellular extracts indicated that H4IIEins cells did not store insulin. However, H4IIE/ND and H4IIEins/ND cells stored 65.5±5.6 and 1,475.4±171.8 pmol insulin per $5x10^6$ cells (n=5), respectively. Unlike the parent cell line or H4IIEins cells, several beta cell transcription factors (*Pdx1, NeuroD1, Nkx2.2, Nkx6.1*) and pancreatic hormones (insulin 1 and 2, glucagon, somatostatin, pancreatic polypeptide) were expressed in both H4IIE/ND and H4IIEins/ND cell lines. The pancreatic exocrine factor p48 was not present in any of the engineered liver cell lines. Transmission electron microscopy revealed the presence of large numbers of storage vesicles in the H4IIEins/ND cell line. Granules were of a similar size and appearance to those seen in pancreatic beta cells. Regulated secretion of insulin in response to increasing concentrations of glucose (0-20 mM) was seen only in the H4IIEins/ND cell line. The glucose response curve of the H4IIEins/ND cell line was near physiological; insulin secretion commenced in the presence of 2.5mM glucose. Transplanted cells coalesced into a reddish friable mass at the site of grafting and grew slowly. The blood glucose levels of all 9 diabetic mice that were transplanted became normal, 5.6 ± 0.1 mM, in 5-10 days after the cells were implanted. Removal of the grafts at 21 days resulted in a prompt increase in the blood glucose levels to hyperglycaemic values, 17.9 ± 4.2 mM. Our results suggest that expression of *NeuroD1* together with insulin may be a useful strategy for inducing islet neogenesis and reversing diabetes without exocrine differentiation.

Towards development of a non-rejectable islet allograft using local expression of indoleamine 2, 3 dioxygenase

R. B. Jalili[1], F. Forouzandeh[1], A. Moeenrezakhanlou[1], A. Medina[1], B. Larijani[2], A. Ghahary[1]

Aims: Success of transplantation of pancreatic islets as a promising therapeutic method for restoring efficient insulin regulation in type 1 diabetes mainly depends on lifelong use of immunosuppressive drugs. Adverse side effect of immunosuppressive agents commonly used after transplantation is a source of major concern not only for islet cell recipients but also for physicians, caregivers and researchers. With the goal of eliminating the necessity of systemic immunosuppressive agents after islet transplantation, in this study we developed and applied a novel non-rejectable islet graft through employing a local immunosuppressive factor, indoleamine 2, 3 dioxygenase (IDO). This idea is adapted from the natural mechanism, which protects the fetus in a mother's uterus from being rejected by her body's immune system during pregnancy. In fact, endogenous IDO has been implicated as one mechanism that helps maintain maternal tolerance toward the fetus. IDO is a tryptophan degrading enzyme and functions as a potent immunomodulatory factor.
Methods: We engineered a three-dimensional composite islet graft equipped with IDO expressing bystander cells as local immunosuppressive system. In this composite graft, expression of IDO in syngeneic fibroblasts by using an adenoviral mediated gene transfer method provided a low tryptophan microenvironment within which T-cells could not proliferate and attack islets. Composite islet grafts consisting of allogeneic mouse islets and syngeneic IDO-expressing fibroblasts embedded within collagen gel matrix were prepared and transplanted into renal subcapsular space of immunocompetent streptozotocin induced diabetic mice. The graft function and criteria for graft take were then assessed.
Results: IDO expressing Islet allografts survived and functioned significantly longer than controls (41.2±1.64 vs. 12.9±0.73 days, $p<0.001$). Allogeneic islets remained intact and functioning in IDO-expressing grafts without administering systemic immunosuppressive agents for more than six weeks. Histological examination of the grafts showed that IDO evidently prevented lymphocyte infiltration into allografts. T-cells densely accumulated in the border of IDO-expressing grafts and kidney tissue but didn't penetrate the composite grafts. Furthermore, production of donor specific alloantibodies was significantly delayed in IDO group.
Conclusion: This promising finding proves the potent local immunosuppressive effect of IDO in islet allografts and sets the stage for development of a long-lasting non-rejectable islet allograft using stable IDO induction in bystander fibroblasts.

Strategies to improve encapsulated islet survival and oxygenation

S. Bilodeau[1], S.K. Tam[2], J. Dusseault[1], G. Langlois[1], J.P. Hallé[1]

[2] École Polytechnique de Montréal, Institut de génie biomédical, Montreal, Canada

The microencapsulation of pancreatic islets is a promising treatment for type 1 diabetes. Although microcapsule biocompatibility has improved, islet cell survival is still problematic. During islet isolation, the extracellular matrix (ECM) around the islet is destroyed, which negatively affects islet function and survival. Also, smaller islets have been shown to have better function and survival. Since encapsulated islets are not re-vascularized, their oxygen supply is entirely dependent upon diffusion. The use of dispersed islet cell re-aggregates of smaller diameter now allows the investigation of microcapsules of further reduced size.
Aim: The aim of this study is to improve microencapsulated islet cell survival, using three approaches: restoring the ECM loss, reducing the microcapsule diameter from 300 µm to ~ 100 µm, and reducing the islet diameter, using islet cell re-aggregates. It is known that dissociated islet cells have the capacity to re-assemble in clusters that have the same properties as a normal islet. The first steps were to 1) characterize ECM in islets, after isolation and encapsulation, 2) produce islet cell re-aggregates and 3) evaluate the feasibility of producing 100-150 µm diameter microcapsules.

Methods: The presence of ECM molecules (collagen I and IV, fibronectin and laminin) was evaluated by immunohistochemistry in islets that were cultured for different time periods, comparing encapsulated to non-encapsulated islets. Secondly, islet-like clusters were formed after dissociation of islets with trypsin and rotational incubation during 5-6 days. Different conditions were tested to achieve an optimal size. Finally, alginate-poly-L-lysine microcapsules were produced using an electrostatic pulse generator, and different fabrication parameters were tested in order to achieve specific capsule diameters.
Results: Collagen IV and laminin were found to be present in whole pancreases used as a control, but only a minimal amount was found in isolated islets for all of the tested conditions. The other proteins under study were present for all conditions(fibronectin, collagen I). Islet-like clusters were produced and encapsulated in small microcapsules. We were able to produce microcapsules with a diameter of 132,32 ± 6,29 µm by extruding alginate through a 30G needle and reducing the alginate flow rate from 3,5mL/min to 0,3mL/min.
Discussion/conclusion: This data suggests that replacing collagen IV and/or laminin in the re-aggregates might be useful. We also showed the feasibility of producing APA microcapsules of approximately 130 µm and of encapsulating islet cell re-aggregates within these microcapsules. Further research will be conducted to determine whether the use of this system improves oxygen supply to islets and islet survival.

Co-transplantation of neural stem cells and pancreatic islets improves graft endocrine function in athymic mice

J. Olerud[1], N. Kanaikina[2], L. Jansson[1], M. Sandberg[1], E.N. Kozlova[2]
[1] Uppsala University, Medical Cell Biology, Uppsala, Sweden
[2] Uppsala University, Neuroscience, Uppsala, Sweden

Aims: Despite improvements in clinical islet transplantations long-term graft failure still represents a major problem. One possibility to achieve better results could be co-transplantation of islets with other cell types, which through the release of growth factors, could promote beta-cell growth and graft endocrine function. The aim of this study was to investigate, in an experimental system, if co-transplantation of neural stem cells and islets would lead to differentiation of the stem cells and whether this could improve insulin release from islet grafts.
Methods: Mouse islets and mouse neural stem cells were transplanted alone (150 of each) or together (75 of each) beneath the right and left renal capsule, respectively, of athymic mice. One month post-transplantation the grafts were removed and perifused with medium containing low (2.8 mmol/l) and high (28 mmol/l) glucose concentrations. Perifused grafts were then removed and stained for insulin, beta-tubulin and neuron subtype markers.
Results: Most of the neural stem cells differentiated to glial and neuronal cells. Despite the fact that only half the number of islets was used when co-transplanted with neural stem cells, compared with islets alone, the insulin release from the grafts was similar in the perifusion experiments. The beta-cell volume in the grafts was also similar in islets transplanted alone or in combination with neural stem cells.
Conclusions: Co-transplantation of neural stem cells and pancreatic islets improved graft endocrine function. This could be mediated through neurotrophic factors, released from differentiated neural stem cells. This opens new possibilities to improve post-transplant islet graft function.

Preservation of human islet function in vitro through EMC reestablishment

D. Jamal[1], M. Petropavlovskaia[2], L. Rosenberg[2], M. Tabrizian[1]
[1] McGill University, Biomedical Engineering, Montreal, Canada
[2] Montreal General Hospital, Surgical Research, Montreal, Canada

Pancreatic islet transplantation requires successful isolation and *in vitro* survival; however, studies have shown that islet isolation exposes the islet to a variety of cellular stresses, destroys the basement membrane (BM) and disrupts the cell-matrix relationship, leading to apoptosis. In the current state of islet regeneration research, we are still unable to re-emulate the ECM conditions of the pancreatic islet and restore the BM which is lost during isolation. The rationale behind this research study is to identify factors responsible for islet preservation and survival *in vitro*. This will lend to emulate the basement membrane of native islet tissue through proper cell-substrate interactions.
This study has shed light into important factors that promote human islet adhesion, morphology, survival and functionality *in vitro*. A direct relationship was observed between surface roughness and wettability of the modified protein surfaces. Also, the AFM analysis showed a homogeneous distribution of the proteins on their respective surfaces. Fibronectin, followed by laminin, possessed the greatest contact angle and surface roughness which directly correlate with hydrophobicity.
Adhesion studies showed that collagen I, collagen IV, and fibronectin surfaces were the most effective in inducing adhesion at levels of over 50%. Also, islets cultured on these surfaces showed high metabolic activity and viability. Islet morphology was maintained best on fibronectin surfaces, while being most compromised on collagen I due to islet spreading and monolayer formation. However, the strongest adhesion occurred on collagen I, followed by collagen IV and fibronectin. Furthermore, glucose-induced insulin release was optimal for fibronectin cultured islets, in contrast to its ECM counterparts. Islet gene expression of insulin, glucagon, somatostatin, pancreatic polypeptide and PDX1 were also elevated relative to islets cultured on BSA-control surfaces. This investigation into appropriate surfaces for islet adhesion and viability provides valuable insight into the optimal conditions to ensure islet survival *in vitro*. More importantly, this forms the basis for further experiments investigating the effects of geometry of the surfaces on adhesion, viability, and differentiation; as well as the implementation of a favourable microenvironment for isolated pancreatic islets.

Understanding the biocompatibility of microcapsules designed for islet cell transplantation

S.K. Tam[1], J. Dusseault[2], G. Langlois[2], S. Bilodeau[2], L.H. Yahia[1], J.P. Hallé[2]
[1] École Polytechnique de Montréal, Institut de génie biomédical, Montréal, Canada
[2] Hôpital Maisonneuve-Rosemont, Centre de recherche, Montréal, Canada

The microencapsulation and transplantation of islet cells is a very promising approach to effectively treat insulin-dependent diabetes mellitus. To encapsulate islets, most research groups use alginate as the base material and then incorporate a polycation into the capsule membrane.
Problematic: The biocompatibility of microcapsules designed for islet transplantation remains difficult to control, predict and reproduce. This has the effect of limiting the long-term function of the graft.
Aim: The purpose of this work is to explain the biological response to alginate-based microcapsules in terms of their fabrication design and surface properties.
Methods: Microcapsules are made using different alginates (Alg I or Alg II) and have either no polycation, poly-L-lysine (PLL), or poly-L-ornithine (PLO) incorporated into the membranes. Alg I is composed of 37% guluronic acid (G) while Alg II is composed of 58% G, as confirmed by nuclear magnetic resonance. To evaluate their biocompatibility *in vivo*, microcapsules are implanted into the peritoneal cavity of C56BL/6 mice for 2 days and then immune cell adhesion to the explanted capsules is measured using a semi-quantitative scoring system with a scale of 0 to 2. Films that recreate the microcapsule structure are analyzed in terms of chemical composition using x-ray photoelectron spectroscopy and Fourier transform infrared spectroscopy. Film hydrophilicity is evaluated using various methods to measure the contact angle at the water/air/surface interface.
Results: In the absence of a polycation, Alg I capsules were almost free from cellular adhesion after 2 days implantation (score 0.05 ± 0.01) while Alg II capsules were often covered with immune cells (score 1.02 ± 0.03). This difference in biocompatibility was significant ($p < 0.001$). Yet, alginate hydrophilicity was similar, as water droplets on dry films had contact angles of 38.7 ± 1.7° and 39.0 ± 1.3° for Alg I and Alg II, respectively. When PLL was added to the capsule membrane, the immune response was more severe ($p < 0.01$), as cell adhesion scores increased to 1.11 ± 0.11 for Alg I and to 1.55 ± 0.07 for Alg II. Similarly, the cell adhesion score increased to 0.49 ± 0.06 when PLO was added to Alg I capsules, indicating a non-significant increase in capsule immunogenicity. A comparison of contact angles of water on dry films containing polycations was not possible due to irregular surfaces and complete wetting. We are currently measuring the contact angles of air bubbles on hydrated films.
Conclusions: The guluronic acid content of alginate has a significant effect on its biocompatibility *in vivo*. Incorporating polycations into the membranes of alginate microcapsules lowers their biocompatibility. So far, these results cannot be explained by the hydrophilicity of the samples.

Efficacy and safety of recombinant human platelet-derived growth factor gel for diabetic neuropathic foot ulcers: a systematic review

H. Tian[1], J.Y. Shi[1], T. Chen[1], X.W. Ran[1], X. Chen[2], Y. Ren[1]
[1] *West China Hospital of Sichuan University, Department of Endocrinology and Metabolism, Chengdu, China*
[2] *West China Hospital of Sichuan University, Laboratory of Endocrinology and Metabolism, Chengdu, China*

Aims: To assess the efficacy and safety of recombinant human platelet-derived growth factor (rhPDGF) gel for diabetic neuropathic foot ulcers.
Methods: We searched MEDLINE, EMBASE, OVID Evidence-Based medicine Reviews(Cochrane DSR, ACP Journal Club, DARE, and CCTR), China National Knowledge Infrastructure (CNKI) and VIP database to July 2008 for randomized controlled trials (RCTs). Meta-analyses were performed with the Cochrane Collaboration's RevMan 4.2 software.
Results: Six RCTs involving 1181 patients were included. Meta-analyses showed that, compared with controls, patients treated with rhPDGF at 100 ug/g had a significantly increase in complete healing rate [RR 1.36, 95%CI (1.16, 1.58)], while patients with rhPDGF at 30 ug/g didn't show an increased rate [RR 1.38, 1 95%CI (0.76, 2.50)]. rhPDGF gel (100 ug/g) is likely to decrease the time to complete healing and reduces the size of the ulcer more effectively. Moreover, rhPDGF gel does not cause apparent adverse effects and is relatively safe for use.
Conclusions: The currently available evidence indicated that rhPDGF gel can increase complete healing rate of neurogenous diabetic foot, shorten the time of complete healing and be helpful to shrink ulcer surface. rhPDGF gel has no apparent adverse effects.

Role of modified total contact cast (window walking cast) in healing of diabetic plantar surface ulcers

G. Goyal[1], A.K. Jain[1], R. Srivastava[1], S. Kapoor[1]
[1] *S.K. Diabetes Research and Education Centre, Diabetology, Kolkata, India*

Background: Dr Paul Brand was the first to widely use Total Contact Cast (TCC) in the mid 1960's to offload the insensate foot in Hansen's disease. It has since then been identified as a gold standard for offloading Diabetic Foot Ulcers (DFU's) within the Diabetic Foot-care community.
This study was designed to assess the effectiveness of a method to offload large neuropathic DFUs. The device used is modified TCC with a MCR insole inside the cast and window around the ulcer.
Aim: This study reports our experience with Modified Total Contact Cast with a window in healing of non-infected neuropathic plantar ulcers as compared to standard TCC.
Materials and methods: Thirty two patients of Diabetic Foot Ulcer (DFU) incolving plantar surface of more than 2 * yrs duration (6 months – 5 yrs) subjected for offloading technique (TCC) after Vibration Perception Threshold (VPT), Ankle Brachial Index (ABI) and X-Ray evaluation.
Twelve patients in Control group (7 male & 5 female, having average age of 49.5 yrs (37 yrs-65 yrs), average HbA1c of 9.6% (8%-10.5%) were given TCC following the standard technique, and twenty patients in Study group (11 male & 9 female, having average age of 48.2 yrs (36 yrs-63 yrs), average HbA1c of 9.7% (7.8% - 11.3 %) were given TCC with MCR Insole inside the plaster cast and window was made for observation and regular dressing.
Results: In control group with standard TCC (without window and MCR insole) the average healing time was 8 weeks (6-20 weeks) while in the study group it was 5.6 weeks (4 – 16 weeks). Foul smell from cast was observed in control group. Four cases of cast damage/breakage occurred in control group and one case of cast damage / breakage occurred in study group. Frequency of change of cast was 2 weeks in control group and 3-4 weeks in study group.
Conclusion: Modified TCC (TCC with MCR insole and window around the ulcer) is an effective technique in healing of non infected neuropathic plantar ulcers for the following reasons:
1. It is not removable and does not depend on patient compliance.
2. The window around the ulcer allows for drainage of ulcer and daily wound care.
3. Requires less frequent change of cast
4. If needed growth factors can be applied.
5. Cost effective

Bacterial etiology and drug resistance profile of diabetic foot infections in North India

J. Ahmad[1], S. Alvi[2], M. Beg[2], A. Khan[3], K.J. Farooqui[1]
[1] *Aligarh Muslim University, Centre for Diabetes and Endocrinology, Aligarh, India*
[2] *Aligarh Muslim University, Department of Medicine J N Medical College, Aligarh, India*
[3] *Aligarh Muslim University, Interdisciplinary Biotechnology Unit, Aligarh, India*

Aims: To determine the bacteriological profile, antibiotic susceptibility patterns of organisms isolated from diabetic foot ulcers (DFU) and establish the predictors of multidrug-resistant organisms (MDROs) and outcome of these infections.
Methods: Bacteriological culture and antibiotic sensitivity profiles were carried out from 154 type 2 diabetic patients admitted with DFU with Wagner's grade 1-5. Twenty four (15.6%) patients had coexisting osteomyelitis. Gram-negative bacilli were tested for extended spectrum ß lactamase (ESBL) production by double disc diffusion method. Staphylococcal isolates were tested for methicillin resistance by using 1-µg oxacillin disc.
Results: Gram negative aerobes were most frequently isolated (81.6%) followed by Pseudomonas. The highest ESBL production was noted in P. aeruginosa (32.8%), followed by E. coli (27.5%) and K. pneumoniae (23.7%). In the multivariate logistic regression model: duration of infection >1month, prior antibiotic use and ulcer size >4cm^2 were independently associated with risk of MDRO infection.
Conclusions: Infection with MDROs was common in diabetic foot ulcers and presence of PVD, past history of amputation, ulcer size, a higher Wagner grading, duration of infection and duration of hospital stay were the factors more likely to be associated with adverse clinical outcome.

See table 1: Antimicrobial susceptibility pattern of isolated bacteria

Secular trends in foot ulcer disease among persons with diabetes: Dar es Salaam, Tanzania, 1997-2008

Z. Abbas[1], J. Lutale[2], L. Archibald[3]
[1] *AMC / MUHAS, Internal Medicine, Dar es Salaam, Tanzania*
[2] *MUHAS, Internal Medicine, Dar es Salaam, Tanzania*
[3] *University of Florida, Internal Medicine, Gainesville, USA*

Background: Lower limb complications in persons with diabetes are associated with substantial morbidity and mortality in Tanzania. Previous reports suggest an epidemiologic linkage between large vessel disease (LVD) and foot ulcer pathogenesis.
Objectives: We carried out these analyses to establish secular trends in the incidence rates of diabetic foot ulcer disease in Tanzania during 1997-2008 (study period).
Methods: We reviewed foot ulcer data aggregated by the Tanzania Diabetic Ulcer Surveillance System (TANDUSS). These data reflect persons with diabetes who were hospitalized in Muhimbili National Hospital (MNH) in Dar es Salaam. Factors assessed include demographics, and occurrence of LVD, peripheral neuropathy (PN), and neuro-ischemia (NI). Ulcer incidence was expressed as a % of all persons with diabetes presenting to MNH with any foot problem during study period.
Results: Of 4,324 diabetes patients admitted to MNH during study period, 736 (17%) had foot ulcers. Of these 736 patients, 511 (69%) were male and 718 (97%) were of African ethnicity. During study period, trends of PN remained upward whereas LVD and NI decreased over the study period to <1% in 2008. Ulcer incidence rates peaked at 24% in 2005 and then fell in parallel with LVD and NI to 8% in 2008.
Conclusion: PN rates continue to increase among persons with diabetes in Tanzania. Incidence rates of foot ulcer disease have been on a downward trend since 2005 and parallel the fall in LVD and NI rates. The epidemiologic linkage and public health implications of these findings remain unascertained.

Effect of percutaneuous transluminal angioplasty in patients with diabetic foot ulcer and ankle-brachial pressure index above 0.9

V. Woskova[1], A. Jirkovska[1], R. Bem[1], M. Dubsky[1], K. Cechova[1], J. Peregrin[2], B. Koznar[2]

[1] *Institute for Clinical and Experimental Medicine, Diabetes Center, Prague, Czech Republic*

[2] *Institute for Clinical and Experimental Medicine, Dept. of Interventional Radiology, Prague, Czech Republic*

Background: According to International Consensus on the Diabetic Foot, Doppler ankle/brachial index (ABI) below 0.9 indicates peripheral arterial disease (PAD). There is little information in the literature to guide subsequent vascular intervention in a patient with foot ulcer and ABI above 0.9. The relationship between ABI prior to percutaneous transluminal angioplasty (PTA) and PTA outcomes is not conclusive. The aim of our study was to compare clinical effect of PTA in terms of TcPO2 (transcutaneous oxygen pressure) changes and ulcer healing in patients with ABI equal or above 0.9 and ABI below 0.9 prior to PTA.

Patients and methods: The retrospective study was conducted to evaluate 55 lower limbs in 53 diabetic patients (mean age 64±11 years, mean diabetes duration 20±11 years, 45 M/8 F) treated at a foot clinic. All patients underwent PTA in 2006-2008 and Doppler assessment was documented. Indication for angiography and subsequent PTA were non-healing diabetic foot ulcers with suspected ischaemia based on complex vascular assessment (mainly TcPO2). The mean follow up period was 10 (8 -12) month. Retrospectively, in the first group lower limbs with ABI equal or above 0.9 were included and in the second group lower limbs with ABI below 0.9 were included. Evaluation of PTA clinical effect was based on TcPO2 changes measured one week after PTA and on ulcer healing – ulcer healing defined as ulcer closure or below-the ankle amputation healed, and healing failure as non- healed ulcer or above- the -ankle amputation.

Results: In the first group (ABI equal or above 0.9) 26 lower limbs and in the second group (ABI below 0.9) 29 lower limbs were evaluated. Using Wagner classification the groups were comparable in severity of lesions; both groups did not differ significantly in the mean TcPO2 prior the PTA (23.7±15.6 vs 23.6±15.6 mmHg, NS). There was significant increase of TcPO2 after PTA both in the first (11.5±18.4 mmHg, p= 0.0035) and the second group (13.8±12.6 mmHg, p<0.001) with no significant differences between both groups. No significant difference between first and second group in clinical outcomes during the follow up period was observed: ulcer healing in 20/26 vs 20/29 (77% vs 69%, NS) and healing failure in 6/26 vs 9/29 (23% vs 31%, NS).

Conclusions: Our study demonstrated no significant differences in the effect of PTA between patients with ABI equal or above 0.9 and in patients with ABI below 0.9. We concluded, that patients with non-healing ulcers can benefit from vascular intervention (PTA) even if ABI above 0.9, which cannot reliably exclude PAD in diabetic patients.

Presentation of diabetic foot ulcer and its outcome at a tertiary care unit in Karachi – Pakistan

A. Basit[1], M. Riaz[1], M.Y. Ahmedani[1], A. Fawwad[2], M.F. Chohan[3], Z. Miyan[1], A. Zafar[1], A. Salman[1]
[1] Baqai Institute of Diabetology & Endocrinology, Department of Medicine, Karachi, Pakistan
[2] Baqai Institute of Diabetology & Endocrinology, Department of Research, Karachi, Pakistan
[3] Baqai Institute of Diabetology & Endocrinology, Department of Diabetic Foot, Karachi, Pakistan

Objective: To study the presentation and risk factors determining the outcome of diabetic foot ulcer at a tertiary care unit.
Methods: We have characterized the presenting features, grade of foot ulceration, risk factors for ulceration and lower extremity amputation (LEA) in 1246 diabetic subjects presenting with foot ulceration from January 2004 to December 2008 at a tertiary care unit in Karachi, Pakistan. Screening for other complications of diabetes and metabolic assessment was also done according to standard guidelines.
Results: Seventy percent of the subjects were male with mean age of 53.52 ± 10.99 years. Majority of the subjects (51.60%) had UT Grade 1 ulceration followed by UT Grade 3 in 26.5% and UT Grade 2 in 13.4% respectively. 35.23% subjects completely healed without LEA while 9.63% subjects required LEA. 24.23% subjects are currently under treatment and 30.4% subjects were either referred to government setup or they left against medical advice (LAMA). Previous history of ulceration was present in 42.5% subjects. The risk of LEA was significantly associated with the UT grade and stage of ulceration at presentation along with increasing age. Foot care practices were followed by only 19.02% of the study population while cause of diabetic foot ulcer was not declared by 58.4% of the subjects. Regarding the type of foot ulcer, 58.10% subjects were having neuropathic ulcer, 40.12% subjects were having neuro-ischemic and pure ischemic ulcers were seen in only 1.28% subjects. Majority (94%) of the subjects were having poor glycaemic control i.e.HbA1c>7 while 72% subjects were having BP> 130/80. Retinopathy and nephropathy was present in 67% and 56% subjects respectively while 11% subjects were having diagnosed CAD.
Conclusion: The outcome of ulceration was determined by the severity and grade of foot ulceration at presentation. Effective foot care advice should be propagated at primary care level to the patients to reduce the burden imposed by diabetic foot complication, particularly in developing countries.

The study on mechanisms of epidermal keratinocyte migration impaired by glycated matrix

S. Zhengiang[1], W.A.N.G. Runxiu[2], L.U. Shuliang[3], Y.U. Demin[4], C.H.E.N. Liming[4], W.A.N.G. Penghua[4]
[1] Tianjin Medical University, Metabolic Diseases Hospital, Tianjin, China
[2] Guangxi Medical University, First Affiliated Hospital, Nanning, China
[3] Shanghai second medical University, Ruijin Hospital, Shanghai, China
[4] Tianjin medical University, Metabolic Diseases Hospital, Tianjin, China

Background and aims: Diabetes mellitus is one of the most common disease in human life. Many kinds of complications caused by diabetes metabolism disorder and its metabolite, including nonhealing wound, now is becoming a difficulty in clinical treatment and academic research. Keratinocyte is the main repair cell participating wound healing, whose migration function is the base of wound re-epithelization. Keratinocyte continuously migrates on the wound edge, while wound size reduces to complete healing. If keratinocyte migration is blocked, then it means that the wound can't heal. So the study of keratinocyte migration behavior is of profound significance for exploring the rule of wound healing. This study is to discuss that keratinoctye migration is impaired by glycated matrix and its mechanism.
Methods: Keratinocytes from six male Sprague-Dawley rats' back, cultured for two to three generations, were used for experiments. Glycated laminin model were made by laminin cultured in glycolaldehyde and AGEs concentrations were assessed by detecting total fluorescence in glycated laminin model and immunohistochemistry assay. Keratinocytes were cultured on glycated laminin and normal laminin as study group and control group respectively. Keratinocyte migration was measured by scratch wound healing assay. Adhesion rate was expressed by Optical Density(OD), determined with MTT assay. Keratinocyte morphology was observed by scanning electron microscopy and inverted microscope. F-actin was observed by immunofluorescence. Integrina3 was determined by flow cytometry.
Results: The amount of migrating keratinocyte in study group is significantly less than control(13±4/HP vs 61±11/HP, P<0.05), which confirmed that keratinocyte migration was obviously inhibited by glycated matrix. There was no difference of adhesion rate between study group and control group(12h OD: 0.102±0.014 vs 0.134±0.062; 24h OD: 0.181±0.050 vs 0.187±0.061,P>0.05), however the morphology of keratinocyte on glycated laminin indicates that the cell body was small and hardly spread compared with that on normal laminin. Microfilament of the keratinocyte on the glycated laminin was sparsely distributed in the cytoplasm and around cell nuclear, but the expression of microfilament in the control group was intensively and distributed on the cell membrane, especially on the free edge. The expression of keratinocyte integrina3 on normal laminin is significantly higher than that on glycated laminin(11.23±5.27% vs 36.58±11.24%, P<0.05).
Conclusions: Keratinocyte migration is inhibited by the glycated laminin. The reason behind the phenomenon is possibly that integrin signaling disorder leads to decrease of integrin and actin expression, followed by the drop of lamellipodia and filopodia development, and the ultimate consequence would be the contribution to the restrained migration.

A comparative study of outcomes of patients with diabetic foot lesions managed with an off-loading device

Z. Abbas[1], J. Lutale[2], L. Archibald[3]
[1] AMC / MUHAS, Internal Medicine, Dar es Salaam, Tanzania
[2] MUHAS, Internal Medicine, Dar es Salaam, Tanzania
[3] University of Florida, Internal Medicine, Gainesville Florida, USA

Background: Foot ulcers in persons with diabetes are the leading cause of non-traumatic lower limb amputation in Tanzania; recent data indicate such ulcers are more likely due to infection rather than neuropathy or vascular disease. Unlike developed nations, where off-loading devices have proven effective in ulcer healing, there are no published data that demonstrate the effectiveness of such devices among diabetes populations in Africa.
Objectives: To determine the utility of a locally made shoe as an off-loading device in the management of foot ulcers among persons with diabetes who attend Muhimbili National Hospital (MNH) diabetes clinic.
Methods: During Sept 1995 through Dec 2005 (study period), consecutive adult diabetes patients with foot ulcers were evaluated and enrolled after informed consent. Detailed clinical and epidemiologic data were recorded and patients were randomly given custom-made off-loading shoes according to the site of the foot ulcer. We followed up patients in the MNH clinic to document progress and outcomes.
Results: Of 885 patients enrolled during the study period, 589 (66%) were male, 660 (75%) were African (vs. 16% Asian), 861 (97%) had type 2 diabetes, 762 (86%) had peripheral vascular disease, 763 (86%) had peripheral neuropathy, and 129 (15%) were fitted with custom-made shoes. All patients received at least one course of antibiotics. The median age and body mass index was 54 (range: 14-98) years and 24.8 (range: 14-45) kg/m^2, respectively. Forty-four (5%) patients died from causes attributed to complication from their foot ulcer. The median time to healing was 49 days. On multivariate analysis using logistic regression, independent correlates for total healing of ulcers were female sex ($p < 0.01$), age <50 ($p < 0.001$), sloughectomy ($p < 0.01$), or tissue loss grade ($p < 0.01$).
Conclusion: In conclusion, we did not document any significant advantage in using a locally made shoe to achieve total healing of foot ulcers in our study population, even among patients with severe ulcers. Adjunct surgery, antibiotics, and education focused on targeted groups of patients appear to be playing a major role in achieving total healing of ulcers.

Moxifloxacin use in complex treatment of neuroischemic form of diabetic foot with collateral blood flow

D.V. Seliverstov[1], I.V. Kondrus[1], V.G. Kutskir[1], I.A. Podyablonskaya[2], V.V. Masevnin[1], N.Y. Terentyeva[1], I.N. Kogarko[3], B.S. Kogarko[3], I.I. Ganeev[3]
[1] MAPHC RRCH, of burulent surgery, Ryazan, Russia
[2] SEE HPE RyazSMU, of surgery, Ryazan, Russia
[3] ICP RAS, of biochemistry, Moscow, Russia

Aim: to evaluate moxifloxacin influence (avelox, Bayer Schering Pharma) on the results of surgical treatment of patients with neuroischemic form of diabetic foot (DF) with collateral blood flow.
Methods: In 2007-2008 40 patients with neuroischemic form of DF with collateral blood flow in the main and comparison groups were treated. In these DF groups with collateral blood flow, patients with toe gangrene prevailed – 62.5 % in each group. In the main group complex treatment included avelox – daily 400 mg intravenously within 2 days, then the same dose perorally within 5 days; but in comparison group a third generation cephalosporin was administered alongside with aminoglucoside and metronidazole within 7 days.
Results: In the main group with collateral blood flow 40 operations were performed: 4 necrectomies, and as a result of complication 1 extremity amputation was done at the level of shin upper one-third, 8 phlegmon openings (1 amputation at the level of shin upper one-third), 8 toe amputations in our clinic modification with secondary suture during the second phase of wound process (1 amputation at the level of hip middle one-third), 20 transmetatarsal amputations (2 amputations at the level of hip middle one-third). In comparison group 40 operations were performed: 3 necrectomies (1 extremity amputation at the level of shin upper one-third), 8 phlegmon openings (2 amputations at shin level), 8 toe amputations in our clinic modification with secondary suture during the second phase of wound process (2 amputations at the level of shin upper one-third), 21 transmetatarsal amputations for toe gangrene (2 amputations at the level of hip middle one-third and 1 amputation at the level of shin upper one-third).
Conclusion: Reliable improvement of surgical treatment results of patients with neuroischemic form of DF with collateral blood flow took place after complex therapy that included 400 mg of avelox daily within 2 days intravenously, then perorally the same dose within 5 days.

Efficacy of dapagliflozin in three populations of patients on different treatment regimens for various stages of T2DM

A. Bastien[1], V. Woo[2], J.P. Wilding[3], C.J. Bailey[4], L. Ying[5], J.F. List[1]
[1] Bristol-Myers Squibb, Global Clinical Research, Princeton, USA
[2] University of Manitoba, Department of Internal Medicine, Winnipeg, Canada
[3] University of Liverpool, School of Clinical Sciences, Liverpool, United Kingdom
[4] Aston University, Diabetes Research, Birmingham, United Kingdom
[5] Bristol-Myers Squibb, Global Biometric Sciences, Hopewell, USA

Aims: Dapagliflozin, a novel oral antidiabetic to treat T2DM, blocks renal glucose reabsorption by selectively inhibiting sodium-glucose co-transporter 2. We compared 3 dapagliflozin trials of patients with inadequate glycemic control at different T2DM stages reflected by their regimens: 1) drug-naïve; 2) metformin; or 3) insulin + insulin-sensitizers (IS). Dapagliflozin, with its insulin-independent action, would be anticipated to work equally well regardless of T2DM stage and background medication.
Methods: Data were derived from 3 double-blind, placebo-controlled trials. Drug-naïve (Study 008): This 12-wk study randomized 389 drug-naïve patients to placebo (PBO), 2.5, 5, 10, 20, or 50 mg dapagliflozin, or metformin 750 mg titrated to 1500 mg. Metformin (Study 014 ST): This 24-wk study randomized 546 patients on metformin =1500 mg to PBO, 2.5, 5, or 10 mg dapagliflozin, plus open label metformin. Insulin+IS (Study 009): This 12-wk study randomized 71 patients on insulin (=50 U/d) + IS (metformin +/or thiazolidinediones) to PBO, 10, or 20 mg dapagliflozin, plus baseline IS and 50% baseline insulin.
Results: The mean T2DM duration, baseline and mean change from baseline for HbA1c, FPG, and weight are presented in the **Table**. Dapagliflozin was efficacious regardless of T2DM stage and background medication. Dapagliflozin produced continuous, progressive weight loss, and lowered glycemia without significant hypoglycemia. AEs were generally balanced, with similar SAE rates in all arms and no deaths. Dapagliflozin did not appear to impact UTI incidence. A trend of higher genital infection incidence was observed with dapagliflozin vs PBO.
Conclusion: Regardless of T2DM stage and background medication, dapagliflozin, as an insulin-independent agent, was efficacious in early stage drug-naïve patients, mid stage patients on steady-dose metformin, and late stage patients on complex insulin-based regimens.

D-0766

Incidence of urinary tract infections and of genital infections in two T2DM populations cotreated with dapagliflozin and oral antidiabetics +/- insulin

A. Bastien[1], A. Gomez Caminero[2], L. Ying[3], J.F. List[1]
[1] Bristol-Myers Squibb, Global Clinical Research, Princeton, USA
[2] Bristol-Myers Squibb, Research & Development, Pennington, USA
[3] Bristol-Myers Squibb, Global Biometric Sciences, Hopewell, USA

Aims: Epidemiological data show higher rates of urinary tract infections (UTIs) and genital infections in T2DM patients vs the general population. Both rates increase with poor T2DM control, T2DM duration, and treatment complexity. Infection risks are reported to increase as patients move from no treatment, to oral antidiabetics, to oral/insulin combinations. The etiologies of UTIs and genital infections in T2DM patients have not been confirmed, but poor glycemic control

and glucosuria are believed to be contributing factors. Dapagliflozin, a novel insulin-independent oral antidiabetic, pharmacologically induces glucosuria (2-3 g/h) to lower glycemia. By inhibiting sodium-glucose co-transporter 2, dapagliflozin modulates renal glucose reabsorption to promote urinary glucose excretion. We compared UTI and genital infection rates after adding dapagliflozin to regimens of T2DM patients who had inadequate glycemic control with regimens of either metformin or insulin+insulin-sensitizers (IS).

Methods: Data were analyzed from 2 double-blind, placebo-controlled trials. Metformin (Study 014 ST): This 24-week study randomized 546 patients on stable-dose metformin =1500 mg to placebo (PBO), 2.5, 5, or 10 mg dapagliflozin, plus open-label metformin =1500 mg. Insulin+IS (Study 009): This 12-week trial randomized 71 patients on insulin (=50 units/d) plus IS (metfomin +/or thiazolidinediones) to PBO, 10, or 20 mg dapagliflozin, plus baseline IS and 50% baseline insulin.

Results: Insulin+IS Study patients had T2DM longer than Metformin Study patients (mean 12.3 years vs 6.1 years, respectively), and higher baseline HbA1c (mean 8.4% vs 8.1%, respectively). All dapagliflozin arms showed glycemic efficacy; adjusted mean changes in HbA1c from baseline ranged from -0.67% to -0.84% (Metformin Study) and -0.61% to -0.68% (Insulin+IS Study). **UTIs**: Metfomin Study patients had similar UTI rates: 4.4–8.1% (dapagliflozin) vs 8.0% (PBO). One patient (4.2%) in the Insulin+IS Study on dapagliflozin 20 mg reported UTI compared to none on PBO or dapagliflozin 10 mg. **Genital Infections**: In the Metformin Study, genital infection rates were 5.1% (PBO) vs 8.0–13.1% (dapagliflozin arms). In the Insulin+IS Study, 1 patient (4.3%) on PBO reported genital infection, none on dapagliflozin 10 mg, and 5 (20.8%) on dapagliflozin 20 mg.

Discussion: Dapagliflozin pharmacologically induces controlled glucosuria to lower hyperglycemia. Despite adding dapagliflozin to different T2DM treatment regimens, UTI rates in this series of patients were similar for PBO and dapagliflozin. A trend of potentially higher genital infection incidence was observed for dapagliflozin vs PBO. These data suggest that glucosuria does not increase the risk of UTI in T2DM patients, but may increase the risk of genital infections. Additional investigation is needed to further elucidate the relationship of glucosuria to these different risks.

JNJ-28431754/TA-7284, an inhibitor of sodium glucose co-transporter 2, reduces body weight gain in zucker fatty rats

Y. Liang[1], T. Martin[2], K. Demarest[3]
[1] *Johnson & Johnson Pharmaceutical Research and Development, Drug Discovery, Spring House, USA*
[2] *Johnson & Johnson Pharmaceutical Research and Development, PRD, Spring House, USA*
[3] *Johnson & Johnson Pharmaceutical Research and Development, ED CDTL, Spring House, USA*

Aims: Inhibition of sodium glucose co-transporter 2 (SGLT2) activity significantly increases urinary glucose excretion, which in turn reduces blood glucose levels. JNJ-28431754 (JNJ1754), an inhibitor of SGLT2 that has been used experimentally in diabetic and obese rodent models, not only lowers blood glucose levels but also results in a significant reduction of body weight gain, accompanied by a decreased feed efficiency index. To explore the potential mechanisms of JNJ1754 on body weight control, a study was conducted on Zucker Fatty (ZF) rats.

Methods: Male ZF rats (n=96 for total of study) fed with different diets (n=24 for each diet) (regular chow, high-fat, high-protein, or high-sucrose diets) were treated with vehicle or JNJ1754 3 mg/kg for 21 days, with or without pair-feeding to the vehicle group (n=8). Body weight, food consumption, blood glucose, body fat/lean mass, and energy expenditure were determined after 21 days of treatment.

Results: The total amounts of Kcal intake for vehicle-treated ZF rats were similar regardless of the different composition of fat, protein, or carbohydrate in the diet. Although JNJ1754 treatment significantly increased urinary glucose excretion, it did not significantly increase food consumption among the different diets. However, a marked decrease of body weight gain was observed in ZF rats fed with regular chow (-14.1%, $P<0.05$), high-fat diet (-10.9%, $P<0.05$), or high-protein diet (-17.2%, $P<0.05$). In ZF rats fed with a high-sucrose diet, JNJ1754 treatment resulted in a trend for less body weight gain (-7.6%). Indirect calorimetry determination showed that there was a significant decrease of respiratory quotient in ZF rats treated with JNJ1754, regardless of the different dietary composition, suggesting an increase of fatty acid oxidation in these rats. The 24-h energy expenditure (VO2 value) was not significantly different between vehicle- and compound-treated groups. In addition, there was a 10-16% reduction of the epididymal fat pad weight in compound-treated rats, although this reduction did not reach statistical significance.

Discussion/conclusion: SGLT2 inhibition in rats significantly increased urinary glucose excretion, which was associated with decreased body weight gain and changes in energy metabolism profile as demonstrated by increased fatty acid oxidation. This effect on body weight loss seems not to be influenced by the nutritional components in the diet. Further studies are needed to investigate if other factors beyond lipid mobilization also participate in the body weight control effect of SGLT2 inhibitor treatment.

JNJ-28431754/TA-7284, an inhibitor of sodium glucose co-transporter 2, ameliorates diabetic syndrome in the ZDF rat

Y. Liang[1], K. Demarest[2], T. Martin[3]
[1] *Johnson & Johnson Pharmaceutical Research and Development, Drug Discovery, Spring House, USA*
[2] *Johnson & Johnson Pharmaceutical Research and Development, ED CDTL, Spring House, USA*
[3] *Johnson & Johnson Pharmaceutical Research and Development, PRD, Spring House, USA*

Aims: Inhibition of sodium glucose co-transporter 2 (SGLT2) activity significantly increases urinary glucose excretion (UGE), which in turn reduces blood glucose levels. JNJ-28431754 (JNJ1754), an inhibitor of SGLT2, has been used experimentally in Zucker Diabetic Fatty (ZDF) rats to examine its effect on diabetic syndrome.

Methods: Male ZDF rats (10-11 wks of age, body weight ranging from 325-375 g) were used in the experiments. These ZDF rats were grouped based on their fed blood glucose levels (n=8 in each group) and treated with vehicle or with either a single dose of JNJ1754 or multiple doses for 4 weeks. The major pharmacologic end points included blood glucose levels in fed and fasted conditions, oral glucose tolerance test (OGTT), UGE, and plasma insulin levels as well as pharmacokinetics.

Table 1

Group	Time after a single-dose administration (h)							
	0	2	4	6	10	24	30	34
	Blood glucose levels (mg/dL)							
Vehicle	423±51	397±40	450±47	435±43	363±38	463±43	455±51	418±43
JNJ1754, 1 mg/kg	454±19	298±4	321±23*	323±19*	263±22*	393±23	410±28	329±17
JNJ1754, 3 mg/kg	434±24	236±26*	254±26*	242±23*	201±17*	303±22*	321±36*	260±21*
	JNJ1754 plasma levels (ng/mL)							
JNJ1754, 1 mg/kg	NA	64.5±21.2	347±184	431±134	62.8±24.7	59.9±27.0	7.30±0.0	ND
JNJ1754, 3 mg/kg	NA	507±84.7	1134±186	937±51.0	737±149	503±276	258±93.6	ND

NA=not applicable; ND=not determined.
*$P<0.05$.

Results: JNJ1754 showed a significant antihyperglycemic effect in ZDF rats that received a single dose of compound (Table). This blood glucose-lowering effect lasted for >34 hr, even if the compound was undetectable in the circulation. In the OGTT, JNJ1754 at 1 mg/kg also significantly increased UGE (191±12 mg/24 h vs 63±10 mg/24 h in the vehicle group, P<0.05) and resulted in a 17±3% reduction of blood glucose AUC vs vehicle-treated rats (P<0.05). A 4-week treatment with JNJ1754 3 mg/kg significantly decreased fed blood glucose levels to 248±14 mg/dL (vs 598±18 mg/dL in the vehicle group, P<0.01), reduced HbA1c to 7.1±0.3% (vs11.5±0.3% in the vehicle group, P<0.01), with an improved insulin release response to glucose challenge (155±12% increase vs vehicle group, P<0.05).

Discussion/conclusion: SGLT2 inhibition in ZDF rats significantly increased UGE, which ameliorated hyperglycemia and reduced HbA1c in these diabetic rats. Improved blood glucose control also enhanced insulin release response to glucose challenge, suggesting an improved pancreatic beta-cell function in JNJ1754-treated rats.

Influence of ß-adrenoceptor antagonists on the hepatic and renal uptake of metformin mediated by organic cation transporters 1 (OCT1) and 2 (OCT2)

I. Bachmakov[1], J. König[1], M.F. Fromm[1], H. Glaeser[1]
[1] *Friedrich-Alexander University Erlangen-Nuremberg, Institute of Experimental and Clinical Pharmacology and Toxicology, Erlangen, Germany*

Aims/methods: The uptake of drugs from the blood into hepatocytes and renal tubular cells is a key determinant for metabolism and elimination and may influence their hepatic and systemic plasma concentrations and, thus, pharmacological effects. Metformin, used for treatment of type 2 diabetes is taken up into hepatocytes and into renal tubular cells by the organic cation transporters 1 (OCT1) and 2 (OCT2), respectively. Since many patients with diabetes type 2 receiving metformin are concomitantly treated with ß-adrenoceptor antagonists, we tested whether ß-adrenoceptor antagonists can inhibit OCT1- and OCT2-mediated metformin transport. Using HEK293- and MDCKII cells stably expressing the uptake transporter OCT1 or OCT2 we analyzed, whether the ß-adrenoceptor antagonists bisoprolol, metoprolol, carvedilol, and propranolol inhibit the transport of OCT1- and OCT2 substrates 1-methyl-4-phenylpyridinium (MPP^+) and metformin.

Results: Neither bisoprolol nor metoprolol significantly inhibited the OCT1-mediated uptake of both MPP^+ and metformin. In contrast, a significant inhibition of the OCT1-mediated MPP^+ and metformin transport was observed for carvedilol und propranolol (IC_{50} carvedilol for MPP^+: 2.3 µM; IC_{50} carvedilol for metformin: 1.5 µM; IC_{50} propranolol for MPP^+: 8.6 µM; IC_{50} carvedilol for metformin: 8.3 µM).

Similarly, the OCT2-mediated uptake of MPP^+ was significantly inhibited by neither bisoprolol nor metoprolol, whereas a significant inhibition was observed for carvedilol und propranolol (IC_{50}: 26.3 µM and 67.5 µM, respectively). Moreover, all ß-adrenoceptor antagonists significantly inhibited OCT2-mediated metformin uptake (IC_{50} bisoprolol: 2.4 µM; IC_{50} carvedilol: 2.3 µM; IC_{50} metoprolol: 50.2 µM; IC_{50} propranolol: 8.3 µM). Low carvedilol concentrations were shown to stimulate OCT2-mediated metformin transport by 40%.

Conclusions: These in vitro results demonstrate that alterations of uptake transporter function by ß-adrenoceptor antagonists have to be considered as potential mechanisms underlying drug-drug interactions in the liver and kidney.

Quick release bromocriptine (Cycloset™) a novel treatment for type 2 diabetes also demonstrates improvements in blood pressure

R. Scranton[1], M. Erzoki[1], W. Farwell[2], J.M. Gaziano[2], A. Cincotta[3]
[1] *VeroScience, Medical Affairs, Tiverton, USA*
[2] *VA Healthcare System, Medicine, Boston, USA*
[3] *VeroScience, Scientific Affairs, Tiverton, USA*

Background and aims: Bromocriptine-QR (BQR), a unique quick release formulation of bromocriptine, a sympatholytic dopamine D2 receptor agonist, improves glycemic control in subjects with type 2 diabetes (T2D) when given once daily in the morning, primarily by reducing post-prandial hyperglycemia without increasing post prandial insulin. In a large randomized trial of subjects with T2D (Cycloset Safety Trial; CST), BQR therapy significantly reduced the cardiovascular event rate by 40%. In this secondary analysis, we investigated the impact of BQR on systolic and diastolic blood pressures (SBP and DBP, respectively).

Methods: The CST was a 52 week, placebo-controlled, randomized trial evaluating the safety and efficacy of BQR versus placebo in 3070 subjects with T2D. Subjects could alter concomitant blood pressure (BP) medications during the trial to manage hypertension. Two physicians blinded to treatment group assignment assessed changes in concomitant BP therapies. Between group differences in mean changes from baseline for SBP and DBP after 52 weeks on treatment were compared using t-test among A) the entire study population, B) subjects on at least one BP medication at baseline and without a change in number of BP medications, and C) subjects on a BP medication with baseline SBP of >130 mmHg and without a change in number of BP medications. Changes in categorical variables were assessed using chi square.

Results: The baseline mean SBP (130 mmHg) and DBP (77 mmHg) were similar in both groups. Fewer subjects randomized to BQR intensified BP therapies during the course of the trial. Fewer subjects randomized to BQR reported adverse events of hypertension (1.5%) compared to placebo (3.1%); p=0.003. Among group A, the mean SBP and DBP changes were -2.3 and -1.9 mmHg, respectively for BQR (n = 1219) compared to -0.6 and -0.9 mmHg, respectively for placebo (n = 732), (between group differences were significant; SBP p=0.03 and DBP p=0.02). For group B, the mean SBP and DBP changes were –2.6 and -2.2 mmHg, respectively for BQR (n =757) compared to –0.7 and –0.4 mmHg, respectively for placebo (n = 453), (between group differences were significant; SBP p=0.05 and DBP p=0.002). For group C, mean SBP and DBP changes were -10.5 and –4.3 mmHg, respectively for BQR (n =344) compared to –7.2 and –2.6 mmHg, respectively for placebo (n = 190), (SBP p=0.02 and DBP p=0.06).

Conclusion: BQR reduced blood pressure and adverse events of hypertension in subjects with T2D. Improvements in SBP and DBP among subjects taking BQR may have in part contributed to the 40% cardiovascular event rate reduction observed in this trial among subjects taking BQR. In addition to improving glycemic control, Bromocriptine-QR improves blood pressure in subjects with T2D.

Associations between the use of oral anti-diabetic drugs and the risk of cancer in type 2 diabetes patients

A. Kong[1], X. Yang[1], W. So[1], R. Ma[1], G. Ko[1], J. Chan[1]
[1] *The Chinese University of Hong Kong, Dept of Medicine and Therapeutics, Hong Kong, Hong Kong China*

Aim: Epidemiological studies reported inconsistent associations between the use of thiazolidinediones and cancer in type 2 diabetes mellitus. We aim to explore the associations between oral anti-diabetic drugs (OAD) and the risk of cancer in Hong Kong Diabetes Registry.

Methods: The Hong Kong Diabetes Registry was established since 1995. All diabetes referred to the Prince of Wales Hospital in Hong Kong underwent comprehensive assessment based on the European DiabCare protocol. Outcome was censored on 30th July 2005 from the Hong Kong Hospital Authority Central Computer System and the Hong Kong Death Registry. From 1995 to 2005, 7920 diabetic patients were enrolled in the registry. Excluding type 1 diabetes, non-Chinese patients, known history of cancer and missing data, 6103 Chinese type 2 diabetes patients were enrolled in this analysis.

Results: The median age of the cohort was 57 years (25th to 75th percentile: 47 to 67 years) and 46% were female. The median duration of diabetes was 6 years (2 to 11 years) at enrolment. After a median follow-up of 4.91 years (2.81 to 6.98 years), 4.44% (n=271) developed incident cancer and the incidence rate was 9.21 (95% confidence interval: 8.12 to 10.30) per 1000 person-years. Diabetes who developed cancers were older, more likely to be smokers and drinkers, have longer duration of diabetes, higher systolic blood pressure, higher levels of urine albumin-creatinine ratio, lower estimated glomerular filtration rate and low density lipoprotein (LDL-C) level <2.8 mmol/L, and albuminuria and LDL-C ?3.8 mmol/L than those diabetes without these clinical and biochemical features. Diabetes with cancer were less likely to use gliclazide, metformin, rosiglitazone, statins and angiotensin receptor blockers compared to diabetes without incident cancer. After adjusted for age, sex, body mass

index, smoking and alcohol drinking status, the use of rosiglitazone, metformin and gliclazide (Hazard ratio: 0.16, 0.58 and 0.73 with p-value=0.0091, <0.0001, 0.0168 respectively) was associated with lower risks of cancer.

Conclusions: We observed a negative association between the use of rosiglitazone, metformin or gliclazide and the risk of incident cancer in Hong Kong Chinese type 2 diabetes patients.

Long-term effects of metformin on endothelial function and inflammation in type 2 diabetes treated with insulin: a randomised, placebo-controlled trial

A. Kooy[1], J. de Jager[1], M.G. Wulffelé[1], C.G. Schalkwijk[2], P. Lehert[3], D. Bets[4], A.J.M. Donker[5], C.D.A. Stehouwer[2]

[1] *Bethesda Diabetes Research Center & Bethesda General Hospital, Department of Internal Medicine, Hoogeveen, The Netherlands*

[2] *Maastricht University Medical Center, Department of Internal Medicine, Maastricht, The Netherlands*

[3] *Faculty of Economics, Department of Statistics, Mons, Belgium*

[4] *E. Merck, Clinical Research and Development, Amsterdam, The Netherlands*

[5] *Free University Medical Center, Department of Internal Medicine, Amsterdam, The Netherlands*

Aims: Three out of 4 patients with type 2 diabetes will die from cardiovascular disease. Treatment with metformin reduces rates of cardiovascular morbidity and mortality in type 2 diabetes, possibly through improvements of endothelial function and/or reduction of low-grade inflammation. Therefore, we studied the effects of metformin on markers of endothelial function and low-grade inflammation in patients with type 2 diabetes.

Methods: 390 insulin-treated patients with type 2 were randomly allocated to either placebo or metformin. 277 subjects (= 72%) completed the trial. During a follow-up of 4.3 years, plasma samples were taken to measure markers of endothelial function (urinary albumin excretion, plasma levels of vWf, sVCAM-1, sE-selectin, t-PA and PAI-1) and markers of low-grade inflammation (plasma levels of CRP and sICAM-1). For each subject, each variable was expressed as standard deviation of difference from the population mean. Mean standard deviation scores (= z-scores) were calculated as:

- endothelial dysfunction z-score = {urinary albumin excretion + vWf + sVCAM-1 + sE-selectin + t-PA + PAI-1}/6
- inflammation z-score = {CRP + sICAM-1}/2.

Results: Metformin treatment versus placebo was associated with a decrease in vWf of 11% (-16 to -6; p<0.001); a decrease in sVCAM-1 of 5% (-8 to -3; p<0.001); a decrease in t-PA of 15% (-20 to -9; p<0.001); a decrease in PAI-1 of 21% (-31 to -9; p=0.001); and a decrease in the endothelial dysfunction z-score of 7% (-10 to -4; p<0.001). Changes in urinary albumin excretion and sE-selectin were not significant. Metformin treatment versus placebo was associated with a decrease in CRP of 17% (-31 to -1; p=0.036); a decrease in sICAM-1 of -5% (-8 to -2; p=0.004); and a decrease in the inflammation z-score of -5% (-10 to +1; p=0.074).

Conclusion: This is the first long-term randomized controlled trial showing that metformin treatment is associated with decreases in the plasma concentrations of vWf, sVCAM-1, t-PA, PAI-1, CRP and sICAM-1, reflecting an improvement of endothelial regulation of haemostasis (vWf), of leukocyte adhesion (sVCAM-1), and of fibrinolysis (t-PA and PAI-1), as well as a reduction of low-grade inflammation.

D-0773

A PPAR-sparing insulin sensitizer is effective in type 2 diabetic patients without causing weight gain

J.R. Colca[1], R.F. Kletzien[1], J.T. VanderLugt[1]

[1] *Metabolic Solutions Dev. Co., Discovery and Development, Kalamazoo, USA*

Background and aim: We have suggested that insulin sensitizing activity of the thiazolidinediones (TZDs) can be separated from their ability to activate the nuclear transcription factor PPARg. Since PPARg-driven transcription has been implicated in many negative effects of both TZD and nonTZD-related insulin sensitizers, a PPAR sparing analog might be expected to have a superior profile of activity. We hypothesized such a compound would exert beneficial pharmacology without causing plasma volume expansion and weight gain. We have previously identified PPAR-sparing analogs with similar insulin sensitizing pharmacology to pioglitazone in preclinical animal models. Here we directly compare the prototypical PPAR-sparing analog, Mitoglitazone™ (MSDC-0160), to pioglitazone hydrochloride (Actos®) in type 2 diabetic patients. MSDC-0160 is an isomer of a known pioglitazone metabolite,

Methods: A double bind, placebo and comparator-controlled phase IIA study was carried out in 76 type 2 diabetic patients at 12 US sites. MSDC-0160 (Mito) was given as two doses of bulk drug [90 mg (Mito1) or 220 mg (Mito2)] chosen to bracket exposures (AUC) predicted for pioglitazone and its active metabolites. Subjects were either drug-free or on a stable dose of metformin. Participants underwent a two week single blind placebo lead-in followed by four weeks of active double blind treatment and a one week follow-up. The primary endpoint was change in postprandial glucose determined by mixed meal tolerance tests.

Results: Mito was well tolerated and no serious adverse events were observed. Exposures of Mito and its metabolite were reached that should not be sufficient to activate PPARg. Both Mito2 and pioglitazone (Pio) significantly (p< 0.05 versus placebo) reduced circulating postprandial blood glucose, triglycerides, and free fatty acids. High molecular weight adiponectin was increased by 102 %, 223%, and 215% for Mito1, Mito2, and Pio, respectively. Both Pio and Mito2 produced a statistically significant time-dependent decrease in circulating fasting glucose (1.1 mM and 0.98 mM, respectively) and a statistically significant time-dependent increase in HDL cholesterol (0.119 and 0.130 mM, respectively). Over this short study period, Pio resulted in a small (1.14 kg), but statistically significant increase in weight gain that was not seen in the Mito-treated patients.

Conclusions: This study suggests that it is possible to achieve clinical responses with a non-PPAR activating thiazolidinedione similar to pioglitazone without the associated weight gain.

Glycemic control and exercise responses in type 1 diabetes mellitus athletes during 217km ultramarathon

T. Belli[1], M. Ackermann[1], G.G. Araújo[1], I.G.M. dos Reis[1], C.L.S. Meireles[1], M.O. Costa[1], P.P.M. Scariot[1], D.V. Macedo[2], C.A. Gobatto[1]

[1] *UNESP, Laboratório de Fisiologia Aplicada ao Esporte (LAFAE) - Departamento de Educação Física, Rio Claro, Brazil*

[2] *UNICAMP, Laboratório de Bioquímica do Exercício (LABEX) - Departamento de Bioquímica, Campinas, Brazil*

Aims: This study was designed to assess the glycemic control, intensity and duration of exercise, body weight and hematocrit of type 1 Diabetes Mellitus (DM1) athletes during 217 km relay ultramarathon.

Methods: It was studied a team composed by three DM1 athletes (35.3±0.9 years; 172.7±3.7 cm of height; 22.3±4.6 years of diagnosis; 14.3±0.9 years of race training; 40-140km/week of training volume) that participated in the "Brazil 217 Ultramarathon Relay". The total gain and loss of altitude during this 217km race were 10 and 9 km, respectively. The blood glucose was measured during the race (Roche Accu Check). The glycemic load of ingested food was also measured to adequate insulin infusion. Blood samples were obtained to hematocrit determination (Sysmex XS1000i) and body weight was assessed (Welmy) before and 5min after the race. One week before the competition and in subsequent days, the athletes individually determined the critical velocity (CV) from four maximal running in different distances (800, 1200, 1600, 2000m). So, the CV was determined by the angular coefficient of the linear fit of distance versus running time. The CV represents the aerobic capacity.

Results: The team completed the race in 29h28min at 3rd place in the competition. The relay was composed by six exercise bouts performed by each

athlete that ran a total of 72.3±6.0km each one. The exercise intensities for the first three and the last three bouts were significantly different (7.5±0.5 and 8.9±0.4 km/h, respectively; 54.2±4.1% and 64.9±3.0% of CV). The exercise time for each athlete at the first three bouts was 2h24min (±9min), longer than the last three exercise sessions (37min±7min). The glycemic values pre-race were in agreement with the position statement of American Diabetes Association, decreasing significantly during the first three bouts (238.9±36.1 vs 107.8±7.3; 166.3±20.7 *vs* 79.0±7.9 and 239.1±31.9 *vs* 83.8±5.7mg/dL). On the other hand, there was no significant differences between pre and post exercise in the three last bouts (258.0±31.0 *vs* 196.5±29.5; 231.0±3.0 *vs* 160.7±46.9 and 249.5±6.5 *vs* 186.0±46.4mg/dL), when the time of exercise was reduced and the intensity was increased significantly. The body weight (70.9±3.1 *vs* 68.6±3.4kg) and hematocrit (45.6±1.5 *vs* 48.1±2.0%) were not changed before and after race.

Discussion/conclusion: The data presented here have shown that DM1 athletes can participate in ultra-endurance races exhibiting high performance since glucose control is made along the race as an important management strategy to keep adequate blood glucose concentrations for physical activity (70-300mg/dL). This efficient control may have prevented the dehydration induced by glycosuria and polyuria, what can be observed by maintenance of body weight and hematocrit.

High physical fitness is independently related to a better glycaemic control and cardiovascular risk profile in a type 2 diabetes cohort

M.D.L. Maia[1], C.R.L. Cardoso[1], S. Monteiro[1], S. Yendrick[1], N.C. Leite[1], F. Palha[1], G.F. Salles[1]

[1] Medical School Federal University of Rio de Janeiro, Internal Medicine, Rio de Janeiro, Brazil

Aims: Physical activity is generally recommended in type 2 diabetes management. However, relatively few studies have evaluated its beneficial effects on metabolic control and complications development. The aim of this study was to investigate in a cross-sectional analysis the independent correlates of physical fitness of type 2 diabetic patients at entry into a cohort study.

Methods: 564 type 2 diabetic individuals were evaluated. Clinical, laboratory, echocardiographic and 24-hour ambulatory blood pressure (BP) monitoring data were recorded at baseline. Exercise capacity was self-reported by a standard questionnaire of daily activities and graded into 3 categories: low fitness (<4 MET), moderate fitness (4-7 MET) and high fitness (>7 MET). In a random sub-sample of 215 patients, physical fitness grades were confirmed by a conventional treadmill exercise test. Statistics included bivariate tests among the 3 categories (ANOVA and chi^2) and multivariate logistic regression with the lowest exercise capacity group as the reference.

Results: 180 patients (31.9%) had low exercise capacity, 217 (38.5%) moderate exercise capacity and 167 (29.6%) high exercise capacity. In comparison to the patients in the low-fitness group, patients with high exercise capacity were younger, more frequently males, and had lower body mass index and waist circumference. They had a lower prevalence of hypertension, lower office and ambulatory BP levels, most notably during the nighttime period, as well as a higher prevalence of the normal dipping pattern, and a lower left ventricular mass. Patients with high physical fitness had a lower prevalence of all micro or macrovascular degenerative complications. They also had lower mean fasting glycemia and HbA_{1c} during the first year of follow-up, but no differences in lipid profile, and a lower high-sensitive C-reactive protein levels at baseline. On multiple logistic regression, the high exercise capacity was independently associated with a lower likelihood of having peripheral arterial disease (OR: 0.26, 95%CI: 0.12-0.60), peripheral neuropathy (OR: 0.39, 95%CI: 0.21-0.73), cerebrovascular disease (OR: 0.25, 95%CI: 0.07-0.84), coronary artery disease (OR: 0.49, 95%CI: 0.24-0.99) and of being obese (OR: 0.41, 95%CI: 0.23-0.73); and with a higher chance of being male (OR: 1.97, 95%CI: 1.07-3.63), of having a lower mean fasting glycemia (< 7.8 mmol/l, OR: 1.95, 95%CI: 1.11-3.42), C-reactive protein (<3 mg/l, OR: 1.79, 95%CI: 1.03-3.10) and a lower nighttime pulse pressure (<51 mmHg, OR: 2.13, 95%CI: 1.22-3.71).

Conclusions: A high physical fitness is independently associated with a lower prevalence of diabetic complications and with a better metabolic glycemic control and cardiovascular risk profile.

Preliminary analysis demonstrates winter reduction in daily steps and winter increase in blood pressure in type 2 diabetes

K. Dasgupta[1], C. Chan[2], I. Strachan[3], S. Christopoulos[4], R.J. Sigal[5], L. Joseph[6]

[1] McGill University, Department of Medicine, Montreal, Canada

[2] University of Alberta, Department of Agricultural Food and Nutritional Science, Edmonton, Canada

[3] McGill University, Department of Natural Resource Sciences, Ste Anne de Bellevue, Canada

[4] Jewish General Hospital, Department of Medicine, Montreal, Canada

[5] University of Calgary, Department of Medicine, Calgary, Canada

[6] McGill University, Department of Epidemiology Biostatistics and Occupational Health, Montreal, Canada

Aims: Among adults with type 2 diabetes (T2D) in Montreal, we are seeking to objectively assess for reductions in walking volume in the winter and associated changes in glycemic control and blood pressure.

Methods: Observational cohort study involving 200 adults (T2D) recruited through McGill-affiliated clinics. All undergo one assessment per season over one year. Seasons are defined as winter (Dec-Feb), spring (Mar-May), summer (Jun-Aug), and fall (Sept-Nov). Assessments involve questionnaires, blood testing (A1C, Biorad II HPLC), and anthropometric measures. Participants are given three pedometers (viewing window concealed). They wear one for one week, the second for another week, and mail all three back to the study centre. The third serves to measure the false steps associated with mailing and delivery.

Results: Mean age is 61 years (SD 10), approximately 70% are White and slightly fewer than half born in Canada. Men and women are equally represented. Average diabetes duration is 9.5 years (SD 8; range 1 to 45 years) with a mean A1C of 7.6% (SD 1.5), mean blood pressure of 137 (SD 16)/81 (SD 11) mm Hg, mean BMI of 31 kg/m^2 (SD 6.0), and mean daily steps of 5,735 (SD 2,804) in men and 5,022 (SD 2,428) in women. Data collection will be completed in June 2009. Preliminary analysis based on winter and summer data from 66 participants demonstrates a mean reduction in walking of 647 steps/day (95% CI 107 to 1,186) during winter with a mean increase in systolic (6 mm Hg, 95% CI 0.1 to 11) and diastolic (2 mm Hg, 95% CI 0 to 4.5) blood pressure. Summer A1C values appeared higher than in winter (0.2%, 95% CI -0.06% to 0.46%) as did measures of abdominal obesity: waist circumference was higher in summer (2.8 cm, 95% CI 0.85-4.65) and waist to hip ratio demonstrated a similar trend (0.02, 95% CI 0 to 0.04). BMI, total energy intake, and carbohydrate intake did not differ significantly between winter and summer.

Discussion: Adults with T2D in Montreal are sedentary (< 5,000 steps/day) to low active (< 7,500 steps/day). During the winter months they experience a 12% reduction in walking volume and substantial increases in blood pressure. The trends in increase in A1C and abdominal adiposity may represent a delayed impact of the winter walking deficit. Accumulation of further data will permit us to assess the inter-relationships among the seasonal changes that we have detected. Our preliminary findings support the need for interventions to increase walking volume, prevent a winter walking deficit, and monitor and treat blood pressure with attention to seasonal differences.

Effect of exercise therapy on lipid profile and oxidative stress indicators in patients with type 2 diabetes

L. Gordon[1], E. Morrison[1], D. McGrowder[2], D. Goorwood[3], Y. Terry Pena Fraser[4]

[1] Diabetes Association of Jamaica, Biochemistry, Kingston 5, Jamaica

[2] University of the West Indies, Pathology, Kingston 7, Jamaica

[3] University of the West Indies, Basic Medical Sciences, Kingston 7, Jamaica

[4] University of the West Indies, Medicine, Kingston 7, Jamaica

Objective: This study investigated the impact of Hatha yoga and conventional physical training (PT) exercise regimens on biochemical, oxidative stress indicators and oxidant status in patients with Type 2 diabetes.

Methods: This prospective randomized study consisted of 231 patients: 77 type 2 diabetic patients in the Hatha yoga exercise group (62 females and 15 males) that were matched with 77 Type 2 diabetic patients in the conventional PT exercise group and another group 77 Type 2 diabetic patients serving as the control group. Biochemical parameters such as fasting blood glucose

(FBG), serum total cholesterol (TC), triglycerides, low-density lipoprotein (LDL), very low-density lipoprotein (VLDL), and high density lipoprotein (HDL) were determined at the beginning (baseline) and at two consecutive three monthly intervals. The oxidative stress indicators (malondialdehyde- MDA, protein oxidation- POX, phospholipase A2-PLA2 activity) and oxidative status [superoxide dismutase (SOD) and catalase activities] were measured.

Results: The concentration of FBG in the Hatha yoga and conventional PT exercise group after six months decreased by 29.48% and 27.43% respectively ($p<0.0001$) and there was a significant reduction in serum TC in both groups ($p<0.0001$). The concentrations of VLDL in the managed groups after six months differed significantly from baseline values ($p=0.036$). Lipid peroxidation as indicated by MDA significantly decreased by 19.9% and 18.1% in the Hatha yoga and conventional PT exercise groups respectively ($p<0.0001$); whilst the activity of SOD significantly increased by 24.08% and 20.18% respectively ($p=0.031$). There was no significant difference in the baseline and six months activities of PLA2 and catalase although the latter increased by 13.68% and 13.19% in the Hatha yoga and conventional PT exercise groups respectively ($p=0.144$).

Conclusion: The findings of the study demonstrate the efficacy of Hatha yoga exercise on fasting blood glucose, lipid profile, oxidative stress markers and antioxidant status in patients with Type 2 diabetes mellitus, and suggest that Hatha yoga exercise as well as conventional PT exercise may have therapeutic preventative and protective effects on diabetes mellitus by decreasing oxidative stress and improving anti-oxidant status.

Effects of resistance exercise and aerobic exercise training on muscular mass and strength in type 2 diabetic subjects

H. Kwon[1], Y.H. Ku[1], H.J. Ahn[1], H.G. Seok[1], J.T. Kim[1], B.K. Koo[1], H.K. Kim[2], G.S. Park[2], K.A. Han[1], K.W. Min[1]

[1] Seoul Eulji Hospital, Internal Medicine, Seoul, Korea

[2] Dae-Jeon Eulji Hospital, Internal Medicine, Dae Jeon, Korea

Object: The energy-restricted diets result in desired body fat loss, and undesired lean tissue loss. Older obese persons with decreased muscle mass or strength are at special risk for adverse outcomes. The purpose of the present study was to investigate the effect of resistance exercise or aerobic training program on muscular mass and strength during weight reduction in individuals with type 2 diabetes.

Method: Twenty eight overweight women with type 2 diabetes (age: 55.7±7.5 years, body mass index 27.1±2.3kg/m^2) were randomly assigned to resistance exercise group (RG, n=13), using elastic band three times per week at about 40-50% of maximal exercise capacity under supervision, and aerobic exercise group by walking (AG, n=15), which was monitored with accelerometer. During the intervention period, all participants were asked to be on the conventional diet. We assessed muscular mass using dual-energy X-ray absorptiometry (DXA, GE, Lunar, Prodigy, USA) and muscular strength using chest and leg press (KEISER, USA) for one repetitive maximum (1RM) of upper extremities (UE) and lower extremities (LE), before and after 12-week exercise program.

Result: After 12-wk training program**,** body weight was decreased significantly in each group, however, there was no difference between groups (RG: -1.1±1.3kg vs. AG: -1.9±1.2kg, P=0.076). Fat mass was reduced in both groups, but the change was more prominent in AG (-5.4% for AG, -1.3% for RG, P=0.038). Muscular mass of UE and LE of RG increased from baseline (+5.3%, +1.3%, respectively), whereas that of AG remained unaltered (-0.3%, -0.1%, respectively), which difference was statistically significant in UE (P=0.001), but not in LE (P=0.322). Furthermore, resistance training was related to greater increase in muscular strength compared with aerobic exercise. RG showed the increase of 1RM (+12.1% of UE, +11.6% of LE), while in case of AG, 1RM was reduced (-11.6% of UE, -7.2% of LE), which made statistically significant differences between groups (P<0.001 for UE, P=0.006 for LE).

Conclusion: We suggest that when body weight loss is induced to the similar extent, resistance exercise training may be more efficient for improving muscular mass and strength than aerobic exercise in obese female type 2 diabetic subjects, although aerobic exercise is more effective in fat loss.

Background: While cardiorespiratory fitness (CF) is an emerging independent determinant of T2DM in adults, its role as a risk factor or biomarker for T2DM in youth has yet to be studied extensively.

METHODS: We recruited 103 adolescents aged 13-18 yrs spanning the natural history of T2DM to participate in a cross sectional study of CF and the risk for T2DM in youth. Between March 2007 and March 2009 we screened 15 healthy weight normal glucose tolerant controls, 63 overweight normal glucose tolerant controls and 26 adolescents with T2DM. The primary comparison of interest was CF between all three groups, after adjusting for confounding variables (adiposity, age and ethnicity). CF was assessed directly by measuring the rate of oxygen consumption at the end of a graded maximal exercise test to exhaustion, and was expressed relative to fat-free mass (FFM). Secondary outcomes for this study that relate to T2DM risk included, (1) insulin sensitivity, measured directly with Bergman's frequently sampled intravenous glucose tolerance test, (2) hepatic triglyceride content measured with magnetic resonance spectroscopy and (3) percent body fat measured with dual x-ray absorptiometry.

Result: The mean age (15 ± 2 yrs) and proportion of girls (~65%) was similar across all three groups. Although youth with T2DM displayed significantly greater BMI Z score relative to normoglycemic overweight controls (2.1 ± 0.5 vs 1.9 ± 0.5, $p < 0.05$) they were evenly matched for percent body fat (37 ± 7 vs 35 ± 8%). The primary outcome measure of maximal oxygen uptake (expressed relative to fat free mass) was 10 and 21% lower in youth with T2DM relative to overweight (40 ± 7 vs 45 ± 7 ml/kgFFM/min; $p<0.01$) and healthy weight controls (40 ± 7 vs 50 ± 7 ml/kgFFM/min; $p<0.001$). Additionally, maximal workload (expressed as watts/kg FFM) was also lower in youth with T2DM (31% and 18% respectively; $p<0.001$), relative to normal weight and overweight subjects. CF was also independently associated with insulin sensitivity (ß = 0.16, p = 0.02) and hepatic triglyceride content (ß = -0.35, p = 0.015) within all 103 adolescents.

Conclusion: Low CF is a characteristic feature of T2DM in youth and significantly associated with objective measures of T2DM in adolescents. These data reinforce the notion that CF is an important modifiable lifestyle factor in the prevention of T2DM in youth.

Introduction: Chronological aging in healthy subjects is associated with declines in muscle mass, strength, endurance, and aerobic fitness, with concurrent increase in adiposity, insulin resistance, and type 2 diabetes. These changes are particularly pronounced after the fifth decade of life. As with young healthy individuals, however, older subjects seem to respond favorably to exercise, suggesting that physical inactivity plays an important role in age-related dysfunctions. We and others have shown that exercise capacity is a strong predictor of all-cause mortality in type 2 diabetes. However, the role of aging has not been investigated extensively.

Methods: A total of 2755 men, age ≥50 years of age with type 2 diabetes from the VAMC, Washington DC, and Palo Alto, California, underwent routine exercise tolerance testing. Peak workload was estimated in metabolic equivalents (METs). Fitness categories (i.e., Low-Fit, Moderate-Fit, High-Fit) were established based on peak METs achieved, adjusted for age. All-cause mortality is reported with a follow-up period of 7.5±5.0 years. The age groups included 50-69 (Group-1; n=2086) and 70 or above (Group-2; n=669). Cox proportional hazard models were applied after adjusting for age, BMI, history

of CV disease, CV medications and traditional CV risk factors (p-values <0.05 using two sided tests were considered statistically significant).
Results: There were a total of 481 deaths in Group-1 (23.1%) and 287 deaths in Group-2 (42.9%). For every 1-MET increase in exercise capacity, the mortality risk was lowered by 21% (HR=0.79; CI: 0.75-0.83; p<0.001) in Group-1 and 15% in Group-2 (HR=0.85; CI: 0.80-0.89; p<0.001). Mortality risk decreased across fitness categories in both age groups. The association was inverse and graded. Specifically, in Group-1, mortality risk was 47% (HR=0.53; CI: 0.44-0.65) and 69% (HR=0.31; CI: 0.22-0.43) lower for Moderate-Fit and High-Fit, respectively, when compared to the Low-Fit. In Group-2, the mortality risk was approximately 42% for the two highest fitness categories (HR=0.58; CI: 0.45-0.75).
Conclusions: Aerobic capacity is associated with lower mortality risk in type 2 diabetic individuals 50-69 years of age and 70 years or older. Physical fitness, as represented by exercise capacity, lowers mortality risk in diabetics in all age groups.

Ethnic-specific differences in physical activity observed in a population-based diabetes screening programme

T. Yates[1], L.G. Gray[2], K. Khunti[2], D. Webb[1], M. Davies[1]
[1] *University of Leicester, Cardiovascular Sciences, Leicester, United Kingdom*
[2] *University of Leicester, Health Sciences, Leicester, United Kingdom*

Aims: The aim of this study was to comprehensively investigate ethnic-specific differences in physical activity in a bi-ethnic population in the United Kingdom (UK). Previous research has suggested that migrant South Asians (SA) engage in lower levels of physical activity compared to white Europeans (WE) in the UK and other Western industrialized countries. However, much of this data comes from crude, non-validated, measures of physical activity.
Methods: This study reports physical activity levels from the Leicester-ADDITION study, UK: a population-based screening study that has screened 6371 WE and SA individuals. Physical activity was measured using the short self-administered format of the International Physical Activity Questionnaire (IPAQ). IPAQ measures the frequency and duration of any walking or other moderate- to vigorous-intensity physical activity undertaken for more than 10 continuous minutes across all contexts over the last seven days and has been extensively validated.
Results: 1165 SA (male = 605, female = 560; missing data = 31%) and 4310 WE (male = 2035, female = 2275; missing data = 8%) had complete physical activity data. Table 1 shows the ethnic-specific differences across various categories of physical activity, overall and stratified by sex. Using regression modelling, the results for moderate- and vigorous-intensity physical activity were attenuated after controlling for age and sex; however the results for overall and walking activity remained unchanged.
Table 1: Ethnic specific differences in physical activity (data displayed as median (interquartile range)

Physical activity category	Energy Expenditure (MET-minutes/week)		P value (Mann-Whitney U test)
	White European	South Asian	
Total walking and other moderate- to vigorous-intensity			
Overall	2578 (918-4746)	1398 (396-4158)	<0.001
Male	2829 (1092-5850)	1710 (450-4175)	<0.001
Female	2246 (753-4158)	1237 (297-3930)	<0.001
Vigorous-intensity			
Overall	0 (0-1200)	0 (0-760)	0.001
Male	120 (0-1920)	0 (0-1200)	<0.001
Female	0 (0-600)	0 (0-480)	0.33
Moderate-intensity			
Overall	40 (0-1200)	0 (0-600)	<0.001
Male	240 (0-1680)	0 (0-720)	<0.001
Female	0 (0-720)	0 (0-360)	0.002
Walking			
Overall	1188 (396-2772)	594 (74-1980)	<0.001
Male	1188 (396-2772)	495 (66-2079)	<0.001
Female	1188 (347-2772)	693 (99-1980)	<0.001

Discussion/conclusion: This study found that SA were substantially less physically active than WE across all measured categories of physical activity. The median level of walking activity, the most accessible form of physical activity for the majority of individuals, was 50% lower in SA men and women compared to their WE counterparts. Given that migrant SA are known to have an elevated risk of developing diabetes and that increased physical activity is strongly linked to metabolic health, developing and evaluating physical activity interventions specifically tailored to SA migrant groups should be a public health priority in industrialized countries.

Assisting health care professionals in helping people with diabetes to overcome barriers to self-care: the Hellenic DAWN Assessment Model of Care (Greece)

S. Shea[1], S. Skovlund[2], M. Benroubi[3], A. Tsapas[4]
[1] *Hellenic DAWN Study Group, Hellenic DAWN Assessment Project, Aegina, Greece*
[2] *Novo Nordisk A/S, Global Patient Focus, Bagsvaerd, Denmark*
[3] *Athens Polyclinic General Hospital, Diabetes Department, Athens, Greece*
[4] *Aristotle University, Second Medical Department, Thessaloniki, Greece*

Aims: Managing diabetes can be a complex process, often leading to psychosocial barriers to self-care. The Hellenic DAWN Assessment Model is designed to encourage proactive interaction between health care professionals (HCPs) and people with diabetes. The model involves the use of a one-page assessment form in routine care, together with a number of optional interactive tools. The aim of the model is to introduce HCPs to basic psychological principles, thus assisting them in helping people with diabetes to overcome barriers to effective management.
Methods: A one page form was developed consisting of the WHO-5 Well-being index, a further 9 items relating to diabetes specific psychosocial distress (DSPD), and a clinical data section. A series of interactive tools designed for optional use were also produced. 23 physicians administered the form to 400 patients (male = 41%, female = 59%) in rural and urban areas across Greece.
Results: The form showed good internal consistency for both the WHO-5 (a = 0.86), and DSPD (a = 0.79) sections of the form. WHO-5 and DSPD significantly correlated with diabetes treatment type (r = -.16, r = -.30, p = 0.01) and clinical measures including HbA_{1c} (r = -.17, r = -.31, p = 0.01), and BMI (r = -.30, p = 0.01). The form discriminated between different patient groups based on HbA_{1c} (p = <.020, p = <.001), sex (p = <0.001, p = <0.001), and treatment type (p = <0.030, p = <0.001). Multiple regression analyses indicated WHO-5 section as a predictor of BMI (p = <0.001), and DSPD as a predictor of HbA_{1c} (p = <0.001). Differences were identified between people attending primary care settings (located mainly in rural regions), and those in secondary care settings.
Discussion/conclusion: The assessment form is psychometrically reliable and valid, and feedback confirms the usefulness of the form and future advantages in the use of the interactive tools. The Hellenic DAWN Assessment Model is of particular value to HCPs with limited resources, and is a useful and practical method for assisting them in the identification and resolution of psychosocial barriers to diabetes self-care. Results from the pilot study indicate strong relationships between the WHO-5 and BMI, and between DSPD and HbA_{1c}. As such, the longer term effects of this approach may lead to positive outcomes in terms of BMI and HbA_{1c} as a result of addressing diabetes related distress and the effects of diabetes on well-being, at an individual patient level. The model is currently undergoing further investigation among GPs in rural island and mountainous regions, with a view to ensuring its cultural relevance amongst indigenous groups of people with specific traditions and beliefs. Evaluation of the use of the interactive tools and guidance documents at a nationwide level will be performed shortly.

Correlates of self-care success in the Diabetes Attitudes, Wishes and Needs youth study

M. Peyrot[1], T. Danne[2], H.J. Aanstoot[3], K. Lange[4], B. Anderson[5]
[1] *Loyola College in Maryland, Department of Sociology, Baltimore, USA*
[2] *Kinderkrankenhus Auf der Bult, Dept. of General Pediatrics and Endocrinology/Diabetology, Hannover, Germany*
[3] *Diabeter, Diabetes Center for Children and Youth, Rotterdam, The Netherlands*
[4] *Medizinische Hochschule, Medical Psychology, Hannover, Germany*
[5] *Baylor College of Medicine, Pediatrics, Houston, USA*

Aims: This study assessed parent-reported and patient-reported social, family, psychological, and health care factors associated with perceived self-care success among youth (age 0-25) with diabetes.
Methods: The Diabetes Attitudes, Wishes and Needs (DAWN) Youth Study conducted two cross-sectional internet surveys of independent national samples of: (1) parents of children/adolescents (age 0-18) with diabetes (N=4099) and (2) young adults (age 18-25) with diabetes (N=1905). Respondents from the US, Japan, Brazil and 5 countries in Europe provided self-report data for all measures. Self-care success was a 7-item scale measuring success in controlling blood glucose, taking medications, SMBG, diet and exercise. Hierarchical multiple regression was used to assess significant ($p<.05$) independent associations with self-care success. All analyses controlled for country of residence and a variety of demographic and disease characteristics. Parallel factors were included in both models, but some unique factors were available in each survey.
Results: In both populations more information at diagnosis and more perceived communication among health care team members were associated with more self-care success. In both populations greater perceived physician support and understanding of the difficulties of living with diabetes, and respondent involvement in decision-making about diabetes care were associated with more self-care success, and the physician factors mediated the relationships of success with information at diagnosis and health care team communication. Health care factors accounted for about one-quarter of the model's explanatory power in both populations. Among young adults family and friend support were both associated with more self-care success. Among young adults diabetes coping success, subjective quality of life, and psychological well-being were associated with more self-care success and accounted for half of the model's explanatory power. Among children/adolescents more parent-reported agreement within the family about diabetes care responsibilities and patient diabetes coping success were associated with more self-care success and accounted for more than half of the model's explanatory power.
Discussion/conclusions: Self-care success of youth with diabetes is multi-factorially associated with social, health care, parent and patient factors. Correlates of self-care success were similar among young adults and children/adolescents. These results suggest that promising strategies for improving self-care outcomes include enhancing greater provider empathy and support, parent and patient participation in health care, parent-child collaboration in self-care, and patient psychological coping with diabetes.

Illness representations as predictor of self-care behaviour and diabetes control in type 2 diabetes patients

G. Freimane[1], J. Butikova[1], I. Rasa[2], I. Pavlina[2]
[1] *Latvian Diabetes Association, Riga, Latvia*
[2] *Riga Eastern Clinical University Hospital Clinic Gailezers, Riga, Latvia*

Background and aims: According to the common-sense model of self-regulation of health and illness (Leventhal et al., 1997), illness representations (IR) are among the key factors impacting health behaviour (HB). The goal of this study was to determine whether and which relationship is there between type 2 diabetes patients' (T2 DM pts) IR and HB, as well as DM control to be able to predict HB. This could raise the possibilities to explore patient's illness perception and adjust it during the education, which will result in achieving an improved adherence to self care and better metabolic control.
Methods: In our study, 67 respondents (43% males and 57% females, T2 DM for more than one year) aged 50-80 yrs were participated. DM was treated with oral antidiabetic agents in 27% cases, with oral antidiabetic agents and insulin in 25% cases, and with insulin alone in 48% cases. Respondents were asked to complete the modified Illness Perception Questionnaire (IPQ-R) and Diabetes Self-Care Behaviour Questionnaire (DSCBQ). The HbA_{1C} level was determined. IPQ-R (Weinman et al., 1996) was designed to measure 8 scales of IR–Identity, Timeline, Illness consequences, Personal control, Treatment control, Illness coherence, Timeline cyclical, Emotional representations. DSCBQ designed by the study group is a 7-item self-report questionnaire, determining how frequently a DM pt was following the HCP advice on self-care within the last 4 weeks. Self-care behaviour index (CSBI) for each respondent was obtained.
Results: A correlation (Spearman's r) between variables in 8 scales of IPQ-R, SCBI and HbA_{1C} was obtained. The r between SCBI and scores in Illness consequences scale and Personal control scale was high (r=0.315 and r=0.322 respectively; $p<0.01$). The r between SCBI and scores in Illness coherence scales and Timeline scales was moderate (r=0.206 and 0.193, respectively; $p<0.1$).
In regression analysis, an increase of SCBI over the period was predicted by both Personal control scale (ß=0.63, $p<0.05$) and Illness consequences scale (ß=0.39, $p<0.05$).
