When predicting changes in $HbA_{1C,}$ Treatment control (ß=0.15, $p<0.05$), Timeline (ß=0.17, $p<0.05$) and Emotional representations (ß=0.1, $p<0.05$) were related to increases in HbA_{1C} values.
Conclusion: Higher HB adherence was found to be associated with DM pt's perception about more serious consequences of the illness and about highest personal control impact on treatment results. Better DM control seemed to be interrelated with higher scores in pt's beliefs in treatment effectiveness, belief in longer duration of the illness and harder emotional consequences of the illness. Facts on connection between IR and HB stated in the study may improve pt's education, supplementing it with activities aimed at investigation of illness perception and its correction.

Characteristics of hypoglycaemia and hypoglycaemic fear in patients with diabetes mellitus in Japan

H. Kitaoka[1], Y. Go[1], H. Inbe[1], M. Miyawaki[1], M. Bessho[1], M. Date[1]
[1] *Seikeikai Hosipital, Internal medicine, Sakai, Japan*

Aims: Hypoglycemia is the most common complication of therapy of diabetes, at the same time, the consequences of hypoglycemia can be quite aversive and potentially life threatening. In Japan, there is no study about hypoglycemic fear, because there is not suitable questionnaire to measure. In this study, it is focused to evaluate hypoglycemic fear in Japanese diabetic patients using the Hypoglycemic Fear Survey (HFS), which was developed as a research tool measuring the degree of fear experienced with respect to hypoglycemia, Japanese version.
Method: Translation of HFS into Japanese was performed following the Guideline Recommended for Translation of Questionnaires.
Two hundred diabetic patients with type1 or type2 participated in this study. All inventories were sent by mail, and the patients who agreed to participate signed, filled out and sent back to the investigator.
The Questionnaire addresses experience related to hypoglycemia within 1 year; presence of symptoms, frequency, assessment of confidence in ability to discriminate hypoglycemia, behavioral responses to hypoglycemia and frequency of SMBG.
HFS focuses on worries about hypoglycemia (HF-Worry) and behaviors designed to avoid hypoglycemia (HF-Behavior).
HbA1c were collected over a 1yr period.
Results: One hundred twenty-five completed inventories were analyzed. While almost all type1 and type2 patients with insulin have hypoglycemic symptoms, over 50% of the type2 patients with OHA had no hypoglycemic symptoms. The patients who have hypoglycemia awareness were about 40 % even in type1 patients.
The mean scores of HF-Behavior and HF-Worry are, 16.1±6.4, 16.8±11.9 in type1 patients, 9.4±6.3, 6.2±6.4 in type2 patients using insulin and 3.2±6.3, 3.8±8.0 in type2 patients using OHA, respectively.
HF-worry is significantly correlated to age, type of diabetes, using insulin, presence of hypoglycemic symptoms, experience of trouble in work due to hypoglycemia, the score of STAI, SDS and MMPI alexithymia scale. There is no significant correlation between hypoglycemic fear and glycemic control.
Discussion/conclusion: Hypoglycemic fear in patients with diabetes in Japan is remarkably low compared with the data of Western studies. The most

important factor affecting exposure to hypoglycemia is type of diabetes. In type1 patients, who have most exposure to hypoglycemia, anxiety has no effect on the score of HF-worry. On the other hand, in the patients with type2 on OHA, who have less exposure to hypoglycemia, those with more anxiety have more hypoglycemic worry. There are several patients with low anxiety and low HbA1c with severe hypoglycemia. These patients are thought to be at high risk of severe hypoglycemia. Understanding of hypoglycemic fear is thought to be important to get good adherence in diabetic treatment, while the psychological characteristic is grasped.

Association between diabetes-related distress and postprandial hyperglycemia in patients with diabetes

S.R. Coleman[1], A.A. Rizvi[1]
[1] University of South Carolina School of Medicine, Department of Medicine, Columbia, USA

Aims: "Diabetes distress" (DD) is a patient's persistent feeling of being overwhelmed by the emotional burden stemming from daily self-management requiring frequent attention, support, and access to care. These responses are found in a substantial number of diabetic patients, are distinct from true depression/anxiety, and can lead to diminished quality of life. They may affect postmeal elevations and excursions of blood glucose (postprandial hyperglycemia, or PPH), because of the close connection between food and emotions. PPH is a frequent contributor to overall suboptimal glycemic control and is a risk factor for cardiovascular mortality in patients with diabetes. The objective of this study was to explore the association between DD and PPH in patients with diabetes.
Methods: We estimated the degree of DD by means of a simple, validated screening scale (the DDS2, Fisher et al. 2008) in patients seen at the Diabetes Unit of an academic specialty practice. The DDS2 is a brief diabetes distress screening instrument consisting of a 2-item questionnaire that asks respondents to rate on a 6-point scale the degree to which the following items caused distress: (1) feeling overwhelmed by the demands of living with diabetes, and (2) feeling that I am often failing with my diabetes regimen. A score ≥6 is significant, with higher scores denoting increased DD. Degree of PPH was measured by the 1,5-anhydroglucitol level (1,5-AG, or GlycoMark). Levels of >10, 5-10, and <5 ug/ml denote postprandial glucose that is well-controlled, moderately-controlled, and poorly controlled respectively (McGill et al. 2004).
Results: The DDS2 was administered to, and the 1,5-AG level measured in, 113 patients with diabetes (71 women and 43 men, average age 54 years). 32 had type 1 and 81 had type 2 diabetes. The average DDS2 score was 6.2 and the average 1,5-AG was 6.4 ug/ml. The average 1,5-AG in patients with mean DDS2 score <6 (n=49) was 4.9 ug/ml and in those with DDS2 score ≥6 (n=64) was 6.8 ug/ml. The average DDS2 score was 7 for women and 4.7 for men.
Discussion: Higher degrees of DD correlate with PPH and may impact it. Mediating factors may include inadequate coping mechanisms, nutritional choices, and pathophysiologic changes. Diabetes-related distress appears to be more in women than men. Although the results point to an interesting association, causality cannot be inferred. Our findings emphasize the need for further research into understanding the dynamics and gender differences related to psychological stressors of diabetes, particularly as they affect diet and meal-related glucose excursions. Simple office-based tools can identify increased DD and such patients can be targeted by a focused multipronged therapeutic approach with supportive, dietary, and pharmacologic interventions.

Lifestyle and self-care behaviours among diabetics with major, minor and no depression: a population based study of adults with diabetes in Quebec

L. Messier[1], N. Schmitz[2], A. Malla[2], A. Lesage[3], R. Boyer[3], J. Wang[4], I. Strychar[1]
[1] CRCHUM (Centre de Recherche du Centre Hospitalier de l'Université de Montréal), Département de Nutrition de l'Université de Montréal, Montreal QC, Canada
[2] Douglas Hospital Research Centre, Department of Psychiatry McGill University, Montreal QC, Canada
[3] Université de Montréal, Département de Psychiatrie, Montreal QC, Canada
[4] University of Calgary, Department of Psychiatry, Calgary, Canada

Adherence to positive lifestyle and self-care behaviours is a challenge for individuals with diabetes and poor mental health. The aim of this study was to determine whether status of depression was associated with lifestyle-related and diabetes self-care behaviours among individuals with diabetes. The method consisted of a telephone survey of a representative sample of 2003 adults with diabetes in Quebec (54.5% women and 45.5% men). Depression status (major, minor, and no depression) was evaluated using the Patient Health Questionnaire (PHQ-9). Lifestyle-related behaviours included: physical activity, tobacco use, BMI, and number of previous dieting attempts. Self-care behaviours included: testing blood glucose on a daily basis, seeing a physician for diabetes in the past 12 months, and perceptions of diabetes control. Results indicated that 8.7%, 10.9%, and 80.4% had major, minor, and no depression, respectively. There were significant associations between depression and lifestyle and self-care behaviours. Subjects with major and minor depression were more likely to be physically inactive (52.9%, 43.2%, no depression 25.5%), smokers (42.5%, 21.2%, no depression 19.0%), perceive poorer diabetes control (43.4%, 34.3%, no depression 19.9%), and less likely to see a physician for their diabetes within the past year (79.3%, 82.9%, no depression 86.1%). Contrary to what was expected, those with major and minor depression were more likely to test their blood glucose levels daily (78.8%, 71.5%, no depression 66.7%). Status of depression (major, minor, and no) was not significantly associated with BMI categories (normal weight: BMI less than 25; overweight: BMI 25-29; obesity: BMI of 30 and more), nor with the number of previous dieting attempts (number of times in a lifetime of going on a diet and losing more than 10 kg body weight). Rates of obesity were high, over 30%, in each group. In conclusion, depression was associated with poorer lifestyle behaviours, poorer diabetes control, and more frequent daily testing of blood glucose levels. Despite more frequent blood glucose testing and poorer perceived control, those with depression did not see their physician as frequently for their diabetes management. Strategies to reach depressed individuals with diabetes in Quebec and provide them with the adequate follow-up care are needed. This study was funded by the Canadian Institutes of Health Research (CIHR).

Investigating racial/ethnic differences in the relationship between psychosocial variables and diabetes self-management

M. DePalma[1], K. Broadwell[1], J. Metzger[1], L. Calabrese[1], B. Zaremba[1]
[1] Ithaca College, Department of Psychology, New York, USA

Diabetes has risen to epidemic proportions worldwide, and understanding the psychosocial factors that may affect behavioral self-management is crucial. Guided by Weiner's (1995) cognitive model of social conduct, we investigated whether a perception of personal responsibility for disease onset and self-blame might lead to better, or potentially worse, disease management for people with diabetes. Previous research in this area suggests that personal judgments of responsibility for disease onset do affect trait anger and self-blame. In turn, these variables influence perceptions of negative and positive social support which have been shown to be important predictors of self-reported disease management. This research, however, was conducted with a largely non-Hispanic white population, and further research is clearly necessary to examine the influence of these psychosocial variables in other groups – particularly those that are disproportionately affected by diabetes (e.g, African Americans, Latinos, etc.). In the present study, fifty-one individuals with diabetes (of which 11 self-identified as Latino/a) completed a confidential survey assessing personal judgments of responsibility for disease onset, trait anger, self-blame,

perceived social support, diabetes self-efficacy, and disease management. An overall multivariate analysis of the effect of race on our model variables was marginally significant, and univariate analyses revealed two interesting findings. First, race was significantly related to perceptions of responsibility for disease onset, *F(1,30) = 4.24, p < .05*.Latinos (*M = 6.86)* rated themselves significantly higher on responsibility for disease onset than did non-Hispanic whites (*M = 3.68)*. Second, race was significantly related to negative social support, *F(1,30) = 10.49, p < .01*. Latinos (*M = 16.14*) rated themselves significantly higher on negative social support than did non-Hispanic whites (*M = 11.16*).Ultimately, diabetes self-efficacy was strongly and positively related to disease management in both groups, F(5, 37) = 8.96, p < .01, partial eta-squared = .55, power = 1.00. The confluence of data in this area indicates that interventions designed to improve diabetes self-efficacy, the perception of available social support, and anger management or disease acceptance may offer additional mechanisms to improve diet, exercise, and blood glucose testing in individuals with diabetes. However, models of cognitive processes predicting the consequences of judgments of responsibility for disease onset do not appear to be sufficiently sensitive to important variability among different racial and ethnic groups. These data indicate that racial, ethnic, and cultural differences are important to understanding diabetes self- management.

Yoga in prediabetes: long term (1-year) follow up in IFG and IGT

G. Arpana[1], A. Usharani[1], G. Chandrakala[1], P. Prabhakara Rao[1], T. Sreenivas[1], I. Vamshi Krishna[1], Y.C. Kalagara[1], A.K. Jain[1], T. Sridevi[1], I. Sreelatha[1], P. Lakshmi Labani[1], P.V. Rao[1]

[1] Nizam's Institute of Medical Sciences, Endocrinology and Metabolism, Hyderabad, India

Yoga and other complementary and alternative medicines have been studied in many countries for controlling both the symptoms and the complications associated with diabetes mellitus, but not yet in prediabetes and prevention of type 2 diabetes mellitus.

Aim: Beneficial effects of Yoga in improving metabolic profiles among subjects with prediabetes are studied.

Methods: A 1-year randomized controlled follow-up trial in subjects (n=25 in control and n=116 in Yoga groups) aged 30-70 years with prediabetes (IFG and/or IGT) was conducted. Baseline demographic, clinical and biochemical characteristics were similar in control and Yoga groups - BMI (26.3±3.0 and 27.1±4.5 kg/m^2), waist-to-hip ratio (0.96±0.06 and 0.92±0.06), systolic BP (129.7±18.5 and 126.1±16.1 mmHg), diastolic BP (81.7±10.3 and 82.8±10.4 mmHg), fasting (103.4±10.3 and 103.2±7.3 mg/dl) and 2-hr OGTT plasma glucose (133.9±36.1 and 148.2±31.0 mg/dl), serum cholesterol (186.6±40.5 and 183.8±22.1 mg/dl), triglycerides (138.8±85.9 and 126.0±37.9 mg/dl), HDL cholesterol (36.9±7.1 and 39.5±6.0 mg/dl) and HbA1c (5.9±0.8 and 5.8±0.5%). Yoga would consist of approximately 30 minutes a day of specific Yoga *asanas* (postures) and *pranayama* (breathing exercises) which are known to improve glucose tolerance. Study subjects were trained to perform Yoga (*Bhujanga, Shalabha, Dhanur, Vichitrakarna, Ardha-Matsyendra, Paschimothana, Yoga Mudra and Shava asanas*) before and during the study by an instructor at 3 monthly intervals.

Results: In Yoga group, by the end of 12 months there were improvements in BMI (27.1±4.5 at entry and 26.8±4.5 after 12 months), systolic BP (126.1±16.1 at entry and 125.2±15.9 after 12 months), diastolic BP (82.8±10.4 at entry and 82.4±13.7 after 12 months) and significant reduction in waist-to-hip ratio (0.92±0.06 at entry and 0.89±0.07 after 12 months, p<0.05). Unlike in controls, subjects in Yoga group have shown significant reductions in fasting (103.4±10.3 at entry and 99.5±14.1 mg/dL after 12 months, p<0.05) and 2-hr OGTT plasma glucose (148.2±31.0 at entry and 135.8±41.7 mg/dl after 12 months, p<0.05), LDLc (122.6±32.5 at entry and 113.7±30.6 mg/dL after 12 months, p<0.05) and an appreciable difference in HbA1c (5.9±0.8 at entry and 5.8±0.5% after 12 months, ns) and HDLc (36.88±7.13 at entry and 38.36±9.70 mg/dL after 12 months, ns). Mean differences between biochemical values (at entry and end of 12 months) revealed significant improvements in 2-hr OGTT plasma glucose, total cholesterol, HDLc and LDLc (p<0.05) in Yoga group.

Conclusion: Prediabetics showed better improvement in their anthropometric and metabolic profiles following Yogic practices than with conventional life style interventions. Early Yoga intervention and thereby avoidance or delay of progression to type 2 diabetes is of enormous benefit to people with prediabetes in terms of increasing life expectancy and quality of life, and potentially in economic terms for society and health-care payers.

Defect glucose-stimulated insulin secretion in diet-induced obesity mice is associated with altered lipid metabolism/signaling

M.L. Peyot[1], J. Lamontagne[1], M.G. Latour[1], E. Pepin[1], R. Lussier[1], M. Pineda[1], S.R.M. Madiraju[1], E. Joly[1], M. Prentki[1]

[1] MDRC-CRCHUM Biotech Angus, Department of Nutrition, Montreal QC, Canada

C57Bl/6 mice develop obesity and mild diabetes when fed with a high fat diet (60% of energy as fat; HFD; DIO mice). Although DIO is perhaps the most widely studied model of obesity associated type 2 diabetes, little is known about the mechanisms responsible for ß-cell failure in DIO mice. After 8 weeks of HFD, individual mice displayed differential weight gains and blood glucose levels. We separated DIO mice in two groups according to their body weight and fed blood glucose values. Following 8 wks of HFD, low-DIO-responders (LDR) weighed 34-38.9g with an average glycemia of 158 mg/dl. High-DIO-responders (HDR) weighed 39g-44g and had an average glycemia of 180 mg/dl. The control group (normal diet, ND), fed with a standard chow (15% of energy as fat), had an average weight of 28g and a glycemia of 140 mg/dl. Hyperinsulinemic-euglycemic clamp showed that HDR are more insulin resistant than LDR mice. First phase glucose-stimulated insulin secretion (GSIS) in vivo was defective in both DIO groups. Isolated LDR islets showed a 50% reduction of GSIS as compared to the ND group, and HDR islets did not respond to glucose. The defect of insulin release was not due to a reduction in glucose metabolism in DIO mice since islet glucose utilization and oxidation were similar in the three groups. Glucose-stimulated lipolysis was decreased in both DIO islet groups, whereas fat oxidation was augmented in HDR islets only. Fatty acid esterification into neutral glycerolipids measured at low glucose was reduced in LDR islets, and further diminished in HDR mice. Reduced fatty acid esterification and lipolysis in DIO islets is indicative of altered glycerolipid/fatty acid (GL/FA) cycling, which has been proposed to be implicated in GSIS and ß-cell compensation for insulin resistance. The islet TG content was similar in all groups, and ß-cell mass was increased in DIO mice.

In conclusion, LDR mice have a milder phenotype in terms of insulin resistance and altered GSIS compared to HDR. Altered ß-cell function in DIO mice is unrelated to a reduction in ß-cell mass, islet steatosis or changes in ß-cell glucose metabolism. It is possibly related to decreased GL/FA cycling. The more pronounced phenotype and altered ß-cell function in HDR mice may be ascribed to a more pronounced reduction of GL/FA cycling and an induction of "lipodetoxification" /fat oxidation with an associated price to pay: the removal of lipid signaling molecule and reduced GSIS.

Pioglitazone acutely causes metabolic deceleration of the pancreatic ß-cell and reduces insulin secretion at submaximal glucose concentrations via AMP-kinase

J. Lamontagne[1], É. Pepin[1], M.L. Peyot[1], É. Joly[1], V. Poitout[1], S.R.M. Madiraju[1], C.J. Nolan[2], M. Prentki[1]

[1] CRCHUM - Technopôle Angus, Centre de recherche du diabète de Montréal, Montréal QC, Canada

[2] The Canberra Hospital and the Medical School - The Australian National University, Department of Endocrinology, Garran ACT, Australia

Thiazolidinediones (TZD) are agonists of nuclear peroxisome proliferator-activated receptor-gamma (PPAR-gamma) that have beneficial effects on glucose homeostasis via enhancement of insulin sensitivity and preservation of islet ß-cell function. The biochemical basis by which TZD preserve ß-cells is uncertain but might involve direct effects via both PPAR-gamma dependent and independent pathways. To gain insight into the PPAR-gamma-independent pathway(s) of TZD action, we assessed the effects of short-term (90 min or

less) exposure to pioglitazone (Pio) (10 to 50 µM) on glucose-induced insulin secretion (GIIS), AMP-activated protein kinase (AMPK) activation, and ß-cell metabolism in INS 832/13 ß-cells and isolated rat islets. Pio caused a right shift in the dose-dependency of GIIS, such that insulin release was reduced at intermediate glucose but unaffected at either basal or maximal glucose concentrations. Palmitate potentiation of GIIS was not altered by Pio nor was K^+-induced insulin release. This was associated in INS 832/13 cells with alterations in energy metabolism, characterized by reduced glucose oxidation, mitochondrial membrane polarization and ATP levels. Pio caused AMPK and acetyl-CoA carboxylase phosphorylation and its action on GIIS was reversed by the AMPK inhibitor compound C. Pio also reduced palmitate esterification into complex lipids (diacylglycerol, triacylglycerol, phospholipids) and inhibited lipolysis, but did not increase palmitate ß-oxidation. As for insulin secretion, the alterations in ß-cell metabolic processes were mostly alleviated at elevated glucose concentrations. In a similar way as Pio, the antidiabetic agents and AMPK activators metformin and berberine caused a right shift in the dose dependence of GIIS.
In conclusion, Pio acutely reduces glucose oxidation, energy metabolism and glycerolipid/fatty acid cycling of the ß-cell at intermediate glucose concentrations. Acute decrease in metabolism is potentially protective against toxic nutrient overload by decreasing reactive oxygen species production and by reducing endoplasmic reticulum stress due to reduced insulin biosynthesis. We suggest that AMPK activation and the metabolic "deceleration" of the ß-cell caused by Pio contribute to its known effects to reduce hyperinsulinemia and preserve ß-cell function, and to act as an antidiabetic agent.

Glucose-stimulated insulin secretion is increased and diabetes prevented in ZDF rats following voluntary running exercise training

V. Delghingaro-Augusto[1], S. Décary[2], M.L. Peyot[1], J. Lamontagne[1], H. Akakpo[2], M.G. Latour[1], O. Birot[2], M. Prentki[1], R. Bergeron[2]
[1] Centre de Recherche-Centre Hospitalier de l'Université de Montréal, Montreal Diabetes Research Center, Montréal QC, Canada
[2] Université de Montréal, Kinésiologie, Montréal QC, Canada

Physical activity improves glycemic control in type 2 diabetes (T2DM) patients. However, several human studies reported either no improvement or a lowering of insulin secretion post-exercise-training. Our aim was to re-evaluate the role of physical activity on insulin secretion and the onset of diabetes using an established animal model of T2DM. At 6 wks of age, Zucker Diabetic Fatty (ZDF) and lean (ZL) rats were housed in a wheel cage where they could engage in voluntary running exercise for a period of 6 weeks. Inactive ZDF rats were characterized by progressive hyperglycemia (>20 mM), hyperlipidemia and marked loss of glucose-stimulated insulin secretion (GSIS). In contrast, physical activity prevented the development of diabetes (glycemia <10 mM). Moreover, active ZDF rats presented an 80% correction of their glucose excursion during an OGTT, which was associated with a 60% increase in plasma insulin (area under the curve). To investigate the biochemical basis of the beneficial effects of physical activity on ß-cell function, we studied isolated pancreatic islets. Voluntary running improved pancreatic islets GSIS and its amplification by free fatty acids. Islets from active ZDF rats had a 20 fold increase in insulin content which was associated with increased expression of the insulin, PDX-1 and mafA mRNAs when compared to inactive ZDF rat islets. In addition, the expression of the incretin hormone receptors for GLP1, GIP and FFA (GPR40) were also increased by training. Surprisingly, the triglyceride content of ZDF rat islets was not higher as compared to islets of ZL rats when expressed per mg islet protein (unlike when expressed per islet which are much larger in ZDF rats), indicating that ZDF islet cells were not steatotic. Exercise did not alter the islet TG content of ZDF rats. Fatty acid oxidation rates were lower in islets of both active and inactive ZDF rats in comparison to islets of ZL animals.
In conclusion, voluntary exercise protects from ß-cell failure in ZDF rats, at least in part by preventing ß-cell exhaustion characterized by a massive reduction in insulin stores. We are proposing a novel exercising paradigm for ZDF rats resulting in the prevention of diabetes via a significant improvement of GSIS. This model will be used to better understand the mechanisms by which physical activity provides protection against ß-cell failure and diabetes.

Glucagon like peptide-1 induced signaling and insulin secretion do not drive fuel and energy metabolism in normal rodent pancreatic beta-cells

M.L. Peyot[1], J.P. Gray[2], J. Lamontagne[1], P.J.S. Smith[3], G.G. Holz[4], S.R.M. Madiraju[1], M. Prentki[1], E. Heart[3]
[1] MDRC-CRCHUM Biotech Angus, Department of Nutrition, Montreal QC, Canada
[2] United States Coast Guard Academy, Department of Chemistry, New London CT, USA
[3] BioCurrents Research Center, Marine Biological Laboratory, Woods Hole MA, USA
[4] State University of New York, Upstate Medical University, Syracuse NY, USA

Glucagon like peptide-1 (GLP-1) and its analogue exendin-4 (Ex-4) enhance glucose stimulated insulin secretion (GSIS) and activate various signaling pathways in the pancreatic beta-cell, in particular cAMP, Ca^{2+} and protein kinase-B (PKB/Akt). In many cells these signals activate intermediary metabolism. However, it is not clear whether the acute stimulation of GSIS by GLP-1 or Ex-4, which is also dependent on stimulatory glucose concentrations, involves in part metabolic alterations and the production of metabolic coupling factors. In the present study GLP-1 or Ex-4 at high glucose concentrations caused the release of ~20% of the total rat islet insulin content over 1h. While both GLP-1 and Ex-4 potentiated GSIS in isolated rat and mouse islets, neither had an effect on beta-cell fuel and energy metabolism over a 5 min to 3h time period. GLP-1 activated PKB without changing glucose usage and oxidation, fatty acid oxidation, lipolysis or esterification into various lipids in rat islets. Ex-4 did not acutely change islet respiration, as neither oxygen consumption nor mitochondrial ATP levels were altered. The results indicate that GLP-1 barely affects beta-cell intermediary metabolism and that metabolic signaling does not significantly contribute to GLP-1 potentiation of GSIS. The data also indicate that insulin secretion is a minor energy consuming process in the beta-cell, and that the beta-cell is different than most cell types in that its metabolic activation appears to be primarily governed by a "push" (fuel substrate driven) process, rather than a "pull" mechanism secondary to enhanced insulin release as well as to Ca^{2+}, cAMP and PKB signaling.

A novel thiazolidinedione BLX-1002 selectively stimulates glucose-, GLP-1- and tolbutamide-induced insulin secretion in diabetic animal models

F. Zhang[1], D. Dey[2], R. Bränström[3], L. Forsberg[3], M. Lu[3], Å. Sjöholm[1], Q. Zhang[1]
[1] Karolinska Institutet, Department of Clinical Science and Education, Stockholm, Sweden
[2] Bexel Pharmaceuticals Inc., Bexel Pharmaceuticals Inc., Union City, USA
[3] Karolinska Institutet, Department of Molecular Medicine and Surgery Unit of Endocrine Surgery, Stockholm, Sweden

BLX-1002 is a novel amino acid conjugated, small thiazolidinedione with no apparent affinity to peroxisome proliferator–activated receptors (PPAR) that was shown to reduce glycemia in type 2 diabetes without adipogenic effects. We have investigated the actions of the drug on insulin secretion in pancreatic islet cells from diabetic and non-diabetic animal models. In the obese, leptin-deficient ob/ob mice, BLX-1002 enhanced insulin secretion stimulated by high (20 mM), but not low or intermediate (3 or 8 mM) glucose concentrations during a 20 min-incubation, while its major metabolite BLX-1015 had no effect. BLX-1002 also potentiated pioglitazone-, but not fenofibrate-induced insulin secretion. BLX-1002, but not BLX-1015, restored glucose-sensitive insulin secretion in pancreatic islets from type 2 diabetic, leptin receptor-deficient db/db mice. Under perifusion conditions, BLX-1002 significantly potentiated insulin secretion induced by GLP-1 or the sulfonylurea tolbutamide in pancreatic islets from type 2 diabetic Goto-Kakizaki (GK) rats, effects that were not observed in islets from non-diabetic Wistar rats. In contrast, BLX-1015 was without effect. Studies in single islet cells from ob/ob mice revealed that BLX-1002 augmented $[Ca^{2+}]_i$ at high glucose, which was abolished either by the L-type Ca^{2+} channel blocker nifedipine or by pre-treatment of the cells with the Ca^{2+}-ATPase inhibitor thapsigargin. The BLX-1002-induced rise in $[Ca^{2+}]_i$ was significantly suppressed by the selective phosphatidylinositol (PI) 3-kinase

(PI3K) inhibitor LY294002. However, BLX-1002 interfered neither with voltage-gated Ca^{2+} channel nor with KATP channel activities as demonstrated using patch-clamp technique. In addition, cellular NAD(P)H stimulated by glucose was not affected by the drug. The stimulatory effect of BLX-1002 on insulin secretion at high glucose was completely abolished by treatment of the cells with the PI3K inhibitors wortmannin or LY294002. Furthermore, stimulation of the b-cells with BLX-1002 induced activation of AMPK at high glucose. Our study suggests that BLX-1002 selectively potentiates insulin secretion induced by high glucose, GLP-1 or tolbutamide in b-cells from obese or diabetic animal models, but not from healthy animals. The effect of BLX-1002 on glucose-induced insulin secretion is dependent on PI3K activity and is associated with an increased $[Ca^{2+}]_i$ and AMPK activation. The glucose-sensitive stimulatory impact of BLX-1002 on b-cell function may translate into substantial clinical benefits of the drug in the management of type 2 diabetes, by avoidance of hypoglycemia.

Differences in metabolic regulation between two sister clonal rat ß-cell line INS-1 832 decides their ß-cell functionality

S. Malmgren[1], V.V. Sharoyko[1], D.G. Nicholls[2], K. Bacos[1], C. Ling[1], H. Mulder[1]

[1] Lund University, Department of Clinical Sciences in Malmö, Malmö, Sweden

[2] Lund University, Department of Clinical Sciences in Lund, Lund, Sweden

Aims: In order to investigate the putative metabolic disturbances in ß-cells that affect glucose-stimulated insulin secretion we investigated two subclones of INS-1 exhibiting different properties: 832/13 cells are glucose-responsive while the 832/2 cells are glucose-nonresponsive. The insulin content of the cells is the same and ATP-independent closing of K^+ channels evokes insulin release in both cell types. This leads us to hypothesize that the difference in insulin response could have a metabolic origin and that the metabolic difference is reflected by differences in gene expression.

Methods: Insulin secretion was measured by RIA. Metabolix flux was assessed by Extracellular flux analyzer XF24 (Seahorse Bioscience, Billerica, MA). Lactate was measured using a colorimetric lactate assay kit (Biovision, Mountain view, CA, USA). A TaqMan Low density array (LDA) (Applied Biosystems, Foster City, CA, USA,) was performed.

Results: The INS-1 832/13 were robust secretors of insulin (>8-fold) when stimulated by an elevation in glucose from 2.8 mM (low glucose) to 16.7 mM (high glucose) whereas the same settings failed to evoke increased insulin release in INS-1 832/2.

INS-1 832/13 cells showed a considerable increase in Oxygen consumption rate (OCR) when stimulated with high glucose; this effect was abundant in INS-1 832/2. They also displayed a poorer response to the metabolic modulators oligomycin, FCCP and Rotenone.

INS-1 832/2 cells secreted 140 nmol/mg prot/h of lactate at high glucose while lactate secretion from the INS-1 832/13 was not detected.

The Extracellular acidification rate (ECAR) of 832/13 cells basically paralleled the OCR, suggesting that it is mainly accounted for by CO_2 production. In the 832/2 cells, the ECAR was 3.6 fold higher, and increased in response to oligomycin and FCCP.

LDAs showed that genes for glycolytic metabolism as well as LDH were up-regulated in 832/2 while a number of mitochondria-related genes were down-regulated compared to glucose-responsive 832/13.

Discussion/conclusion: We conclude that tight coupling between the glucose stimulus, via glycolysis, and the rate of oxygen consumption determines ATP production which is crucial for the ability of the ß-cell to respond to high glucose with insulin secretion. The INS-1 832/2, which express LDH, have regained their ability to speed up glycolysis to reflect energy demands and substrate levels. This gives them an advantage as it makes them less vulnerable but occurs at the expense of ß-cell functionality, such as their ability to secrete insulin in response to glucose.

Development of an in silico model to extrapolate whole body glucose – insulin homeostasis by altering tissue specific effects, simulation of SGLT-2 inhibition in type 2 diabetes

N.R. Hill[1], J.C. Levy[1], D.R. Matthews[1]

[1] University of Oxford, Oxford Centre for Diabetes Endocrinology & Metabolism, Oxford, United Kingdom

Aims: The inhibition of gut and renal sodium-glucose co-transporters (SGLTs) has been proposed as a novel therapeutic approach for the treatment of diabetes. SGLT-2 inhibitors acutely induce renal glucose excretion by a change in the renal threshold.

Homeostatic Model Assessment (HOMA) is a model based on the interaction of organs or tissues represented by equations derived from empirical data. It has become an international standard for measuring beta-cell function and insulin resistance in large studies where detailed physiology is not possible. We have developed an interactive Homeostatic Model of Assessment (iHOMA) in which the parameters of the individual models are modifiable through an onscreen interface using visual analogue controls. The iHOMA model can be used for *in silico* calculations of the specific effects drugs may have on glucose metabolism.

The aim was to mathematically model the effect of an SGLT-2 inhibitor in patients with Type 2 diabetes (T2DM) using the iHOMA program.

Methods: A total of 428 patients (239 Male) with T2DM were retrospectively analysed from the Diabetes in Families (DIF) study. The DIF study was a population-based collection of patients with T2DM and their siblings sampled from GP practices in Oxfordshire and Northamptonshire. Although patients were on a variety of drugs none of these were likely to interfere with their renal glucose excretion. They had a mean BMI 30.4 (±5.6) kg/m^2, mean age 62(±11) years, mean HbA1c 7.9 (±1.6), mean Fasting Plasma Glucose(FPG) of 9.6 (±3.1) mmol/l and geometric mean Fasting Plasma Insulin (FPI) of 112.0 (range 65.8 – 190.5) pmol/l.

iHOMA was developed by the authors at the University of Oxford and has been validated against the original HOMA algorithms. iHOMA was used to mathematically simulate the effect of an SGLT-2 inhibitor by decreasing the renal glucose excretion threshold by 50%. FPG and FPI were then calculated for each subject using iHOMA adjusted for these.

Results: Using iHOMA, which can account for tissue-specific glucose metabolism effect, the simulated whole body effect by altering renal excretion of glucose was moderate. A paired-sample t-test revealed a significant difference in the mean FPG (9.6 vs. 8.9, $p<0.01$) mmol/l a decrease of 0.7 mmol/l. The FPG change in concentration was accompanied by a change in the geometric mean FPI (112.0 vs. 99.3, $p<0.01$) pmol/l a decrease of 12.7 pmol/l.

Conclusion: The development of iHOMA enables the investigation of pharmacological effects of a novel therapy on glucose metabolism *in silico.* The model suggests that SGLT-2 inhibitors have the potential to effect a moderate change in glucose in people with T2DM. However, it is important that these data are replicated and validated in a prospective randomised control trial.

Nocturnal hypoglycemia in children with type 1 diabetes is associated with increased incidence of anxiety and depression symptoms in the parents: a population-based study

A. Haugstvedt[1], T. Wentzel-Larsen[2], M. Graue[1], B. Rokne[3]

[1] Bergen University College, Faculty of Health and Social Sciences, Bergen, Norway

[2] Haukeland University Hospital, Centre for Clinical Research, Bergen, Norway

[3] University of Bergen, Department of Public Health and Primary Health Care, Bergen, Norway

Background: Parenting children with a chronic disease such as diabetes has been shown to be a risk factor for increased level of parental emotional distress.

Aim: The aim of this study was to analyze associations between factors related to the child with diabetes and emotional distress in the parents. We hypothesized that higher frequency of hypoglycemic events, experience with nocturnal hypoglycemia or hypoglycemia with unconsciousness, higher

frequency of blood glucose measurements, higher level of HbA1c, lower age in the child and shorter diabetes duration were associated with increased level of anxiety and depression symptoms in the parents.

Sample and method: Mothers (103) and fathers (97) of 115 children with type 1 diabetes participated in this population-based survey which included parents of close to all children (1-15 yrs) with type 1 diabetes in the current Norwegian county (response rate: 72%). To assess emotional distress the Hopkins Symptom Checklist-25-item questionnaire (HSCL-25) measuring the presence and intensity of anxiety and depression symptoms during the previous two weeks, was used. Total HSCL-25 score is rated from 1 to 4 and cutoff for symptomatic mental problems is set at a score >=1.75. To test the hypothesis, the generalized estimating equations procedure for regression models with correlated data was used (R package gee).

Results: Mean age of the 115 children was 10.6 yrs (range 1.6-15.9), mean diabetes duration 3.9 yrs (0.3-14.2) and mean HbA1c level 8.1% (SD 1.03). The parents of 69% of the children reported that they have experienced nocturnal hypoglycaemia in their child at least once, while parents of 21% reported that they have experienced hypoglycaemia with unconsciousness at least once. The parents of 87% of the children reported >=4 blood glucose measurements/day and parents of 27% reported to measure during the night at least once a week. The analysis showed a significant association between a higher HSCL-25 score and experience with nocturnal hypoglycemia (regr coeff 0.11, P =0.012). In addition, the analysis showed significant associations between a higher HSCL-25 score and a shorter diabetes duration (regr coeff 0.02, P =0.035) and a higher age in the child (regr coeff 0.02, P =0.015). The mothers had a significantly higher HSCL-25 score compared to the fathers (regr coeff 0.12, P <0.001, mean score 1.39 vs 1.22).

Conclusion: In addition to shorter diabetes duration, nocturnal hypoglycemia in children with type 1 diabetes seems to be an important risk factor for increased level of anxiety and depression symptoms in the parents. The findings highlight the importance of appropriate strategies to prevent hypoglycaemia in children with type 1 diabetes.

D-0798

Relationship between diabetes long-term duration and health-related quality of life - a Swedish Population Based Study

V. Sparring[1], P.M. Jonsson[1], K. Burström[2]

[1] *Karolinska Institutet, Department of Learning Informatics Management and Ethics/Medical Management Centre, Stockholm, Sweden*

[2] *Karolinska Institutet, Department of Learning Informatics Management and Ethics and Department of Public Health Sciences, Stockholm, Sweden*

Background: Between four to five percent of the Swedish population have diabetes mellitus, a life-long disease that may affect both length of life and health-related quality of life (HRQoL). We hypothesise that HRQoL eight years after diagnosis, when the disease is more stable and the negative effect on HRQoL during the early phase of diabetes has decreased. Long-term complications are likely to appear 15 years after diagnosis, after 24 years the prevalence of these complications are considerable which may negatively affect HRQoL.

Aim: This study aims to describe HRQoL using the generic EQ-5D in a diabetes population 8, 15 and 24 years after diagnosis to investigate the relationship between disease duration and self-assessed health status.

Methods: Since 1983, the Diabetes Incidence Study in Sweden (DISS) prospectively registers all incident cases of diabetes mellitus in the age group 15-34 years. In this study, three cohorts were selected from DISS and two controls per case randomly selected from the general population, matched by age, sex and county of residence. Data were collected 2007 by postal questionnaires to the three diabetes cohorts (response rate was 57.7%, n=721) and controls (response rate 54.8%, n=1360). EQ-5D, measuring health status on five dimensions (mobility; self-care; usual activities; pain/discomfort; anxiety/depression) in three levels of severity, was included in the survey. EQ VAS records overall self-rated health on a 0-100 visual analogue scale. EQ-5D index (1=full health; 0=dead) was calculated.

Results: Having no problem on any EQ-5D dimension was rated by 44.5%, 47.1% and 33.2% of the cases 8, 15 and 24 years after diagnosis, respectively. Corresponding figures for controls were 52.9%, 46.0% and 42.3%. Most problems were reported on the dimension pain/discomfort: 37.8%, 40.5% and 56.6% of the cases compared to 34.5%, 41.7% and 50.1% of the controls. Problems on anxiety/depression dimension were reported by 36.4%, 35.1% and 40.3% of the cases compared to 27.1%, 33.6% and 30.7% of the controls. Lowest percentage of problems was reported in the dimension self-care. Mean EQ-5D index value for the cases was 0.87, 0.82 and 0.77 and for the controls 0.88, 0.84 and 0.82, respectively. Mean EQ VAS for the cases was 78.5, 75.9 and 72.9 and for the controls 83.7, 87.2 and 80.1.

Discussion: The gap between cases and controls was widening with disease duration suggesting that HRQoL was related not only to age but also to long-term duration of diabetes. As HRQoL is likely to be negatively affected by the intensified counselling and treatment efforts in early diabetes, data are currently collected on a diabetes population one year after diagnosis. Investments in the early phases may have a positive effect on not only HRQoL but also costs in a long-term perspective.

Conflicts between personal self-regulating goals and life values among adults with type 2 diabetes

B. Karlsen[1], B. Oftedal[1], E. Bru[1]

[1] *University of Stavanger, Department of health studies, Stavanger, Norway*

Background: It is well documented that goals and values have a significant impact on motivation and play a crucial role in understanding self-regulating behavior. Little is, however, known about how life values and personal goals for self-regulation among adults with type 2 diabetes may compete, and thus influence motivation.

Aim: The aim of this study is to describe how goals for personal self-regulation may compete with other life values among adults with type 2 diabetes.

Design and methods: This study was conducted as a pilot study prior to a Norwegian national longitudinal, prospective survey. A descriptive/explorative qualitative design that includes focus groups was used to collect data. The sample consisted of 19 adults included in the study. The participants, aged between 30 and 65 years, with disease duration of at least one year and able to speak Norwegian, were included in the study. They were recruited from three separate sources in south-western part of Norway: 1) The Coping and Learning Centre at a University hospital, 2) a local Diabetes Association and 3) general practitioners (GPs). The participants were divided into three focus groups, and the interviews took form of two sessions. Two main topics were addressed: 1) Personal goals for self-regulation of diabetes and 2) life values that may compete with goals for self-regulation. Data were analyzed using qualitative content analysis.

Results: Findings revealed personal goals for self-regulation as more general than specific. Moreover, six themes of conflicts between life values and personal goals for self-regulation emerged: 1) value of bodily well-being (e.g. perceiving exercise as too demanding), 2) value of belonging (e.g. being stigmatized), 3) value of work performance (e.g. work demands interfere with self-regulation), 4) value of presenting a positive body image (e.g. feeling uncomfortable in displaying their body in exercise situations, 5) value of self-determination (e.g. high value of self-determination makes one ignore advice for self-regulation) and 6) value of engaging in activities of interest (e.g. preferring non-physical activities).

Conclusions: The findings indicate that personal goals for optimal self-regulation were formulated in more general than specific terms, something that may lead to low motivation for optimal self-regulation. Moreover, the participants' life values seemed often to compete with the requirements on adequate self-regulation, which, in turn, may have influenced their motivation for attaining personal goals for self-regulation.

Factors associated with depression and anxiety disorder in diabetic patients in Turkey

O. Demir[1], U. Unluturk[1], R. Emral[1]

[1] *Ankara University School of Medicine, Endocrinology and Metabolic Diseases, Ankara, Turkey*

Objective: The aim of this study was to describe the factors associated with depression and anxiety in diabetic patients in Turkey

Method: 219 diabetic patients (F/M: 133/86, age: 56 ± 13.68 yrs) who had been treated at the endocrinology outpatient unit were analyzed. At their last visits, demographic and anthropometric features, educational levels, occupations, marital and economic statuses, social problems, treatment periods, applied medications, fasting and postprandial glucose measures,

A1C levels and diabetic complications of the patients were recorded. Patients completed The Hospital Anxiety and Depression Scale (HADS) while waiting for their routine outpatient appointment.

Results: 200 type 2 and 19 type 1 diabetic patients were included in the study. 125 (57.1%) patients had depression, 113 (51.6%) had anxiety disorder and 87 (39.7%) of the them had both depression and anxiety disorder. There was no difference among the types of diabetes for depression or anxiety status. Logistic regression analyses demonstrated that high educational level (> 8 years) and social problems were found to be statistically significant risk factors associated with anxiety and depression. Furthermore, male sex was found to be a major risk factor only for anxiety disorder in Turkish diabetic patients (table 1).

Table 1 Logistic regression analyses of risk factors

Risk Factors for Anxiety Disorder	Adjusted odds ratio	95% CI for OR		p
		Lower	Upper	
Male sex	5.42	2.56	11.47	<0.001
Educational level	2.98	1.45	6.11	0.003
Social problems	0.15	0.07	0.30	<0.001
Risk Factors for Depression				
Educational level	3.64	2.02	6.55	<0.001
Social problems	0.50	0.28	0.91	0.022
CI: Confidence interval, OR: Odds ratio				

Conclusion: In Turkish diabetic patients, especially with male sex, high educational level and social problems are significant risk factors for mood disorders. Therefore, this group of patients should be considered for psychologic support.

New diabetic patient, new views of life

M.T. Meneses Jimenez[1], J. Aguilera Carrasco[1], M.J. Saez Garcinuño[1], F. Gomez Alfonso[2], A. Fraile[2], A. Lopez Guzman[2], M.C. Rico Fontsabre[1], M.D. Lopez Lopez[1], Y. Varas Reviejo[1]

[1] *Colegio Profesional de Enfermeria, Departamento de formacion-investigacion, Avila, Spain*

[2] *Centro de Especialidades Perifericas, Consulta de Endocrino, Avila, Spain*

Aims: The aim of the study was to explore the relationship between new experiences and psychological repercussions about the new diabetic diagnosis on a woman, and her role in diabetes education treatment.

Methods: Qualitative, exploratory study. One new Patient was interviewed in the Diabetic Education Nurse Consultation using semi-structured questions on illness history, coping strategies, perceived barriers to care, the illness, and its management.

Results: The findings have implications for, and are discussed in relation to, issues of control, regimen adherence, and what it means to be a 'good' or 'successful' diabetic. The goal of patient was to integrate the control of their diabetes into daily life. This involved an emphasis on the way the new patient viewed her role in diabetes management. Furthermore, her attitude towards diabetes treatment was variable, and she changed her views and switched categories when she realized she improved her capillary glycaemic control and her quality of life perceptions after working according to the Diabetic Education Nurse Consultation.

Conclusion: From the perspective of Diabetic Education Nurse Consultation, it is important to know how the person with diabetes perceives his/her role in disease management and to determine if a change in perception would be followed by intervention to adjust glycaemic control. The satisfaction of personal goals and a focus on psychological as well as physical health may be very important if positive quality of life outcomes are to be attained in the context of Type 2 diabetes. Consequently, individuals' perception of disease management should be incorporated in patient education programmes and routine diabetes cares to enable customized care and prevent stagnation in negative roles.

Factors that interfere with quality of life with diabetes: patients' views

S. Soares Lemos[1], J. Dullius[1]

[1] *Universidade de Brasilia, Faculdade de Educação Fisica, Brasília, Brazil*

The number of people with Diabetes Mellitus (DM) has been increasing due to an inappropriate lifestyle, highlights are physical inactivity and a non-healthy diet that lead to a decreased quality of life (QOL). The study was done using a semi-structured questionnaire designed to this search, taking as reference the WHOQOL-BREF and DQOL. The sample of 80 individuals with the average age of 60 years (± 13), 66.25% were women, 87.5% type 2 diabetes, average of 11 years (± 8) of diagnosis, 67.5% were using the public health system. The nutritionist was the professional most quoted in the monitoring process of diabetes by 48.75%. The diet and physical activity was quoted by 80% and 70% respectively as part of treatment. In addition to data from their personal profile, the respondents were asked to spontaneously list the factors that interfere in their QOL; after that the questions with specific variables were presented. In these questions there was an interval scale with numbers from 1 to 5. The numbers corresponded to the degree of interference of variable (interferes nothing to interferes a lot) in QOL of the patients. The factors most mentioned spontaneously were: eating 25%, financial situation and domestic problems 22.5%, stress 17.5% and the care with health and with diabetes 12.5%. The least mentioned were: daily injections, blood glucose control, have to do exams and need to be more reserved with 1.5%. Among the specific variables suggested, the most important were: care with eating, financial situation, physical activities, being a diabetic and pain. The least mentioned were: family relationships, physical aesthetics, attitudes of other individuals, free time. Many questions had a great diversity of responses, in which opposing categories were much cited. In these questions it was tried to find out what characteristics were decisive in these cases. Thus, it is important to note that the individuality, the education on diabetes, the support of family and interdisciplinary work are points that should be noted on the work with individuals with diabetes.

Type 1 diabetes and early school wastage among Congolese diabetic children

M. Mvitu Muaka[1], M. DeClerk[2], G. Mbenza[2], D. Yekoladio[2]

[1] *Université de Kinshasa, Ophtalmologie, Kinshasa 1, Democratic Republic of Congo*

[2] *CS Boyambi Armée du Salut, Clinique Diabétique, Kinshasa 1, Democratic Republic of Congo*

Aim: To determine the frequency and leading causes of school wastage among Congolese children with type 1 diabetes.

Methods: A cross-sectionnal study was perfomed in a population of type 1 diabetic Congolese children between December 2007 and July 2008. The study was conducted in the diabetic clinic of Boyambi Centre, a primary health care centre. All patients underwent a routine ophthalmologic examination after an interview with a pre-established questionnaire.

Results: 212 diabetic children were included in this study. There were 127 (59.9%) girls and 85 (40.1%) boys. Mean age was 19.7±SD5.23 years (range from 9 to 38 years). At the time of the diabetes diagnosis, mean age was 15 years±0 (range from 4 to 29 years). Mean diabetes duration was 4.65 years±SD3.7 (range from 0 to 20 years).

There was 56.1% of school wastage from this whole of children; 65% of them did not complete their primary school, 30.7% reached the secondary level and 4.2% completed their secondary level school. Psychologic repercussions of diabetes was the leading cause of the school wastage (58.1%). The others causes were: poverty (38.7%), family conflicts (2.7%) and visual impairment (0.5%).

From the whole of all children included in this study, 51.9% were not living under guardianship of their parents (father or mother); 26.4% of them took themselves under their wing and did odd jobs to survive; 23.6% have a tutor from their family and 1.9% were under guardianship of alms-houses.

Conclusion: Psychologic repercussions of type 1 diabetes seems to be a leading cause of early school wastage. This needs to associate psychologic counselling in type 1 diabetes cares in developing countries.

Diabetes shockers – short films to raise diabetes awareness in an indigenous community

T. Delormier[1], S. Whitebean[1], A. Jacobs[1], L. Peterson[1], A.C. Macaulay[1], S. Whitebean Sisters[1], R. McComber (deceased)[1], P. Leclaire[1], M. Deer[1], E. Delaronde[1]
[1] *Kahnawake Schools Diabetes Prevention Project, Kahnawake, Canada*

Aims: Short films were used to document experiences of people living with type 2 diabetes in order to raise awareness on the impacts of diabetes, and to support diabetes prevention. The films, produced entirely by a community diabetes prevention project, bring to the forefront the often untold impact of diabetes on the families and individuals living with diabetes.
Methods: The Kahnawake Schools Diabetes Prevention Project (KSDPP) is a community-directed research and intervention project aiming to prevent type 2 diabetes in the Mohawk community of Kahnawake, near Montreal, Canada. In 2006 an elder, who is also a member on the KSDPP community advisory board, proposed documenting his experiences with dialysis as a way to raise awareness in the community about the complications of diabetes.
Results: The project developed into a collection of four short films, each focusing on an aspect of the impacts of type 2 diabetes; (1) "Living with Diabetes" – Three individuals tell their stories about how diabetes affects daily living (2) "Dealing with Reality" – a young woman discusses recently being diagnosed with type 2 diabetes (3) "The Effects on a Family" – a family coming to terms with the death of a young parent due to diabetes complications (4) "Damage Control" - filmed during his dialysis treatmen,t an elder reflects on how diabetes has affected him.
Conclusion: The films were effective educational tools for raising awareness about living with diabetes in Kahnawake, and they re-emphasized the importance of primary prevention of this disease. They are available to buy on a DVD at www.ksdpp.org

Risk factors for developing type 2 diabetes: awareness amongst the public and healthcare staff

B. Lim[1], N. Othman[2], L. Tan[2], M. Jong[3], R. Dalan[3], J. Soh[4]
[1] *Tan Tock Seng Hospital, Dept of Endocrinology/Operations Support Services, Singapore, Singapore*
[2] *Tan Tock Seng Hospital, Dept of Nurse Clinicians, Singapore, Singapore*
[3] *Tan Tock Seng Hospital, Dept of Endocrinology, Singapore, Singapore*
[4] *Tan Tock Seng Hospital, Clinical Research Unit, Singapore, Singapore*

Aim: To determine the awareness of risk factors which predispose one to Type 2 diabetes (DM) amongst the Public (PB) as well as Healthcare staff (HCS).
Methodology: The subjects were recruited from a public health screening event. The participating subjects were shown ten risk factors associated with DM. The risk factors included were: ethnicity, high BMI, hypertension, family history (FH) of DM, sedentary lifestyle, older age, high-calorie diet, medication, high-stress level and previous gestational diabetes mellitus.
The questionnaires were conducted by volunteers during a public health screening event, and self-administered questionnaires by healthcare staff. A 4-parameter beta regression model was applied to analyse how the factors were associated with the overall score of DM risk perception (permissible range: 0—10). Analysed with Stata 10.0, all statistical tests were conducted at 5% level of significance.
Results: A total of 695 respondents participated in the survey. A typical respondent was a Chinese female (46.9%) with a mean age of 48 (s.d.: 15.2). The average score of DM risk awareness was 7.35 (s.d.: 1.85). 26.6% were HCS and the mean scores of DM risk perception were 7.25 (s.d.: 1.77) for HCS and 7.41 (s.d.: 1.87) for PB. There was no significant difference in risk perception between HCS and PB after adjusting for educational attainment, gender, age, ethnicity, marital status, DM status and FH of DM. HCS & PB who had a FH of DM were more aware of the risks associated with DM.
Conclusion: PB and HCS were generally aware of the risk factors for DM. Educational activities should be continued to promote and increase awareness of risk factors associated with DM.

Complications - dyslipidemia

D-0806

Endothelial lipase and reverse cholesterol transport in type 2 diabetes mellitus

K. Tan[1], S. Shiu[1], H.L. Zhou[1], Y. Wong[1]
[1] *The University of Hong Kong, Department of Medicine, Hong Kong, Hong Kong China*

Aims: Endothelial lipase (EL) is a phospholipase with little triacylglycerol lipase activity and plays an important role in the metabolism of HDL. Modulation of HDL by EL may affect reverse cholesterol transport. We have investigated whether serum EL concentration is associated with changes in the serum capacity to induce cholesterol efflux in patients with type 2 diabetes mellitus.
Methods: 172 diabetic patients and 175 controls were recruited. Serum EL was measured by ELISA and cholesterol efflux to serum was determined by measuring the transfer of [3H]cholesterol from Fu5AH cells to the medium containing the tested serum.
Results: Diabetic patients had significantly higher plasma triglyceride ($p<0.01$), lower HDL cholesterol ($p<0.01$) and elevated high sensitivity C-reactive protein (CRP) ($p<0.01$) compared to the controls. Serum EL was significantly increased in the diabetic patients (27.7 ± 16.6 ng/ml vs 24.0 ± 11.3 respectively, $p<0.05$) and cholesterol efflux to serum was impaired (15.1 ± 2.5% vs 16.7 ± 3.1 respectively, $p<0.01$). In the control subjects, serum EL correlated inversely with cholesterol efflux to serum ($r=-0.16$, $p=0.03$) but no significant association was seen in the diabetic patients. Linear regression shows that in the controls, plasma HDL, serum EL and waist circumference were the major independent determinants of cholesterol efflux to serum whereas in the diabetic cohort, the major independent determinants of cholesterol efflux to serum were HDL, age and CRP.
Conclusion: Although serum EL concentration was increased in type 2 diabetic patients, impaired serum capacity to induce cholesterol efflux was mainly related to low HDL and subclinical inflammation in these patients.

Aspirin reduces transient flushing and glucose increases during therapy with niacin extended-release

R.J. Padley[1], R.B. Thakkar[1], P. Jiang[1], S.L. Krause[1], M.H. Davidson[2], H.A. Punzi[3]
[1] *Abbott, Global Pharmaceutical Research & Development, Abbott Park IL, USA*
[2] *The University of Chicago Pritzker School of Medicine, Preventive Cardiology, Chicago IL, USA*
[3] *Texas Woman's University, Allied Health Institute, Dallas TX, USA*

Aims: Proprietary niacin extended-release reduces most pro-atherogenic lipids while increasing anti-atherogenic lipids. In addition to flushing, therapy with niacin has been associated with a transient increase in blood glucose levels, although long-term effects on HbA1c are not usually observed. Both flushing and increases in blood glucose may be mediated via associated pathways. Since aspirin has been demonstrated to mitigate flushing during adaptation to niacin extended-release therapy, we evaluated the effects of aspirin on changes in blood glucose in patients with mixed dyslipidemia treated with niacin extended-release.
Methods: Data are from a double-blind, parallel group, multi-center, placebo-controlled study. Patients were randomized to receive niacin extended-release (500 mg/day week 1; 1000 mg/day week 2; 2000 mg/day weeks 3-6) and either 325 mg/day aspirin (n = 90) or placebo (n = 90). Both maximum severity of flushing [1- to 10-point scale] and the mean % change from baseline in fasting blood glucose were compared between the two treatment groups using one-way analysis of variance.
Results: Over the entire 6 weeks of treatment, aspirin reduced mean maximum flushing severity by 33% (3.5 aspirin vs 5.2 placebo; $P < 0.001$). Baseline fasting blood glucose levels were similar for both groups (niacin extended-release + aspirin, 109.1 mg/dL, niacin extended-release + placebo, 107.3 mg/dL, $P = 0.66$). Aspirin use reduced the magnitude of the increase in fasting blood glucose by 55%. The mean % increases in fasting blood glucose over the 6 weeks of treatment were 5.6 ± 17.7, with aspirin, and 12.5 ± 25.2, with placebo, $P = 0.03$.

Conclusions: Among patients with mixed dyslipidemia, aspirin effectively mitigates flushing symptoms during adaptation to niacin extended-release therapy. Treatment with aspirin may also reduce the magnitude of the increase in fasting blood glucose associated with niacin extended-release therapy.

Adiponectin is an independent predictor of apolipoprotein B/A1 ratio in Korean impaired fasting glucose patients

K. Chul Sik[1], J. Park[2], M. Cho[2], C. Ahn[2], K. Kim[2], B. Cha[3], E. Lee[3], S. Lim[3], H. Lee[3], Y. Song[4]

[3] *Yonsei University College of Medicine Severance Hospital, Internal Medicine, Seoul, Korea*
[4] *National Health Insurance Corporation Ilsan Hospital, Internal Medicine, Ilsan, Korea*

Recent studies have reported that Apolipoprotein B/A1 ratio is a better predictor of atherosclerotic vascular disease compared to LDL-C. The aim of this study was to assess the association of serum Apolipoprotein B/A1 ratio with insulin resistance and PWV in patients with impaired fasting glucose (IFG). 658 subjects with fasting plasma glucose level of between 100 and 125 mg/dl and without a history of diabetes were enrolled in this study. BMI, WC, and serum concentration of apolipoprotein B, apolipoprotein A1, glucose, lipids (triglycerides, LDL cholesterol, HDL cholesterol, and total cholesterol) were measured. Insulin resistance was estimated by the insulin resistance index of homeostasis model assessment (HOMA-IR) & serum adiponectin. PWV was evaluated to assess arterial stiffness.
Apolipoprotein B/A1 ratio significantly correlated with total cholesterol (r=0.288, P<0.01), TG (r=0.130, P<0.01), LDL-C (r=0.394, P<0.01), HDL-C (r= -0.336, P<0.01), adiponectin (r= -0.149, P<0.01), HOMA-IR (r=0.081, P=0.037), insulin (r=0.082, P=0.041), BMI (r=0.083, P=0.03), WC(r=0.092, P=0.02), and peripheral PWV (r=0.088, P=0.042). Multiple regression analysis showed that Apolipoprotein B/A1 ratio was significantly associated with total cholesterol (ß=0.179, P<0.01), LDL-C (ß=0.120, P<0.01), HDL-C (ß= -0.184, P<0.01), and adiponectin (ß= -0.135, P=0.03).
In conclusion, apolipoprotein B/A1 ratio is significantly associated with insulin resistance, and serum adiponectin is an important independent factor associated with Apolipoprotein B/A1 ratio in Korean IFG patients.

Perilipin, IL-1, ADRB and MCR-4 gene variants identify bariatric surgery patients who are predisposed to dyslipidemia

N. Aziz[1], V. Kondragunta[1], P. Prabhakar[1], K. Shaver[1], K. Kornman[1], C. Wood[2], G. Gerhard[2], C. Still[2]
[1] *Interleukin Genetics, Research and Development, Waltham MA, USA*
[2] *Weis Center for Research and Geisinger Obesity Institute, Geisinger Clinic, Danville PA, USA*

There are many comorbidities of obesity including diabetes, hypertension, cardiovascular disease and stroke. Dyslipidemia is an underlying causative factor in many of these comorbidities. Obese subjects with dyslipidemia are at a greater risk than those with normal blood lipid profiles and require rigorous medical management. Several genetic variants associated with obesity are in the genes that regulate satiety or fat and carbohydrate metabolism or inflammation. Although the mechanism of obesity-induced insulin resistance and type2 diabetes is not fully understood, tissue stress and/or abnormal infiltration of macrophages in adipose tissues is known to trigger an inflammatory response. Therefore, in an effort to understand if genetic variants in some of these obesity-related genes are associated with abnormal lipid metabolism we conducted a study on 824 obese subjects enrolled in a preoperative bariatric surgery program at the Geisinger Clinic. These patients were medically managed for a 6-8 month period in an effort to lose 5-10% of their body weight to decrease the incidence of perioperative complications. Body weight and blood lipids were measured at baseline before subjects went on a preoperative weight loss program. We genotyped DNA from 824 subjects who had consented to genetic analysis. A total of 23 SNPs in 9 genes (IL1A, IL1B, IL1RN, Perilipin, ADRB2, ADRB3, FABP2, PPARg, MCR-4) either previously associated with obesity and/or involved in the regulation of inflammation or metabolism/absorption of fat and carbohydrate, or satiety were investigated for association with abnormal levels of HDL, LDL, and triglycerides at baseline using linear regression analysis. Polymorphisms within the ADRB2 (ß= -1.651; p= 0.0275), MCR-4 (ß= -2.838; p= 0.008) genes, and IL1B gene promoter (ß= -2.687; p = 0.014) were strongly associated with lower HDL levels after adjusting for age, gender, metabolic score (scoring the metabolic comorbidities) and antidepression medications. The PLIN1 SNP in the perilipin gene (ß= 8.693; p=0.0231) was associated with higher levels of LDL after adjusting for age, gender, diabetes and cholesterol medications. IL1B (ß= 0.1558; p=0.027), IL1RN (ß= 0.254; p= 0.0138) and perilipin (ß = 0.1364; p= 0.008) genes were strongly associated with higher levels of triglycerides (log transformed). FABP2, PPARg, ADRB3 and IL1A genes were not associated with dyslipidemia. We suggest that these associated genetic polymorphisms may confer susceptibility to abnormal levels of blood lipids and could have clinical utility in the identification and management of obese patients.

Apolipoprotein B levels in adults with type 1 diabetes not receiving lipid-lowering therapy

H. Tildesley[1], A. Mazanderani[2], S. Wise[3]
[1] *St. Paul's Hospital University of British Columbia, Endocrinology and Metabolism, Vancouver, Canada*
[2] *St. Paul's Hospital, Endocrinology and Metabolism, Vancouver, Canada*
[3] *University of British Columbia, Medicine, Vancouver, Canada*

Objective: Cardiovascular disease (CVD) is the leading cause of death in patients with type 1 diabetes (T1D). Apolipoprotein B (apoB) has been shown to be a better marker of CVD risk and response to lipid-lowering therapy than LDL cholesterol (LDL-C). This study investigated apoB levels in 169 consecutive, consenting, adult patients with T1D with no previous history of CVD and not receiving lipid-lowering therapy.
Research design: Subjects were divided into two groups: males (M) and females (F). Primary analysis examined lipid parameters. Secondary analysis involved classifying patients according to the Canadian Diabetes Association's (CDA) LDL-C and apoB targets of 2.0 mmol/L and 0.90 g/L respectively.

Results:

Table 1: Demographic and clinical characteristics of the study population.

	M (n=90)	F (n=79)
Age (years)	46.6 ± 12.5	47.4 ± 14.5
Duration of DM (years)	23.3 ± 12.0	22.9 ± 12.4
Age of Onset	23.3 ± 11.1	24.5 ± 13.1
Weight (kg)	82.9 ± 13.6	67.3 ± 12.3
Hb A1C (%)	7.8 ± 1.3	8.0 ± 1.4
Blood pressure (mmHg)	122.3 ± 17.5/71.0 ± 8.7	118.8 ± 15.7/70.3 ± 6.9
Total cholesterol (mmol/L)	4.6 ± 0.9	4.8 ± 0.8
HDL-C (mmol/L)	1.6 ± 0.4	1.9† ± 0.5
LDL-C (mmol/L)	2.6 ± 0.7	2.5 ± 0.7
Triglyceride (mmol/L)	0.88 ± 0.5	0.86 ± 0.5
Cholesterol:HDL-C	3.1 ± 0.9	2.7‡ ± 0.7
ApoB (g/L)	0.81* ± 0.17	0.78* ± 0.18
ApoB (g/L) with TG<1.5 (mmol/L)	0.79 ± 0.17	0.77 ± 0.17
ApoB (g/L) with TG=1.5 (mmol/L)	0.94 ± 0.15	0.92 ± 0.22
Data are shown as means ± SD.		
*Significantly lower than 1.2 g/L (p < 0.0001) and 0.90 g/L (p < 0.0001).		
†Significantly higher in F than M, p < 0.0001.		
‡ Significantly lower in F than M, p < 0.001.		

We found that the prevalence of elevated apoB is low among all patients with T1D and the level of HDL-C was significantly higher in females. We also found that among patients who failed to achieve the CDA LDL-C target, 62% of males and 66% of females met the apoB target. Proportions of individuals who were categorized as above LDL-C and apoB targets were significantly different in both groups (p < 0.0001).

Table 2. Patients classified according to the LDL-C target and assessed based on apoB target of 0.90 g/L, McNemar's test p-values for the LDL-C and apoB targets are shown

	M		F	
	apoB<0.90g/L	apoB=0.90g/L	apoB<0.90g/L	apoB=0.90g/L
LDL-C=2.0mmol/L	16 (100%)	0	15 (100%)	0
LDL-C>2.0mmol/L	46 (62%)	28 (38%)	42 (66%)	22 (34%)
p-value	< 0.0001		< 0.0001	

Conclusion: The low prevalence of dyslipidemia among patients with T1D may indicate that other factors such as poor glycemic control may be responsible for the increased risk of death due to CVD. In addition, there is discordance between the proportions of patients meeting either LDL-C or apoB targets. Approximately 18% of patients met CDA's LDL-C target while more than 70% met the apoB target, thus a significant number of patients may be prescribed lipid-lowering medications unnecessarily.

Lipoprotein (a) levels in black South Africans are not associated with metabolic characteristics

T. Matsha[1], E. Blanco-Blanco[2], M.S. Hassan[3], Y. Yako[4], R.T. Erasmus[4]

[1] *Cape Peninsula University of Technology, Biomedical Sciences, Cape Town, South Africa*

[2] *Walter Sisulu University, Chemical Pathology, Mthatha, South Africa*

[3] *Cape Peninsula University of Technology, Nursing and Radiography, Cape Town, South Africa*

[4] *University of Stellenbosch, Chemical Pathology, Cape Town, South Africa*

Background: Lp(a) plays a role in the atherosclerotic process and several retrospective studies have indicated that elevated Lp(a) concentrations are a strong independent risk factor for premature heart disease, cerebrovascular and peripheral vascular disease and early occlusion of coronary artery bypass grafts and femoropopliteal vein grafts. However, mean and median Lp(a) levels vary considerably among populations.

Methods: Fasting blood samples of 327 participants were analysed for blood glucose, lipids and lipoproteins using standard methods (Beckman SGX5). Lp(a) was assayed by immunonephelometry with a commercial kit using anti-Lp(a) antibodies.

Results: Obesity was present in 23.2% of all cases, and it was significantly higher in females than males, 52.4% and 9.5% respectively, p< 0.001. Because the distribution of the serum Lp(a) values was skewed, these were log-transformed. The 75th percentile for males was located at 40.8 mg/dL and for females at 41.0 mg/dL. No correlations were observed between Lp(a) levels and age, BMI, WHR, LDL-cholesterol, HDL-cholesterol, triglycerides and blood pressure. Using the 75th percentile to indicate hyper-Lp(a)-aemia and possibly increased atherogenic risk, 25% of our subjects were classified into this category and had significantly higher total cholesterol levels.

Conclusion: In contrast to observations made in Nigerian blacks, Lp(a) levels though also high, were not influenced by either sex, age, BMI, WHR, BP, or LDL-cholesterol concentrations. Our results confirm that high serum Lp(a) levels seem to be characteristic of all black populations studied, however in black South Africans these values do not seem to be influenced by metabolic factors, therefore the role of genetic factors needs to be investigated. Furthermore, cut-off values indicative of increased atherogenic risk need to be developed for black populations since the 30 mg/dl used may not be applicable to this population group that already has high serum Lp(a) levels.

Background and aims: This study was designed to explore the dyslipidemia still present in statin-treated patients with diabetes, along with the characteristics of co-morbid conditions that provide additional risk of cardiovascular events.

Materials and methods: DYSIS was a cross-sectional epidemiology study conducted in 11 European countries and Canada. Patients were consecutively recruited from the practices of 2987 general practitioners, cardiologists, endocrinologists/diabetologists and internists. Inclusion criteria included: ≥ 45 yrs of age, statin treatment for ≥ 3 months, a clinical exam and a record of ≥ one lipid value.

Results: Between April 2008 and February 2009, 22,063 patients were enrolled. Of these, 19,196 had full lipid values. Patients with diabetes represented 39.5% of that population. 58.5% were at LDL-C goal. Of those not at LDL-C goal, 16.2% had normal HDL-C and TGs. 3.9% had high TGs, 8.3% had low HDL-C with high TGs and 3.2% had low HDL-C. 25.4% had low HDL-C and/or high TGs.

Conclusions: Despite statin therapy, patients with diabetes potentially remain at high risk for CV events. Of note are several additional modifiable risk factors: a sedentary lifestyle, hypertension, and obesity. Most of these patients have the metabolic syndrome and are candidates for an intensive lipid and lifestyle management program.

Patient Characteristic	Patients with DM N = 8613 (39.0%)
Age (years, ± SD)	66.3 (± 9.4)
Female (%)	41.2%
Sedentary Lifestyle (%)	54.9%
HTN (%)	84.7%
Current smoker (%)	14.6%
Ischemic Ht Disease (%)	35.5%
BMI>=30 kg/m2	46.4%
CVD (%)(CHD, CV dis, HF a/o PAD)	47.5%
Heart Failure (%)	11.2%
PAD (%)	12.8%
Cerebrovascular disease	10.3%
MetS (ATPIII) (%)	76.5%
MetS (IDF GL) (%)	86.8%
Parental Hx DM (%)	47.0%
Mean HbA1C (DM only)	7.0+/-1.2
Fasting glucose (mean)	137.7 +/-41.7

Efficacy of fenofibric acid in combination with simvastatin in patients with type 2 diabetes mellitus and mixed dyslipidemia

S. Mohiuddin[1], M. Kelly[2], C. Setze[2], J. Ansquer[3], D. Sleep[2]
[1] Creighton Cardiac Center, Dept. of Medicine, Omaha, USA
[2] Abbott, Global Pharmaceutical Research and Development, Abbott Park, USA
[3] Laboratories Fournier SA, Global Clinical Development, Daix, France

Background: Patients with type 2 diabetes mellitus (T2DM) are at high risk for coronary heart disease and frequently have mixed dyslipidemia (high triglycerides, low HDL-C and elevated LDL-C), which may be refractory to single-agent lipid-altering therapy. This pre-planned analysis of a multicenter, double-blind phase 3 study of patients with mixed dyslipidemia evaluates the efficacy of the combination of fenofibric acid (FA) and simvastatin (S) on multiple lipid parameters in a subgroup of patients with T2DM.
Methods: A total of 657 patients with LDL-C ≥ 130 mg/dL (3.36 mmol/L), triglycerides ≥ 150 mg/dL (1.70 mmol/L) and HDL-C < 40 mg/dL (1.03 mmol/L) for men (< 50 mg/dL [1.29 mmol/L] for women) were randomized to either FA 135 mg, S (20, 40 or 80 mg) or combination therapy (FA+S20 or 40 mg) and treated for 12 weeks. A total of 142 (22.9%) of the 621 patients included in the primary efficacy analysis had T2DM. The primary efficacy comparisons were mean % changes in HDL-C and triglycerides (FA+S vs. S) and LDL-C (FA+S vs. FA). Secondary endpoints included mean % changes in non HDL-C and apolipoprotein B (FA+S vs. S).
Results: All treatments improved multiple lipid parameters (Table). FA+S resulted in greater improvement in triglycerides than the equivalent S monotherapy, dose and greater improvements in LDL-C than FA monotherapy. FA+S20mg also resulted in a greater improvement in HDL-C, non-HDL-C and apolipoprotein B than S20mg. All treatments were generally well tolerated and no case of rhabdomyolysis was reported.

	FA	S20	FA +S20	P-Value	S40	FA+ S40	P-Value

Prevalence, awareness, treatment and control of elevated blood pressure among U.S. adults with diagnosed diabetes, 2001-2006

S. Saydah[1], D. Rolka[2], G. Imperatore[2], L. Geiss[2]
[1] Centers for Disease Control and Prevention, Division of Diabetes Translation, Hyattsville, USA
[2] Centers for Disease Control and Prevention, Division of Diabetes Translation, Atlanta, USA

Aim: Hypertension control, treatment and awareness are important components of diabetes treatment and care. The objective of this study is to examine the prevalence, awareness, treatment and control of elevated blood pressure (BP) among older adults with diagnosed diabetes in the U.S.
Methods: We used data from the National Health and Nutrition Examination Survey (NHANES) for the years 2001 through 2006. Our sample included 1181 adults age 45 years and older with self-reported diagnosed diabetes. Elevated BP was defined as mean systolic BP (SBP) ≥ 130 or diastolic BP(DBP) ≥ 80 mmHg or current use of prescription medication. Among those with elevated BP, awareness was defined as self-reported, diagnosed hypertension; treatment was defined as current use of prescription medication, and control was defined as having mean SBP <130 and DBP < 80 (<130/80), SBP <130 and DBP< 85 (< 130/85), or SBP <140 and DBP < 90 mmHg (< 140/90).
Results: Among adults with diagnosed diabetes, 81% (95% Confidence Interval [CI] 78-84%) had elevated BP. Prevalence was higher among adults 65 years and older (89%; 95% CI 86-92%) compared to adults 45-64 years (74%; 95% CI 68-80%); women were more likely to have elevated BP compared to men (84%; 95% CI 81-88% vs. 77%; 95%; CI 72-82%); and non-Hispanic blacks and non-Hispanic whites were more likely to have elevated BP (88%;95% CI 82-93% vs. 82%;95% CI 78-86%) compared to Hispanics (67%;95% CI 58-76%). Among adults with diabetes and elevated BP, 84% (95% CI 81-88%) were aware of their condition and 78% (95% CI 74-82%) were under treatment. However, only 27% (95%CI 24-31%), 31% (95% CI 27-35%), and 57% (53-61%) had mean BP <130/80, <130/85, or <140/90 mmHg, respectively.
Conclusions: The prevalence of elevated BP is high among adults 45 years and older with diagnosed diabetes in the U.S. Although the majority of these adults are aware of their condition and under treatment, control remains poor with less than a third of adults with diabetes and hypertension having blood pressure < 130/80 mmHg.

Isolated office hypertension (white coat effect) is independently associated with increased central aortic stiffness in type 2 diabetes

C.R.L. Cardoso[1], M.T. Ferreira[1], P.H. Conte[1], N.C. Leite[1], E.S. Muxfeldt[1], G.F. Salles[1]
[1] Medical School Federal University of Rio de Janeiro, Internal Medicine, Rio de Janeiro, Brazil

Aims: Isolated uncontrolled office hypertension or white coat effect has been associated with structural cardiac abnormalities; however, its relation to a worse cardiovascular prognosis remains uncertain. The aim of this study was to investigate whether white coat effect (WCE) was independently associated with two subclinical markers of cardiovascular disease, increased aortic stiffness and left ventricular hypertrophy, in patients with type 2 diabetes.
Methods: 514 type 2 diabetic patients were evaluated in a cross-sectional study. Clinical, laboratory and 24-hour ambulatory blood pressure monitoring (ABPM) data were obtained. Controlled hypertension was defined by office blood pressure (OBP) < 140/90 mmHg and daytime BP < 135/85 mmHg on ABPM, whereas WCE by OBP ≥ 140/90 mmHg and daytime BP < 135/85 mmHg. Arterial stiffness was assessed by carotid–femoral (aortic) pulse wave velocity (PWV) measurement and left ventricular mass indexed to body surface area (LVMI) by echocardiography. Statistics included bivariate analysis and multivariate logistic regression to investigate if increased aortic PWV (>12m/s) and LVMI was independently associated with the WCE.
Results: According to blood pressure patterns, 28.7% had controlled hypertension, 32.9% WCE, 8.3% masked hypertension (or isolated uncontrolled ambulatory hypertension) and 30.2% uncontrolled hypertension both in the office and in ABPM. Patients with WCE were older, had greater prevalence of

diabetic retinopathy, used more antihypertensive drugs, had higher serum LDL-cholesterol levels and greater LVMI and aortic PWV than those with controlled hypertension. On multiple logistic regression, an increased aortic PWV was independently associated with WCE (OR=2.96; 95%CI: 1.43-6.13 p=0.004), after adjusting for other possible confounding variables, whereas LVMI was not associated with WCE. Other variables associated with WCE were the number of antihypertensive drugs in use, 24-hour systolic blood pressure, LDL-cholesterol and smoking status.

Conclusions: In type 2 diabetic patients, isolated office hypertension (white-coat effect) is associated with increased aortic stiffness; this may be a link to augmented cardiovascular risk independent of other established determinants of vascular damage.

D-0816

A blunted nocturnal blood pressure reduction is associated with several unfavorable cardiovascular risk markers in type 2 diabetes

G.F. Salles[1], G.M.B. Teixeira[1], N.C. Leite[1], E.S. Muxfeldt[1], C.R.L. Cardoso[1]

[1] *Medical School Federal University of Rio de Janeiro, Internal Medicine, Rio de Janeiro, Brazil*

Aims: A blunted nocturnal blood pressure reduction or an abnormal circadian BP variability (non-dipping) pattern had been reported as a worse cardiovascular prognostic marker in several clinical conditions. However, their importance in diabetic patients is controversial. The aim of this study was to evaluate the independent correlates of a blunted nocturnal BP fall or the non-dipping pattern in type 2 diabetic patients.

Methods: 514 type 2 diabetic patients were examined in a cross-sectional design at entry into a cohort study. Clinical, laboratory, echocardiographic and 24-hour ambulatory BP monitoring data were obtained. Aortic stiffness was assessed by carotid-femoral pulse wave velocity measurement. Non-dipping was defined as a nocturnal BP reduction <10% of daytime BP. Statistical analyses included multiple linear regression (with continuous nocturnal BP fall as the dependent variable) and logistic regression (with dipping/non-dipping status as the dependent variable).

Results: 303 patients (58.9%) were non-dippers. Non-dippers were older, had longer diabetes duration, higher post-prandial glycemia and higher mean HbA_{1c} during the first year of follow-up than normal dipping patients. They had a higher prevalence of hypertension, used more anti-hypertensive drugs, particularly ß-blockers and diuretics, and had higher office systolic BP than normal dippers, but had equal ambulatory daytime BP levels. Non-dippers had also a greater prevalence of dyslipidemia, physical inactivity, left ventricular hypertrophy (LVH), increased aortic stiffness, and of all macro and microvascular degenerative complications. On multivariate logistic regression, the presence of LVH (OR: 1.82, 95%CI: 1.24-2.66) and of dyslipidemia (OR: 1.86, 95%CI: 1.06-3.27), the use of ß-blockers (OR: 1.65, 95%CI: 1.30-2.41), a low ankle-brachial index (<0.9, OR: 1.66, 95%CI: 1.05-2.61) and either a post-prandial glycemia >10.0 mmol/l (OR: 1.81, 95%CI: 1.15-2.86) or a mean HbA_{1c} >7.5% (OR:1.54, 95%CI: 1.05-2.25) were the independent correlates of the non-dipping pattern. On multiple linear regression, a blunted nocturnal BP fall was independently associated with an increased aortic stiffness, increased left ventricular mass, higher HbA_{1c} levels, higher serum total cholesterol, presence of peripheral neuropathy and use of ß-blockers.

Conclusions: A blunted nocturnal BP fall and the non-dipping pattern are independently associated with several untoward prognostic markers in type 2 diabetic patients. These relationships may explain the worse cardiovascular outcome associated with abnormal circadian BP variability patterns.

One-year follow-up of biologic correlates for arterial blood pressure in type 2 diabetes

E. Matteucci[1], M.C. Masoni[1], C. Consani[1], A. Troilo[1], O. Giampietro[1]

[1] *University of Pisa, Internal Medicine, Pisa, Italy*

Aims: Previous results suggested that blood pressure (BP) response to exercise was significantly correlated with HbA1c levels in healthy normotensive non-diabetic control subjects. Present investigation evaluated the biologic determinants of arterial BP during one-year follow-up in patients with type 2 diabetes (T2D).

Methods: Cardiovascular risk factors were assessed at baseline, 1, 3, 6, 9 and 12 months in 20 T2D (age 60±5 y). Were measured: body mass index (BMI), waist to hip ratio (WHR), mean BP, fasting plasma glucose (FPG), HbA1c, plasma LDL cholesterol, folate and total homocysteine (tHcy), urinary albumin excretion (UAE). Dietary habits were estimated at each visit by administering a 2-d 24-h dietary recall (24HDR).

Results: BMI was 31±5 kg/m2, WHR 0.97±0.06, mean BP 98±10 mm Hg, FPG 159±42 mg/dl, HbA1c 7.4±1.2%, LDL 118±31 mg/dl, folate 8.9±6.6 ng/ml, tHcy 11.5±3.4 µmol/l. UAE ranged from 0 to 2957 µg/min (median 15.8). Multivariate regression analysis of longitudinal data found the following independent variables to be associated with MBP ($|r| = 0.54$, $P<0.0001$): HbA1c (t-value 5.24), folate (-2.84), and LDL (2.21). Estimated daily intake of folic acid was 286±129 µg/day significantly lower than Recommended Dietary Allowance.

Conclusion: Present study confirms in T2D previous observations in healthy people. There is a significant positive correlation between protein glycosylation and arterial BP. Additional influential factors are plasma folate and LDL cholesterol. These findings strengthen the need for maintaining a strict metabolic control (glycosylation of matrix proteins affects artery compliance) and promoting an adequate dietary intake of folate.

Pulse pressure and pulse wave velocity as markers of arterial stiffness in patients with type 1 diabetes

J.C. Philips[1], P. Xhignesse[2], M. Marchand[1], A. Saint-Remy[2], J.M. Krzesinski[2], A. Scheen[1]

[1] *CHU Sart Tilman, Division of Diabetes Nutrition & Metabolic Disorders, Liège, Belgium*

[2] *CHU Sart Tilman, Division of Nephrology and Hypertension, Liège, Belgium*

Aims: Type 1 diabetes is associated with an acceleration of arterial stiffness with age and an increased cardiovascular risk as compared to nondiabetic controls. The aim of the study was to compare two markers of arterial stiffness, arterial Pulse Pressure (PP) and Pulse Wave Velocity (PWV), in type 1 diabetes patients and in age-matched controls.

Methods: 59 (20-55 years) type 1 diabetic patients (24 women/35 men, 41±9 years, 20±9 years of diabetes, HbA1c 8.5±1.6 %) and 31 age-matched control subjects were evaluated with a continuous noninvasive arterial blood pressure monitoring (Finapres®). Recordings were performed in standing position (1 min), in squatting position (1 min), and again in standing position (1 min), but most presented data correspond to average PP (systolic - diastolic pressure) values calculated during the overall period. PWV was measured in supine position between the carotid and femoral peripheral artery sites with a SphygmoCor Vx®. Twenty-two diabetic patients were treated with a renin-angiotensin inhibitor, mainly because of microalbuminuria.

Results: PP was significantly higher in diabetic than in nondiabetic subjects (58±14 vs 50±10 mm Hg; p<0.002). The relative PP increase from standing to squatting tended to be higher in diabetic than in nondiabetic individuals (+6±9 vs +4±4 mmHg; p= 0.185). This posture difference was amplified in diabetic individuals above 40 years (+8±9 vs +4±10 mmHg; p= 0.141). PWV was also significantly increased in the diabetic group when compared with the control group (5.2±1.5 vs 4.4±1.5 m/sec; p=0.026). No differences were detected according to gender (5.2±1.6 m/sec in diabetic women vs 5.2±1.4 m/sec in diabetic men, NS; 4.6±1.6 m/sec in nondiabetic women vs 4.1±1.4 m/sec in nondiabetic men, NS). No significant differences in PP and PWV were observed in patients receiving (62 ± 19 mm Hg; 5.5±1.6 m/sec) or not receiving (55 ± 10 mm Hg; 4.9±1.3 m/sec) a renin-angiotensin blocker (p=0.11 and p=0.12, respectively). In the diabetic population, positive correlations were observed between PWV and PP (r=0.3127; p=0.0179), PWV and age (r=0.3460; p=0.0073), PWV and diabetes duration (r=0.3009; p=0.0206), PP and age (r=0.4339; p<0.0001), and PP and diabetes duration (r=0.1761; p=0.2240). In contrast, no such correlations were observed in the nondiabetic controls, neither between PWV and PP (r=-0.09; NS) nor between each of these two indices and age (r=-0.2129, NS, for PWV and r= -0.08, NS, for PP).

Conclusion: Type 1 diabetes was associated with an increase in both PP and PWV as compared to a nondiabetic population. In the diabetic population, a close correlation between the two indirect markers of arterial stiffness was found and also between each of them and age (or diabetes duration), but not in controls. These observations support the concept of an earlier arterial stiffness in type 1 diabetes with rather poor glycemic control.

[6] Oshima Clinic, Internal Medicine, Asahikawa, Japan
[7] Sapporo-kosei General Hospital, Internal Medicine, Sapporo, Japan
[8] Asahikawa-kosei General Hospital, Internal Medicine, Asahikawa, Japan

Aims: In type 2 diabetes, microalbuminuria is an important risk factor not only for the progression of nephropathy but for cardiovascular events. Thus, the reduction of urinary albumin excretion is important. In the present study, we compared the effect of pioglitazone with metformin on urinary albumin/creatinine ratio and metabolic parameters for 52 weeks in type 2 diabetic patients with microalbuminuria and hypertension who were treated with RAS-inhibitor (ARB or ACE-I).
Methods: We conducted an open-label, randomized trial in patients with type 2 diabetes and hypertension. After treatment with RAS inhibitor at least 12 weeks, 70 patients with microalbuminuria (urinary albumin/creatinine ratio > or = 30mg/gCr to < 300 mg/gCr) received either pioglitazone (15 or 30mg/day;. n = 37) or metformin (500 or 750mg/day; n=33) for 52 weeks. Treatment dose of RAS inhibitor was not changed during the study. Urinary albumin/creatinine ratio, HbA1c, FPG, blood pressure, lipids, body weight were measured every 12 weeks.
Results: The mean urinary albumin/creatinine ratio decreased significantly (-16.6% ; 148.0 mg/gCr at 0W and 123.4 mg/gCr at 52W) in the pioglitazone group compared to an increase of 53.7% (114.5 mg/gCr at 0W and 175.9 mg/gCr at 52W) in the metformin group ($p < 0.05$ between groups). The mean HbA1c decreased 0.8% in the pioglitazone group and 0.3% in the metformin group. The mean systolic blood pressure decreased 3.3mmHg in the pioglitazone group and increased 5.6mmHg in the metformin group. The differences of HbA1c and systolic blood pressure between the groups was not significant. There were no significant differences in FPG, LDL-cholesterol, HDL-cholesterol and triglyceride between groups.
Conclusion: This study indicates therapeutic benefit of pioglitazone add-on to RAS inhibitor as compared with metformin, in terms of reduction of urinary albumin excretion, for type 2 diabetic patients with hypertension.

Prevalence of hypertension and microalbuminuria in type 2 diabetic patients

V. Pankiv[1], I. Pankiv[2]
[1] Centre of Endocrinology, Preventive Endocrinology, Kiev, Ukraine
[2] Regional Hospital, Endocrinology, Kolomyja, Ukraine

Aims: Microalbuminuria is believed to be a marker of cardiovascular disease not only in subjects with diabetes mellitus (DM) but also in the general population. Metabolic syndrome (MS) has been associated with a high incidence of cardiovascular events. In a cross-sectional study we aimed to evaluate the prevalence of MS and its relationship with microalbuminuria and cardiovascular events in a cohort of patients with type 2 DM.
Methods: This cohort consists of 459 type 2 diabetics with MS (52% M, 48% F; mean age 64±10 yrs, diabetes duration 10.5±8.1 yrs, BMI 32.2±3.8 kg/m^2, HbA1c 8.2±1.7%). The MS was defined according to ATPIII criteria. The incidence of fatal and non-fatal cardiovascular events (myocardial infarction, ischemic stroke) was recorded. These data were compared to 122 type 2 diabetic patients without MS (54% M, 46% F; mean age 62±10 yrs, diabetes duration 9.6±7.2 yrs, BMI 26.9±3.4 kg/m^2, HbA1c 8.1±1.7%).
Results and discussion: Among diabetic males the prevalence of microalbuminuria was higher in subjects with MS (23.2%) than in those with no MS (10.9%, p<0.005). In females the same features were: with MS 15.9%, with no MS 6.2% (p<0.001). Prevalence of microalbuminuria increased with the number of components of MS both in males and in females. Estimated glomerular filtration rate was lower in diabetic patients (males and females) with MS than in those with no MS. Multiple regression analysis indicated the number of MS components, age and HbA1c to be independent predictors of microalbuminuria. Type 2 diabetic patients with MS had more incidence of ischemic stroke (7.1% vs 0.7%; p<0.05), more myocardial infarction (6.9% vs 0.6%; p<0.05) as compared to the diabetic patients without MS.
Conclusion: The prevalence of microalbuminuria is higher in type 2 diabetic patients with MS. Microalbuminuria showed graded relationship with the number of MS components. The aggregation of MS involved more cardiovascular risk in patients with type 2 DM.

Evaluation of candesartan compared to olmesartan on insulin-sensitivity related parameters in type 2 diabetic hypertensive patients

G. Derosa[1], A.F.G. Cicero[1], S.A.T. Salvadeo[1], I. Ferrari[1], A. Gravina[1], R. Mereu[1], P. Maffioli[1], I. Palumbo[1], A. D'Angelo[1], R. Fogari[1]
[1] University of Pavia, Department of Internal Medicine and Therapeutics, Pavia, Italy

Aims: The correlation among retinol-binding protein-4 (RBP-4), visfatin, vaspin and markers on insulin sensitivity and glucose metabolism is unclear. Few studies considered the actions of sartans on these parameters. Our study aimed to compare the effect of Candesartan (C) vs Olmesartan (O) on insulin-sensitivity-related parameters, before and after antihypertensive therapy.
Methods: After 4 week washout placebo period, 105 hypertensive (DBP ≥ 80 mmHg and SBP ≥ 130 mmHg) patients with well controlled type 2 diabetes (HbA1c < 7%) were randomised to C 8 mg o.d. or O 10 mg o.d. and titrated after 1 month to C 16 mg o.d. or O 20 mg o.d.; the treatment period had a 1 year duration. We evaluated SBP, DBP, and collected plasma samples of (RBP-4), visfatin, and vaspin at baseline, and after 1 year.
Results: Ninety-eight patients completed the study (52 in C and 47 in O group). SBP and DBP were significantly reduced by both treatments [from 144±8 / 88±6 mmHg to 126±5 / 77±4 by C (p< 0.001) and from 145±9 / 89±7 mmHg to 128±7 / 79±5 mmHg by O (p< 0.001)] without any difference between them. The RBP-4 was reduced by 21.3±7.8 mg/ml in C group (p< 0.01), and by 4.4±1.5 mg/ml in O group (ns vs baseline, p< 0.05 vs C). Visfatin increase was 7.8±4.7 ng/ml in C group (p< 0.05), and 3.1±1.8 ng/ml in O group (ns vs baseline, p< 0.05 vs C), and vaspin reduction was 0.3±0.1 ng/ml in C group (p< 0.05), while was unchanged in O group (ns).
Conclusion: Candesartan therapy compared to O therapy improved insulin-sensitivity, beyond the same reduction in blood pressure.

Which grading tool for diabetic polyneuropathy is most useful clinically ?

S. Sakkal[1]
[1] Metabolic Care Center, Endocrinology & Metabolism, Mason-Ohio, USA

Aims: Loss of vibration sensation is an early sign in sensory diabetic polynueropathy (DPN). We devised a practical grading scale (Sakkal's scale), easy to do in the first office visit and every follow-up visit within 2 minutes. This study is to compare its application to the Oyer's grading system in clinical practice.
Methods: We tested 52 consecutive patients with two grading systems (Sakkal's and Oyer's). The Sakkal's grading with the 128 Hz tuning fork records the loss of vibration sensation, at the first office visit and every follow-up visit,at 10 levels from the hip downward: 1-toes and foot bottom 2-mid foot 3-ankle 4-lower third of the shin 5-mid shin 6-upper third of shin 7-knee 8-thigh 9- hip 10-above the hip. The Oyer's grading records the vibration time in seconds at the big toe. Each patient had intermediate outcome measures (FBS, PPG, HbA1C, etc...) tested before and after therapy (metabolic control, Trazadone, and adjuvant analgesic).
Results:
At baseline
Sakkal's Scale: loss of sensory vibration was found in 30 patients (57.7%) at the following levels: Below the ankle 16/30(53%),above the ankle14/30(47%)
Oyer's test showed decreased vibration in 31 patients (59%): 8 by 5 seconds, 23 by 10 seconds or more. Average FBS was 248, average HbA1C was 9.2%.

After therapy

Sakkal's Scale: loss of sensory vibration clearly improved within 2-4 weeks and up to 4 months in 91% of patients, normal or Below the ankle in 20/30 patients (67%), above the ankle 7/30 (33%). 6 patients(20%) became completely normal, and none were above the knee.

Oyer's test showed Improved vibration in 86% of patients by 2 seconds Average. FBS became 133, HbA1c 7.2%.

Comparing baseline with after therapy **for the total group:** FBS decreased by 115, HbA1c decreased by 2%. In Sakkal's Scale improvement in sensory vibration by any level was seen in 27 of the total 30 original patients with neuropathy or 90% with near complete improvement above the knee and nearly 70% reaching below the ankle level. In Oyer's test it improved in 86% by 2 seconds in nearly each group reaching below 5 seconds level in 52% of patients.

Discussion: Documenting the level of the loss of sensory vibration in diabetic neuropathy is an objective, accurate, easy to implement, time saving, reproducible clinical grading tool (Sakkal Scale) which correlates well with patient symptoms and metabolic control. It improves communication in research and clinical care in most patients. Improvement seen was a very important objective sign to patient and physician alike. Patients were able to see easily each level of improvement correlated with metabolic control, making patients more committed to treatment plan.

Conclusion: The improvement in diabetic polyneuropathy was strikingly seen in more than 70% of patients with Sakkal's Scale below the ankle (52% with the Oyer's test below 5 seconds) pointing to a significant reversible component probably related to glycaemic/metabolic control.

Prediction of 4-year diabetic neuropathy risk using a semi-quantitative monofilament score.

B. Perkins[1], A. Orszag[1], V. Bril[2]

[1] University of Toronto, Endocrinology, Toronto, Canada

[2] University of Toronto, Neurology, Toronto, Canada

We previously defined the cross-sectional characteristics of a semi-quantitative 10g monofilament score in assessing the presence or absence of diabetic sensorimotor polyneuropathy (DSP) in 478 diabetes subjects from the Toronto Diabetic Neuropathy Cohort. A score of 7 or more correct responses out of 8 ruled out - while a score of only 3 correct responses or fewer ruled in - the presence of DSP with sufficient sensitivity and specificity. We hypothesized that a score between 3 and 7 could represent incipient nerve injury (akin to microalbuminuria as an indicator of incipient kidney injury) and could predict with sufficient sensitivity subsequent risk of clinical DSP onset. Of the 249 diabetes subjects without DSP in the Cohort (according to the criteria of England et al., 2005), we re-examined 175 (70%) a mean of 4.1 years later. The study group was 33% female, 16% type 1 diabetes, had mean age 56±9y, and diabetes duration 12±10y. Baseline monofilament scores ≤3 were uncommon (only 35 subjects): These subjects had the highest 4y risk of DSP (57%). In contrast, those with scores ≥7 had the lowest 4y DSP risk (13%). Those with intermediate scores (>3 but <7) had 28% 4y DSP risk. Receiver-operating characteristic (ROC) curve analysis determined the optimal threshold for the 4y DSP risk to be 5/8. The positive and negative screening test results (corresponding to scores of ≤5 and >5, respectively) had 74% sensitivity, 64% specificity, and positive and negative likelihood ratios of 2.1 and 0.4 (Chi^2 20.7, $p<0.0001$). The area under the ROC curve was 0.675. This study defines the clinical utility of a semi-quantitative monofilament score for DSP screening. A simple threshold of 5 discriminates those individuals at the lowest and the highest 4y risk of DSP. Of greatest importance, the sensitivity of a negative test result has major implications for a simple DSP screening program generalizable to the clinical setting – A negative screening test result has acceptable sensitivity for ruling out the intermediate-term DSP risk, akin to the low nephropathy risk observed for an individual with normoalbuminuria.

CPT(Current Perception Threshold) is useful to estimate the progression of peripheral diabetic neuropathy

Y. Fujioka[1], H. Kinoshita[1], S. Taniguchi[1], T. Ohkura[1], K. Matsuzawa[1], H. Shiochi[1], N. Yamamoto[1], K. Sumi[1], S. Izawa[1], K. Ishida[2], C. Shigemasa[1]

[1] Tottori University Faculty of Medicine, Multidisciplinary Internal Medicine, Yonago, Japan

[2] JA Hiroshima Kouseiren Hiroshima General Hospital, Internal Medicine, Hiroshima, Japan

Aims: Diabetic peripheral neuropathy is the most common microangiopathy in patients with diabetes. But, it is easily underestimated because the early phase neuropathy is clinically latent and hard for absolute grading. In order to estimate the early phase peripheral neuropathy, it is important to use the absolute estimation strategy. In this study, we estimated CPT(Current Perception Threshold) values of patients with type 2 diabetes using neurometer.

Methods: We conducted the new diagnostic criteria of neuropathy for 62 patients with type 2 diabetes. Based on the progression of neuropathy, the diagnostic criteria (I–V) of diabetic peripheral neuropathy was developed by the Japan working group. This criteria is summarized as followings: stagel(presymptomatic), II(sensory symptom),III(sensory disturbance/lack of ATR), IV(severe sensory disturbance/autonomic dysfunction), V(motor system impairment). We simultaneously estimated CPT values stimulated by three distinct electrical stimuli (5, 250, 2000Hz) using neurometer. Then, we analyzed the relationship between the CPT value and HbA1c, nerve conduction velocity, which may contribute to diagnose the progression of peripheral neuropathy.

Results: According to the criteria, 62 patients were divided into the following five groups: stage I(29), II(15), III(11), IV(4), V(3). The progression of neuropathy was correlated with the duration of diabetes and the frequency of diabetic retinopathy. Most patients showed abnormal CPT value in stage III which include sensory disturbance as well as the impairment of Achilles' tendon reflex. The average CPT value increased in accordance with the progression of stage criteria. Moreover, even in presymptomatic stage I, the prevalence of CPT abnormality was 5Hz(5 / 29:17.2%), 250Hz(5 / 29:17.2%), 2000Hz(8 / 29:27.6%). CPT of 2000Hz was inversely correlated with SCV, and CPT of 5Hz and 250Hz was inversely correlated with SCV, MCV and CVRR. The significant correlation of CPT value was observed between 5Hz, 250Hz and 2000Hz stimuli. There was no positive correlation between CPT and HbA1c.

Discussion: CPT value is significantly associated with the progression of peripheral neuropathy. There was no relevant discrepancy between CPT values of three distinct stimuli. The progression of neuropathy appears to result in the dual impairment of CPT values (5, 250, 2000Hz). The negative correlation between CPT and SCV indicates CPT reflects the electrical disturbance of peripheral nervous system. It is noteworthy that 17-28% of patients in presymtomatic stage already showed the impairment of CPT. In conclusion, CPT value could contribute to detect the early phase diabetic neuropathy and estimate the quantitative progression of peripheral neuropathy.

Stage of Neuropathy	(1)	(2)	(3)	(4)	(5)
Duration of DM(year)	6.0±5.8	8.4±5.8	16.0±11.4	14.5±3.8	15.7±6.6
CPT(2000Hz)	293.8±86.4	323.8±91.8	430.3±103.0	524±117.1	999

Efficacy of epalrestat in patients with diabetic neuropathy and its influence on blood taurine levels

D. Suzuki[1], M. Toyoda[1], T. Umezono[1]

[1] Tokai University School of Medicine, Internal medicine, Isehara, Japan

Aims: Many diabetic patients complain of various symptoms of diabetic neuropathy such as localized painful muscle cramps. It has been reported that cramp is caused by various factors, such as abnormal peripheral nerve excitation, dehydration, electrolyte abnormalities, and abnormalities of lactic acid and taurine metabolism. The influence of a decrease of taurine in the plasma and nerve cells is considered particularly important under hyperglycemic conditions. Accumulation of sorbitol due to an abnormal increase of polyol metabolism under hyperglycemic conditions is considered to be one of the causes. Epalrestat is an aldose reductase inhibitor that is currently the only drug used clinically to correct abnormal activation of the polyol pathway. It was

recently reported that epalrestat suppressed the uptake of taurine into nerve cells and prevented an increase of nerve cell osmolality in an animal model. The drug is thus expected to show the effect for ameliorating neuropathy symptom via suppression of decrease in taurine. Changes of the symptoms associated with peripheral neuropathy and changes of the serum taurine concentration were investigated in this study during administration of epalrestat to patients with diabetic neuropathy.

Methods: Epalrestat was administered to 46 patients with diabetic neuropathy. Before and after 3 months of administration, the serum taurine concentration was measured, a monofilament touch test and a vibration test (C64 tuning fork) were performed, and symptoms were investigated (cramp, numbness, and dysesthesia of the sole). Each of the symptoms was classified using 3 grades: absent, tolerable, and intolerable.

Results: Compared with baseline, the serum taurine concentration improved to the normal reference range (43.9 - 57.1 nmol/ml) after 3 months of administration, and the symptom of cramp was significantly improved. Improvement was also observed in the monofilament touch test. There was no significant change of the HbA_{1C} level after 3 months of epalrestat administration compared with baseline.

Conclusion: Treatment with epalrestat for 3 months in patients with diabetic neuropathy was suggested to improve symptoms and correct neurological dysfunction. The serum taurine concentration may be used as an objective index of the efficacy of epalrestat treatment.

Modern questions of diagnostics and treatment of diabetic polyneuropathy

D.V. Seliverstov[1], I.V. Kondrus[1], V.G. Kutskir[1], I.A. Podyablonskaya[2], V.V. Masevnin[1], N.Y. Terentyeva[1], I.N. Kogarko[3], B.S. Kogarko[3], I.I. Ganeev[3]

[1] *MAPHC RRCH, of purulent surgery, Ryazan, Russia*

[2] *SEE HPE RyazSMU, of surgery, Ryazan, Russia*

[3] *ICP RAS, of biochemistry, Moscow, Russia*

Aim: to study alpha-lipoic acid influence on diabetic polyneuropathy (DPN) course.

Method: In 2006-2007 100 patients of the main and comparison groups were treated (neuroischemic form of diabetic foot (DF) – 70 patients, neuropathic form -30 patients). Main group patients were administered alpha-lipoic acid preparations ("Tioctacid", "ASTA Medika", Pliva; "Berliotion", "Berlin-Chemie") –daily 600 mg, dissolved in 200 ml of 0.9 % NaCl solution within 3 weeks, then perorally 600 mg once a day within 14 weeks. Control group patients were administered 200 ml of 0.9 % NaCl solution and 1 % riboflavin solution intravenously, using a dropper, within 3 weeks, then patients were taking polyvitamins for 5 weeks. Neurological investigation results were evaluated in 10, 30 days and in 3 months. Subjective manifestations were evaluated by means of TSS-complaint scale, DPN objective symptoms were evaluated by means of NIS-scale and NIS_{LL} modified scale. Instrumental investigation of peripheral innervation was done by computer stimulating electromyography (EMG), using OI-MBN-electroneuromyograph.

Results: In the main group an average score of TSS and NIS_{LL} scales as a result of treatment was reliably decreased by 30 day and continued decreasing by 90 day. Essential positive dynamics of EMG values was found out (residual latency (RL), M-response, ESS_M (excitement spreading speed). Statistically meaningful effect arose within the interval 10-30 days of treatment and gradually increased by 90 day. In comparison group reliably significant difference was not obtained in RL, M-response amplitude and ESS_M. All values had $p > 0.05$.

Conclusion: Efficiency of use of alpha-lipoic acid preparation (daily 600 mg, dissolved in 200 ml of 0.9 % NaCl solution within 3 weeks, then perorally 600 mg once a day within 14 weeks) in patients with DPN as compared to preparations of water-soluble B-group vitamins was proved.

Nerve conduction study among patients with type 2 diabetes – predictive factor of neuropathy?

A.I. Calota[1], I. Codita[2], E. Adamescu[1], C. Dobjanschi[1]

[1] *"N. Malaxa" Hospital, Diabetes Nutrition Metabolic Diseases, Bucharest, Romania*

[2] *University Hospital "Elias", Neurology, Bucharest, Romania*

Background: Diabetic sensorimotor polyneuropathy (DSP) is one of the most frequent and costly complications of type 2 diabetes. It may be asymptomatic, but, once established it is irreversible and may finally be disabling. Nerve damage is considered to be related to poor metabolic control and duration of diabetes. Nerve conduction study (NCS) is a sensitive method for the early detection of peripheral neuropathy.

The aim of the study: to estimate the prevalence of neuropathy in type 2 diabetic patients, to identify which risk factors are related to the severity of DSP and to demonstrate the importance of neurophysiologic examination in patients with diabetic neuropathy.

Material and method: We present the results of nerve conduction studies (NCS) performed in 86 type 2 diabetic patients - 40 F, 46 M - mean age 56±10 years and the mean duration of diabetes 7.2 years. Clinical evaluation was performed according to the "Toronto Clinical Scoring System for DSP". Needle electromyography (EMG) studies were performed. The parameters that were measured: ulnar motor and peroneal motor, sural sensory nerves *conduction velocity*, sural sensory nerve *action potential amplitude* and *F-wave latency* of the ulnar and peroneal nerves. BMI, HbA1c and lipid profile were used for the assessment of metabolic control. Diabetes treatment, existence of chronic complications, the presence of hypertension and smoking were recorded.

Results: Clinical neurologic examination was abnormal in 61 patients (71%). Isolated sensory symptoms and signs were more common (40%) than motor ones (19%). NCS revealed sensorimotor polyneuropathy in 63.3% pts. The mean HbA1c value was 9.5% in patients with abnormal NCS vs. 8.7% in patients with normal parameters (P=0.06). Prolonged F-wave latency - after exclusion of other causes of radiculopathy – was noted in 67% patients with abnormal NCS, only 28% of them having motor symptoms. Impaired nerve conduction velocity has been found more frequently in smokers, in patients with other chronic complications (rethinopathy, nephropathy) and in the presence of hypertension. A negative correlation existed between serum HDL-cholesterol level and Prolonged F-wave latency. Motor and sensory nerve action potential amplitude were more affected in males ($P<0.05$).

Conclusions: The most common form of neuropathy that has been found is sensorimotor polyneuropathy. Poor glycemic control (Hb A1c ≥ 9 %) is an important factor related to the severity of neurological impairment. The risk factors for atherosclerosis, such as hypertension, smoking, and decreased HDL cholesterol levels, might also be risk factors for DSP. Most patients with diabetic polyneuropathy could be apparent asymptomatic, making detection extremely dependent on careful neurological examination.

Treatment of diabetic peripheral neuropathy in patients with type 2 diabetes mellitus

L. Nikoleishvili[1], R. Kurashvili[1], N. Khachapuridze[1]

[1] *Georgian Diabetes Center, Functional Diagnostic, Tbilisi, Georgia*

Background: Diabetic Neuropathy (DN) leads to raised incidence of morbidity and mortality in Diabetic Patients. Increasing interest deserves positive results obtained with alpha-lipoic acid in terms of DN pathogenic treatment approach. The aim of our study was to evaluate the action of alpha-lipoic acid ("Thiogamma" Wörwag Pharma, Germany) in patients with Type 2 Diabetes with Distal Symmetric Polyneuropathy (DSP).

Materials and methods: 61 patients (pts) with type 2 Diabetes at the age of 40-65 years and HbA1c<8% were evaluated in two matched groups by age, sex, diabetes duration and the grade of DN; 31 pts in study group and 30 pts in the control group. Thiogamma according to following scheme: 50 ml intravenously for first 3 weeks, after that orally - 600 mg/daily for 4 weeks was additionally administered to the patients of the study group. Patients were evaluated before, after 3 and 7 weeks of treatment. The efficiency of Thiogamma was evaluated according to: Dynamics of changes of Neuropathy Symptoms Score (NSS) and Neuropathy Deficit Scores (NDS), including the evaluation of neuropathy signs and reflexes.

Results: After 3 weeks of therapy permanent and high-intensity nocturnal pain, as well as other types of paresthesia were decreased significantly in the study group compared to the control group. After the intravenous course of therapy in the study group NSS significantly decreased (8,4± 2,7 vs 4,12±2,35 (p<0.0001)); as well as NDS (4,9 ± 2,3 vs 2,8 ±0,7 (p=0.001)). Following oral administration of Thiogamma not only maintains the reached effect, but also ensures the positive dynamics of NSS scores (p<0.0001). During the therapy, the HbA1c level was statistically significantly reduced in the study group (from 7.69±0.73% to 6.73±0.8%) compared to control group (from 7.39±0.75% to 6.59±0.85%), indicating the positive effect of Thiogamma treatment on carbohydrate metabolism. There was no statistically significant reduction of NSS and NDS in the control group.
Conclusion: This study suggests that alpha-lipoic acid effectively reduces signs and symptoms of DN and improves metabolic control in patients with Type 2 Diabetes.

Diabetic neuropathy and depression in patients with type 2 diabetes

G. Kurashvili[1], R. Kurashvili[1], L. Tsutskiridze[1], E. Shelestova[1]
[1] Georgian Diabetes Center, Clinical Care, Tbilisi, Georgia

Background and aims: Peripheral neuropathy (DPN) affects 30% of people with diabetes, and positively correlates with DM duration, its severity and increased mortality. Current studies suggest that diabetes is often associated with depression. At the moment of diagnosis type 2 diabetes (T2DM) is already present for 5-7 years, and several long-term diabetes complications, including peripheral neuropathy, can be observed. The latter makes development of depression more likely and its degree more severe, thus worsening the quality of life of people with DM. This in turn accelerates progression of DM complications. The aim of the present work was to study the rates of diabetic neuropathy and depression and their relationship in T2DM patients.
Design and methods: There were 59 patients with type 2 diabetes (33 males / 26 females, mean age - 46 ± 5.72 yrs, mean HbA1c - 8.2±2.1%) without overt macrovascular complications and/or nerve damage of non-diabetic origin. Diabetes duration was ≥ 6 months. Peripheral nerve function was assessed by NEUROMETER® R-CPT neuroselective sensory nerve evaluation method. The electric current perception threshold was measured for three frequencies: 5Hz, 250Hz, and 2000Hz, using automated double-blind methodology (+/- 20 μAmperes) at two sites – the distal phalanx of the hallux in both feet (the lateral and medial aspects of the toes). Abnormal and normoesthetic R-CPT measures from T2DM patients were compared to depression incidence. For depression assessment Hamilton's and Beck's scales were used.
Results: The tests revealed that 19 out of 59 patients (32.2%) had depression of various severities. The prevalence of sensory dysfunction accounts for (35.59%) 21 patients. Difference in depression rates was observed between the patients with peripheral nerve damage and the patients without peripheral nerve damage. Nine out of 21 patients (42.85%) with peripheral nerve damage, and 10 out of 38 normoesthetic patients (26.31 %), had depression of various degree.
Conclusion: The highest percentage of depression was observed in the group of patients with peripheral nerve damage, and the lowest in the group of patients without peripheral nerve damage. Results have shown slight positive correlation between peripheral nerve damage and depression rates. Further studies are recommended.

Sensitivity analyses of the primary efficacy endpoint in a randomized-withdrawal phase 3 trial of tapentadol extended release (ER) in patients with painful diabetic peripheral neuropathy (DPN)

M. Etropolski[1], A. Steup[2], D.Y. Shapiro[1], A. Okamoto[1], J. Haeussler[1]
[1] Johnson & Johnson Pharmaceutical Research & Development L.L.C., Research & Development, Raritan NJ, USA
[2] Grünenthal GmbH, Research and Development, Aachen, Germany

Aims: Tapentadol is a novel, centrally acting analgesic with 2 modes of action, μ-opioid receptor agonism and noradrenaline reuptake inhibition. Sensitivity analyses assessed the robustness of observed treatment effects on the primary efficacy endpoint of a randomized-withdrawal, placebo-controlled study of tapentadol ER in patients with painful DPN.
Methods: Patients were titrated to an optimal dose of tapentadol ER (100-250mg bid) during a 3-week open-label (OL) phase. Patients with >=1 point improvement in pain intensity (0-10 NRS) were randomized 1:1 to receive tapentadol ER or placebo for a 12-week double-blind (DB) phase. Efficacy was assessed as change in mean pain intensity from start to end of the DB phase. Intermittent missing data were imputed using linear interpolation. The primary imputation method for missing data after discontinuation was last observation carried forward (LOCF). Sensitivity analyses were performed on the primary efficacy endpoint using the following imputation methods: baseline (start of DB) observation carried forward (BOCF), worst observation carried forward (WOCF), placebo mean imputation (PMI), modified BOCF (combination of BOCF and LOCF: if Patient Global Impression of Change was "much improved" or "very much improved" at discontinuation, LOCF was applied to pain intensity; otherwise BOCF was used), and no linear interpolation or carrying forward methods of imputation for observed cases (OC) for patients who completed treatment. Primary efficacy and sensitivity results were evaluated using analysis of covariance.
Results: Of 588 patients in the OL safety population, 395 were randomized to DB treatment and 389 were analyzed for safety and efficacy in the DB phase. For the primary efficacy evaluation, patients receiving tapentadol ER in the DB phase maintained the improvement in pain intensity scores observed during the OL phase, but patients in the placebo group significantly worsened (least squares mean difference [LSMD] between treatment groups, -1.3; $P<0.001$). Differences in mean pain intensity scores from baseline to Week 12 of the DB phase were significant (all $P<0.001$) for tapentadol ER versus placebo for all other imputation methods used, including BOCF (LSMD vs placebo, -0.6), WOCF (-1.1), PMI (-0.6), modified BOCF (-0.8), and OC for patients who completed treatment (-1.0). The most frequently reported treatment-emergent adverse events were nausea, dizziness, and somnolence in the OL phase, and nausea, anxiety, and diarrhea in the tapentadol ER group in the DB phase.
Conclusion: Significant improvement in the primary endpoint was demonstrated with all imputation methods used, indicating that the efficacy of tapentadol ER was robust in this study of patients with moderate to severe chronic pain related to DPN.

Health status (EuroQol-5 Dimension [EQ-5D]) in patients with painful diabetic peripheral neuropathy (DPN) treated with tapentadol extended release (ER): results of a randomized-withdrawal phase 3 study

A. Okamoto[1], D.Y. Shapiro[1], B. Lange[2], R. Lange[2], M. Etropolski[1]
[1] Johnson & Johnson Pharmaceutical Research & Development L.L.C., Research & Development, Raritan NJ, USA
[2] Grünenthal GmbH, Research and Development, Aachen, Germany

Aims: Health status was assessed using the EQ-5D questionnaire in a randomized-withdrawal study of tapentadol ER in patients with painful DPN.
Methods: Patients were titrated to an optimal dose of tapentadol ER (100-250mg bid) during a 3-week open-label (OL) phase. Patients with >=1 point improvement in pain intensity (0-10 NRS) were then randomized 1:1 to receive tapentadol ER or placebo for a 12-week double-blind (DB) phase; patients receiving tapentadol ER took the individually determined optimal fixed dose from the OL phase. Efficacy was assessed as change in mean pain intensity from start to Week 12 of DB maintenance using last observation carried forward to impute missing pain scores after discontinuation. EQ-5D was completed at pre-specified time points; it measures health outcomes in 5 dimensions (mobility, self-care, usual activities, discomfort/pain, anxiety/depression); results were evaluated using analysis of covariance.
Results: Of 588 patients who received >=1 dose of tapentadol ER during the OL phase, 389 received >=1 dose of study drug and were analyzed for safety and efficacy in the DB phase. Patients receiving tapentadol ER in the DB phase maintained the improvement in pain scores observed during the OL phase, but patients in the placebo group worsened (least squares mean difference ± standard error vs placebo, -1.3±0.20; $P<0.001$). For EQ-5D, from start of OL to start of DB, the percentage of patients in the DB intent-to-treat population who reported "no problems" increased and mean scores decreased for mobility (changed from 14.7% at baseline to 34.7% at start

of DB; mean change, -0.2), usual activities (30.1% to 49.6%; -0.2), pain/discomfort (0.0% to 10.0%; -0.5), and anxiety/depression (52.7% to 62.0%; -0.1). Differences in mean changes from start to end of DB were significantly in favor of tapentadol ER (lower score=improved health) for mobility (mean [SD] change: tapentadol ER, -0.0[0.45]; placebo, 0.1[0.47]; *P*=0.006), usual activities (-0.0[0.49] vs 0.1[0.48]; *P*=0.003), and pain/discomfort (-0.0[0.46] vs 0.2[0.52]; *P*=0.001) dimensions, and were similar in both groups for self care (0.0[0.38] vs 0.1[0.37]; *P*=0.905) and anxiety/depression (0.1[0.50] vs 0.0[0.50] *P*=0.341). Mean (SD) change from start to end of DB on EQ-5D health status index (higher score=improved health) was significantly different between treatment groups, favoring tapentadol ER (-0.0[0.21]) over placebo (-0.1[0.26]; *P*<0.001). Treatment-emergent adverse events reported by >10% of tapentadol ER-treated patients included nausea, dizziness, somnolence, and constipation.

Conclusions: In patients with painful DPN, tapentadol ER was effective and well tolerated in a 12-week randomized-withdrawal study, with greater maintenance of improvement in health status than placebo.

Thiazolidinediones but not sitagliptin exacerbate ovariectomy-induced bone loss in rat

T. Cusick[1], J. Mu[2], C. Li[2], Z. Li[2], K. Lu[2], B. Pennypacker[1], K. Scott[1], H. Glantschnig[1], X. Shen[3], N. Thornberry[2], D. Kimmel[1], B. Zhang[2]
[1] *Merck, Bone Research, West Point, USA*
[2] *Merck, Metabolic Disorders, Rahway, USA*
[3] *Merck, Laboratory Animal Resources, Rahway, USA*

Recent reports have established that thiazolidinediones (TZDs) increase risk of bone loss and fracture in patients with type 2 diabetes. Sitagliptin (Sita) represents a new class of antihyperglycemic agents and is a potent and selective inhibitor of dipeptidyl peptidase-4 (DPP-4). In this head-to-head study, we investigated effects of rosiglitazone (Rosi), pioglitazone (Pio), and Sita on ovariectomy (OVX)-induced bone loss in Sprague Dawley rats. OVX rats were treated once daily by oral gavage for 3 months with vehicle (Veh), Sita (100 and 300 mg/kg), Rosi (5 and 30 mg/kg), or Pio (5 and 30 mg/kg). The bone-resorption inhibitor alendronate (ALN) (0.015 mg/kg; 2x/wk, sc) was used as a control and prevented OVX-induced loss in bone mineral density (BMD). A sham-operated group was included. No significant treatment related changes in body weight or glucose were observed among different groups, however fat body mass and fat content in femur were increased by TZDs. TZDs at 5mg/kg ($p<0.05$) and 30 mg/kg ($p<0.01$) significantly exacerbated OVX-induced loss of BMD in the whole femur, while Sita was without effect. At the central femur, OVX did not induce significant BMD loss; however, both TZDs (at 30 mg/kg), but not Sita, significantly reduced regional BMD, cortical thickness and cortical area ($p<0.05$) in the OVX rats. The effect of both TZDs exacerbating OVX-induced bone loss was also evident in the proximal and distal femur, but not in the metaphyseal region of the distal femur. Moreover, TZDs significantly ($p<0.05$) exacerbated loss in lumbar spine BMD by 9-10% under all conditions tested. Caudal vertebrae BMD, though unaffected by estrogen-deficiency, was markedly reduced by TZDs (10-14%; $p<0.05$). In contrast, Sita, at dosages which achieved near complete inhibition of plasma DPP-4, had no significant or dose-related effect on any of the above bone parameters. Dynamic histomorphometry to mechanistically elucidate bone cell activities and bone marrow adiposity at the above skeletal sites in TZD and Sita treatment groups is ongoing. These data highlight important differences between sitagliptin vs. the TZD class in this rodent model of high bone turnover and suggest that sitagliptin, unlike TZDs, has no adverse effect on bone mineral density.

Pioglitazone and sitagliptin compared to pioglitazone and metfomin therapy on glycaemic control and on insulin resistance in type 2 diabetic patients

G. Derosa[1], A.F.G. Cicero[1], P.D. Ragonesi[1], S.A.T. Salvadeo[1], I. Ferrari[1], F. Querci[1], I.G. Franzetti[1], G. Gadaleta[1], L. Ciccarelli[1], M.N. Piccinni[1], A. D'Angelo[1], R. Fogari[1]
[1] *University of Pavia, Department of Internal Medicine and Therapeutics, Pavia, Italy*

Aims: our study aimed to compare the effects of pioglitazone (P) plus sitagliptin (S) vs pioglitazone (P) plus metformin (M) on glycemic control and on insulin resistance related-parameters in type 2 diabetic patients.
Methods: ninety-nine type 2 diabetic patients with uncontrolled type 2 diabetes mellitus (HbA1c > 7.5 %) were randomised to P 30 mg o.d. and S 100 mg o.d. or to P 15 mg b.i.d. and M 850 mg b.i.d. All type 2 diabetic patients were resulted not well controlled with diet and physical activity and P at dosage of 30 mg/day. The treatment period had a 9 months duration. We evaluated BMI, HbA1c, FPG, PPG, FPI, Homa index and collected plasma samples of adiponectin (ADN), resistin (R), tumor necrosis factor-alpha (TNF-a), and high-sensitivity C reactive protein (Hs-CRP) at baseline, and after 9 months.
Results: ninety-two patients completed the study (46 in PS and 46 in PM group). BMI was significantly reduced by PM, but not by PS (from 27.8±1.4 to 27.4±1.1 Kg/m^2, ns vs baseline, and from 27.6±1.2 to 26.8±0.9 Kg/m^2, p< 0.05 vs PS, respectively). HbA1c was decreased by 1.1±0.07 % (p< 0.01), and by 1.3±0.09 % (p< 0.01); FPG was reduced by 17±3 mg/dl (p< 0.01), and by 23±4 mg/dl (p< 0.01); PPG was decreased by 29±5 mg/dl (p< 0.01), and by 31±6 mg/dl (p< 0.01), in PS and PM group, respectively. FPI was decreased by 3.0±0.2 mU/ml (p< 0.05), and by 3.9±0.3 mU/ml (p< 0.01 vs baseline, p< 0.05 vs PS), and Homa index by 1.6±0.5 (p< 0.05), and by 2.1±0.6 (p< 0.01 vs baseline, p< 0.05 vs PS) in PS and PM group, respectively. ADN was increased by 0.2±0.002 mg/ml (ns vs baseline), and by 1.2±0.2 mg/ml (p< 0.05 vs baseline, p< 0.05 vs PS), in PS and PM group, respectively. Resistin was reduced by 0.2±0.001 ng/ml (ns vs baseline), and by 2.2±0.3 ng/ml (p< 0.05 vs baseline, p< 0.05 vs PS), TNF-a by 0.2±0.001 ng/ml (ns vs baseline), and by 1.0±0.3 ng/ml (p< 0.05 vs baseline, p< 0.05 vs PS), and Hs-CRP by 0.7±0.005 mg/l (p< 0.05), and by 0.7±0.005 mg/l (p< 0.05), in PS and PM group, respectively. There was a significant correlation between Homa index decrease and ADN increase (r= -0.57, p< 0.01), R decrease (r= 0.55, p< 0.01), and TNF-a decrease (r= 0.53, p< 0.01).
Conclusion: both combinations ameliorated diabetes control, but only PM improved insulin resistance related-parameters. The ADN increase, R and TNF-a decrease seem to be related to Homa index improvement.

D-0834

Pioglitazone-based fixed-dose triple combination therapy in office practice for type 2 diabetes in a resource-limited Indian Setup – PRIDE III Study PRIDE III investigators

S.R. Joshi[1], S.S. Hoskote[1], V. Panikar[2]
[1] *Joshi Clinic, Endocrinology, Mumbai, India*
[2] *KJ Somaiya Medical College, Medicine, Mumbai, India*

Aim: There is insufficient data on the use of a pioglitazone-based fixed-dose triple drug therapy in the treatment of type 2 diabetes mellitus (DM). We aimed to evaluate the safety and efficacy of a fixed-dose combination of pioglitazone (PG), metformin (MF) and glimepiride (GP) in the management of type 2 DM patients in a resource-limited Indian setup.
Methods: The study was conducted as a prospective, open, multicentric, non-comparative cohort study. Included patients were >18 years old, of either sex and inadequately controlled (glycated hemoglobin >7%) with mono- or dual therapy using sulfonylurea or MF or a thiazolidinedione; or if there was non-adherence with three different oral agents. Cardiac, renal or hepatic dysfunction were exclusion criteria.
The 1534 patients selected (mean age = 55 years, body weight = 66 kg, BMI = 25.46 kg/m^2) were started on a combination of PG (15 mg), MF (500 mg; slow release) and GP (1 or 2 mg, depending on glycemic values at inclusion). Patients were asked to continue their medications for concomitant illnesses. Baseline values for fasting plasma glucose (FPG) and post-prandial plasma glucose (PPG) and glycated hemoglobin (HbA1c) were measured. FPG and PPG were measured at 3-weekly intervals and HbA1c was measured after 3 months. The paired t-test was used for before-after comparisons. P<0.05 was taken as significant.

Results: Mean values for FPG, PPG and HbA1c decreased significantly from baseline during the course of therapy over 3 months (Table 1) and 752 (49%) of overall patients reaching the FPG treat-to-target goal. Triple combination therapy was well tolerated throughout the study. There were no reports of patient withdrawal due to elevated hepatic enzymes.

Table: Glycemic control at baseline and after 3 months

	Baseline	After 3 months	P value
Fasting plasma glucose*	194.43	117.2	<0.05
Post-prandial plasma glucose*	287.34	166.67	<0.05
Glycated hemoglobin	8.94%	6.93%	<0.05

* Units: mg/dl

Discussion: In patients with type 2 DM uncontrolled on mono- or dual therapy, fixed-dose triple drug combination therapy of PG, MF and GP significantly improved glycemic control with an acceptable tolerability profile. This therapy can, potentially, reduce the problem of treatment non-adherence. Though our study did not evaluate the effect of combination therapy in patients taking insulin, the synergistic effect of PG, MF and GP can reduce the insulin requirement significantly. For patients poorly controlled on mono- or dual therapy, our study makes a strong case for triple combination therapy as an attractive alternative to insulin.

Effect of pioglitazone and metformin fixed-dose combination on biomarkers of inflammation and dyslipidemia in patients with type 2 diabetes

A. Perez[1], Z. Zhao[1], R. Spanheimer[2]

[1] *Takeda Global Research & Development Center Inc., Clinical Sciences, Lake Forest, USA*

[2] *Takeda Pharmaceuticals North America, Medical and Scientific Affairs, Deerfield, USA*

Inflammation and dyslipidemia are recognized markers of cardiovascular risk in type 2 diabetes mellitus (T2DM). This 24-week, double-blind trial compared efficacy and safety of a fixed-dose combination of pioglitazone/metformin (PIO/MET) with respective monotherapy in T2DM patients who had stable HbA1c for 3 months on no antidiabetes medications. The primary endpoint was change from Baseline in HbA1c. Changes in hs-CRP, triglycerides, and lipid fractionations were secondary endpoints.

Measurements of hs-CRP showed significant decrease from Baseline to Week 8 and Week 24/Final Visit with PIO/MET compared with MET monotherapy, and PIO monotherapy showed significant decrease compared with MET at Week 8 (Table 1).

Table 1: Median Percent Change from Baseline in hs-CRP by Study Visit

	PIO 15 mg BID/MET 850 mg BID N=201	PIO 15 mg BID N=189	MET 850 mg BID N=210
Baseline Median, mg/L	3.545	2.885	3.08
Median Percent Change from Baseline			
Week 8	–36.33	–31.8	–12.32*†
Week 24/Final Visit	–36.7	–34.03	–26.22*

*P<0.05 vs PIO/MET therapy. †P<0.01 vs PIO. BID = twice daily.

Triglycerides decreased from Baseline to Final Visit in all 3 treatment groups (not statistically significant), with the largest decrease in PIO/MET (–5.95%), followed by PIO (–5.54%) and MET (–1.78%) monotherapies. High-density lipoprotein cholesterol (HDL-C) increased from a mean Baseline of 42.6 mg/dL to Final Visit in all 3 groups. The highest increase was with PIO/MET (14.20%), followed by increases in PIO (9.88%, P<0.05) and MET (6.09%, P<0.0001 compared with the combination).

PIO/MET and PIO therapies resulted in mean increases of 1.19% and 6.08% from Baseline, respectively, in low-density lipoprotein (LDL). Mean LDL particle concentrations decreased in all 3 treatment groups, with greater decreases observed in the PIO/MET and PIO groups than in the MET group (not statistically significant). Increases in LDL mean particle size were greater (P<0.001) in the PIO/MET and PIO groups than in the MET group (Table 2).

Table 2: LS Mean Change from Baseline in LDL-C Fractionation

	PIO 15 mg BID/MET 850 mg BID N=201	PIO 15 mg BID N=189	MET 850 mg BID N=210
LDL Particle Concentration			
Baseline, nmol/L	1460.9	1517.1	1471.2
Change, Baseline to Final	–240.6	–217.2	–176.4
LDL Mean Particle Size			
Baseline, nmol/L	20.28	20.31	20.35
Change, Baseline to Final	0.55	0.60	0.20*†

*P<0.0001 vs PIO/MET therapy. †P<0.0001 vs PIO. BID = twice daily.

Incidences of adverse events were 50.7% for PIO/MET, and 52.1% and 53.1% for PIO and MET, respectively. In conclusion, PIO/MET and PIO monotherapy improved a marker of inflammation and indices of diabetes dyslipidemia compared to MET.

Does magnesium replacement improve insulin resistance in patients with metabolic syndrome? A 12-week randomized double bind study

T. Cruz[1], M.L. Lima[2], L.E. Rodrigues[2], O. Bomfim[2], J. Melo[2], R. Correia[2], M. Porto[2], A. Cedro[2], L. Olivieri[2]

[1] *Faculdade de Medicina da Universidade Federal da Bahia, Medicine, Salvador, Brazil*

[2] *Escola Bahiana de Medicina e Saúde Pública, Medicine, Salvador, Brazil*

Magnesium (Mg) is an important metallic co-factor for fundamental enzymes to intracellular insulin signaling. Studies have shown reduced Mg levels in patients with insulin resistance (IR), high blood pressure, and metabolic syndrome (MS).

Aim: To evaluate the effect of magnesium (Mg) replacement on insulin resistance and cardiovascular risk factors in patients with metabolic syndrome without diabetes.

Methods: This 12-week clinical randomized double blind study compared the effects of 400 mg/day of chelated Mg with those of a placebo (n=72) on weight, blood pressure, fasting glucose, insulin, HOMA-IR, lipid profile, and C reactive protein (CRP). Mg was measured in serum (SMg) and in mononuclear cells (MMg). The study was approved by a local ethical committee.

Results: Hypomagnesaemia (SMg<1.7mg/dL) was seen in 23.2% and intracellular depletion in 36.1% of patients. MMg concentrations were lower in patients with obesity (0.94 ± 0.54 *vs*. 1.19 ± 0.6 µg/mg of proteins, P=0.04), and insulin resistance (0.84±0.33 *vs*. 1.14±0.69 µg/mg of proteins, P<0.05). Mg replacement in the usual dose (400mg/day) did not change SMg (1.82±0.14mg/dL *vs.* 1.81±0.16mg/dL, P=0.877) and tended to increase MMg (0.90±0.40 *vs*. 1.21±0.73, P=0.089). Mg replacement was well tolerated, and there were no relevant side effects, which occurred in the same proportion in patients taking Mg or placebo: slight epigastric pain (5.4% *vs*. 8.6%), nausea (2,7% *vs*. 5,7%), and diarrhea (2,7% *vs.* 2,9%), that did not require treatment or interruption of medications. Both groups lost weight, but only in the Mg group a modest fall in systolic blood pressure (134±12 *vs.* 124±27 mmHg, P=0.004) was observed, even though the changes in the averages after treatment when the groups were compared, were not statistically significant (–8.5±27.8 *vs*. –4.0±19.7, P= 0.498). Fasting blood sugar showed a tendency to fall in magnesium group (104±16 vs.102±12 mg/dL, P=0.09). HOMA-IR reduced in both groups, but the averages difference was not statistically significant. There was no change in lipid profile or in CRP.

Conclusions: Serum and intracellular Mg depletion is common in patients with Metabolic Syndrome (MS), especially in obese and insulin resistant. Mg replacement did not increase significantly Mg levels, in spite of the recommended replacement dose. As insulin resistance can impair Mg entrance into the cells, increasing doses and/or administering Mg replacement for more prolonged periods should be tested to evaluate the benefits of Mg replacement in these patients. Patients are presently being followed to evaluate the incidence of diabetes mellitus or glucose intolerance in both groups.

Safety and effectiveness of biphasic insulin aspart 30/70 (BIAsp 30) used with different combinations of oral antidiabetic drugs in patients with type 2 diabetes: results of the IMPROVE™ study

P. Valensi[1], R. Kawamori[2], Z. Bosnyak on behalf of the IMPROVE study group expert panel[3]

[1] *Jean Verdier Hospital Paris Nord University, Endocrinology Diabetology Nutrition, Paris, France*

[2] *Juntendo University, Graduate School of Medicine, Tokyo, Japan*

[3] *Novo Nordisk, Global Medical Affairs, Copenhagen, Denmark*

Aims: Many oral antidiabetic drugs (OADs) are combined with biphasic insulin aspart 30/70 (BIAsp 30) to treat type 2 diabetes. We investigated whether OAD choice affected safety and effectiveness outcomes.

Methods: We analysed data from patients taking BIAsp 30 with biguanides (B), sulphonylurea (S), biguanides and S (B+S), acarbose (A) or thiazolidinediones (T) during the 26-week IMPROVE™ study. Only patients who did not change treatment during the study were included (n=9396).

Results: At the end of the study all measures of glycaemic control were significantly reduced in all subgroups (p<0.001), with a trend to greater reductions in the BIAsp 30+A and BIAsp 30+T subgroups. Thus, more patients reached HbA_{1c}<7% in these subgroups (Table). Weight change was not significant in most subgroups, although small but significant changes were seen in the BIAsp 30+B (-0.3 kg) and the BIAsp 30+T (+0.4 kg) subgroups. Rates of major hypoglycaemia were significantly reduced in all subgroups except in the BIAsp 30+A subgroup (the reduction was not significant). Rates of minor hypoglycaemia were significantly reduced in the BIAsp 30+S and BIAsp 30+B+S subgroups and increased significantly in the BIAsp 30+A subgroup.

Conclusions: BIAsp 30 combined with any OAD effectively controls glycaemia with a low risk of hypoglycemia or weight gain. Caution should be applied when BIAsp 30 is used with acarbose, due to the slight increase in minor hypoglycaemia.

Miglitol, an alpha-glucosidase inhibitor, decreases gene expressions of inflammatory cytokines/cytokine-like factors in peripheral leukocytes in parallel with the reduction in blood glucose fluctuations in patients with type 2 diabetes

K. Mochizuki[1], T. Osonoi[2], M. Saito[2], N. Fukaya[1], T. Muramatsu[1], T. Goda[1]

[1] *The University of Shizuoka, Laboratory of Nutritional Physiology, Shizuoka, Japan*

[2] *Naka Kinen Clinic, Ibaraki, Japan*

Background and aims: Many patients with type 2 diabetes are treated with a-glucosidase inhibitors, which have beneficial effects in improving postprandial hyperglycemia. Miglitol, an a-glucosidase inhibitor, is more potent in reducing early postprandial blood glucose than other a-glucosidase inhibitors, such as acarbose and voglibose, and delays the peak of postprandial glucose. In this study, we focused the daily blood glucose fluctuations and gene expressions of inflammatory cytokines/cytokine-like factors in patients with type 2 diabetes and examined the effects of the switch from acarbose or voglibose to miglitol on them.

Methods: The subjects comprised 43 patients with type 2 diabetes (22 men and 21 women) aged 26–81 years with HbA_{1c} levels from 6.5% to 7.9%. They had received combination therapy with acarbose (100 mg/meal) or voglibose (0.3 mg/meal) and insulin or sulfonylurea for more than six months. At the start of the study, all alpha-glucosidase inhibitors were switched to miglitol (50 mg/meal) and the new treatments were continued for three months. At each end of the study period, basic clinical parameters, such as HbA_{1c}, fasting glucose, triglyceride, total-cholesterol and C-reactive protein, were measured, and the severity of adverse events, such as hypoglycemia, fecal disturbance (diarrhea/constipation), flatulence and abdominal distention were monitored. Blood glucose was determined just before and one hour after meals by self-monitoring. Gene expressions of inflammatory cytokines/cytokine-like factors in peripheral leukocytes were determined by real-time RT-PCR.

Results: The levels of HbA_{1c} and fasting blood glucose were maintained even after acarbose or voglibose was switched over to miglitol. Meanwhile, hypoglycemic events were significantly reduced by 58% (p<0.001) after the change of treatments. Blood glucose fluctuations were ameliorated and the M-value was decreased by 24% (p<0.001). In peripheral leukocytes, the gene

expression levels of IL-1ß, TNF-a, S100a4, S100a6, S100a9, S100a10, S100a11 and S100a12 were significantly decreased by 25% ($p<0.01$), 24% ($p<0.001$), 17% ($p<0.05$), 20% ($p<0.05$), 23% ($p<0.05$), 19% ($p<0.01$), 25% ($p<0.01$) and 24% ($p<0.05$), respectively.

Conclusion: After the switching from other alpha-glucosidase inhibitors, miglitol improved blood glucose fluctuations without changes in HbA_{1c} and fasting blood glucose in patients with type 2 diabetes. On the other hand, miglitol also decreased the gene expressions of inflammatory cytokines/cytokine-like factors in peripheral leukocytes. These results suggest that the blood glucose fluctuation may affect the gene expressions of inflammatory cytokines/cytokine-like factors in peripheral leukocytes in type 2 diabetes.

D-0839

Efficacy and tolerability of alpha-glucosidase inhibitors: a systematic review and meta-analysis of clinical trials

H. Chen[1], V. Saundankar[1], D. Bhowmik[1], K. Birtcher[1], L. Radican[2], Y. Qiu[2]

[1] *College of Pharmacy University of Houston, Clinical Sciences and Administration, Houston, USA*

[2] *Merck & Co. Inc., Global Outcomes Research & Reimbursement, Whitehouse Station New Jersey, USA*

Aims: The purpose of the study was to conduct a systematic literature review and meta-analysis to compare the efficacy (glycemic control) and tolerability (hypoglycemia, gastrointestinal events) of Alpha-Glucosidase inhibitors (AGIs) vs. other oral antihyperglycemic agents (OAHAs) in patients with type 2 diabetes.

Methods: Four databases including MEDLINE, Science Citation Index (SCI), Cochrane Central Register of Controlled Trials (CENTRAL) and EMBASE were searched to identify related randomized controlled clinical trials (RCTs) published between 1966 and 2008. After screening, 22 studies were identified. AGIs were used as monotherapy in 9 studies and as adjunct therapy with other OAHAs in the remaining 13 studies. In most studies, AGI was compared to metformin and sulfonylurea (SU) mono- or combination therapy. Acarbose is the AGI that has been most extensively studied.

Results: For each study identified, qualitative summary, number of events, and relative risk (RR) estimates related to glycemic control, hypoglycemia and GI events were extracted. Fixed effect models were employed to estimate the pooled effects. When pooled effect on change in mean HbA1c level was estimated, studies that had placebo as control were excluded. All analyses were performed using STATA9. The pooled results showed that, as compared to patients taking other OAHAs, diabetic patients using AGIs had similar change in mean HbA1c level [Difference in change of mean HbA1c: -0.013% (-0.136, 0.111); Baseline HbA1c: 7.8-10.6%], two times more GI adverse events [Pooled RR: 2.17(1.92, 2.47)] and 56% less hypoglycemia cases [Pooled RR: 0.64 (0.44, 0.83)]. The decreased risk of hypoglycemia is likely due to the fact that sulfonylurea mono- or combination therapy was often the control group in RCTs and SU are known to increase the risk of hypoglycemia.

Conclusion: In summary, the pooled results suggest that, as compared to other OAHAs, AGIs have similar efficacy, are associated with increased risks of GI events and decreased risks of hypoglycemia. Considering that AGIs have been commonly used in the Asia Pacific region, there is a need to identify other OAHAs that have better efficacy and tolerability than AGIs.

D-0840

A meta-analysis of the effect of oral antidiabetic agents on A1C levels at 12 weeks

D. Sherifali[1], K. Nerenberg[1], H. Gerstein[1]

[1] *Mc Master University, Medicine, Hamilton Ontario, Canada*

Aim: Pharmacological treatment of type 2 diabetes requires the use of single or multiple oral antidiabetic (OAD) agents. Various clinical guidelines outline the expected decrease in A1C level with the initiation of an OAD. However, the estimated drop in A1C for each class of agents that is listed in these guidelines is based on qualitative summaries of primary studies of varying rigour and validity and not on a careful synthesis of relevant studies. The purpose of this review is to systematically identify randomized double-blind, placebo-controlled trials of adequate methodologic quality and meta-analyze the results at 12 weeks.

Methods: A comprehensive literature search of three electronic databases (Cochrane, Embase and Medline) from January 1980 to March 2007 identified 4319 citations. All randomized double-blind placebo-controlled trials that assessed the effectiveness of currently available OAD agents to reduce A1C levels in non-pregnant adult individuals with type 2 diabetes were reviewed. Eligible studies must also meet the following criteria: published in English, peer-reviewed journals; sample size of at least 50 participants in each study arm; duration of at least 12 weeks; and had at least 70% follow up in each arm at 12 weeks. In total, 83 of 4319 (1.9%) citations met the eligibility criteria for the meta-analysis.

Results: Only 14 of the eligible trials provided 12 week data. These trials involved 6 classes of drugs and the meta-analyses are summarized in the table.

Drug	# of Studies	Treatment Effect			
		Dose	Mean Difference	95% C.I.	p-value
Alpha Glucosidase Inhibitors	2	300 mg	-0.56	(-1.14, 0.02)	0.057
DDP-4 Inhibitors	2	200 mg	-0.75	(-1.22, -0.28)	0.002
Lipase Inhibitor	2	360 mg	-0.41	(-0.59, -0.24)	< 0.001
Meglitinides	2	260 mg	-0.61	(-0.83, -0.38)	< 0.001
Secretagogues	3	20 mg	-1.24	(-1.61, -0.88)	< 0.001
TZDs	3	8 mg	-0.80	(-1.25, -0.36)	< 0.001

Discussion: The 12 week results demonstrate the effect of various OADs, with secretagogues and TZDs demonstrating the greatest drop in A1C. Continuing meta-analyses of data from 1.9% of the included trials will provide clinicians with evidence-based information of the effectiveness of different OAD agents over various time points. Additional analyses will determine the effect of age, sex, ethnicity, background therapy and OAD agent dose on the changes in A1C.

Conflict of interest:
Commercially-sponsored research: Merck Frosst sponsored the systematic review and meta-analysis.

EDUCATION

Innovative education tools and IT application to diabetes education

D-0841

Revising and up-dating an educational tool to promote understanding of diabetes physiology

J. Sumner[1], P.A. Dyson[2]

[1] *Oxford Centre for Diabetes Endocrinology & Metabolism, Churchill Hospital, Oxford, United Kingdom*

[2] *University of Oxford, Oxford Centre for Diabetes Endocrinology & Metabolism, Oxford, United Kingdom*

Background: Bodylink was originally produced by Boehringer Mannheim and has been used successfully in diabetes education programmes since 1992, but is no longer available. Bodylink delivers information about diabetes physiology in an interactive format by manoeuvring tokens and symbols around a three-dimensional board.

Aims: To design and produce an interactive, flexible educational tool utilising the Bodylink format in collaboration with Roche diagnostics.

Methods: The educational tool (Accu-Chek Diabetes Link) was designed to support a philosophy of patient empowerment and experiential learning. A professional graphic design team was employed to produce a cost-effective, portable, versatile instrument that could be used in routine clinical care. Accu-Chek Diabetes Link includes an A1 poster with an outline of a body with diagrams of key organs relating to diabetes. Interactive tokens representing relevant hormones, glucose, ketones and lipids and symbols denoting the effects of exercise, pregnancy and alcohol have been designed and can be moved around the diagram of the body to encourage active involvement and

to promote links with individual experiences. Accu-Chek Diabetes Link can be utilised to explore physiology of diabetes, hyper and hypoglycaemia, stress responses and tissue damage associated with diabetes. A4 printed handouts of the Accu-Chek Diabetes Link are available for the patients' reference.

Discussion: Subjective evaluation of this educational tool in patient education sessions has shown positive feedback. Patients report increased knowledge and have been able to relate this to self-care practices. It has also encouraged the application of different teaching methods to support various learning styles and has aided development of problem solving. By changing the emphasis from formal teaching with lengthy explanations to brief visual images and active participation, connections are more easily made between personal experience and physiology and this focuses available time on relevant topics. The design of Accu-Chek Diabetes Link allows reinforcement of previous learning and can be used to build information incrementally to prevent information overload.

Conclusion: A revised, up-dated interactive educational tool to promote understanding of diabetes physiology has been designed and produced and is being applied in clinical practice.

Storybook teaching tool - a happy ending for expectant mothers

A. Kennedy[1], M. Ekmescic[2], L. Sparrow[1], R. Fung[3]
[1] Toronto East General Hospital, Diabetes Resource Team, Toronto, Canada
[2] Ryerson University, 4th yr. student - Nursing Science, Toronto, Canada
[3] Toronto East General Hospital, Department of Endocrinology, Toronto, Canada

Background: Located in a dense, residential area of Toronto, the Gestational Diabetes Program of our busy community teaching hospital serves a high risk multicultural population. A high referral rate from surrounding Primary Care providers and the hospital's busy Obstetrical service results in 6 – 9 new referrals per week.

Our teaching team, comprised of a Diabetes Nurse Educator and a Registered Dietitian delivers the essentials of glycaemia self-management in a 90-minute session for small to mid-sized classes of expectant mothers accompanied by family. Participants are culturally diverse, and of varying education and literacy levels. Often, no two participants share the same language of origin.

Inconsistency in the uptake of basic concepts motivated the team to welcome an innovative educational approach.

Aim: To reduce fetal and maternal complications associated with gestational diabetes by facilitating timely acquisition of concepts of glycaemia self-management principles in pregnancy. Our challenge was to improve our delivery of these concepts in this diverse group setting while staying within our 90-minute class time frame. We sought to create a universal group teaching tool that could achieve these goals.

Method: A large storybook design was conceived and constructed by the Nursing student. Essential concepts are communicated primarily with sequenced pictures highlighting the benefits of healthy eating, physical activity and monitoring/recording after-meal blood sugars. Sections of the storybook incorporate a removable insulin pen and a dinner plate that can be assembled with food models to facilitate carbohydrate-counting.

In-class trials lead to edits that helped clarify concepts. A 3-ring binder design allowed for removal of entire poster pages for focusing on single concepts or individual learning. Focused interviews with participants after their teaching session will be conducted to qualitatively evaluate this educational tool.

Results: We observed that the giant storybook design captured the attention of class participants, and invited broader interest from attending family members. We immediately noted that question time at the end of class shortened by 10min.

At clinic follow-up, educators noted improved adherence to self-management concepts.

Discussion: Expectant mothers faced with learning self-management of high blood sugar in pregnancy can feel overwhelmed by frequent blood glucose testing and the possibility of starting insulin. Mothers and families may require more support, yet educator time is limited. The storybook format invited increased class participation and accelerated uptake of essential concepts. The picture book was portable, not dependent on technology, reproducible and culturally adaptable.

No conflict of interest

D-0843

Patient education - a new dietary dimension

S. James[1], R. Shetty[1], K. Bhatia[1], S. Sabnis[1]
[1] Diabetic Association of India, Nutrition Department, Mumbai, India

Background: The prevalence of Diabetes Mellitus and its associated complications in India have increased drastically. One should start at early diagnosis of diabetes so that complications can be avoided (Secondary Prevention). At present diabetes prevention is centered on preventing the complications of Diabetes (Tertiary Prevention). At the same time, those at higher risk of Diabetes should be identified and preventive therapy should be started (Primary Prevention). To prevent and to treat Diabetes life style modifications play a major role. As India has diversified cultures so are the eating habits and serving size, a live display of various food items from different communities can help each subject to understand and opt for healthy food in the right quantity.

Aim: To educate Subjects with Diabetes from various communities about diet, nutrition and serving size so as to make healthy food choices via a live food display on November 16th, 2008 at S.L.Raheja Hospital.

Materials and Methods: 135 subjects with diabetes from various communities were educated with the help of posters, household measurements, standard measuring cups and spoons, caloric charts, food display of 227 food items explaining the nutrients, calories, standardized portion size of both healthy and unhealthy food. We have included all food items that are readily available and consumed in different parts of India. This helped the participants to understand about the different cuisines available which they can include in their regular meals. Each food item was displayed with its caloric and nutrient content. Caloric charts explained the 100 kilocalories exchange in brief and individual diet consultation helped to correlate the exchange list and the food that is displayed.

Results: The interactive session revealed that 97% of the subjects had misconceptions about the nutritional facts of various food items, quantity of various food items as per the calories, food choices and varieties of dishes and food. 90% of the subjects were not having the proper knowledge about the diet to be consumed during the religious fasts, festivals and restaurants

Discussion: Since India's culture and eating habits are diversified, a self assessment to choose the right food as per their eating habits helps them to understand the diet better than just giving diet chart. It is easy for a person with diabetes to understand the portion size, caloric content, permitted food and nutrients. The Education Program conveyed the importance and flexibility to follow an individualized diet to 135 subjects with diabetes.

D-0844

The creation and evolution of diabetes conversation luncheon map

K. Yamada[1], I. Yamada[1]
[1] Kenichi Yamada Internal Medicine Clinic, Internal Medicine, Tagajo Miyagi, Japan

Background: The medical team in our clinic focuses on the importance of "educating the people with diabetes". There are some approaches to facilitate individual interventions and small group education programs. Meanwhile, a drawing with a message, as an appealing way that we are always here and our communication lines are open to each patient, is posted every month in the waiting hall. These hand-drawings and messages work on them quietly and inspire their aspiration. The conversation luncheon map was made by the same concept to reflect their mind by the method of metaphor.

Aims: As a support tool for our monthly diabetes awareness class, we have created our own diabetes conversation luncheon map (A3 size). We offered to use this map as an interactive learning tool and also to look at their life from the birds-eye view.

Materials and methods: This map has instituted to include the use of visual art works in conjunction with the "awareness enforcer" promoted by an emphasis on a multifaceted approach to lifestyle optimization, providing information on the diagnostic procedure, possible causes, complications, treatments and control and evaluation of symptoms, stress coping strategies, self-dialogue, aspirations and goals (9 items). We connect the map and the 9 items as a cognitive power. The concept was initially introduced to us at the US Diabetes Conversation Maps Seminar held as part of 2007 annual meeting of ADA in Chicago. We were encouraged to create our original conversation map in Japanese.

Results: This program has become more effective in encouraging active participation as the results of questionnaire after the class. In addition we made memo cards each corresponding to one of the 9 items to help to inspire smooth and effective dialogues between patients with diabetes and the medical professionals. The laminated map can also be used at home as the tool for improving awareness of family members as well as patients. This map is also used in newly diagnosed patients with diabetes and objective data are collected with regard to efficacy of the map as a tool. Concerning the case study, for example, a 74-age male diabetic patient with recognition disorder could catch the awareness not only to familiarize himself with the 9 items of our holistic approach but also to bring him the meaning of the wholeness of his life by using the map. As a result, his HbA1c was improved from 7.6% to 6.3% after 3months. Another two cases are reported in the poster session. And in these three cases, cerebral MRI and SPECT were done. Mini-Mental State Examinations before and after applying the map were also done. Their responses to the map were remarkable and their QOL were improved.
Conclusion: Our original diabetes conversation luncheon map is effective in diabetes education.

Development of nutrition education resources for educators and consumers

S. Zeiler[1], J. Mercer[2], L. Maillhot-Hall[3], B. Lamoureux[4], B. Belfer[5]
[1] *Canadian Diabetes Association, Research Professional Education & Government Affairs, Toronto, Canada*
[2] *Alberta Children's Hospital, Diabetes Clinic, Calgary, Canada*
[3] *Grey Bruce Health Services, Unit 8-1, Owen Sound, Canada*
[4] *Health Canada, First Nations and Inuit Health, Winnipeg, Canada*
[5] *GlaxoSmithKline, Clinical Development, Mississauga, Canada*

Aim: To develop teaching tools that will enable diabetes educators to implement the recommendations in the *Canadian Diabetes Association 2008 Clinical Practice Guidelines for the Prevention and Management of Diabetes in Canada*.
Healthcare professionals across Canada are using many diverse and sometimes conflicting tools to educate people with diabetes. The aim was to produce resources that could be used across the country to help health professionals implement the Clinical Practice Guidelines.
Who we are: The committee consists of diabetes educator volunteers (dietitians, nurses, pharmacists) from across Canada who believe that people with diabetes should have access to consistent accurate information about the management of their diabetes regardless of their geographic location. The committee was formed in September 2000, and has since created 8 resources: *Just the Basics, The Glycemic Index, Basic Carbohydrate Counting, Sugars & Sweeteners, Alcohol & Diabetes, Cholesterol & Diabetes, Eating Away from Home and Managing Weight & Diabetes.* This year, 2009, the committee is working on a hypertension resource.
Method: A survey is completed yearly at the Canadian Diabetes Association/ Canadian Society of Endocrinology and Metabolism (CDA/CSEM) Professional Conference to determine the topic for resource development. Once the topic is chosen, the committee is divided into working groups researching the different components and creating a draft. The committee meets monthly to define the content of the tool. A designed hard copy of the draft resource is sent out to healthcare professionals for their feedback. All feedback is collated and assessed. The resource is revised based on the feedback received. It is then printed and launched at the following CDA/CSEM Professional Conference. As well, the committee develops additional supporting materials that are available for reference and downloading on the Canadian Diabetes Association website, www.diabetes.ca, along with the resource. Several months after the launch of the tool, a survey is sent to diabetes educators across Canada to evaluate the impact and use of the tool.
Conclusion: The results to date have been quite favourable. The resources are displayed on this poster.

D-0846

A digital tool to assist front-line physicians to self diagnose their continuing professional development (CPD) needs, to maintain medical expertise in diabetes

L. Lajoie[1], J. Basque[1], J.M. Ékoé[2], J. Desforges[3], D. Gagnon[4], C. Guimond[5], P. Raîche[6]
[1] *Télé-Université / Université du Québec à Montréal, LICEF Research Center, Montreal, Canada*
[2] *University of Montreal, Medicine Endocrinology Metabolism and Nutrition, Montreal, Canada*
[3] *Centre de référence sur le diabète Sud-Ouest-Verdun, Diabetes, Verdun, Canada*
[4] *Rockland MD, Family Medicine, Ville Mont-Royal, Canada*
[5] *Fédération des médecins omnipraticiens du Québec, Continuous Professional Training, Montreal, Canada*
[6] *Fédération des médecins omnipraticiens du Québec, Continuous Professional Training, Montréal, Canada*

Aims: To comply with the Code of Ethics of their regulatory authority, all Quebec physicians are required to maintain their competence. Self-managed CPD plans are offered to ensure a reflective approach to the overall self-analysis of their practice and core competencies based on the CanMEDS framework. Several authors question the validity of the clinical competencies self-assessment. Our research aims to develop an online prototype to self-diagnose CPD needs in the diabetes mellitus domain, targeting front-line physicians; evaluating tool satisfaction; and assessing usefulness to CME stakeholders.
Methods: This collaborative research and development project, carried out with stakeholders in the field, comprises 4 phases: 1) needs analysis and preliminary tool design; 2) collaborative re-design; 3) prototype development; 4) usability testing. The modeling technique proposed in the *MISA™* as well as the *Expert & Learner Verification and Revision* approach were used to design and validate the tool's utility profile.
Results: The first 3 phases are complete. Phase 1: A survey among 153 physicians confirmed a need for a self-assessment tool for expertise in diabetes and allowed us to recruit a potential of 59 volunteers for phase 4. The formative system blueprint of the self-assessment tool is based on CDA guidelines, and its design has been developed in a constructivist perspective and principles of the *Competent Situated Action* approach. A mockup using the *infoCompétences+* tool was validated by an endocrinologist and two target physicians. Phase 2: Detailed specifications and a non-functional prototype (*Diabète*Compétences+)* were validated by 6 specialists in the fields of Endocrinology, CME and educational technology. A self-diagnostic process juxtaposes the physicians' needs and the results of a self-assessment of their medical expertise in diabetes. Automated features help perform analyses, develop an action plan and generate anonymous, individual or group statistics. Phase 3: The tool content was approved by a specialist in Endocrinology, and 3 Category 1 credits awarded by the FMOQ confirmed the tool's educational intent based on recognized accreditation criteria.
Discussion/conclusion: Based on performance standards, the process (3 hrs) is educational and anonymous, which may increase the validity of the self-assessment. Creating a holistic view of and situational approach to competency, the tool enables users to identify their CPD needs and note potential care gaps and barriers to clinical application of guidelines. The tool could be used in combination with self-managed CPD plans to facilitate the creation of a diabetes action plan, or as an electronic tool for CME professionals to identify group needs for future learning/practice resources. Testing will be conducted on a larger scale in spring '09 to further assess the prototype's educational and usage value (phase 4).

Development of a computer-based nutrition and physical activity self-management tool for people recently diagnosed with type 2 diabetes

A. Booth[1], C. Lowis[2], S. Hunter[3], M. McKinley[1]
[1] Queen's University Belfast, Nutrition and Metabolism group, Belfast, United Kingdom
[2] Food and Health Communications, Nutrition, North Yorkshire, United Kingdom
[3] Belfast Health and Social Care Trust, Regional Centre for Endocrinology and Diabetes, Belfast, United Kingdom

Background: Didactic approaches to diabetes education have had limited success. Educational strategies that employ a skills based approach and are developed in close consultation with the target group may be more successful in improving self-management behaviours.
Aim: To develop a computer-based, interactive, nutrition and physical activity educational resource for people recently diagnosed with Type 2 diabetes.
Methods: Initially, interviews were held among health professionals (n = 7) and six small focus groups were held among the target group (people recently diagnosed with Type 2 diabetes, n = 16) to direct the content of the resource. Interviews and focus groups were transcribed and analysed using NVivo. The multimedia design team produced screen shot images which were presented to the target group and discussed in a second round of focus groups. Next, prototype versions of each individual section of the resource were developed and tested with the target group (n = 17-20 per section, 5 sections). Feedback on content, style and functionality was incorporated. Following one further round of testing (n = 10) and modification, a fully functional version was produced.
Results: Key barriers identified by the focus groups and interviews include changing habits of a lifetime, cooking or shopping to please the whole family, eating and drinking in social situations and the perception that the dietary regime is boring and unappealing. Based on these results, the research team (which had clinical, nutrition and communication expertise), together with the multimedia design team, decided on the range of interactive activities that should be included. Key activities included; recording and monitoring dietary intake with feedback and goal setting, recording and monitoring of physical activity with tailored feedback and goal setting, provision of information on a range of topics, a quiz to identify gaps in knowledge and short video clips to illustrate how other individuals who have been diagnosed with Type 2 diabetes manage their condition.
Discussion/conclusions: This interactive, computer-based resource was developed with extensive input from people with type 2 diabetes as well as experts from a variety of relevant disciplines including psychology, nutrition, and medicine. Consistent engagement with the target group and multiple stages of modification and refinement extended the duration of the development process but has created a promising education resource that is designed to promote patient education and support improved adherence to lifestyle change. The effectiveness of this tool will now be examined in a randomised controlled trial.

Web-based versus face-to-face education: a longitudinal experiemental study

H. Kelley[1], M. Chiasson[2], A. Downey[3], B. Lockhart[4], S. Spenceley[4], D. Pacaud[5]
[1] University of Lethbridge, Faculty of Management, Lethbridge, Canada
[2] Lancaster University, Building Healthy Lifestyles, Lancaster, United Kingdom
[3] University of Victoria, Faculty of Business, Victoria, Canada
[4] Alberta Health Services, Building Healthy Lifestyles, Lethbridge, Canada
[5] University of Calgary, Pediatrics, Calgary Ab, Canada

Aim: This study employs a longitudinal experiment to examine the effectiveness of using the Web to deliver education to clients and to provide electronic interaction between clinicians and their clients newly diagnosed with type 2 diabetes. Participants were referred by their physicians to nurses and dietitians in a healthy lifestyle program.
Methods: Computer literate adult participants (n = 79, repeated measures) were randomly assigned for one year to one of three modes of delivery - traditional face-to-face appointments (e.g., group education sessions, paper journals and education material, virtual visits, and normal care visits), static web content (e.g., digitized education material, enhanced blood glucose log book, and normal care visits), or interactive web system (e.g., enhanced interactive electronic journal, discussion boards, chat rooms, email, virtual appointments with clinicians/coaches, and normal care visits). Group effects and gender differences were explored.
Results: Information on self-care practices and HbA1c levels was collected initially and quarterly thereafter for one year. The differences in mean changes in HbA1c between the three group are significant ($F = 4.01$, $p = 0.022$). The largest drop in HbA1c occurred in the interactive group, next in the face-to-face group, and the smallest change in the static web-based group. The gender interaction with group on the change in HbA1c is also significant ($F = 8.578$, $p = .000$). Males experience the largest drop in HbA1c in the interactive group with females showing the largest drop in HbA1c in the face-to-face group. A similar interaction effect of group and gender on self-care practices such as blood glucose testing habits was significant ($F = 10.098$, $p = .000$).
Discussion/conclusion: These findings suggest that interaction with a clinician/coach, regardless of the medium, is very important for increasing diabetes control in people newly diagnosed with type 2 diabetes. We should be careful in assuming that we can deliver only static education via the web without interaction capabilities. Furthermore, the results reveal that males perform well in an electronic interactive environment whereas females experience greater change in HbA1c values in a face-to-face interactive environment.

Educating today's health educator: an innovative use of online technology to access, apply and grow resources

B. Madrick[1], S. Wiens[1], A.L. Edwards[2], C. Jones[2]
[1] Calgary Health Region Alberta Health Services, Diabetes Hypertension and Cholesterol, Calgary, Canada
[2] Calgary Health Region Alberta Health Services, Department of Medicine, Calgary, Canada

Aims:
1. To use online technology to facilitate consistent training and certification of outpatient health educators undergoing role expansion in a large geographical area.
2. To provide health educators remote access to resources required daily to perform in their roles.

Method: The Department of Medicine within the Calgary Health Region partnered with the University of Calgary to access the online learning platform called Blackboard©. Through Blackboard©, a password protected website for hosting learning resources, exams and interactive discussion boards was developed. Learning modules included downloadable documents, website links, online articles, videos and exams with automated marking. Formal learning modules were posted under relevant navigation buttons – Diabetes, Hypertension, Lipids, Insulin Pump and Diabetes in Pregnancy. Other navigation buttons - Client Resources, Useful Stuff, Teaching Aids, Our Services - contained resources provided by educators to aid in their daily practices. These included links to community resources, self-developed documents, policies, contact numbers, graphics, regional handouts and other resources.
Results: In the past year, 12014 hits have been recorded within the content area from 130 users (not including webmaster). Approximately 67% of hits were to content within formal learning modules. Diabetes was the most visited module with almost 35% of the total hits (4160). Lipids and hypertension modules totalled approximately 24% (2856 hits). The remainder of hits were to educator submitted resources, with "Client Resources" being the most visited with over 14% of the total hits (1717). Almost 100 exams have been completed online and electronically marked since available in 2008. Discussion boards were not successful but have become an organized repository for informative emails.
Comments: As diabetes diagnoses and services increase, so does the need for maintenance of standards and competencies. Blackboard© provides one method for addressing these needs in a technological age.
Early challenges in this project included staff hesitancy to try the technology. Innovative incentives successfully enticed educators to quickly log on. Blackboard© is now accessed daily for clinical resources within learning modules and educator submitted resources. The latter include information on grocery store tours, compassionate drug supplies, smoking cessation programs, contact numbers, drug databases, rural diabetes centres and online nutrient analysis to name a few. Completion certificates are provided for completion of formal learning modules. Continued growth is expected with the addition of modules and further memberships provincially, as well as potential national partnerships.

Tracing of hematopoietic lineage cells in the pancreas during ß-cell regeneration

A. Chamson-Reig[1], E. Arany[1], D.J. Hill[1]
[1] Lawson Health Research Institute, Diabetes & Metabolism, London, Canada

Regeneration of pancreatic ß-cell mass following damage is possible in the young rodent and decreases with age. However, transplantation of bone marrow-derived hematopoietic stem cells following ß-cell loss with streptozotocin (STZ) treatment in adult mice induced regeneration of ß-cell mass. Bone marrow-derived cells preferentially colonized the damaged pancreas and almost 10% demonstrated markers of endothelial precursor cells, probably differentiating into vascular endothelial cells that promoted ß-cell regeneration.
The objective was to determine the association between hematopoietic lineage cells in the neonatal mouse pancreas and the capacity for ß-cell regeneration after STZ injury. We examined the ontogeny of hematopoietic lineage cells within islets during regeneration, and the phenotype of the hematopoietic derived cells contributing to islet development.
A double transgenic mouse model *Vav-iCre;R26R-EYFP* was used where only cells derived from the hematopoietic lineage express the enhanced yellow fluorescent protein (EYFP). We induced partial ß-cell loss by *sc* injection of 35mg/kg STZ or vehicle injections (control) at postnatal days 2 and 4. Body weight and glycemia were monitored regularly. Males and females were sacrificed at days 10, 14, 21, 40 and 130, collecting blood samples and pancreas. Immunofluorescence for insulin, glucagon, EYFP, CD31, and cytokeratin 19 were performed to assess ß-cell mass, %EYFP+ve cells, and possible co-localization with endothelial and epithelial markers. EYFP+ cells infiltrated the pancreatic islets at all studied ages showing an increase in number within the islets as mice aged. Following STZ treatment ß-cell mass had decreased at d10 but no change in the number of hematopoietic derived cells was observed. At d40, an increase in EYFP+ cells was observed compared to control. Full regeneration of ß-cell mass was not reached by d130, males being more affected. Male STZ treated mice showed a decrease in hematopoietic derived cells at d130 compared to control, but females showed no change. Co-localization of insulin within hematopoietic derived cells was not evident suggesting that they did not transdifferentiate into ß-cells. The hematopoietic derived cells did not express the endothelial cell marker CD31 or the epithelial cell marker cytokeratin 19.
In conclusion, unlike other studies that have focused on transplanted hematopoietic lineage cells, we have shown that upon ß-cell damage there is an increase in the presence of endogenous hematopoietic derived cells in the islet especially at d 40 and that this corresponds to an increase in ß-cell mass. However, this regeneration is not sustained in the long-term.

Neonatal mouse beta cells can be differentiated in vitro

C. Beamish[1], B. Strutt[1], E. Arany[1], D.J. Hill[1]
[1] Lawson Health Research Institute, Metabolism and Diabetes, London, Canada

Type 1 diabetes mellitus is an autoimmune disease which destroys the insulin-producing ß-cells in the islets of Langerhans, and one treatment is islet transplantation. Despite its success, this treatment is limited by available islets from cadaver source.
Aims: We therefore seek to create insulin-producing cells for use in transplant. Our approach is to attempt islet amplification *in vitro*. Hypothetically, mature islets retain their developmental "memory", which could be induced to proliferate if shunted to the appropriate growth mode. Multiple groups have investigated ß-cell precursor differentiation to form islet-like structures by manipulating extracellular matrix selection, or combinations of growth factors, but with little consistency. Can ß-cells be induced to proliferate and subsequently differentiated? What cellular population(s) arise after long term culture? We hypothesized that the cell types contributing to the dedifferentiation and redifferentiation processes will include the ß-cell.
Methods: We have developed *in vitro* protocols for the culture of neonatal mouse islets, resulting in the reversion to an epithelial-like phenotype. Isolated islets were cultured on collagen in the presence of EGF and cholera toxin. After 4 weeks, the resultant monolayer was transferred to Matrigel-coated plates, and cultured with FGF-7 and IGF-II to induce the formation of islet-like structures. Genetic analysis by RT-PCR amplification and immunohistochemical protein assays were used to determine differentiation states. We have employed an inducible transgenic mouse strain, RIPCreER;Z/AP, that allows tagging of ß-cells with a human placental alkaline phosphatase (HPAP) reporter protein.
Results: Islets plated for dedifferentiation lost all morphological, genetic, and protein markers of mature function, including insulin and Pdx1 expression. Proliferation increased significantly. Expression of ductal markers (CK19) increased. Redifferentiation methods could not restore insulin expression, however Pdx1 was restored. Tagging of ß-cells with HPAP was accomplished in the transgenic mouse. After four weeks in culture, HPAP expression was maintained. Once replated for redifferentiation, HPAP+ cells were seen in the islet-like clusters.
Conclusions: Neonatal mouse ß-cells can be dedifferentiated *in vitro* to a proliferative phenotype under the conditions examined. While insulin expression was lost after differentiation, the ß-cell itself is involved in the redifferentiation process, as HPAP was found at all time points evaluated. Future experiments will be aimed at evaluating the staining frequency of HPAP. Methods supporting insulin reexpression are being examined. While the ß-cells are present in the resultant monolayers, are these cells truly differentiated? Co-labelling of HPAP+ cells with Ki67 and CK19 will be assessed.

Expression and regulation of HNF1 alpha and genes related to beta cell neogenesis and metabolism by prolonged culture of newborn pancreatic islets.

A.R. Leite[1], C. Lellis-Santos[1], G.F. Anhe[1], S. Bordin[1]
[1] Institute of Biomedical Sciences, Physiology, São Paulo, Brazil

Maturity-onset diabetes of the young type 3 (MODY3) is characterized by an autosomal dominant mutation in the gene encoding hepatocyte nuclear factor 1a (HNF1a) leading to deficient insulin secretion. Several studies using HNF1a functional deletion or overexpression highlighted that this transcription factor regulates target genes related to the pancreatic b cell phenotype. However, the precise mechanisms by which HNF1a regulates gene expression are still not completely understood. Fetal and/or neonatal pancreatic islets present a low profile insulin secretory response as compared to adult islets. Prolonged culture of neonatal islets has been extensively described to improve glucose-induced insulin secretory response. In this study we investigated whether neonatal islets exposed to prolonged culture correlates improvement of secretory response with HNF1a expression and binding to promoter region of target genes. In order to achieve this goal, pancreatic islets from newborn Wistar rats were isolated by collagenase and cultured for 3 and 7 days (respectively, 3d and 7d) in RPMI 1640 supplemented with 10 mM glucose and 5% FBS. Gene expression was assessed by RT-PCR and protein content was analyzed by Western Blotting. HNF1a binding to DNA was investigated by chromatin immunoprecipitation assay (ChIP assay). Prolonged culture of neonatal pancreatic islets induced a time dependent upregulation of HNF1a. The increase of HNF1a expression was positively correlated with upregulation of b cell neogenesis-related genes Nkx6.1 and NeuroD1 whereas no differences were found in PDX1, PAX4, and PAX6 expression. We also observed that an increase in mRNA content of genes related to the mature b cell phenotype GLUT2 and insulin2 occurred in parallel to the *in vitro* upregulation of HNF1a. Additionally, we have found that, after 3d culture, pancreatic islets exhibited an increase in HNF1a binding to insulin2 and PDX1 promoters. Altogether, our results demonstrate that prolonged culture of neonatal pancreatic islets results in upregulation of HNF1a content and enhanced expression of Nkx6.1, NeuroD1, GLUT2 and insulin2. The present data suggest that increase of HNF1a during the *in vitro* maturation of neonatal pancreatic islets might not exclusively account for the establishment of the b cell phenotype since its binding to PDX1 promoter does not correlate with increased PDX1 transcription. However, HNF1a is likely to play an important role in this process as it apparently upregulates insulin2 throughout neonatal pancreatic islet maturation.

Gene expression changes during beta cell regeneration in offspring of female mice exposed to a low protein diet

A. Cox[1], E.J. Arany[1], D.J. Hill[1]
[1] Lawson Health Research Institute, Metabolism and Diabetes, London, Canada

We previously demonstrated the ability of young female mice to replace beta cells after multiple low dose streptozotocin (STZ) treatment. Regeneration of beta cells was complete by day 30, but glucose intolerance was observed at day 42, with beta cell mass deteriorating by day 130. We have also shown that protein restriction (low protein-LP diet) during fetal life leads to the development of glucose intolerance in adulthood. Furthermore, offspring of LP-fed dams treated with STZ were unable to replace beta cell mass.
Our current objective was to identify genes differentially expressed in offspring from LP vs control-fed animals and during ß-cell regeneration after STZ treatment.
Pregnant Balb/c mice were placed on a control (C) (20% protein) or an isocaloric LP (8% protein) diet throughout gestation. All dams were placed on the C diet at birth. Female offspring were injected i.p. with 35 mg/kg STZ or vehicle at birth on days 1 to 5 for each dietary treatment. On day 30, the mice were sacrificed and the pancreas was removed and snap frozen in liquid nitrogen. Total RNA was extracted (for n=3/group), purified and then hybridized to an Affymetrix Mouse Genome 430 2.0 GeneChip to determine gene expression profiles. Results were analyzed using GeneSpring v7.2 and classified based on Gene Ontology (GO).
In C+STZ mice, we found 137 genes were decreased by >1.5 fold compared to control, 22 of which were classified as involved in cell cycle and cell proliferation. Genes involved in insulin signaling and glucose homeostasis were downregulated including insulin I, insulin II, glucagon, glut2 transporter, and glucose-6-phosphatase (Table 1). In the LP and LP+STZ mice, 426 and 845 genes, respectively, were decrease by >1.5 fold compared to controls. Both these groups had decreased expression of insulin signaling and glucose homeostasis genes, with a greater affect in the LP+STZ group (Table 1). The effect of LP exposure was evident by the downregulation of genes related to translation, ribosome biogenesis, protein folding, electron transport, cell redox homeostasis, cell cycle and cell proliferation. In the LP+STZ mice, the number of downregulated genes was further increased, suggesting a more detrimental effect, resulting in beta cell failure.
While beta cells have regenerated by Day 30 in C+STZ mice, genes critical for glucose homeostasis have been downregulated, a precursor to the glucose intolerance previously observed by day 42. Failure of beta cell regeneration in LP+STZ mice is consistent with extensive gene downregulation involving cell proliferation, function and survival.

Table: Fold decrease in gene expression compared to controls.

Gene	C+STZ	LP	LP+STZ
Insulin I	5.0	2.4	4.0
Insulin II	3.3	2.1	3.5
Glucagon	1.8	3.0	2.1
Glut2	1.9	3.7	1.9
Glucose-6-Phosphatase	5.3	3.7	3.9
Islet Amyloid Polypeptide	5.3	3.4	4.3

Effect of inducible nitric oxide synthase (iNOS) gene silencing on islet cell apoptosis in early islet graft

S.H. Ihm[1], M.-G. Choi[1], H.-J. Yoo[1], B.-W. Lee[2]
[1] Hallym University Sacred Heart Hospital, Internal Medicine, Anyang, Korea
[2] Yonsei University, Internal Medicine, Seoul, Korea

Aims: Pancreatic islet transplantation is a promising therapeutic intervention for type 1 diabetes mellitus. One of the significant obstacles to successful islet transplantation is a high number of cell deaths in islet grafts during the first few days after implantation, mostly from inflammatory and hypoxic damage. To overcome these obstacles and improve the outcome of islet transplantation, genetic modification of islets has been attempted. The expression of iNOS has been shown to increase in the initial days after islet transplantation and is thought to mediate graft inflammation and hypoxic islet damage in early islet transplantation. Therefore, we investigated the effect of iNOS gene silencing on islet cell apoptosis in early islet graft.
Methods: Rat insulinoma INS-1 cells or isolated rat islets were transfected with chemically synthesized small interfering RNAs (siRNAs) for iNOS or negative control-siRNA complexed with Lipofectamine. iNOS gene expression was assessed at mRNA level by real time RT-PCR. The effect of gene silencing was also assessed with inflammatory cytokine-induced NO production (Griess reaction) and apoptosis (AV-PI flowcytometry). Five hundred rat islets transfected with iNOS-siRNA or negative control-siRNA were transplanted syngeneically under the kidney capsule. Grafts were harvested 3 or 5 days after transplantation, and the apoptosis of islet graft was determined by TUNEL assay.
Results: Transfection of INS-1 cells with siRNA for iNOS silenced iNOS gene expression by >60%. Gene silencing of iNOS significantly prevented INS-1 cells or rat islet cells from cytokine-induced NO production. In addition, cytokine-induced apoptosis in transfected INS-1 cells was markedly decreased. Compared with negative control-siRNA transfected islet grafts, apoptotic cells were significantly less in iNOS-siRNA transfected islet grafts, on 3 or 5 days after transplantation.
Conclusion: Our data suggest that iNOS plays an important role in the early islet cell death after islet transplantation, and ex vivo iNOS gene silencing with nonviral carrier could be a feasible approach to prevent islet cell apoptosis in the initial days after islet transplantation and improve the outcome of islet transplantation.

Autophagy protects against cell death induced by human islet amyloid polypeptide

S. Morita[1], S. Sakagashira[2], Y. Shimajiri[1], M. Ueyama[1], A. Yamana[1], M. Furuta[1], H. Hiddinga[3], E. Norman[4], T. Sanke[1]
[1] Wakayama Medical University, Clinical Laboratory Medicine, Wakayama, Japan
[2] Hidaka General Hospital, Internal Medicine, Gobo, Japan
[3] Mayo Clinic, Medicine, Rochester, USA
[4] Mayo Clinic, Biochemistry and Molecular Biology, Rochester, USA

Background and aims: Human islet amyloid polypeptide (hIAPP), or amylin, is the amyloid-fibril-forming polypeptide in the islet of type 2 diabetes, differently from rat IAPP (rIAPP) which has no amyloid-forming property. It was reported that in COS-1 cells expression of endogenous hIAPP leads to amyloid genesis and induction of cell death in human islet beta cells. We also reported that expression of hIAPP induced intracellular amyloidogenesis and apoptosis in vitro. However, the molecular mechanisms by which hIAPP mediates cell death have not been identified. Autophagy is a major pathway for degrading aggregated proteins and damaged organelles. Although autophagy is implicated in various diseases including neurodegenerative disease, its role in cell death associated with hIAPP has not been examined. We thus performed the in vitro experiments using COS-1 cells to determine whether cell death mediated by hIAPP could be related to autophagy.
Materials and methods: COS-1 cells were transfected with hIAPP or rIAPP gene. The viability of the cells was evaluated by modified MTT assay at 48, 72, 96 and 120 hours after transfection. The cells were examined with electron micrography at 48 hours after transfection. We analyzed the conversion from microtubule-associated protein 1 (MAP-1) light chain 3 -I (LC3-I) to LC3-II by western blot using the cell lysates. The viability of the cells and the conversion of LC3 were also examined after treatments with autophagy inducer or inhibitor.
Results: The viability of the cells transfected with hIAPP was significantly decreased compared with rIAPP at 96 and 120 hours after transfection ($P < 0.01$). Electron micrography indicated the formations of autophagosomes and autolysosomes in the cells transfected with hIAPP. The conversion from LC3-I to LC3-II was also detected, under conditions representing autophagosomes. In the experiments using inducer or inhibitor of autophagy, the viability of the cells transfected with hIAPP was assessed using correction by rIAPP. When the autophagy was suppressed by 3-methyladenine (3-MA: 0.5mM), an inhibitor of autophagy, the viability of the cells transfected with hIAPP was decreased. On the other hand, the rapamycin (100nM), an inducer of autophagy, increased the viability of the cells transfected with hIAPP.
Conclusions: Autophagy plays a protective role against cell death induced by hIAPP expression *in vitro*.

XOMA 052, a potential disease-modifying anti-interleukin-1 beta (IL-1 beta) regulatory antibody, shows reductions in hs-CRP, HbA1c and FPG after subcutaneous injection in a randomized, blinded, placebo-controlled trial in subjects with type 2 diabetes mellitus

J.D. Feldstein[1], P.R. Urquilla[1], K. Der[1], H. Zayed[1], S. Guzy[1], A.F. Maurer[1], J. Whitmore[1], R.K. Hansen[1], P.J. Scannon[1]
[1] XOMA (US) LLC, Clinical and Preclinical Development, Berkeley CA, USA

Background: XOMA 052 is a potent anti-inflammatory antibody that binds human IL-1 beta with a very high affinity (300 fM) and may regulate the inflammatory component of type 2 diabetes mellitus (T2D) responsible for reduced pancreatic beta cell function and decreased insulin sensitivity, with the potential to delay the progression of T2D and simplify disease management. Chronically elevated glucose creates a locally toxic state in the pancreas causing production of excess IL-1 beta, leading to macrophage infiltration and beta cell dysfunction. XOMA 052 has a novel molecular mechanism of action that permits regulated attenuation rather than complete blockade of the IL-1 pathway, and in preclinical models improves glucose control, beta cell function and mass, and insulin resistance. Prior interim clinical data from part 1 of this study showed that XOMA 052 administered as a single intravenous (IV) dose reduced hs-CRP and HbA1c and increased insulin production.
Aims and methods: A randomized, 3-part, blinded, placebo-controlled study of escalating doses of XOMA 052 in subjects with inadequately controlled T2D. In parts 2 and 3, separate groups of subjects received single subcutaneous (SC) doses of 0.03, 0.1, or 0.3 mg/kg, or three SC doses given every other week of 0.03 or 0.3 mg/kg. In each group, five subjects received XOMA 052 and one subject received placebo; subjects were followed 56 to 84 days. The aims were to evaluate the safety and pharmacokinetics of XOMA 052 in subjects with T2D. Additional assessments were performed as exploratory measures of biologic and clinical activity.
Results: XOMA 052 was well-tolerated with no evidence of serious drug-related adverse events to date. The beta half-life for both SC and IV administration was 22 days, with no apparent difference in clearance between the routes of administration. Mean SC bioavailability across all doses was 60%, with individual estimates between 30 and 90%. After 14 days, a single dose of XOMA 052 reduced hs-CRP by a median of 52% (range of 25 to 79%) among all treated groups vs. a median increase of 8% for placebo. XOMA 052 changed HbA1c by a median of -0.1% (range of -2.2 to +0.7%) at 42 days vs. placebo with a median of +0.3%. XOMA 052 also reduced FPG by a median of 10% (20 mg/dL) at 42 days compared to 2% (7 mg/dL) for placebo.
Conclusions: The data from the single dose SC part of this study with the anti-IL-1 beta antibody, XOMA 052, confirms and builds upon the prior IV data and supports a potentially new disease modifying approach to T2D by a novel antibody therapeutic. Based on these promising results, future phase 2 testing with monthly or less frequent dosing is planned.

Long-term high fat and sucrose feeding of wistar rats induces early diabetic changes in a non-genetic predisposed wistar rat model

J. Louw[1], C.R. Roux[1], C.J.F. Muller[1], A. Krygsman[1], C.S. Chapman[1]
[1] Medical Research Council, Diabetes Discovery Platform, Tygerberg - Cape Town, South Africa

Introduction: Long-term high fat feeding of rats not predisposed to developing diabetes induces obesity and insulin resistance without the development of overt signs of diabetes. The addition of simple sugars to high fat feeding exacerbates insulin resistance and results in T2D.
Aims: This study aims to determine how the addition of sucrose to a high fat diet affects the glucose metabolism and islet morphology.
Materials and methods: Wistar rats were randomized into the following three experimental groups (n=6 per group): a high fat diet group (HFD) receiving a diet containing 40 % energy as fat, 15% protein, 45% carbohydrates; a café diet group receiving the high fat diet with the addition of 15% sucrose in their drinking water and a control group receiving standard rat chow (10 % energy as fat, 15% protein, 75% carbohydrates). The different diets were given from weaning up to 12 months.
Results: After 12 months the body mass of the rats receiving HFD and the café diet were significantly higher than the controls (908.6 ± 131.1g and 947.2 ± 51.5g vs. 599.07 ± 35.7g; p=<0.0001). Fasting blood glucose values were significantly increased in the café diet group compared against both the HFD group and the control group (7.14 ± 1.5mmol/l vs. 6.05 ± 1.1mmol/l; p=0.03 and 5.7 ± 0.8mmol/l; p=0.006). IVGTT AUC values were significantly increased in the café diet compared to both HFD and the controls (850 ± 71.7 vs. 596.1 ± 53.1; p=0.001 and 526.4 ± 128.7l; p=0.001). Fasting insulin levels were significantly lower in the HFD group vs. the café diet and control groups (4.4 ± 2.9 ng/ml vs. 11.6 ± 6.1 ng/ml; p=0.0003 and 8.5 ± 5.3 ng/ml; p=0.01). The intravenous glucose stimulated insulin secretion rate AUC values were significantly decreased in the café diet group versus the controls (175.4 ± 135.7vs. 495.2 ± 236; p=0.03). Insulin resistance as determined by the HOMA-IR model was significantly increased in the café diet group vs. the controls and the HFD group (3.7 ± 2.0 vs. 2.1 ± 1.3 and 1.3 ± 1.1; p=<0.0008).
Morphologically there was a significant increase in the occurrence of large hypertrophied irregular islets with amyloid deposits and fibrous changes in both the HFD and café diet groups. These morphological changes were limited to the large islets while the smaller islets appeared normal.
Conclusion: These results showed that maintaining Wistar rats on a HFD from weaning for 12 months induced obesity without significantly decreasing insulin sensitivity. When sucrose is added to the HFD, insulin resistance is worsened and early signs of T2D appear. Morphologically however, type 2 diabetic changes to the pancreatic islets were already present in the high fat diet groups.

Is an 8 hour fasting status to assess blood glucose as a risk factor in epidemiological studies mandatory ? Impact of time since last caloric intake on blood glucose concentrations in individuals with and without diabetes mellitus

S. Moebus[1], L. Göres[1], C. Lösch[1], K.-H. Jöckel[1]
[1] Institute for Medical Informatics Biometry and Epidemiology, University Hospital Essen University of Duisburg-Essen, Essen, Germany

Aims: Blood glucose concentrations (BG) are usually measured after a certain period of fasting. Evidence-based recommendations for the definition of a fasting status are missing, and only by convention a caloric restriction for =8 hours is the most commonly used implementation. In epidemiological studies the need for fasting complicates logistics and in general it is not feasible to reliably control for fasting status. Here we analyzed the BG distribution with regard to the last caloric intake in order to determine the minimal duration where non-fasting and fasting BG do not differ.
Methods: In October 2005 we enrolled 35,869 participants (age range 18-99) in randomly selected general practices. Blood samples were analyzed in a central laboratory. The time of the last caloric intake was assessed by asking participants for time and type of the last meal or drink before blood withdrawal. We stratified the sample according to Diabetes mellitus (DM) status, defined as physicians' diagnosis or participants' self-report of DM or use of anti-diabetic medication. We used generalized linear models to assess the effect of time since last caloric intake adjusting for age and other factors (time of blood withdrawal, BMI, smoking status, physical activity, hypertension, alcohol use). Age-adjusted mean change from fasting BG and 95% confidence limits (95%-CI) were calculated.
Results: We included n=29,221 participants with data for outcome, exposure and age. Mean random BG was 90.8±17.9mg/dL in individuals without and 143.8±57.4mg/dL in individuals with DM (n=3,686). Highest BG in individuals without DM was measured in the first hour after caloric intake with an age-adjusted mean change from fasting BG (≥8hours) of 4.9mg/dL (SE±0.8). Already after 3 hours the mean BG did not differ any more from the mean BG of individuals with fasting status. The analysis of covariance revealed in men an age-adjusted decline of BG according to the time of last caloric intake of <1h: 6.7mg/dL (95%-CI: 3.5;9.9) and 3h:-1.5mg/dL (-2.7;-0.3), women <1h: 4.5mg/dL (2.7;6.3), 3h:-1.3mg/dL (-2.1;-0.6). In individuals with DM this time dependence was more distinctive, i.e. men 1h: 26.8mg/dL (18.9;34.7), 3h: 13.1mg/dL (5.6;20.6), 4-5h:-3,9 mg/dL (-13.0;5.2) women 1h: 20.3mg/dL (12.1;28.5), 3h: -3.9mg/dL (-11.7;3.9), 4-5h: -10.6mg/dL (-19.8;-1.5). Considering influencing factors did not essentially change the results.

Discussion/conclusion: Our results suggest that blood glucose concentrations in individuals without diabetes mellitus measured 3 hours after caloric intake may already yield valuable results. We suggest reconsidering a fasting status of >8hours when measuring BG as risk factor in epidemiological studies.

Strength of cross-sectional relationship of abdominal obesity with diabetes and hypertension varies according to gender and age: results from IDEA Argentina

C. Boissonnet[1], J. Krauss[2], P. Hernandez Moran[3]
[1] CEMIC, Cardiology, Buenos Aires, Argentina
[2] Hospital Italiano, Cardiology, Buenos Aires, Argentina
[3] Sanofi-aventis, Medical Department, Buenos Aires, Argentina

Background: It is well-known that abdominal obesity is related with diabetes and hypertension. We aim to quantify the strength of this association, according to gender and age,
Material and methods: IDEA (International Day for the Evaluation of Abdominal Obesity) was an international cross–sectional study that recruited 168,159 consecutive patients aged 18 to 80 years who attended the offices of randomly chosen primary care physicians on two pre-specified half days in 2005. IDEA included consecutive patients from rural and urban general practitioners in all geographic areas of all participating 63 countries, giving a representative sample of the patients attending primary care consultations. The present analysis compares, in the 2958 patients with complete data included in the IDEA study in Argentina, the association of abdominal obesity (IDF criteria, waist $\geq$ 94 cm men; $\geq$ 80 cm women) with prevalent diabetes and hypertension in women (n=1862) and men (n=1096), and in different age groups: < 50 years (n=1120), 50 -60 years (n=611), 60-70 years (n=603), > 70 years (n=624).
Results: In both genders, abdominal obesity was related with diabetes and hypertension, with a clear trend to stronger association in women: OR (CI 95%) for diabetes in women 6.1 (3.0 – 14.6), in men 2.9 (1.7 – 4.9); OR (CI 95%) for hypertension in women 5.2 (3.9 – 7.2), in men 3.3 (2.4 – 4.4). The association of abdominal obesity with both diabetes and hypertension attenuates as age advances, becoming statistically non significant in the oldest group: a) OR (CI 95%) for diabetes in < 50 years 3.0 (1.2 – 5.0), 50 - 60 years 3.0 (1.3 – 8.7), 60 - 70 years 2.2 (1.02 – 5.5), > 70 years 2.0 (0.9 – 4.9); b) OR (CI 95%) for hypertension in < 50 years 5.4 (3.3 – 9.0), 50 - 60 years 3.8 (2.3 – 6.5), 60 - 70 years 2.0 (1.3 – 3.3), > 70 years 1.3 (0.7 – 3.1).
Conclusions: The cross-sectional association of abdominal obesity with diabetes and hypertension seems to be stronger in women and in younger people. From an epidemiological and a clinical perspective, these data are useful to target efforts against abdominal obesity in those people most vulnerable to its negative cardiometabolic effects.

The applicability of the Hypertriglyceridemic Waist Syndrome to Non-Hispanic Blacks: analyses of NHANES 1999-2004

O.E. Imoisili[1], C.C. Cowie[1], A.E. Sumner[1]
[1] National Institutes of Health, National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, USA

The Hypertriglyceridemic Waist (HTGW) Syndrome was designed to predict cardiovascular disease risk in non-Hispanic whites (NHW). It has two requirements: hypertriglyceridemia defined as triglyceride levels (TG) $\geq$177 mg/dL and elevated waist circumference (WC) (Men$\geq$90 cm; Women$\geq$85 cm). However, non-Hispanic blacks (NHB) often have lower TG levels despite a higher rate of cardiovascular disease than NHW and Mexican Americans (MA). Therefore, the validity of HTGW Syndrome in NHB is uncertain. Our goal was to compare TG levels, WC and the prevalence of HTGW Syndrome in NHB, NHW and MA in 3749 non-diabetic adults from NHANES 1999 to 2004, age$\geq$20y (mean 43y). Mean (SE) TG levels in NHB, NHW and MA were 99(3), 130(2) and 135(4) respectively (P<0.001 NHB vs. NHW or MA). The percent of subjects with TG$\geq$177 mg/dL was lower in NHB than NHW or MA (both P<0.001) (Table). Mean (SE) WC levels in NHB, NHW, and MA men were 93(0.9), 99(0.5), and 96 (0.9), respectively. For women, the mean WC levels for NHB, NHW, and MA were 97 (1), 90 (0.6), and 94 (0.9), respectively. WC and percent of subjects with increased WC was not significantly different between NHB, NHW and MA. However, the prevalence of HTGW Syndrome was much lower in NHB than NHW or MA (P<0.001 NHB vs. NHW or MA) (Table). Although NHB have more cardiovascular disease than NHW or MA, NHB have a lower prevalence of HTGW Syndrome. This paradox can be attributed to low TG levels in NHB. Hence, the value of HTGW Syndrome in NHB requires confirmation.

Table: Characteristics by Ethnicity

	NHB	NHW	MA	*P*-value
%TG$\geq$177	8.8(1.4)	20.8(1.1)	22.0 (1.5)	a***, b***
%WC Elevated	65.4(1.8)	67.3(1.3)	70.5(2.4)	NS
% HTGW Syndrome	7.6 (1.4)	18.4 (1.0)	20.9 (1.4)	a***, b***

[a] NHB vs. NHW, [b] NHB vs. MA, [c] NHW vs. MA
P*$\leq$0.05, P**$\leq$0.01, P***$\leq$0.001

Metabolic syndrome in Cameroon - comparison and concordance of two definitions

D. Mandob Enyegue[1]
[1] University, Biochemistry, yaounde, Cameroon

Aims: This study was performed to determine the concordance of metabolic syndrome (MetS) prevalence according to International Diabetes Federation (IDF) 2005 and National Cholesterol Education Program Adult Treatment Panel III (NCEP/ATP III) 2001 definitions in a Cameroonian population and to determine the most accurate definition.
Methods: Among the 1949 participants received during the study in Yaoundé (the capital city of Cameroon and a cosmopolitan town), based on the WHO 1998 classification of obesity, a total of 1520 overweight or obese adults aged ≥18 years (1193 women and 327 men) were selected for the biochemical tests. Blood samples were analyzed, blood pressure and waist circumference assessed, data on lifestyle, medication, chronic disorders, and socio-demographic characteristics collected. Kappa test was done to examine the agreement between the definitions.
Results: The mean age of the group was 34.87 ± 10.97 years for men and for women 36.9 ± 11.28 years. The prevalence of MetS using NCEP/ATP III and IDF definitions was 13.0% and 19.5% respectively. The agreement rate between the IDF and NCEP/ATP III was good (Kappa = 0.72). The subjects defined only with NCEP/ATP III and not IDF were all women. They had lower body mass indices, waist circumferences but higher triglyceride levels than those defined by both NCEP/ATP III and IDF.
Discussion/conclusion: The agreement between ATPIII and IDF definitions was very good, especially in women. In addition, the IDF definition of MetS, with the absence of central obesity criteria in the African population is not accurate for the detection of Mets prevalence in Cameroon. Further studies on MetS in African populations should be done with NCEP while awaiting recommended values for waist circumference in Africa. MetS in Cameroon requires the execution of urgent preventive measures, especially promotion of healthy life style.

Ferritin concentrations, type 2 diabetes, metabolic syndrome and insulin resistance in a Chinese population

Y. Ren[1], Y. Liu[1], J. Song[1], H. Tian[1]
[1] West China Hospital of Sichuan University, Division Of Endocrinology And Metabolism, Chengdu, China

Aims: we examined the association among serum ferritin concentrations, DM, metabolic syndrome(MS) and insulin resistance in a Chinese population in Sichuan province.
Methods: We conducted a cross-sectional study in 3040 subjects from three communities in Sichuan. Serum ferritin concentrations, glucose tolerance status, plasma lipids, alanine aminotransferase, aspartate aminotransferase, uric acid and creatinine were determined in all subjects. Blood pressure, BMI and waist circumferences were also measured. Metabolic syndrome was diagnosed using the IDF criteria.
Results: Individuals with newly diagnosed DM, previously diagnosed DM and prediabetes had elevated serum ferritin concentrations compared with those of normal glucose tolerance (191.13±114.96µg/l vs. 184.63±109.51µg/l vs.

164.77±116.25µg/l vs. 119.58±97.57µg/l, P<0.05). After adjusting for age, race, BMI, smoking, alcohol consumption, activity, family history, education, residential district, waist circumferences, WHR, blood pressure, plasma lipids and uric acids, the odds ratio of prediabetes and DM was 1.54 (95% CI: 1.08-2.19) in men with ferritin concentrations ≥300µg/l and was 1.80 (95% CI: 1.36-2.39) in women with ferritin concentrations ≥150µg/l, respectively. the odds ratio of prediabetes and DM was 1.46 (95% CI 1.05-2.03) in men with ferritin concentrations in the highest quartile (=271.1µg), and 1.76 (95% CI 1.34-2.33) in women with elevated ferritin concentrations(=141.5µg).
The prevalence of MS in subjects with serum ferritin concentrations in the highest quartile was significantly higher than those in the lowest quartile, either in men (32.2% vs 10.1%, P<0.001) or women (38.8% vs 10.7%, P<0.001). After adjusting for age, race, BMI, smoking, alcohol consumption, activity, family history, education and residential district, the odds ratios of MS in subjects with serum ferrtin concentrations in the highest quartile were 1.71 (95% CI 0.92-3.19) in men and 1.67 (95% CI 1.03-2.70) in women when compared with those in the lowest quartile. In all subjects, the serum ferritin concentrations increased gradually with increasing numbers of co-existing metabolic components accordingly (P<0.001). This positive relationship between the numbers of co-existing metabolic components and serum ferritin concentrations remained significant when male and female subjects were analyzed separately (P<0.001).
A positive association was found between serum ferritin concentrations and HOMA-IR. HOMA-IR (=1.98) was associated with a higher level of ferritin and uric acid.
Conclusion: Serum ferritin concentrations increased remarkably in DM patients, and elevated serum ferritin concentrations were associated with an increased risk of prediabetes and DM. Furthermore, we found a positive association between serum ferritin concentrations and MS. Also elevated level of ferritin was positively associated with insulin resistance.

Body mass index, triceps skinfold and waist circumference in screening for adiposity and risk of metabolic syndrome in Romanian rural children aged 3-11 years

V. Mocanu[1], E. Zbranca[2], D. Azoicai[3], R. Haliga[1], R. Costan[2], A. Balanica[1], C. Galesanu[2], V. Luca[1], M. Badescu[1]
[1] *"Gr. T. Popa" University of Medicine and Pharmacy, Pathophysiology, Iasi, Romania*
[2] *"Gr. T. Popa" University of Medicine and Pharmacy, Endocrinology, Iasi, Romania*
[3] *"Gr. T. Popa" University of Medicine and Pharmacy, Epidemiology, Iasi, Romania*

Objective: Childhood obesity has been rapidly increasing in both developed and developing countries. Considering the lack of reference values in Romania, we determined the prevalence of overweight and risk of metabolic syndrome using the body composition characteristics, weight, body mass index (BMI), triceps skinfold (TSF), and waist circumference (WC) in rural preschool and primary school children in Miroslava, Romania.
Methods: The present study is based on cross-sectional data of 210 children (106 boys and 104 girls) aged 3–11 years measured in 2008. Participants were recruited from schools in Miroslava, eastern Romania.
Results: Overall, 15.1% of the boys and 21.1% of the girls were above the 90th weight-for-height percentile. Using international cut-off values for body mass index, the overall prevalence of overweight and obesity was 14.2% (above 85th percentile) and 5.7% in boys (above 95th percentile), and 22.1% (above 85th percentile) and 10.6% (above 95th percentile) in girls. The excess of fat was measured by triceps skinfold, 14.2% of the boys and 23.1% of the girls being above the 95th triceps skinfold for age percentile. The prevalence of metabolic syndrome using WC values above 90th for age percentile was 4.7% in boys and 4.8% in girls. For both sexes a highly positive correlation was found between waist circumference and BMI, skinfold thicknesses, and percentage of body fat.
Conclusions: Our study supports high frequencies of childhood overweight and obesity in developing countries. A substantial number of overweight 3- to 11-year-olds have abnormal abdominal obesity, indicating that overweight in early adolescence may put children at risk for adult-onset cardiovascular disease and/or type 2 diabetes well before they become teenagers.

The cutoff level of waist circumference for predicting the presence of multiple risk factors for cardiovascular disease in the Vietnamese population

Y. Matsushita[1], S.T. Pham[2], H. Kajio[3], Q.N. Nguyen[2], M. Kishimoto[3], S. Kanagawa[4], H.T.H. Pham[2], Y. Takahashi[3], M. Noda[3], H.T. Tran[2], L.D. Do[2], V.L. Nguyen[2]
[1] *Research Institute International Medical Center of Japan, Department of Epidemiology and International Health, Tokyo, Japan*
[2] *Bach Mai Hospital, Vietnam National Heart Institute, Hanoi, Vietnam*
[3] *International Medical Center of Japan, Department of Diabetes and Metabolic Medicine, Tokyo, Japan*
[4] *International Medical Center of Japan, Travel Clinic, Tokyo, Japan*

Aims: Metabolic syndrome is characterized by a cluster of risk factors for cardiovascular disease (CVD). Waist circumference is the easiest measure of central obesity, and it has been recommended that ethnic group-specific cutoffs for waist circumference should be used to link subjects to CVD risk. Therefore, we analyzed surveillance data to determine the most suitable cutoff level of waist circumference for the diagnosis of metabolic syndrome in the Vietnamese population.
Methods: We recruited 1516 participants in this cross-sectional study conducted in Hanoi, Vietnam, in 2009. Among them, 1459 subjects (483 men and 976 women) between 25 to 96 years of age completed the measurements of all the items of the metabolic syndrome; these subjects were included in the analyses. The waist circumference was measured twice at the midpoint between the lowest rib and the iliac crest, and its mean value was used in the analysis. The following 4 risk factors were defined by the criteria of the National Cholesterol Education Program's Adult Treatment Panel III (NCEP-ATP III): (1) triglycerides, ≥150 mg/dl; (2) high-density lipoprotein cholesterol, <40 mg/dl in men and <50 mg/dl in women; (3) systolic blood pressure, ≥130 mmHg, or diastolic blood pressure, ≥85 mmHg; and (4) fasting plasma glucose, ≥110 mg/dl. Subjects with 2 or more of the abovementioned 4 risk factors were defined as having multiple risk factors. Subjects with a history of or those undergoing medical treatment for hyperlipidemia, hypertension, or diabetes were deemed as having each risk factor, regardless of their biochemical values. The optimal cutoff value of waist circumference for the definition of central obesity was assessed by ROC curve to predict the presence or absence of 2 or more risk factors of the metabolic syndrome other than the waist circumference.
Results: The mean age (SD) of the study subjects was 55.9 (14.6) years for men and 53.5 (13.0) years for women. Multiple risk factors were prevalent in 52.6% of the men and 46.8% of the women in the study, respectively. The optimal cutoff point of waist circumference yielding the maximal sensitivity plus specificity was 82 cm in men and 72 cm in women. A cutoff waist circumference of 76 cm in men and 73 cm in women yielded at least 80% sensitivity for predicting the presence of multiple risk factors.
Discussion/conclusion: The cutoff point of waist circumference yielding the maximal sensitivity plus specificity for predicting the presence of multiple risk factors for CVD was lower in the Vietnamese population as compared to that in the Japanese population. Therefore, this study clarifies the need of investigating this cutoff point for specific ethnic groups.

The hypertriglyceridemic waist syndrome does not predict the metabolic triad in blacks

A.E. Sumner[1], O.E. Imoisili[1], M.F. Luercio[1], B.V. Miller[1], M. Ricks[1]
[1] *National Institutes of Health, National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, USA*

Metabolic Triad predicts premature coronary artery disease (CAD). The criteria for the Metabolic Triad are: hyperinsulinemia, hyperapolipoprotein B (apoB) and small dense low density lipoprotein (LDL) particles. In whites, Hypertriglyceridemic Waist (HTGW) Syndrome predicts the Metabolic Triad. To diagnose HTGW Syndrome, both waist circumference (WC) (Men≥90cm; Women≥85cm) and triglyceride (TG) concentration (≥177mg/dL) must be elevated. As blacks have more obesity but lower TG levels than whites, the ability of the HTGW Syndrome to predict the Metabolic Triad must be verified in blacks. Our goal was to compare the prevalence of HTGW Syndrome and Metabolic Triad in blacks. All 190 blacks (48% Male, Age 35±8y, (mean±SD), BMI 30.2±7.4, 18.5-54.7kg/m^2) had WC, TG, insulin, apoB and LDL size determined. Prevalence of HTGW Syndrome and the Metabolic Triad were

compared in overweight and glucose intolerant blacks. Both groups are at high risk for premature CAD. For overweight blacks, 85% had increased WC but only 3% had TG≥177mg/dL. HTGW Syndrome occurred in just 3% of overweight subjects; yet 52% had the Metabolic Triad. For glucose intolerant blacks, 91% had increased WC but only 7% had TG≥177mg/dL. HTGW Syndrome occurred in 7% of glucose intolerant blacks, but 52% had Metabolic Triad. Median TG levels in blacks with Metabolic Triad are provided in the Table. In conclusion, the low prevalence of HTGW Syndrome in blacks is due to the relative absence of hypertriglyceridemia. As the Metabolic Triad in blacks is approximately 10 times more common than HTGW Syndrome, HTGW Syndrome should not be used to predict the Metabolic Triad.

Table: Subject Characteristics

Category	Increased WC (%)	TG≥177 mg/dL (%)	HTGW Syndrome (%)	Metabolic Triad (%)	Metabolic Triad Median TG (mg/dL)
Overweight	85	3	3	52	83
Glucose Intolerant	91	7	7	52	104

Development and Implementation of a European Guideline and Training Standards for Diabetes Prevention - The IMAGE project: a report of the IMAGE Study Group on the current status and perspectives

P.E.H. Schwarz[1], U. Gruhl[1], M. Hall[2], M. Roden[3], P. Kronsbein[4], M. Peltonen[5], M. Fischer[6], J. Tuomilehto[7]
[1] *TU Dresden, Internal Medicine III, Dresden, Germany*
[3] *Karl Landsteiner Institute, Endocrinology and metabolic disorders, Vienna, Austria*
[4] *Niederrhein University of Applied Sciences, Nutritional Science, Mönchengladbach, Germany*
[5] *National Institute for Health and Welfare, Diabetes Unit in the Department of Health Promotion and Chronic Disease Prevention, Helsinki, Finland*
[6] *Private University Witten-Herdecke, Institute for didactics and education research in health care, Witten, Germany*
[7] *University of Helsinki, Public Health, Helsinki, Finland*

Background: The dramatic increase of type 2 diabetes has become a serious burden for European health care systems. Clinical studies clearly demonstrated that prevention programs can significantly reduce the risk of developing diabetes. At the political level there is a clear consensus that immediate strategic action is needed to counter the diabetes epidemic. A variety of national prevention management concepts do exist which can be implemented into clinical practice. In view of the still lacking EU-wide strategies, the IMAGE Project was submitted to the European Commission under the call for proposals 2006 for the program of community action in the field of public health (2003-2008). With over 40 partner organizations from 16 EU- and 6 non-EU member states it is one of the largest projects in the public health sector recommended for co-funding.
Objectives: Effective primary prevention is the key to reducing the epidemic in type 2 diabetes. The IMAGE project will help to address this through the development of four specific objectives:
1. European practice-oriented guidelines for the primary prevention of type 2 diabetes
2. A European curriculum for the training of prevention managers
3. European standards for quality control
4. A European e-health training portal for prevention managers

Current status: The project duration is three years (06/2007 – 05/2010). In the second quarter of 2009 the guideline will be finalized and reviewed by external experts. Also the other tools developed in the first project half (curriculum, quality management system, e-health portal) will be tested in 2009 in a pilot phase with about 100 participants all over Europe. From October 29-31 2009 the IMAGE study group will meet for the final convention in Lisbon, Portugal, to present and discuss the outcomes.
Perspectives: The final results will be presented at the 6th World Congress on the Prevention of Diabetes and its Complications in Dresden, Germany on April 8-11, 2010.
The implementation of IMAGE results will provide unique European-wide guidance for the first time in a new evolving field of health care. Particularly implementing the guideline and quality standards so that they are in everyday use will be a great merit of the EU commission and the IMAGE consortium also beyond the official project duration.

Large-scale implementation of diabetes prevention programs: an Australian experience

P. Reddy[1], J.A. Dunbar[1], G. Johnson[2], R. Audehm[2]
[1] *Deakin University, GGT UDRH, Melbourne, Australia*
[2] *Diabetes Australia Victoria, Life! program, Melbourne, Australia*

Aims: This paper describes the process of translating the results of clinical trials in the prevention of diabetes to large-scale implementation in Australian primary care.
Methods: In 2004-2006 we conducted a national demonstrator diabetes prevention program in Australia based on the Finnish clinical trials starting with intensive individual interventions and moving to structured group programs. Our six-session group diabetes prevention program focusing on lifestyle change was selected by the Victorian government targeting 25,000 high-risk individuals over the age of 50 years. It is called *Life! Taking action on diabetes*.
Results: We present the pragmatic aspects of this large-scale intervention including the balance between fidelity and adaptation for systematic application of the Health Action Process Approach behaviour change theory; standardization of the intervention and training of 160 group facilitators; recruitment strategies including social marketing; engagement of stakeholders including primary care practitioners; performance measurement; and continuous quality improvement. Early results suggest that the effects the *Life!* program are comparable with other studies.
Discussion/conclusion: Implementation on a scale that requires 25,000 participants is complex. Many lessons have been learned which may benefit future diabetes prevention programs. An analysis of the successes and lessons learned for widespread implementation will be presented. A benefit of the diabetes prevention program recruitment process was the greater awareness of diabetes in the community and diagnosis of pre-existing diabetes, but recruitment required greater planning, effort, and time to create groups than anticipated. Another benefit is the contribution of the program to a skilled healthcare workforce that can conduct cost-effective group interventions for a great and growing health problem.

Primary prevention program in Pakistan; impact of intervention on the prevention of type 2 DM

M.Z.I. Hydrie[1,2], A.H. Hussain[1], A.B. Basit[2], A.S.S. Shera[3]
[1] *Institute of General Practice and Community Medicine Faculty of Medicine University of Oslo, Department of International Health, Oslo, Norway*
[2] *Baqai Medical University, Baqai Institute of Diabetology and Endocrinology, Karachi, Pakistan*
[3] *Diabetic Association of Pakistan, WHO collaborating centre, Karachi, Pakistan*

Aims: South Asians have higher cardio-metabolic risk factors and often present at younger ages with diabetes than other populations. Since prevention is a cost effective way to reduce the burden of diabetes, and studies on primary prevention in South Asians are very limited, the objective of this study was to prevent the development of type 2 diabetes in persons with impaired glucose tolerance (IGT).
Methods: A joint collaborative study was initiated in 2007 between University of Oslo, Diabetic Association of Pakistan and Baqai Institute of Diabetology and Endocrinology for a period of three years. Total 1,825 high risk subjects aged > 30 yrs were screened by oral glucose tolerance test (OGTT) for abnormal glucose tolerance. Demographic and socioeconomic information was collected through a structured questionnaire. Subjects identified as having IGT were invited to participate in the intervention program for a period of 18 months.
We developed an intervention team comprising of one project coordinator, one

medical officer, two dieticians and two physical therapists to supervise and guide the subjects during the study about lifestyle modifications.
We are following these subjects for 18 months and have OGTT, fasting lipid profile, fasting insulin and HbA1c done at 0, 9 and 18 months. Also a FFQ diet assessment plan was filled on 0, 9 and 18 months by the dieticians.
Results: Out of 1,825 subjects, 195 (10.7%) subjects were newly diagnosed type 2 diabetes while 400(22%) subjects had IGT. Majority (72%) of the study subjects were males. Overall mean age of the subjects was 41.5 years while mean ages of normal, impaired and diabetic subjects was 40.2, 43.8 and 44.6 years respectively.
The subjects were initially divided into standard (n=178) and intensive (n=222) lifestyle modification groups. Metformin was the drug option given to half of the subjects in both the groups. Since some subjects refused to take the drug we had uneven number of subjects in the final four groups. Thus we had 107 subjects in the standard group while 71 subjects in the drug group. Similarly we had 142 subjects in the intensive group while 80 subjects in the intensive + drug group.
So far 252 subjects have completed the study and of these 29 have become diabetic while 150 have reverted back to normal glucose tolerance. The final subject would be assessed by May 2009 and we hope to present the final results in October at the IDF conference.
Conclusion: Preliminary data show that 6.6% of subjects in intensive group developed diabetes compared to 10.8% of standard group. Final assessment would be done after completion of study in May.

[4] Toyama Hospital International Medical Center of Japan, Diabetes and Metabolic Medicine, Tokyo, Japan
[5] Higashiyama Takeda Hospital, Internal Medicine, Kyoto, Japan

Background: In Japan, the number of patients with type 2 diabetes (T2DM) is rapidly increasing and medical expenditure for T2DM is crucial. Previous studies showed that overweight people can prevent or delay the initiation of T2DM by achieving the weight loss through the lifestyle modification. However, previous intervention programs were relatively intense, needed large skilled human resources and cost a great deal. Therefore, we launched a nationwide trial to evaluate if the program dealing with more participants with lower cost and lighter workload is also effective for T2DM prevention.
Methods: The study design is a cluster randomized intervention trial. High-risk people for T2DM are recruited on the basis of results of annual health checkup at the workplace and community healthcare centers. Main inclusion criteria are age (20-65 years) and fasting plasma glucose (100-125 mg/dl). Participants are assigned to either the intervention group (IG) or the control group (CG) by the healthcare centers they belong to. Each participant in the IG is given a weight scale and a pedometer and receives regular newsletters. In addition, he/she is provided with about six interventional phone calls by health nurses or dietitians to facilitate to achieve healthy life style in the first year. Each participant in the CG is also given a weight scale, a pedometer, and receives regular newsletters, but no phone calls. The contents of newsletters and phone calls are focused on four major topics; exercise, weight control, vegetable intake, and alcohol intake. Main endpoint of this study is an incidence rate of T2DM defined as fasting plasma glucose 126mg/dl or over on annual health checkup or diabetes diagnosed by a physician. Secondary endpoints are BMI, habits of diet and exercise, and health behavior change. Follow-up period is 3 years.
Results: The total number of clusters was 43 (22 in the IG, 21 in the CG). By the end of January 2009, 2904 subjects were registered (1375 for the IG, 1529 for the CG). Participation rate was 20%. Mean age of the registered participants was 49 years old, 84% was male, mean BMI was 24.3kg/m^2, and mean fasting plasma glucose was 106mg/dl. Between the IG and the CG, there was no difference in age, male-to-female ratio, BMI, and fasting plasma glucose. Approximately 82% of the participants in the IG had finished receiving intervention by the end of January 2009. This study is currently in progress.
Conclusions: This is a large-scale preventive study and intervention is carried out not face-to-face, but by telephone call from the health professionals. The result of this study could contribute to make a strategy for T2DM prevention and provide scientific evidence to national health policy in Japan.
This research is supported by a Health and Labour Sciences Research Grant for Research on Diabetes from the Ministry of Health, Labour and Welfare, Japan.

Diabetes can be prevented: a six–month campaign at www.fundaciondiabetes.org

C. Marín[1], V. Salaverría[1], J.R. Calle[1]
[1] Fundación para la Diabetes, Madrid, Spain

Background: Clinical evidence has proven that primary Type 2 Diabetes (DM2) prevention is attainable when modifiable risk factors are impacted. Via its Diabetes Strategy, Spain's National Health Service has been staging awareness campaigns directed at the general public, regarding inherent DM2 risks and healthy lifestyle patterns, which serve to prevent or delay the onset of this condition.
Objective: The aim has been to ascertain to what degree on-line information campaigns would be useful in preventing diabetes and obesity. This is achieved via personal DM2-risk self-testing and customized lifestyle adjustment recommendations, made in accordance with each person's risk profile.
Method: The FINDRISK population DM2-risk filter Test comprises 8 scored questions, the results of which serve to predict what the chances are that the person will develop DM2 over the coming 10 years, with 14 points having been set as the most likely cut-off point in predicting high risk probability.
The FINDRISK test is just part of an interactive program that facilitates risk factor self-testing and which, based on this risk factor, will recommend lifestyle changes that could help avoid or delay the onset of DM2.
Results: The Campaign got underway on September 30th 2008 and, by March 30th 2009, 13,511 on-line tests had already been done: 72.74% in Spain, 21.98% in Latin America and 5.28% in other countries, of which 44.93% were men and 55.07% were women.
Spain. Of the 9,828 tests done, 14.87% scored 14 points and over on the Findrisk scale. There were 4 age groups, as follows: under-45s, 45 to 54s, 55 to 64s and over-64s. The resulting 14+ high-risk factor percentage groups were as follows: 6.1%; 20.9%; 33.4% and 39.7%. BMI was greater than 30 for 14.4% of all participants. BMI breakdown, by age groups, was: 11.0%; 18.1%; 21.8% and 17.0%. Contrary to results in other categories, however, moderate levels of physical exercise, as declared by 51.0% of all participants, showed an increase with age: 44.9%; 54.0%; 64.6% and 72.9%.
Latin America. Of the 2,970 tests done, 21.3% scored 14 points and over on the Findrisk scale. There were 4 age groups, as follows: under-45s, 45 to 54s, 55 to 64s and over-64s. The resulting 14+ high-risk factor percentage groups were as follows: 10.3%; 31.2%; 46.0% and 64.1%. BMI was greater than 30 for 23.5% of all participants. BMI breakdown, by age groups, was: 20.4%; 28.6%; 27.2% and 31.5%. 39.8% of all participants practice moderate levels of physical exercise. By age groups: 36.4%; 40.1%; 53.2% and 52.2%.
Conclusion: The high number of on-line FINDRISK tests completed, serves to prove citizen awareness campaigns are viable, interactive, multinational, low cost and open to an ever-increasing number of people, via the Internet.

Pre-diabetes, weight loss and well being

D. Greenwood[1], C. Reynolds[1]
[1] Sutter Medical Foundation, Diabetes Education, Sacramento, USA

Objective: Prediabetes is a serious public health problem. Successful diabetes prevention programs have shown that weight loss, healthy eating with less than 25% from fat, and 150 minutes of physical activity can slow or halt the progression from prediabetes to diabetes. The goal of this project was to evaluate a weight loss program implemented for people with prediabetes.
Design/methods: Diabetes Prevention program consisted of a one time two hour pre-diabetes class; using the Small Steps, Big Rewards tools from the National Diabetes Education Program; followed by a 12 week group weight loss program called LEARN, team taught by an RD, CDE and behaviorist. Pre-program and post-program survey results were collected and tabulated. Self-reported behavior change results were reported by participants. WHO 5 survey

administered pre-program and post-program. Height, weight, blood pressure, waist circumference, and lab values were evaluated pre and post program. Qualitative results were tabulated and reported for "additional information". Percent of participants reporting greater than 150 minutes of exercise per week post program reported. Percent change in BMI, weight, blood pressure and waist circumference reported. The WHO 5 well-being score is reported in a percentage, a 10% difference indicates a significant change. Individual participant changes were scored.

Results: Of 23 participants enrolled, 19 (76%) completed the program. 93% of participants reported establishing a goal for weight loss, 93% of participants established a goal for physical activity and 86% of participants established a goal for calorie and fat intake. 47% of participants reported at least 150 minutes per week of physical activity. 72% reported being successful in behavior change. Participants average weight loss was 4.2%. Average change in waist circumference -3.2%. 86% had a two hour oral glucose tolerance test completed. Average change in WHO 5 was 15%. 71% of participants had significant change WHO 5 results, indicating a significant improvement in well-being post program.

Limitations: Pre-diabetes class preceded weight management program. Weight was measured at beginning of 12-week weight loss class, but pre-diabetes program initiated behavior changes in participants prior to weight collection. Actual weight loss results may have been greater if weight had been measured earlier in the program.

Conclusions: Improved well-being and positive behavior changes, in people with prediabetes, can be achieved by attending a weight management program. Diabetes educators need to increase the number of prevention programs and weight management programs offered to participants. Additional research needs to be undertaken to identify cost effective ways of implementing prevention programs.

Promoting diabetes prevention after gestational diabetes: the "Zoet Zwanger" project

F. Muylle[1], S. Verstraete[2], K. Decochez[3], R. Devlieger[4], A. Verhaegen[5], J. Wens[6], C. Mathieu[7]
[1] *Flemish Diabetes Association, Scientific coworker, Ghent, Belgium*
[2] *Flemish Diabetes Association, Project coordinator "Zoet Zwanger", Ghent, Belgium*
[3] *UZ Brussel, Department of Diabetology, Brussels, Belgium*
[4] *UZ Leuven, Department of Obstetrics & Gynaecology, Leuven, Belgium*
[5] *ZNA Jan Palfijnziekenhuis, Department of Endocrinology, Merksem, Belgium*
[6] *University of Antwerp, Department of General Practice Interdisciplinary Health Care and Geriatrics, Antwerp, Belgium*
[7] *UZ Leuven, Department of Endocrinology, Leuven, Belgium*

Background: The global burden of type 2 diabetes (T2DM) is rising rapidly, clearly driven by modifiable risk factors such as obesity and sedentariness. Effective prevention strategies are urgently needed to curb this epidemic. According to the IDF Consensus on diabetes prevention (2007), particular attention should be paid to targeting high risk populations. Women with gestational diabetes (GDM) are at the highest risk to develop T2DM early in life: up to 50 % will have diabetes within 5-10 years after delivery. However, follow-up after GDM is often lacking due to a low self-risk perception among these women, issues related to healthcare provider awareness, and specific barriers within healthcare systems. GDM women are not receiving appropriate postpartum screening according to current guidelines, and typically maintain health risk behaviour after delivery. On the other hand, promoting healthy, active lifestyles and 5-10 % weight loss may have a large impact on diabetes prevention in these young women.

Aims: "Zoet Zwanger" ("Sweet & Pregnant") is a new diabetes prevention project coordinated by the Flemish Diabetes Association (VDV) from 2009 to 2012 in the region of Flanders, Belgium, aimed at bridging the described prevention gap, by promoting metabolic follow-up and introducing realistic lifestyle interventions in women with previous GDM.

Methods: The first part of the project consists of an awareness campaign directed at all healthcare providers involved in the follow-up of GDM women using web-based materials, folders, posters, or information sessions. Secondly, women diagnosed with GDM will have the opportunity to participate in a GDM follow-up system (recall register), with annual reminders asking them to see their general practitioner for a check-up. The project will be implemented in collaboration with the region's professional associations of obstetricians-gynaecologists (VVOG) and general practitioners (Domus Medica).

A flow chart has been agreed between all partners involved, defining the steps in the process, from detection of GDM to registration in the system and defining the post-delivery follow-up strategy. Evaluation criteria include compliance with blood glucose screening, screening outcome, and BMI.

Expected results and conclusion: The perinatal registry (SPE) in Flanders indicates a (diagnosed) GDM prevalence of at least 2% and suggests an increasing trend. Women diagnosed with GDM receive information about treatment goals **during** pregnancy. With the proposed project we want to improve long-term outcomes **after** delivery by creating awareness on the likely progression to T2DM, and by using a follow-up strategy including lifestyle advice and early detection of T2DM.

Conflict of interest:
Other substantive relationships: The "Zoet Zwanger" project is funded by a grant from the Flemish authorities.

Adult Health Promotion Record (AHPR) – a tool for prevention of diabetes, metabolic syndrome and cardiovascular disease

P. Katulanda[1], K. Wickramasinghe[2], D.R. Matthews[3], M.H.R. Sheriff[1]
[1] *University of Colombo, Diabetes Research Unit Department of Clinical Medicine, Colombo, Sri Lanka*
[2] *University of Oxford, Department of Public Health, Oxford, United Kingdom*
[3] *University of Oxford, Oxford Centre for Diabetes Endocrinology and Metabolism, Oxford, United Kingdom*

Introduction: Cardiovascular disease (CVD) has become the main cause of mortality in most countries. Cigarette smoking, hypertension, dysglycaemia, dyslipidaemia and obesity are lifestyle-related modifiable risk factors of CVD. Metabolic syndrome is a constellation of CVD risk factors. Despite proof of concept, lifestyle modification has not translated into large scale community level prevention of diabetes and CVD.

Objectives: We aimed to develop a simple and low-cost tool for community level prevention of lifestyle-related diseases and health promotion (Adult Health Promotion Record – AHPR) targeting multiple and clustered CVD risk factors.

Methods: We identified CVD, type 2 diabetes, obstructive pulmonary disease, alcoholic cirrhosis, tobacco and lifestyle related malignancies as important causes of mortality, morbidity and economic loss in the world. Based on the existing evidence, we identified obesity, physical inactivity, tobacco smoking, hypertension, alcohol abuse, dyslipidaemia and dysglycaemia as related and common modifiable risk factors. The AHPR was developed to indicate graded risk for these risk factors. Visual scales coded in green, yellow, amber and red were constructed based on currently available ethnic and gender specific data. The AHPR was designed to indicate the level of risk in an individual and for disease prevention through empowerment and personal motivation. It includes vital messages and recommendations for health promotion and disease prevention. It can also be used for prospective follow up by the health care system.

Conclusions: This simple, low-cost tool for prevention of diabetes, CVD and other non-communicable diseases can be used in large scale community interventions for health promotion and disease prevention.

Is asymmetric dimethylarginine (ADMA) a predictor of the diabetic cardiovascular diseases?

M. Miuchi[1], H. Konya[2], S. Ida[3], S. Kataoka[3], K. Konishi[3], E. Nagai[3], M. Tokuda[3], K. Murai[3], T. Katsuno[3], T. Hamaguchi[3], J. Miyagawa[3], M. Namba[3]
[1] Hyogo college of medicine, Division of Diabetes & Metabolism Internal Medicine, NishinomiyaHyogo, Japan
[2] Ashiya municipal hospital, Internal Medicine, AshiyaHyogo, Japan
[3] Hyogo college of medicine, Division of Diabetes & Metabolism Internal Medicine, NishinomiyaHyogo, Japan

Background and aims: Diabetic cardiovascular diseases are the common risks for determining morbidity and mortality in the diabetic population. ADMA has been established as an inhibitor of endogenous nitric oxide (NO) synthesis, and the relationship between ADMA and arteriosclerosis including cardiovascular diseases has been reported. If ADMA could become the predictor of diabetic cardiovascular diseases, we may prevent the progress of diabetic cardiovascular diseases and improve their morbidity and mortality. In the study, we have examined whether ADMA and other cardiovascular risk factors are the useful predictors for diabetic cardiovascular diseases, namely cerebro- and cardio-vascular events and peripheral artery diseases.
Materials and methods: We have analyzed 87 type 2 diabetic patients (47 men and 40 women, 40 to 83 years old, HbA1C 9.4±2.2%, BMI 23.4±4.2). After the measurement of the respective cardiovascular risk factors, we have followed up the enrolled type 2 diabetic patients for 5 years. We investigated the risk factors as follows, ADMA, angiotensin II, hepatocyte growth factor (HGF), advanced glycation end products (AGEs), plasma plasminogen activator inhibitor type 1 (PAI-1), mean intimal-medial thickness (IMT) and plaque score of the common carotid artery. Furthermore, we measured serum creatinine (Cr), creatinine clearance (CCr), albumin urine (U-Alb), blood pressure, cholesterol, triglyceride, free fatty acid, HbA1C, and calculated eGFR (male: $194 \times Cr^{1.094} \times Age^{-0.287}$, female: $194 \times Cr^{1.094} \times Age^{-0.287} \times 0.739$, CKD guideline in Japan). We compared retrospectively the above factors between 2 groups, with or without cardiovascular diseases.
Results: Ten people dropped out within 5 years, so we have finally analyzed with 77 patients. Diabetic cardiovascular disease developed in 15 cases newly within 5 years, and 4 cases recurred. The concentrations of ADMA in plasma (0.56±0.09 vs. 0.45±0.07μmol/l, p<0.00001) was significantly higher in 19 diabetic patients with cardiovascular diseases than in 58 diabetic patients without cardiovascular diseases. U-Alb (319.9±522.6 vs. 83.5±199.4μg/ml, p<0.001) and mean IMT (1.39±0.33 vs. 1.16±0.30mm, p<0.001) were also higher in patients with cardiovascular diseases. Any other risk factors were not associated with the development of the cardiovascular diseases within 5 years.
Conclusions: We demonstrated an association with diabetic cardiovascular diseases and high concentration of ADMA, U-Alb and high level of mean IMT. Above all, ADMA could be the most useful predictor of the diabetic cardiovascular diseases in type 2 diabetes.

Association of sleep disorder with risk factors for cardiovascular disease in type 2 diabetic patients

E.J. Shim[1], H.J. Lee[1], J.Y. Oh[1], Y.A. Sung[1]
[1] Ewha Womans University Mokdong Hospital, Endocrinology, Seoul, Korea

Aim: Sleep disorder, characterized by hypoxia during sleep and sleep loss, is known to be related with insulin resistance and cardiovascular risks. We studied the frequency and characteristics of sleep disorder in patients with type 2 diabetes.
Methods: We surveyed 780 patients with type 2 diabetes (395 male and 289 female, 54±12 years, body mass index (BMI) 24.8±3.3 kg/m2) to evaluate the sleeping disturbances. Pittsburgh Sleep Quality Index (PSQI) was used to evaluate the sleep quality, Berlin Questionnaire (BQ) to evaluate the severity of obstructive sleep apnea(OSA) and Epworth Sleepiness Scale (ESS) to evaluate daytime sleepiness. We observed the relationship between sleep disorders and clinical and biochemical characteristics.
Results: PSQI results showed poor sleep quality in 301 patients (38.4%), BQ showed 124 patients (15.8%) with high risk for OSA, and ESS showed 34 patients (6.3%) with daytime sleepiness. The high risk group for OSA was much more obese (BMI > 25 kg/m2) than non-obese group (26.1% vs. 8.1%, p<0.05) and was significantly higher in male than female (20.3% vs. 11.4%, p<0.05). In this group, sleep quality was poor (5.9±2.5 vs. 5.0±2.6, p<0.05) and daytime sleepiness scale was higher(5.3±4.4 vs. 3.5±3.0, p<0.05). Other factors such as BMI, systolic and diastolic blood pressure, serum insulin level, HOMA-IR, serum triglyceride level were significantly higher than low risk group (p<0.05). Logistic regression analysis showed male, BMI, HOMA-IR as a significant risk factor for OSA.
Discussion: Sleep disorder was commonly seen in type 2 diabetes and related to risk factors for cardiovascular diseases.

The impact of glycemic variability on diabetes related complications: use of postprandial glucose as a proxy

C. Weber[1], O. Schnell[2]
[1] Institute for Medical Informatics and Biostatistics, Health Economics, Basel, Switzerland
[2] Diabetes Research Institute, Heart and Diabetes Research, Munich, Germany

Aims/background: There is a growing body of evidence that the mere use of HbA1c is insufficient to reflect the metabolic situation of patients with diabetes mellitus adequately. The risk for development of diabetes related complications is apparently not only dependent on a long-term stability of glucose values, but also on the presence or occurrence of short-term glycemic peaks and nadirs in terms of minutes or hours during a day, leading thus to a phenomenon called glycemic variability.
We assessed the existing evidence for the clinical relevance of short term glucose variations and the existing different measures of glycemic variability.
Methods: Studies were selected for this review based on a search in MEDLINE and EMBASE using the following terms: "diabetes mellitus" or "postprandial glucose" or "glycaemic variability" in combination with the Boolean operator "AND": morbidity, mortality, cardiovascular disease, coronary heart disease, myocardial infarction, stroke, nephropathy, retinopathy, amputation. Studies identified from each search were examined for their relevance and actuality, because we applied no temporal search limits. Relevant citations were crosschecked for additional, relevant citations.
Results: 12 different measures for glycemic variability could be identified. Actually no gold standard for the assessment of glycemic variability does exist. The indices published in the literature vary in complexity, are serving different needs and often require continuous glucose monitoring devices (CGMS).
Only a few prospective trials in an ICU setting analyzed the impact of glycemic variability on patient relevant endpoints, but a plethora of epidemiological studies identify high postprandial glucose values as an independent risk factor for cardiovascular events.
Conclusion: There is growing evidence and consent, that intra-day glycemic variability plays a major role in the development of diabetes related complications. The use of PPG as a proxy for glycemic variability seems justified. Especially in patients with type 2 diabetes, achieving tight glycemic control with a limited intra-day variability of the glucose readings, can be attained by intensive monitoring in distinct intervals and the definition of target ranges, where adjustment of the therapeutic regimen should take place if readings are out of range (e.g. 7-point profiles during 3 days monthly). This method is an option in hand while awaiting tools and devices for the measurement of glycemic variability which are easier to handle and more affordable than the CGMS systems currently on the market.

D-0877

Prevalance of peripheral arterial disease (PAD) by means of ABI in asymptomatic type 2 diabetes patients and its corelation with hypertension and other metabolic factors

R. Kapoor[1], S. Chopra[1]
[1] Carewell Heart & Super speciality Hospital, Cardiology, Amritsar, India

Background and aims: Peripheral Arterial Disease (PAD) is common in diabetes subjects, though its prevalence is a function of the diagnostic

methods employed and patient's characteristics. Ankle Brachial Index (ABI) - a non invasive measure of peripheral arterial disease (PAD) is widely used in epidemiological studies. Aim of the study is to evaluate the prevalence of peripheral arterial disease (PAD) by means of ankle-brachial index (ABI) in asymptomatic Type 2 Diabetes patients.-stageI grade0 category0 (Fontaine's stages & Rutherford categories classification of PAD) in North Indian population.
Methods: Between winter 2005 & winter 2008, 2750 asymptomatic (no complaints pertaining to PAD) Type 2 Diabetes patients with mean age 50.37± 13.26 were enrolled. Blood pressure, BMI, baPWV, HbA1c, Total Cholesterol, HDL, LDL & Triglycerides values were collected. The ABI was measured with VP-2000/1000-Colin Corporation, hyayashi komaki, Japan. PAD was considered when ABI measured was <0.9 in either leg.
Results: An ABI <0.9 was found in **2.45%** patients. 60.30% subjects of positive ABI cases had HbA1c more than 7 (r = -0.005, p= NS). Subjects with ABI <0.9 were dyslipidemic as follows- 51.61% had cholesterol >200mg (r = 0.15,p=NS),58.04% had LDL>100 (r = 0.019, p=NS), 51.61% had HDL<35 (r = -0.07,p=NS) and 93.90% had TG>150 (r = 0.108, p=NS). Of those with PAD, 15.37% subjects were females. 64.51%patients were obese with BMI >25 (r = 0.023, p=NS). S.B.P>140mmHg was observed in 83.87%(r = -0.09,p=NS) and D.B.P>86mmHg was observed in 53.30% (r = -0.06,p=NS) among the subjects with PAD. 77.50% patients with positive ABI showed increased baPWV (arterial stiffness index) (r = 0.45, p=<.001).

Table: Correlation of Ankle brachial Index With other parameters

	p=values (RT)	p= values (LT)
baPWV (RT)	<.001	<.001
baPWV (LT)	<.001	<.001
HbA1c	NS	NS
BMI	NS	NS
S.B.P.	NS	NS
D.B.P.	NS	NS

Conclusion: Prevalence of PAD in this study of North Indian population, as represented by ABI<0.9, is LOW as compared to western population. No significant correlation of ABI was observed with Hypertension and other traditional risk factors. ABI had strong correlation with brachial pulse wave velocity –important marker of sub clinical atherosclerosis. However low prevalence of ABI <0.9 observed in this study really questions all of us whether such screening for PAD in asymptomatic diabetes population should really be kept as an option in future or not.

D-0878

Prevalence of obstructive sleep apnea in patients with metabolic syndrome

A. Telner[1], A. Gervais[1]
[1] Carling Metabolic Syndrome Clinic, Metabolic Diseases, Ottawa, Canada

Aim: Recent studies[1] have shown an association between diabetes and obstructive sleep apnea (OSA). Since OSA increases a patient's risk of cardiovascular disease, hypertension and stroke, diagnosis and managing OSA is important, especially in patients with diabetes, who are already at increased cardiovascular risk. Prevalence studies for OSA in patients with metabolic syndrome are sparse. The objective of this study was to determine the prevalence of undiagnosed sleep apnea in patients with metabolic syndrome who were referred to a community interdisciplinary metabolic syndrome clinic.
Methods: Patients referred to the Carling Metabolic Syndrome Clinic[2] for comprehensive management of their metabolic syndrome[3] completed the Berlin Questionnaire[4] in order to assess their risk for OSA. Patients who screened positive in the Berlin Questionnaire test were offered a sleep study for definitive diagnosis.
Results: Of the 44 consecutive patients with metabolic syndrome referred between March 2008- August 2008, 22 (50%) were female and the mean age was 54.9 years (range 36-77). Twenty eight (64 %) had type 2 diabetes and 7 (16 %) had impaired fasting glucose. Five patients were already using CPAP for sleep apnea and hence did not complete the Questionnaire. Nineteen patients (43 %) had negative results on the Berlin Questionnaire. Twenty patients (45%) scored positive and were offered a sleep study. Two patients declined. Of the 18 patients who underwent the sleep study, 11 (61%) had a positive result (3 mild, 7 moderate, 1 severe), and 7 had negative sleep studies.
Conclusion: Eleven of 44 patients (25%) referred to a metabolic syndrome clinic had previously undiagnosed sleep apnea. Five of the 44 patients (11%) were already being treated for sleep apnea. Overall prevalence of OSA in this study was 36%. Results of this study support screening all patients with metabolic syndrome for OSA in order to decrease the morbidity and mortality of these chronic conditions.

Effects of dietary ω-3 polyunsaturated fatty acids and statins in the treatment of type 2 diabetes mellitus patients with cardiomyopathy

V. Serhiyenko[1], A. Urbanovich[1], A. Serhieynko[1], L. Serhiyenko[1], V. Segin[1]
[1] Medical University, Endocrinology, Lviv, Ukraine

Aims: To study the effect of simvastatin (SIM), ω-3 polyunsaturated fatty acids (ω-3 PUFA) and their combinations on heart rate variability (HRV), dynamics of biochemical parameters in Type 2 diabetic patients with diabetic cardiomyopathy (DCMP).
Methods: 86 patients with Type 2 DM and DCMP (51,2±4,3 years), BMI 26,3±2,79 kg/m2 were observed. Patients were allocated to three groups. Patients of group A (n=25) received SIM 20 mg tid; B (n=37) - capsules of fish oil [(1,0 g eicosapentaenoic (EPA), 1,0 g docosahexaenoic (DHA)] acid and 0,1% α-tocopherol acetate tid; C (n=24) - SIM 10 mg tid plus capsules of fish oil. All patients were on the same diet. The duration of the study was 3 months. Statistics: ANOVA.
Results: Lipid disorders [high level of total cholesterol (TC), low density lipoprotein-cholesterol (LDL-C), triglycerides (TG) and decreased level of high density lipoprotein-cholesterol (HDL-C) in the patients with DCMP is accompanied by a decrease of root mean square successive difference (RMSSD), QTc interval parameters. It has been discovered that the monotherapy by SIM is accompanied by negative dynamics of activity of enzymes of a liver that proved by of ultrasonic scanning. After 3 months of treatment there was a more significant positively influenced were observed in group C. In particular, the increasing of RMSSD parameters (4,72±0,53 ms and 6,81±0,63 ms-after treatment, p<0,001), low- (LF), high-frequency (HF) bands (859,7±12,6 ms^2 and 1134,6±17,4 ms^2, p<0,001), coefficient of variation (CV), (8,7±0,3 % and 6,2±0,2 %, p<0,001). The authentic decreasing of QTc interval parameters (0,57±0,069 and 0,52±0,057, p<0,05), the increasing activity of superoxide dismutase (10,94±0,22 mcmol GSH/min 1 g Hb, p<0,001) were observed in the group C (Table).

Mean % change from baseline at 3 months	SIM (n=25)	ω-3 PUFA (n=37)	SIM / ω-3 PUFA (n=24)
RMSSD, ms	+14,9	+23,6*	+44,1**
LF, ms^2	+11,3	+19,8*	+30,2**

Conclusions: Usage of SIM and ω-3-PUFA are accompanied by decreasing of clinical developments of DCMP, significantly improvement of the lipid profile, HRV, QTc interval parameters. The combination SIM and ω-3 PUFA allows a lower dose of SIM, that allows to recommend their combination in the treatment of lipid disorders in patients with DCMP.

Day-to-day variation of insulin requirements in type 2 diabetic patients with end-stage renal disease treated by maintenance haemodialysis

S.T. Enoru[1], E. Sobngwi[2], G. Ashuntantang[3], M. Dehayem[3], M. Azabji[3], A.E. Onana[3], G.E. Loni[3], M.D. Chobufor[3], D. Biwole[3], J.-C. Mbanya[3]
[1] *University of Yaounde 1, Internal medicine, yaounde, Cameroon*
[2] *Newcastle University Newcastle upon Tyne, Internal medicine, Newcastle, United Kingdom*
[3] *University of Yaounde 1, Internal medicine, Yaounde, Cameroon*

Background and aims: We aimed to evaluate day-to-day variations of insulin needs in Type 2 diabetic patients with end-stage renal failure on maintenance haemodialysis (HD), as significant glycaemic excursions are frequent in this population.
Materials and methods: We developed a 24-hour euglycaemic clamp applicable to free living conditions in patients receiving 2200 calories with 55% carbohydrate in a standardized 3-meal and 2-snack regimen per day. Insulin was infused intravenously at variable rates, adjusted every 30 minutes to clamp the glycaemia at 5.55±1.11mmol/l over 24 hours pre-HD, during HD session, and 24 hours post HD. We studied 10 volunteers (6 men and 4 women, age: 55.7±8.7 years, duration of DM: 11.9±4.5 years, BMI: 22.7±4.5kg/m2, dry weight: 61.6±10.7 kg, duration of HD: 2.3±2.3 years).
Results: The mean capillary glycaemia was 5.5±0.3mmol/l pre-HD and 5.3±0.2mmol/l post-HD (p=0.39). This was achieved with the infusion of 23.6±7.7 IU/24h pre-HD vs. 19.9±4.9 IU/24h post-HD, indicating an overall 15.3% decrease (p=0.09). The basal insulin needs per hour were decreased significantly from 0.4±0.1/hour pre-HD to 0.3±0.1/hour post-HD (p=0.01). The total boluses were decreased by 2.2±3.1 IU (-18.6%, p=0.15). The change in blood urea induced by HD did not correlate with the change in daily insulin needs (r=0.1, p=0.79).
Conclusion: In conclusion, the 15% reduction in insulin needs to achieve normoglycaemia after versus before HD observed in these type 2 diabetic patients, being equivalent to almost 4 IU per day, is likely to be clinically significant despite marginal statistical significance. Further investigations with intermittent subcutaneous protocol based on the present results are warranted to further guide clinical practice recommendations.

The efficacy of N-acetylcysteine in preventing contrast-induced nephropathy in type 2 diabetic patients without nephropathy

F. Sar[1], T. Saler[1], A. Ecebay[1], R. Kazancioglu[2], Z.A. Saglam[1], S. Kurnaz[1]
[1] *Haseki Training and Research Hospital, Internal Medicine, Istanbul, Turkey*
[2] *Haseki Training and Research Hospital, Nephrology, Istanbul, Turkey*

Aim and introduction: Contrast media presentation to T2DM individuals with nephropathy intensifies the deterioration of renal function. N-acetylcysteine (NAC) is reported to have potential for contrast-induced nephropathy (CIN) prevention but there isn't enough study on diabetic patients without nephropathy. The aim of this study was to assess the efficacy of NAC for preventing CIN in T2DM without nephropathy.
Materials and method: A total of 45 patients without any pre-existing renal impairment (serum creatinine: SCr <1,1mg/dl) who were undergoing a computerized tomographic investigation and would be receiving radio-opaque medication (300 mg iohexaol/100 ml) were enrolled. They were randomized to have either high-dose NAC (1,200 mg) and hydration prophlaxis (Group 1; n = 25; M/F=13/12; age: 59,3±10,9 yrs) or only hydration (Group 2; n = 20; M/F= 11/9; age: 55,5±13,3 yrs). The creatinine levels were determined 48 hours later and the relationship between pre- and postprocedural creatinine was investigated.
Result: Both groups were analyzed for any rise in SCr. In Group 1 SCr decreased from 0,83 to 0,79 mg/dl, whereas SCr increased from 0,81 to 0,94 mg/dl in Group 2 (p>0,05 for both). However there was a significant difference between the creatinine dispcrepancies of two groups (p=0,03). Furthermore, the groups were analyzed according to overall incidence of CIN defined as: 1) 0,3 mg/dl elevation of creatinine from baseline or 2) an increment of 20% over baseline creatinine. The increase of SCr in Group 2 was significantly higher than in Group 1 in terms of the second definition (p=0,045).
Conclusion: Adding NAC to hydration seems more beneficial than hydration alone in preventing contrast-induced renal function deterioration in T2DM patients without nephropathy.

Diabetes mellitus has an additive effect on vascular calcification in chronic kidney disease

K. Beard[1], L. Ferreira[2]
[1] *Agro Health Associates Inc., Market Access, Burlington, Canada*
[2] *Genzyme Canada Inc., Director - Renal, Mississauga, Canada*

Aims: More than 2 million Canadians have Diabetes Mellitus (DM) and its prevalence is increasing. DM is the leading cause of chronic kidney disease (CKD) and end-stage renal disease (ESRD), and 40% of all patients on dialysis have diabetic nephropathy. Furthermore, 2-year survival rates are markedly reduced for dialysis patients with DM compared to those without DM. Cardiovascular disease (CVD) is the leading cause of death among patients with DM and/or CKD. Vascular calcification, which is a common feature of CKD, dialysis and DM, predicts mortality and may contribute to future outcomes. Patients with DM are more likely to develop macrovascular calcification than those without DM. Furthermore, medial arterial calcification has been shown to be a strong independent predictor of total CVD and of future CV events, strokes and amputations among patients with DM. The aim of this review was to compare the prevalence of vascular calcification among CKD patients in the presence and absence of DM.
Methods: A literature search using MEDLINE was conducted using the following terms: DM, CKD, ESRD and calcification. Studies reporting the prevalence or scoring of vascular calcification (i.e., aortic calcification index (ACI), coronary artery calcification score (CACS)) were used for data extraction.
Results: The prevalence of vascular calcification among CKD patients with DM was greater than in patients without DM: 54% to 92% vs. 8% to 54% (n=5 studies). DM was associated with increased ACI among CKD patients compared to patients without DM: 27% to 57% vs. 7% to 45% (n=2 studies). In addition, a greater proportion of patients with DM and CKD had CACS equal to or greater than 400 than those without DM: 28% to 55.7% vs. 3.5% to 6.9% (n=2 studies).
Conclusions: DM is associated with increased prevalence and severity of vascular calcification among patients with CKD. Given that vascular calcification is associated with poorer outcomes among DM and CKD patient populations, the additive effect of DM on vascular calcification among patients with CKD may hold greater significance. Further research on the effect of vascular calcification on patient outcomes and the prevention of its progression in DM and CKD is required.

Androgen versus erythropoietin for the treatment of anemia of predialysis diabetic chronic kidney disease (CKD)

A.J.I.T. A.K. Paul[1], Z. Prof. Zafar A. Latif[2], F. Dr. Md. Feroz Amin[2], S. Dr. Sarwar Iqbal[2], A. Dr. S.M. Ashrafuzzaman[2]
[1] *Comilla Diabetes Hospital, Endocrinology, Comilla, Bangladesh*
[2] *BIRDEM, Endocrinology, Dhaka, Bangladesh*

Aims and objectives: Chronic kidney disease is a microvascular complication of DM. Anemia is an important clinical manifestation to treat in chronic kidney disease. Many subjects with poor socio-economic status having CKD and anemia in a developing country can not afford the treatment with erythropoietin(EPO). This study was designed to see the efficacy of nandrolone in comparison with recombinant human erythropoietin (rh EPO) for management of anemia of predialysis diabetic chronic kidney disease. Initially 118 subjects were interviewed. All were explained about both the options of treatment modalities. On the basis of their consent they are divided into two groups.
Methods: Sixty adult diabetic patients with anemia of chronic kidney disease on conservative treatment were enrolled. Patients were divided into two groups (1 and 2) of 30 patients each. Group 1 patients received nandrolone deaconate 50 mg deep intramuscular and Group 2, recombinant human erythropoietin 100 IU per kilogram of body weight subcutaneously once weekly. Patients of both groups received oral supplements in order to maintain body iron stores.

All the relevant hematological and renal parameters were evaluated at the end of 3rd and 6th month.

Result: There was a statistically significant rise in hemoglobin concentration, packed cell volume, in both groups. The rise in hemoglobin concentration in Group 2 was more marked than in Group 1, at the end of 3rd (Group 1, 9.59-1.13 vs Group 2, 10.51-1.23; p value 0.004), and 6th months, (Group 1, 10.8-1.26 vs Group 2, 11.36-0.97; p value 0.057). Hemoglobin raised significantly in Group 1, at the end of 3rd & 6th months (8.61-0.94 vs 9.59-1.13; p value 0.001 and 8.61-0.94 vs 10.8-1.26; p value 0.001) & also in Group 2 (8.31-0.91 vs 10.51-1.23; p value 0.001 and 8.31-0.91 vs 11.36-0.97; p value 0.001). Packed cell volume was increased similarly like hemoglobin. Role of nandrolone on glycemic status was evaluated by HbA_1c & reduced in both groups, but significantly (p value 0.012) at the end of 6th months, on Group 1 than Group 2. Nutritional parameters of nandrolone was evaluated by albumin level, and showed significant increase (p value 0.001) in albumin level in relation with erythropoietin at the end of 3rd and 6th months.

Conclusion: Nandrolone, though not equally effective as erythropoietin, may be considered as a valid alternative therapy for the treatment of anemia of predialysis diabetic chronic kidney disease, specially for low socioeconomic population, to make the treatment more cost effective. Further study is needed to see the safety and efficacy for longer duration of treatment with nandrolone in diabetic CKD.

Impaired erythropoietin response to anemia in diabetic nephropathy

S. Martynov[1], M. Shestakova[1], A. Ilyin[2], M. Arbuzova[2], A. Knyazeva[2], I. Dedov[3]

[1] Endocrinology Research Centre, Diabetic Nephropathy and Dialysis, Moscow, Russia

[2] Endocrinology Research Centre, Central Biochemical Laboratory, Moscow, Russia

[3] Endocrinology Research Centre, Endocrinology Research Centre, Moscow, Russia

Background and aims: Diabetic nephropathy (DN) is associated with early development of anemia compared to chronic kidney disease (CKD) of other etiology. The main cause of anemia in CKD is deficiency of erythropoietin (EPO) production by damaged kidneys. The purpose of the study is to determine serum EPO level and its response to anemia in patients (pts) with DN.

Materials and methods: 131 pts with DN were studied (47 pts with diabetes mellitus (DM) type 1 and 84 with DM type 2) - 66 males, 65 females, mean age 50.6±14.7). Among them 59 pts had microalbuminuria, 72 macroalbuminuria. Glomerular filtration rate (GFR) was calculated using the Cockcroft-Gault formula. Renal function was evaluated according to stage of CKD of National Kidney Foundation-Kidney Disease Outcomes Quality Initiative (NKF/KDOQI) - 36 pts had GFR ≥90 ml/min/1.73 m^2, 44 pts had GFR 60-89 ml/min/1.73 m^2, 32 pts had GFR 30-59 ml/min/1.73 m^2 and 19 pts were with GFR 15-29 ml/min/1.73 m^2. Anemia was defined as hemoglobin (Hb) < 13.5 g/dl in men and < 12.0 g/dl in women by the definition of anemia for CKD by NKF/KDOQI. The prevalence of anemia in total group was 45.0% (59 pts). Serum EPO was measured using ELISA and the laboratory normal range of serum EPO was 4.3-32.9 mIU/ml (Biomerica). Pts with GFR<15 ml/min and treated by erythropoietin-stimulating agents were not included.

Results: Mean EPO level was similar in pts with anemia and without anemia 7.6±4.4 mIU/ml and 8.4±5.5 mIU/ml, respectively. We did not find significant differences of EPO concentration in anemic and non-anemic pts with microalbuminuria (9.0±4.2 mIU/ml and 8.5±5.8 mIU/ml, respectively) and macroalbuminuria (7.3±4.4 mIU/ml and 8.2±5.0 mIU/ml, respectively). Comparison of the level of EPO based on stages of CKD and between pts with micro- and macroalbuminuria also did not find significant discrepancy in EPO value. The significant physiological inverse correlation of EPO and Hb was found for pts with GFR=60 ml/min/1.73 m^2 (R=-0.25; p<0.05). And the intensity of correlation between EPO and Hb increased when GFR level enhanced: GFR=70 ml/min/1.73 m^2, R=-0.32; p<0.01, GFR=80 ml/min/1.73 m^2, R=-0.40; p<0.01 and at GFR=90 ml/min/1.73 m^2, R=-0.51; p<0.01. No correlation of EPO and Hb was observed in pts with GFR<60 ml/min/1.73 m^2.

Conclusion: The renal EPO production in DN pts with anemia is not elevated and remains inappropriately at the same level as in pts without anemia. Low response of EPO expression to anemia is observed when moderate decrease of GFR develops (GFR < 60 ml/min/1.73 m^2) and mainly is related with early disturbance of EPO production by interstitial cells of kidneys and other factors which may affect EPO metabolism in diabetes (neuropathy, inflammation, hyperglycemia etc.).

Putting research into action in indigenous communities: improving public health practices and slowing the epidemic of ESRD in American Indians and Alaska Natives

K. Acton[1], K. Sheff[1], D. Gohdes[1]

[1] Indian Health Service, Division of Diabetes Treatment & Prevention, Albuquerque, USA

Epidemiologic studies of diabetes have been conducted in many indigenous communities. Translating the findings and techniques from research studies into preventive care is a key step to ensure that indigenous communities reap the benefits from these studies. In 1986, using health data from its outpatient facilities that serve 1.6 million American Indians and Alaska Natives (AI/AN) from 557 federally-recognized tribes in 35 states, the Indian Health Service (IHS) developed an annual audit of diabetes care and outcomes which reflects the risk factors for diabetes complications such as end stage renal disease (ESRD). A random sample of charts from the local registry is audited yearly either by hand or electronically to assess the implementation of current IHS Standards of Care for Diabetes. The Standards, created in 1986, are updated every two years and revised as research findings are published. In 1993 the IHS Standards of Care revision included recommendations to test for albuminuria, as epidemiologic studies had shown it to be associated with kidney failure in longitudinal studies of the Pima Indians. Subsequent revisions encouraged IHS providers to use the Albumin/Creatinine ratio and later the e-GFR to monitor for early kidney disease and treat more aggressively. From 1995 to 2004, rates of albuminuria screening in AI/AN with diabetes increased from 2% to 85%. In 1996 monitoring for use of ACE inhibitors/ARBs was added when studies showed that these agents could delay or prevent the onset of diabetic nephropathy. Rates of ACE/ARB use increased from 25% in 1996 to 69% in 2004. In 2004, 52% of AI/AN with diabetes had mean blood pressures below 140/90 mm Hg; mean systolic BP was 132.9 mm Hg and mean diastolic BP was 74.9 mm Hg. The United States Renal Data System (USRDS) monitors incidence of ESRD in the US by diagnosis and ethnicity. According to the USRDS, from 1994 to 2004 the age-adjusted diabetes-related ESRD incidence in AI/AN increased from 358.6 per million to a peak of 440.4 per million in 1999; by 2004 the incidence had decreased to 362.4 per million, and the decrease was attributed to improved diabetes management and reduction of other risk factors. Indigenous communities can benefit from the knowledge gained in studies by adapting information systematically to the local context and monitoring the implementation of preventive care.

Association of left ventricular remodeling and chronic kidney disease in type 2 diabetic patients

K. Sakai[1], A. Sato[1], M. Harada[1], T. Kunugi[1], M. Yoshino[1], Y. Iwamoto[1]

[1] Tokyo women's medical university, Diabetes center, Tokyo, Japan

Background and aim: Left ventricular (LV) hypertrophy is an independent risk factor of morbidity and mortality in cardiovascular disease. Chronic kidney disease (CKD) is also a substantial risk of cardiovascular disease. Recently, stage of CKD is classified by estimated glomerular filtration rate (eGFR). LV mass is known to increase with progression of CKD stage in diabetic patients. The aim of this study is to evaluate the effect of CKD on LV remodeling in patients with type 2 diabetes mellitus.

Subjects and methods: Echocardiography was performed in consecutive 304 type 2 diabetic patients (199 men, age 59±13 years (mean±SD)) from January to December in 2005.

We measured LV ventricles by M-mode echocardiography, and calculated LV mass according to Penn's formula and indexed by body surface area (LVMI). LV remodeling was classified normal(N), concentric remodeling(CR), eccentric hypertrophy(EH) and concentric hypertrophy(CH) by LVMI and relative wall thickness. Stage of CKD was defined by eGFR according to the formula for Japanese ($0.741 \times 175 \times Age^{-0.203} \times Cr^{-1.154}$ (Female × 0.742) mL/min/1.73m^2), and stage(S) of CKD were classified as following eGFR;S1: ≥90, S2:60-89, S3:30-59, S4:15-29, S5:<15 mL/min/1.73m^2. We assessed the presence of

retinopathy and hypertension. Hypertension was defined as systolic blood pressure >140, diastolic blood pressure>90mmHg or taking antihypertensive drugs. BMI, HbA_{1c} and urinary albumin creatinine ratio (ACR) were measured.
Results: 304 type 2 diabetes patients were classified by stage of CKD, S1:53, S2:106, S3:68, S4:19, S5:58. The average LVMI increased with progression of CKD stage. (S1:104±24, S2:112±26, S3:118±30, S4135±29, S5153±36g/m^2, respectively). The proportion of LV remodeling classification in each CKD stage were S1(N 53, CR 13, EH 25, CH 9%), S2 (N 42, CR 13, EH 27, CH 18%), S3 (N 45, CR 10, EH 27, CH 18%), S4 (N 11, CR 21, EH 36, CH 32%), and S5 (N 16, CR 2, EH 54, CH 28%). On LV remodeling, around a half of patients was normal in CKD stage 1, 2 and 3, and high reverence of EH was shown in CKD stage 4 and 5.
We evaluated clinical factors for LV remodeling in each CKD stage by one-way analysis of variance. In S1 and S2, there were significant differences about age(N:57±12, CR: 61±12, EH: 61±11, CH: 65±12 years ($p<0.05$)) and hypertension(N 44, CR 62, EH 81, CH 71% ($p<0.01$))among LV remodeling. There were significant differences about BMI(N:24.9±3, CR: 22.6±4, EH:27.1±5, CH:27.6±5kg/m^2 ($p<0.05$)) in S3, and eGFR((N:11±6, CR:21±10, EH:10±7,CH:12±7ml/min/1.73m^2 ($p<0.05$)) in S4 and 5.
Conclusion: The LV remodeling progresses from N to EH with deteriorating CKD stages in type 2 diabetic patients. It suggests that a good control of blood pressure in early stage of CKD may play an important role for prevention of EH.

Influence of insulin resistance on blood pressure level and on kidney function

H. Baïzri[1], C. Garcia[1], J.P. Le Berre[1], L. Bordier[1], O. Dupuy[1], B. Bauduceau[1], H. Mayaudon[1]
[1] Hôpital Bégin, Endocrinologie, Saint Mandé, France

The purpose of this study was to assess the consequences of insulin resistance on blood pressure level and on urinary albumin excretion rate (UAE).
Methods: This study included 1936 non diabetic male subjects, mean age 37.8 ± 8 years. They were divided into two groups according to whether their abdominal circumference was less (group 1, N = 1722) or more (group 2, N = 241) than 102 cm, according to the NCEP-ATPIII criteria for abdominal obesity diagnosis. Insulin resistance was assessed by the HOMA index (Homeostasis Model Assessment = fasted insulin x fasted glycaemia / 22.5). Renal effect was appreciated by measurement of urinary albumin excretion rate.
Results: Subjects in group 2 were older than those in group 1 (42.4 ± 8.4 vs. 37.2 ± 8.6 years, $p<0.001$) and HOMA index was significantly increased (3.54 ± 2.35 vs. 1.72 ± 1.06, $p<0.001$). This index of insulin resistance was correlated with the waist circumference ($r=0.493$, $p<0.0001$). The blood pressure in group 2 subjects was significantly higher than in group 1 (SBP: 135 ± 14 vs. 125 ± 13 mmHg, $p<0.001$ and DBP: 82 ± 12 vs. 77 ± 9 mmHg, $p<0.001$). SBP and DBP were correlated with waist circumference ($r=0.256$, $p<0.0001$ for the SBP and $r=0.263$, $p<0.0001$ for DBP) and HOMA index ($r=0.215$, $p<0.0001$ for SBP and $r=0.210$, $p<0.0001$ for DBP). The waist circumference and HOMA index both explained 10% of BP variance with a major contribution of waist. The UAE of group 2 patients was significantly higher than those of group 1 (10 ± 20 vs. 18 ± 42 mg/l, $p<0.01$). It was correlated to HOMA index ($r=0.231$, $p<0.0001$), to the SBP ($r=0.178$, $p<0.0001$) and to the DBP ($r=0.144$, $p<0.0001$), these two first parameters explaining 7% of UAE variance.
Conclusion: Abdominal obesity was a cause of insulin resistance. Abdominal obesity and insulin resistance were both implicated in the increase of BP. In these patients, recorded UAE increase was either due in part to this increased blood pressure and also to insulin resistance, and is usually associated with an increased cardiovascular risk.

Chronic kidney disease, but not metabolic syndrome, is a risk factor for cardiovascular disease in Japanese patients with type 2 diabetes. The Otowa Hospital Diabetes Observational Study 1 (OHDOS 1)

K. Inoue[1], Y. Inoue[1], T. Shimada[2], M. Shigemoto[1], C. Takagi[1], K. Doi[1]
[1] Rakuwakai Otowa Hospital, Department of Endocrinology and Metabolism, Kyoto, Japan
[2] Kyoto University Graduate School of Medicine and Public Health, Department of Epidemiology and Healthcare Research, Kyoto, Japan

Aims: Type 2 diabetes is a potent risk factor for cardiovascular disease (CVD). Recently chronic kidney disease (CKD) is increasingly recognized as an independent risk factor for CVD in the general population. In the same population, metabolic syndrome (MetS) is also associated with an increased risk of CVD. We conducted a retrospective chart review to investigate the clinical significance of CKD and MetS for atherosclerosis in Japanese patients with type 2 diabetes.
Methods: Overall 568 consecutive outpatients with type 2 diabetes who came to Rakuwakai Otowa Hospital in Kyoto, which is a teaching hospital with 588 beds, in 2003 were studied retrospectively for 6 years or until they experienced a cardiovascular event or died. CVD during follow-up was defined as myocardial infarction, angina, silent myocardial ischemia and stroke. Renal function was evaluated by estimated glomerular filtration rate (eGFR), proteinuria and urinary albumin. MetS was diagnosed using the International Diabetes Federation criteria. Statistical analysis was performed by Cox proportional hazard model to estimate hazard ratios of CKD and MetS.
Results: The mean age of 568 patients was 63±12 years. Approximately 38% of patients were women (350 men and 218 women). Median duration of diabetes were 10.0±9.7 years, and 21% of patients were taking aspirin. One hundred twenty patients had CKD (21.1%) and 233 patients had MetS (41.4%). The mean glycated hemoglobin (HbA1c) was 7.4%. HbA1c of patients with CKD was 7.3±1.2% and 7.4±1.4% in patients without CKD. HbA1c of patients with MetS and without MetS was both 7.4±1.4%. After 6 years follow-up, CKD had increased CVD risks (hazard ratio, 1.80; 95% confidence interval [CI] 1.13 to 2.86; p=0.013). However, MetS had not increased CVD risks (hazard ratio, 0.71; 95% CI 0.46 to 1.10; p=0.124).
Discussion/conclusion: CKD is associated with CVD risk factors, such as diabetes, dyslipidemia and hypertension. In addition, reduced renal function may be associated with increased levels of atherogenic risk factors, such as oxidative stress, inflammation and so on. On the other hand, It is reported that MetS is closely associated with low-grade adipose tissue inflammation that potentiates insulin resistance. MetS is characterized by visceral obesity, insulin resistance, and hypertension contributing to endothelial dysfunction and, subsequently, to accelerated atherosclerosis. In this study, our findings indicate that CKD was a risk of CVD in Japanese patients with type 2 diabetes. This result means that CKD is an independent risk factor for CVD in not only the general population, but also type 2 diabetes patients. Meanwhile, we suggested that MetS was not strongly associated with CVD in type 2 diabetes patients. In conclusion, diabetes is a strong risk factor for atherosclerosis and CKD, and CKD accelerates atherosclerosis in diabetic patients.

Diabetes in children

D-0889

Increasing prevalence of overweight at onset of childhood type 1a (autoimmune) diabetes mellitus

I. Libman[1], V. Arena[2], C. Baldwin[1], S. Brooke[1], P. Balfour[1], D. Becker[1]
[1] *Children's Hospital of Pittsburgh, Pediatric Endocrinology and Diabetes, Pittsburgh, USA*
[2] *Graduate School of Public Health University of Pittsburgh, Statistics, Pittsburgh, USA*

Aims: We have previously reported that in children with insulin-treated diabetes mellitus at onset of their disease, the prevalence of being overweight more than tripled from 1979-1989 (period I) to 1990-1998 (period II). The current study evaluates whether this increase has continued in the period 1999-2006 (excluding the year 2003) (period III), focusing on those with evidence of autoimmunity.
Methods: All Black children < 19 years of age, diagnosed with diabetes and treated with insulin at onset, admitted to Children's Hospital of Pittsburgh during three periods (period I: 01/01/79-12/31/89; period II: 01/01/90-12/31/98 and period III: 01/01/99-12/31/06) were matched with White children by sex, age at onset and year of diagnosis. Data were obtained from retrospective review of medical records and ß-cell antibodies (ICA, GAD65, IA-2 and insulin autoantibodies) measured at onset. Overweight was defined as body mass index >= 85th percentile for age and sex.
Results: Data were available for 298 children out of 376 (79%). Overall, the prevalence of being overweight more than tripled from period I, 12.6% to period II, 36.8% increasing further to 41.1% in period III (p=0.001). Mean BMI percentile increased from 40.4 ± 36.2 in period I, to 58.8 ± 37.6 in period II and 60.4 ± 39.9 in period III (p=0.003). ß-cell antibodies were available for 219 (74%), of which 173 (78%) had at least one positive. This was similar in the three periods (81%, 76% and 87% in periods I, II and III respectively).
The prevalence of overweight (%) by period and antibody status is seen in the table below.

Prevalence of overweight	Period I	Period II	Period III
>= 1 autoantibody positive (n=173)	5%	25%	31%*
Absent antibodies (n=46)	46%	70%	75%

*p=0.002

The increase in prevalence of overweight was more noticeable in the African American children with autoimmunity (7.4% to 38% to 46% in the the the three periods respectively, p=0.008) vs Whites (3.2% to 14.1% to 18.7%, p=0.18). There was no significant difference in frequency of ketoacidosis between the three periods (36% vs 37% vs 39% respectively, p=0.92). The frequency of metformin plus insulin at follow up increased from period I (7.6%%) to period II and III (27% and 18% respectively, p=0.09). Five percent of children with evidence of autoimmunity were placed on metformin in addition to insulin.
Discussion/conclusion: The phenotype of children with insulin-treated diabetes at onset is changing. A third of children with type 1a (autoimmune) diabetes mellitus are now overweight despite frequent onset weight loss. The rise is greatest in African American children with evidence of autoimmunity. Prospective studies may determine whether this weight excess is related to the continued increase in type 1a diabetes incidence or if it affects rates of complications.

Increased hepatic and skeletal muscle triglyceride content is associated with insulin resistance in adolescents

B. Wicklow[1], K. Wittmeier[1], A. Mackintosh[1], E. Sellers[1], H. Dean[1], J. McGavock[1]
[1] *Manitoba Institute of Child Health, Endocrinology and Metabolism, Winnipeg, Canada*

Background: Excessive triglyceride accumulation in non-adipocytes is being elucidated as an important biomarker of glucose intolerance. Little information exists describing determinants of hepatic and muscle triglyceride in youth. This observational study of 78 normoglycemic adolescents classified as either healthy weight or overweight aimed to describe anthropometric and biochemical characteristics of youth considered at risk of glucose intolerance based on liver and muscle steatosis.
Methods: Hepatic and muscle triglyceride content was determined non-invasively with ^{1}H-magnetic resonance spectroscopy, allowing for discrimination of intracellular lipid accumulation. Percent body fat (DEXA), height, weight, and waist circumference were measured to assess anthropometric variables. Serum triglycerides and free-fatty acids during an oral glucose tolerance test were measured to investigate the association between level of lipemia and organ triglyceride content.
Results: We studied 63 overweight (BMI Z score: 1.9 ± 0.5) and 15 healthy weight (BMI Z score: 0.2 ± 0.6) adolescents aged 13-18yrs (mean 16± 2 yrs). Multiple linear regression analyses revealed hepatic lipid content was positively associated with percent body fat (p 0.05), BMI z score (p 0.001), and serum triglyceride levels (p 0.001). Muscle triglyceride content was not significantly associated with either anthropometric variables or serum triglyceride concentrations. Interestingly, hepatic and muscle triglyceride content were only modestly associated with one another, suggesting the potential for a unique pathogenesis of lipid accumulation in these organs.
Conclusions: 1H-magnetic resonance spectroscopy is a reliable method to non-invasively measure intracellular lipid content, and may be useful to advance future study of tissue steatosis. Our data suggest serum triglyceride levels and generalized adiposity (% body fat and BMI) are critical determinants of hepatic steatosis in adolescents. Lack of association of these variables with muscle steatosis suggests a unique as yet undetermined process which requires further study. Interventions aimed at reducing serum lipid, and percent body fat may reduce tissue lipid content, and the progression of glucose intolerance in youth.

Monitoring of diabetes care in children with diabetes aged 0-18yrs in Georgia

K. Amirkhanashvili[1], T. Lapanashvili[1], N. Bikashvili[1], N. Shengelia[1], R. Kurashvili[2], L. Tsutskiridze[2], E. Shelestova[2]
[1] *Diabetic Childrens Protection Association da Jamrteloba/ Georgian Diabetes Center, Endocrinology dept., Tbilisi, Georgia*
[2] *Georgian Diabetes Center, Clinical care, Tbilisi, Georgia*

All children with diabetes in Georgia, aged 0-18yrs are registered at the DChPA, where following data were accumulated for 2004-2008: 2004–577 children registered (fresh diabetes mellitus (FDM)–62, girls–35, boys–27), 2005–581 children (FDM–63, girls–31, boys–32), 2006-594 children (FDM–81, girls–38, boys–43), 2007-602 children registered (FDM–85, girls–32, boys–53), 2008–639 children (FDM–70, girls–39, boys–31). In 0-18yr age group mean annual HbA1c levels were: 2004–9.56%, 2005–10.23%, 2006–9.25%, 2007–9.5%, 2008–9.16%. Following 4 groups (Gr.) were separated: Gr.1– age 0-5yrs; n=19; HbA1c (2006-2008)–7.93%, 8.88%, 8.86%, respectively. Gr.2–age 6-9yrs; n=74; HbA1c (2004-2008)–9.98%, 10.16%, 9.15%, 9.03%, 8.81%, respectively. Gr.3–age 10-11yrs; n=152; HbA1c (2004-2008)–9.44%; 9.95%, 9.0%, 9.16%, 9.04% respectively. Gr.4–age 14-18yrs; n=316, HbA1c (2004-2008)–9.58%, 10.34%, 9.75%, 9.31%, respectively. Fundus examinations were performed in all children once in 6 months. We found that 40 children had diabetes complications (retinopathy–29, cataract–11). Tuberculosis was diagnosed with Mantoux test PPD (K14/23, K997 biopreparation). Positive reaction had 36 DM children, all had tubintocsication (MGB negative). Their HbA1c (2004-2008) was: 9.5%, 10.28%, 9.52%, 9.26%, 9.2%, respectively. Eight children had extra-pulmonary MGB positive form, HbA1c–10.2%, 12.76%, 10.21%, 9.95%, 9.26%, respectively; 2–pulmonary MGB negative one; HbA1c (2005-2007)-8.45%, 8.34%, 8.95%, respectively; and 2 more-pulmonary MGB positive form, HbA1c (2003-2007)-10%, 11.03%, 10.78%, 11.19%, 9.33%, respectively. In all cases standard antituberculosis therapy was carried out. Positive clinical and X-ray changes were observed 2 months post treatment, complete reconvalescation - 6 months post treatment.

Longitudinal growth in children with diabetes mellitus type 1

M. Altamirano[1], N. Altamirano[2], A. Valderrama[2], C. Robles[2], R. Calzada[2], H. Montesinos[2], C. Cuevas[3]
[1] *Centro Médico Nacional Siglo XXI IMSS, Unidad de Economía de la Salud, Mexico DF, Mexico*
[2] *Instituto Nacional de Pediatría, Servicio de Endocrinología, Mexico DF, Mexico*
[3] *Universidad Anáhuac, Escuela de Actuaria, Mexico DF, Mexico*

Introduction: The diabetes mellitus type 1 (DM1) is one of the most frequent metabolic illnesses in children. The measurement of growth is a fundamental parameter in the follow up of the children with DM1. The objective of the study was to determined the growth pattern and its alterations in patients with DM1.
Methodology: We reviewed the clinical files of the patients from the endocrinology services at the INP with diagnosis of DM1.
Results: We studied 264 patients with diagnosis of DM1. 116 (43.9%) male and 148 (56 %) female, with an average age at the time of diagnosis of 8.5 years ± 4.0 years (3 months -189 months), and evolution time of 6.1 years (4-210 months).
The graphic appearance of the height and weight curves suggest that the varianzas of both characteristics according to the age. The height at time of diagnosis in the girls was similar to that of the boys pz -0.54 (-1.89 a 0.8 d.e.) versus 0.14 (-2.7 a 2.7), respectively. The boys weighed more than the girls 45.7 (18.3-81) pc 75 (5-95) versus 40.3 (18.7-75) pc 50 (10-95).
The height correlated inversely with the HbA1c (r= 0.8, p = 0.000). The weight correlated directly with the height (r = 0.955, p = 0.000). The speed of growth in the group with better metabolic control HbA1c < 9% increases significantly after seven years compared with the group with bad metabolic control HbA1c ≥ 9%. (6.9 ± 2.3 cm/year versus 4.4 ± 2.1 cm/year,) (p = 0.003) respectively.
Conclusions: Growth is significantly altered in children and teenagers with DM1. The pubertal peak is less and so the linear growth diminishes from the first year of evolution without a clear correlation between changes in metabolic control and weight.

The use of premixed 30/70 insulin in high risk youth with type 1 diabetes: a quality audit

N. Van Walleghem[1]
[1] *Health Sciences Centre, Diabetes Education Resource for Children and Adoelscents, Winnipeg, Canada*

Aim: To determine if the use of premixed 30/70 insulin reduced the incidence of DKA without deterioration in glycemic control or causing severe hypoglycemia in a group of high risk youth with T1DM.
Methods: 25 youth were identified sequentially in a 6 year period (2002-2008) who had suspected, deliberate insulin omission, A1c consistently >10%, recurrent DKA or an inability or unwillingness to use a more physiological insulin regimen. Glycemic control, measured as A1c, was evaluated at the initiation of premixed 30/70, 1 year after 30/70 start and at the most recent clinic visit using paired *t* tests. Incidence rates of acute complications were calculated. DKA was defined as a pH≤ 7.35 and $HC0_3$ <15. Severe hypoglycemia was defined as loss of consciousness or seizure.
Results: At initiation of 30/70, the youth (52% male) had a mean age of 14.5 years (range 12-17 years). Mean duration of diabetes was 5.2 years (range 2 months to 15.1 years). 12 youth switched from a TID regimen, 7 from a BID regimen, 5 from a basal-bolus regimen and 1 from an insulin pump. 15 youth (60%) had involvement with child welfare agencies. Mean follow-up was 15.1 months (range 2 months to 4.6 years). For the females (n=12), mean A1c decreased 0.87% by one year and 0.69% by their most recent clinic visit. For youth who had used 30/70 for ≥1 year (n=16), mean A1c did not change during the first year (11.51% at 30/70 initiation vs. 11.64% after one year). However, mean A1c decreased significantly by their most recent visit (-0.78%, p<0.05). Mean follow-up was 21.4 months (range 12 months to 4.6 years). There was 1 case of severe hypoglycemia (3.24 cases per 100 pt-yrs), and 8 episodes of DKA (25.90 cases per 100 pt-yrs). There were no deaths. It is difficult to determine if the use of 30/70 prevented DKA in youth at the DER-CA. Prior to switching to 30/70, 6 of these youth had at least one episode of DKA in the preceding 24 months; with the exception of one youth, none had DKA after switching to 30/70. 5 youth, none of whom had a prior history of DKA, each experienced one episode of DKA after switching to 30/70. In this group, it is arguably a victory to have minimized their individual risk of DKA to one case each.
Conclusions: The use of premixed 30/70 insulin is a viable option for high risk youth with T1DM. Although, the incidence rate for DKA for these youth using 30/70 insulin is almost 7 times that found in the overall population of children with T1DM at the DER-CA, this report suggests that 30/70 may be effective in increasing adherence to insulin injections without increasing severe hypoglycemia or worsening glycemic control; 72% of youth had an improved or unchanged A1c while using 30/70.

The first experience of insulin detemir in Georgia

K. Amirkhanashvili[1], R. Kurashvili[2], G. Amirkhanashvili[1], T. Lafanashvili[1], N. Bikashvili[1], N. Shengelia[1], M. Khutsishvili[1], G. Kurashvili[2]
[1] *Diabetic Children's Protection Association, Endocrinology, Tbilisi, Georgia*
[2] *Georgian Diabetes Center, Endocrinology, Tbilisi, Georgia*

The aim of this work was to define efficacy of basal Insulin Detemir and NPH in patients with Type 1 Diabetes during intensive insulin therapy.
Materials: The study comprises of 111 patients with Type 1 Diabetes of 14-22 years of age. Subjects received Insulin Detemir (Det) or NPH once daily, plus human insulin at mealtimes for 24 weeks. In the first Group were included 53 patients on Det, Gr. 2 – 58 patients – on NPH. Gr. 1 age – 19.5 ± 1.69 yrs, diabetes duration 8.3 ± 2,16 yrs, HbA1c – 9,0 ± 1,51%. The patients performed glycemic self-monitoring (3 days per week– 6-7 measurements).
Results: HbA1c level decreased in both groups: in Gr. 1 – by 1.39% (p=0,000), Gr.2 – by 1.38% (p=0.000). Fasting gl. (FG) in both groups at the baseline was: Gr. 1 – 198.2 ± 20.8 mg/dl and Gr. 2 – 201.5 ± 24.9 mg/dl (p=0.876), and after 24 weeks FG level decreased in Gr.1 by 59.3 mg/dl (p=0.000) and in Gr.2 by 41.1 mg/dl (p=0.000), however in Gr.1 FG level was statistically significantly lower, in comparison with Gr.2 (p=0.000).Postprandial gl. (PG) in both groups at the baseline was: Gr. 1 – 256.4 ± 19.8 mg/dl and in Gr. 2 – 258.8 ± 17.6 mg/dl (p=0.500), and after 24 weeks PG level decreased in Gr.1 by 92.1 mg/dl (p=0.000) and in Gr. 2 by 87.3 mg/dl (p=0.000). However in Gr. 1 PG level was lower, than in Gr. 2 (p=0.022). The rate of hypoglycemic episodes during the last month of the study was in Gr. 1 – 13.3 ± 4.04 hypo/month and in Gr. 2 – 19.7 ± 5.28 hypo/month (p=0.000).
Opthalmological investigation detected no deterioration of retina in both groups.
Conclusion: In patients with Type 1 diabetes the similar decrease of HbA1c levels has been observed, both treated with Insulin Detemir and NPH, however FG and PG levels have been lower in the patients on Detemir, and the rate of hypoglycemic episodes (especially nocturnal) has been lower in the patients on NPH. Utilizing of Detemir as basal insulin during intensive insulin therapy, obtained more stable course of diabetes, in comparison with those of NPH. Immediate pre-meal injection has been assessed positively by all patients.

Calcitriol administration in type 1 diabetic adolescents and its effect on bone turnover

N. Napoli[1], D. Pitocco[2], E. Di Stasio[2], C. Bizzarri[3], D. Maggi[1], R. Strollo[1], I. Barchetta[1], C. Suraci[4], P. Pozzilli[1], IMDIAB group[1]
[1] *Univeristà Campus Bio-Medico, Endocrinology and Diabetes, Rome, Italy*
[2] *Università Cattolica del Sacro Cuore, Internal Medicine, Rome, Italy*
[3] *Ospedale Pediatrico Bambino Gesù, Endocrinology, Rome, Italy*
[4] *Ospedale Sandro Pertini, Endocrinology and Diabetes, Rome, Italy*

Background and aims: In recent onset Type 1 Diabetes (T1D), the lack of anabolic effect of insulin and amylin may disturb bone remodelling, particularly in puberty, a critical period for bone mass increment. The role of other factors, such as blood glucose control and vitamin D in bone remodelling is not clear. Aims of the study were to determine the effect of metabolic control and 1 year treatment with calcitriol on bone turnover in subjects with T1D by analyzing Osteocalcin (a bone formation marker) and ß-CrossLaps (a bone resorption marker).
Methods: In a double blind study, 25 subjects with recent-onset T1D and baseline C-peptide > 0.25 nM, were randomized to calcitriol at 0.25 µg daily

dose or placebo, and followed-up for 1 year. Osteocalcin and ß-CrossLaps, were evaluated by ECLIA method (modular E170, Roche Diagnostics, Mannheim, Germany) at diagnosis and at 1 year follow-up.

Results: At onset, Osteocalcin and ß-Cross Laps levels were not different from literature-derived values for heathy subjects, and remained unmodified after 1 year in placebo group, despite improvement in blood glucose control. Conversely, at 1 year follow-up osteocalcin and ß-CrossLaps dropped by 38.6% and 47.3%, respectively in the calcitriol treated group, but their levels were not significantly different compared to diagnosis due to high variability. No significant differences were also found at 1 year comparing calcitriol vs. the placebo group for both osteocalcin (25.1±3.6 (sem) ng/mL vs 46.1±14.2 (sem) ng/mL; p=0.157) and ß-CrossLaps (0.29±0.6 (sem) ng/mL vs 0.48±0.1 (sem) ng/mL; p=0.151). By stratifying patients according to age, we found that at 1 year follow-up as compared to diagnosis, calcitriol treated patients ≤18 years of age (mean age 16 years ± 1.46) showed statistically significant 61% drop of osteocalcin (68.8±17.6 (sem) ng/mL vs 26.8±11.5 (sem) ng/mL, respectively, p=0.04) and a 67% reduction in ß-CrossLaps (0.92±0.77 (sem) ng/mL vs 0.31±0.08 (sem) ng/mL, respectively, p=0.09). In this age range, patients on calcitriol therapy vs. placebo showed at 1 year follow-up a trend for lower osteocalcin (74.2±23.7 (sem) ng/mL vs 26.8±4.8 (sem) ng/mL; p=0.08) and significantly lower ß-CrossLaps (0.76±0.15 (sem) ng/mL vs 0.31±0.1 (sem) ng/mL; p=0.03). Differences were not statistically significant in patients >18 years of age.

Discussion/conclusion: Improvement in metabolic control is not associated with significant modification in bone turnover following calcitriol treatment. On the other hand calcitriol treatment reduces markers of bone turnover in the adolescent cohort, indicating that it may counter the physiological increase in bone turnover during puberty.

Foot care 3

D-0896

Risk factors for major amputation of diabetic foot gangrene

M. Cardino[1], C. Josol[1]
[1] Philippine General Hospital, Endocrinology, Manila, The Philippines

Background: Diabetic foot ulcers are very common in the Philippines, accounting for 16-20% of the yearly emergency room admissions at the Philippine General Hospital. Major amputation (below & above the knee amputation, hip disarticulation) rate was 70%. We look into the risk factors for major amputation among diabetic foot ulcer patients after a multispecialty team named Diabetes Extremity Care Team (DECT) was created. No data has been reported from the Philippines.

Objectives: To compare the clinical and biochemical characteristics of diabetic foot ulcer patients who underwent major amputation and those who underwent minor and non-amputation and; to identify the risk factors associated with major limb amputation.

Methods: Cross-sectional, analytical. A retrospective review of charts was done from 2004 to 2007 with the diagnosis of diabetic foot ulcer. Five-hundred one charts reviewed (retrieval rate: 76%); 9 excluded (lost pages). University of Texas was used in the classification of diabetic foot ulcers. Difference in means was tested using T-test and difference in proportions tested using Chi Square test. Multiple logistic regression analysis was done to determine which variable was associated with major amputation.

Results: Major amputation was done in 51.42% (253 of 492) of patients which was significantly lower than the pre-DECT at 70% (p<0.001) however still above the ADA recommendation of <40%. There was a non-significant association with major amputation and male sex (49.01%, 149 of 492, OR: 1.05, p0.806), smoking (49.03%, OR:1.05, p0.792), alcohol abuse (48.75%, 1.02, p0.932), retinopathy (59.01%, OR:1.03, p0.899), nephropathy (50.66%, OR: 1.09, p0.537) ischemic heart disease (49.27%, OR:1.05, p0.795), peripheral vascular disease (49.2%, OR:1.07, p0.714), hypertension (49.33%, OR:1.08, p0.675), >25% missed antibiotics dose (50%, OR: 1.13, p0.497), duration of diabetes > 5 years (53%, OR: 1.17, p0.497) compared to the minor or non-amputation group. On multiple logistic regression, University of Texas 3D (OR: 2.2, p<0.01) and neuropathy (OR: 1.63, p0.02) were the predictors for major amputation.

Conclusion: Major amputation was done in 51.42% of diabetic foot ulcer patients. This study showed that patients with neuropathy and University of Texas 3D classification were likely to undergo major amputation, thus the need for adequate foot care among diabetic patients.

Foot ulceration and lower limb amputation in diabetic patients at Ataturk Training and Research Hospital in Turkey

G. Oruk[1], D. Kurt[1], S. Isli[1], N. Ozen[1]
[1] Ataturk Training and Research Hospital, Endocrinology and Metabolism, Izmir, Turkey

Lower extremity ulcers are a serious complication of diabetes. Whereas only 7% of the population has diabetes in Turkey, prevalence of diabetic foot ulcer can be more. The aim of this study is to establish the condition in our patient group. Data were collected from the hospitalized patients at our hospital in a 2-year period. Totally 1777 patients were evaluated for diabetic complications, diabetic foot lesion, diabetes duration (new diagnosis, 0-10 years, 11-20 year, 21-30 year, >30 year). 977 of them were female (55%), 800 of them were male (45%). 303 (17.1%) patients had serious diabetic foot ulcer, 195 of them were male (24.4%), 108 female (11.1%) (p<0.001). Amputation was applied to 39 (12.8%) patients 26 of whom were male (66.6%). When the patients who have diabetic foot ulcer were investigated, it was found that 293 (77.8%) patient had diabetic neuropathic symptoms. According to the evaluation of diabetes duration, it was noticed that the patients who had diabetes for >30 years had more diabetic foot ulcer (31.3%), but amputation rate is higher in the group which has diabetes for 21-30 years (46.8%). As a result it can be concluded that diabetic foot ulceration and amputation is highly prevalent in Turkish population. Diabetic neuropathy is an important risk factor. Males seem to experience diabetic foot ulceration and amputation more. Also as the diabetes duration increases, incidence of diabetic foot ulceration and amputation increases. This emphasizes the need for all those who provide diabetes care for diabetic patients to recognize high risk patients and refer them to specialized centers as soon as possible.

Actovegin use in complex treatment of diabetic foot syndrome complicated by purulent necrotic process

D.V. Seliverstov[1], I.V. Kondrus[1], V.G. Kutskir[1], I.A. Podyablonskaya[2], V.V. Masevnin[1], N.Y. Terentyeva[1], I.N. Kogarko[3], B.S. Kogarko[3], I.I. Ganeev[3]
[1] MAPHC RRCH, of purulent surgery, Ryazan, Russia
[2] SEE HPE RyazSMU, of surgery, Ryazan, Russia
[3] ICP RAS, of biochemistry, Moscow, Russia

Aim: to evaluate actovegin influence on wound process course in patients with diabetic foot (DF), complicated by purulent necrotic process.

Method: In 2007-2008 patients with DF, complicated by purulent necrotic process, presenting the main and comparison groups, were treated; there were 150 patients in each group. In both groups with neuropathic form of DF patients with trophic ulcer prevailed – 44.34 % and 46.67 % accordingly; in patients with neuroischemic form of DF with magistral changed blood flow trophic ulcer, osteomyelitis, phlegmon and toe gangrene were met in 20-28 % of cases. In the group with neuroischemic form with collateral blood flow patients with toe gangrene prevailed – 62.5 %. Complex therapy was administered in both groups, and in the main group 20 % solution of actovegin intravenously (dissolved in 0.9 % solution of NaCl, vol. 250 ml, NO. 10) was included with the following administration of 200 mg thrice a day within 3 months. For result evaluation, wound surface area was measured and wound healing speed (WHS) was calculated. Cytological investigation of Pap smears was done to determine wound process phase.

Results: In main group patients with magistral blood flow WHS was 6.98±0.85 % per day (p=0.001); term of the second phase starting of wound process – 18.6±3.5 days (p=0.007). WHS in patients with magistral changed blood flow was on average 3.43±0.73 % per day (p=0.04). The second phase of wound process took place in 30.97±9.8 days (p=0.008). In patients with collateral blood flow WHS was on average about 2.87±0.62 % per day (p=0.05). The second phase of wound process started in 50.07±15.03 days (p=0.009).

Conclusion: Reliable WHS increase and term decrease of the second phase starting of wound process in patients with DF, complicated by purulent necrotic process, took place after administering complex therapy with actovegin preparation (20% solution, dissolved in 0.9 % solution of NaCl, vol. 250 ml, NO. 10, with the following administration of 200 mg of it thrice a day within 3 months).

High prevalence of undiagnosed diabetes and amputations in patients with leg infections in an African setting: case of Yaounde central hospital

L. Fonkoue[1], J. Bahebeck[2], M. Dehayem[3], A.P. Kengne[4], E. Sobngwi[5], J.C. Mbanya[6]

[1] *Bafia Central Hospital, Internal Medecine, Bafia, Cameroon*
[2] *Yaounde Central Hospital, Surgery, Yaounde, Cameroon*
[3] *Yaounde Central Hospital, Centre National D'obesite D'hypertension Et De Diabete, Yaounde, Cameroon*
[4] *University Of Sydney, George Institute For International Health, Sydney, Australia*
[5] *Yaounde Central Hospital, Centre National D'obesité D'hypertension Et De Diabète, Yaounde, Cameroon*
[6] *University Of Yaounde, Internal Medecine, Yaounde, Cameroon*

Background: In 2007, almost 80% of diabetic patients in developing countries are unaware of their status. Consequently, the disease is usually revealed by complications among which diabetic foot infections and/or gangrene. Unfortunately, these may contribute to a higher rate of amputations, which could have been avoided. This study was carried out to determine the prevalence of diagnosed and undiagnosed diabetes in patients with leg gangrene and/or acute infections at the Yaoundé Central Hospital (Cameroon), and short term rate of amputations in these diabetic patients.
Methods: From August 2006 to January 2008, we consecutively recruited all patients admitted for gangrene and/or acute leg infections, non related to a major trauma. Participants were screened for diabetes using standardized methods for those who were not known to be diabetic before the lesions. The follow up was done until discharge from the hospital.
Results: Out of 73 patients included in analysis, 49% were known diabetic with a mean duration of diabetes of 10 years. Among those remaining, 19% had undiagnosed diabetes. During the study period, 40% of all these diabetic patients were amputated of the foot, with 42% being major amputations. The amputation rate was not different between known and undiagnosed diabetic patients.
Conclusions: In hospital settings in our environment, diabetes mellitus is the main aetiological factor for gangrene and acute limb infections, but remains unknown in about 19% of patients before hospital admission. Unfortunately it is still associated to high incidence of amputation. This suggests that systematic detection of diabetes and early adequate management of the lesions should be aggressively implemented.

Distribution of foot pressure of patients with diabetic foot syndrome after amputations of toes

A. Krakowiecki[1], G. Rosinski[1], E. Sobol[1], M. Kasprowicz[1], B. Mrozikiewicz-Rakowska[1], P. Krasnodebski[1], W. Karnafel[1]

[1] *Medical University of Warsaw, Department of Gastroenterology and Metabolic Diseases, Warsaw, Poland*

Aim: The aim of work was to check if the amputations of toes influence the distribution plantar pressure.
Methodology: From among 1166 patients from Outpatient Clinic for Diabetes Foot Syndrome, 192 amputations of toes were executed. In 74 of them pedobarogram after the amputation were executed using the pedobarograph MediCapterus co-operating with program TWIN99. Maximum value of pressure was estimated in four regions of foot: 1. lateral and 2. medial areas including phalanges and the heads of the metatarsal bone; 3. area including the remaining part of metatarsal bone and tarsal; 4. area including heel. The Clarke's angle was also estimated.
Patients were divided into two groups: with and without amputation of great toe. The patients with amputation of great toe and other toes were not analyzed.

gender	58 men	16 women
diabetes	69 type 2	5 type 1

Characteristic of the patients

Amputation	Numbers	Age (year)	Max pressure (g/cm²)	Average pressure (g/cm²)
Great toe	17	66,8 +/- 10,9	890,7 +/- 235,4	344,8 +/- 111,4
Other toes	39	65,4 +/- 9,2	846,6 204,1+/-	341,3 +/- 118,3
Both	18	69,8 +/- 10,9	852 +/- 228,2	385,9 +/- 132,7

Characteristic of the patients (continuation)

Results: There were no statistic significant differences between groups in average and maximum pressure (890,7 +/- 235,4; 846,4 +/- 204,1 g/cm²; p=0,2) as well as plantar foot surface after amputation (134,6 +/- 28,2; 146,2 +/- 32,8 cm²; p=0,44). A difference between maximum pressure in middle foot area (area 3) was found (268,1 +/-136,4; 387,3 +/- 158,2 g/ cm²; p<0,01) as well as value of Clarke's angle (26,2 +/- 15,4; 40,4 +/- 21,5 of degree; p<0,01).

Amputation	Area 1 (g/cm²)	Area 2 (g/cm²)	Area 3 (g/cm²)	Area 4 (g/cm²)	Clark's angle (degrees)
Great toe	0 +/-0,0	448,4 +/-241,2	268,1 +/-136,4	707,2 +/-252,6	26,2 +/- 15,4
Other toes	120,8 +/- 136,1	428,9 +/- 227,2	387,3 +/- 158,2	695,4 +/-219,3	40,4 +/- 21,5
p	<0,01	0,36	<0,01	0,42	<0,01

Conclusions:
1. So-called small amputations of toes significantly influence the redistribution of maximum plantar pressure.
2. The amputations of great toe lead to axial platypodia.
3. There is a question why some patients after the amputation do not have axial platypodia.

Risk factors for amputation in diabetic foot patients

B. Mrozikiewicz Rakowska[1], P. Krasnodebski[1], W. Karnafel[1], G. Rosinski[1], A. Krakowiecki[1], E. Sobol[1], M. Jasik[1], A. Cacko[1], M. Kasprowicz[1], M. Karlinski[1], P. Stelmasiak[1]

[1] *Medical University of Warsaw, Department of Gastroenterology and Metabolic Diseases, Warsaw, Poland*

Aims: Prevalence of diabetes mellitus (DM) is systematically growing. Vascular and neuropathic complications decrease life expectancy, quality of life, and create serious socioeconomic burden. Proper management of diabetic foot allow to avoid or delay surgical interventions. However, in many patients distal and proximal foot amputations are still necessary.
Our aim was to identify potential risk factors for complications leading to foot amputation in patients diagnosed with diabetic foot.
Methods: Study involved 157 patients admitted at the Outpatient Clinic for Diabetic Foot at the Department and Clinic of Gastroenterology and Metabolic Diseases, Medical University of Warsaw, and diagnosed with diabetic foot. Data was obtained through a detailed questionnaire including clinical evaluation by a specialist and patient's medical history. Study group consisted of 59 patients (47 males, mean age 60.5±12.0, BMI 29.6±6.1, 82.1% type 2 DM) who underwent amputation due to diabetic foot. Remaining 98 patients (61 males, mean age 63.6±11.2, BMI 28.4±4.6, 85.6% type 2 DM) comprised the control group. Statistical analysis involved univariate and multivariate logistic regression.
Results: Patients with a history of amputation were diagnosed with diabetic foot of neuropathic (45.8%), vascular (20.3%) or mixed (33.9%) etiology. Mean duration of DM in the study group was 16.6±10.9 and 14.3±8.4 in the control group. Amputation occurred in 14.6±10.7 year of DM, after 8.3±10.3 years of insulin therapy. Major risk factors were male sex (OR 1.60, 95%CI: 1.11–5.08), overall number of hospitalizations (OR 1.32, 95%CI: 1.08–1.62 for each additional hospitalization). They remained significant after adjusting for other covariates in a multivariate model. Age at diagnosis of DM (OR 0.87, 95%CI: 0.77–0.99 for each additional 5 years) was less important.
Conclusions: Higher risk of complications requiring amputation in patients diagnosed with diabetic foot appears to be associated with male sex, the number of hospitalizations and lower age at DM diagnosis. Therefore, it may be reasonable to provide them with additional care as a prophylactic measure.

Early impact of comprehensive diabetic foot centre on diabetes-related amputation rates at Georgetown Public Hospital Corporation, Guyana

M.G. Rambaran[1], B. Ostrow[2], R.G. Sibbald[3], K. Woo[3]
[1] Georgetown Public Hospital Corporation, Medical and Professional Services, Georgetown, Guyana
[2] University of Toronto, Office of International Surgery, Toronto, Canada
[3] University of Toronto, Women's College Hospital, Toronto, Canada

Aim: To prevent amputations in persons with diabetes in Guyana.
Methods:
1. Identify high risk patients by 60 second screening and refer them for a follow-up and education program.
2. Exam feet at every clinic visit to identify ulcers at an early stage.
3. Treat foot ulcers at Diabetic Foot Centre (DFC), an interprofessional patient-centered unit, according to Wound Bed Paradigm, a holistic approach focusing on cause (vascular, infection, pressure); patient-centered concerns and local wound care with active surgical debridement of healable wounds.
4. Apply model throughout Guyana

Results: An audit of the first 9 months of activity (over 500 discrete patients) will be presented. One-half of the DFC patients are referred from Georgetown Public Hospital Corporation (GPHC): 36% screened and 15% inpatients with severely infected ulcers. The other half are referred from outside the GPHC system – reflecting the huge unmet need for diabetic foot care. A 3 year retrospective analysis of all major amputations performed at GPHC prior to the DFC will be compared to the first 6 month period after its initiation. The incidence rates of diabetes-related major amputations are calculated before and after the operation of the DFC. A retrospective comparison of hospital length of stay of patients with diabetic foot ulcers is made before and after DFC opened. Diabetes-related amputations rates in Guyana are benchmarked in comparison to that in other Caribbean and low-income countries.
Discussion/conclusions: World literature indicates that 85% of amputations in persons with diabetes are preceded by a diabetic foot ulcer (DFU). High major amputation rates reflect poor ulcer and patient-related outcomes. Previously unpublished data from Guyana show that 42% of patients admitted to GPHC with a DFU undergo an amputation, of which 45% are major, below-knee and above-knee, amputations and that 60% of admitted patients stay more than 1 week in hospital. Decreased amputation rates and lengths of stay are major indicators of improving quality of diabetic foot care.

An interdisciplinary approach to limb salvage: Toe, Flow & Metabolic Know approach

M. Bharara[1], R. Fitzgerald[1], H.L. Rilo[1], D.G. Armstrong[1]
[1] University of Arizona, Department of Surgery, Tucson, USA

There is an epidemic of diabetic limb loss that is increasing as the incidence and prevalence of diabetes mellitus increases throughout the world. Patients developing lower extremity complications of diabetes demonstrate significant morbidity and mortality. These include lower extremity ulceration. Limb loss in people with diabetes is a consequence of multifactoral pathology and it is therefore appropriate to utilize an interdisciplinary approach to address the specific and varying etiologies that combine to create lower extremity ulceration, infection, and subsequent amputation.
The components of the limb salvage team are largely determined by the major pathology noted at presentation. It is our experience that the irreducible minimum for such an interdisciplinary approach be founded in a team that is composed, at its core, of a) clinicians caring for the structural and surgical aspects of the foot, and b) clinicians caring for the vascular interventions into the foot, and c) clinicians caring for the metabolic physiological responses.
Healing and perfusion to the extremity are related in a sigmoid-esque curve. If we then apply that curve to the team, we are able to define who manages the patient at what time. It is vital to emphasize that the role of the "endocrinologist/diabetologist" for the metabolic know component is consistent along this curve.
If the acute problem at hand is more flow than toe, then the flow team takes primacy, pushing the patient up the healing curve. When that problem has been addressed, then the embedded toe team takes over to heal and prevent the problem. The literature demonstrates that each of these skills are vital in the management of diabetic lower extremity disease, and in combination, they provide the necessary starting point for targeted limb salvage.
The interdisciplinary approach to limb salvage has been demonstrated to provide improved efficiency in patient outcomes, with an overall decrease in major limb amputation rates. Such integrative teams allow for increased communication and perspective between team members, which fosters a spirit of learning and exchange of ideas that benefits both patients and team members.

Diabetes related amputations: a call to arms to make a difference

M. Bharara[1], D.G. Armstrong[1], H.L. Rilo[1], J. Mills[1]
[1] University of Arizona, Department of Surgery, Tucson, USA

Diabetes related amputations remain a major public health issue, despite huge progress in offloading, aggressive wound healing protocols and prevention. Clearly, this progress is rather subdued when comparing the epidemic in developing and developed nations on the same scale. In many ways, diabetes-related amputations are strikingly similar to those associated with landmines. This intriguing comparison emphasizes the silent nature of the 'warfare' and the sinister consequences on the life of patients/victims. From a pubic health standpoint, diabetes-related amputations are now more common than those resulting from exploding hidden landmines, leading to 70% of the lower extremity amputations around the world. This high incidence of diabetes, coupled with the associated 43-55% five-year mortality rates after new-onset diabetic limb ulceration, which increase up to 74% for patients with lower-extremity amputation, will mount significant pressure on global healthcare infrastructure. It is striking to note that these mortality rates are higher than those for several types of cancer including prostate, breast, colon, and Hodgkin's disease. Despite a surprisingly high 5-year mortality associated with this preventable scourge, the lay public and press seem largely unaware and policy-makers have failed to appropriately respond. As with landmines, the effects of diabetes are irreversible. They both lurk silently before suddenly exploding, destroying the limbs and lives of their innocent victims. Diabetes around the globe results in one major limb amputation every 30 seconds, over 2500 limbs lost per day! In India alone, 40,000 amputations are performed annually. These staggering figures underline the enormous scale of the problem. On the other hand, there are two landmine related amputations every hour, but there are 1500 Non-Governmental Organizations and 90 countries working together to solve this landmine crisis, which has made huge differences The authors wish to sound the alarm. To save limbs, we call to arms the public, the media, the health care community, and policymakers throughout the world to join together in battle.

The pilot screenings of diabetic patients - Introduction and follow-up of plastic offloading

I. Rozsos[1], L. Mecseky[2], R. Mezo[3]
[1] University of Pécs, Theta Health Center, Pécs, Hungary
[2] Hungarian Diabetic Foot Association, private practice, Budapest, Hungary
[3] South-Pest Hospital, Rehabilitation Department, Budapest, Hungary

Aims: The pilot screenings commenced in 2007 were the introductory measures of the nationwide 7-center screening program. In the framework of the pilot screening, we have screened 1000 patients in four centres- in the gravity zones of Budapest, Debrecen, Gyöngyös and Pécs- which we linked with a modern method of offloading- and in cases of 99 patients we utilised weight relieving total contact soft cast.
Method: In cases with significant structural deformation and trophic wound on the sole, or where the risk of such existed, the patients were directed to the offlloading program, in the course of which plastic plaster was applied - with a structure adapted to the deformations.
In the examination year we applied such treatment instrument in the cases of 99 patients, out of which in 90 cases we were able to monitor it even beyond the required minimum follow-up time. We monitored the patients' wound healing tendency, the improvement of loadability, and changes in walk distance.

After one year we reexamed 71 patients. In this time we monitored the general health conditions- trophic ulcer and walking capacity.
Results: The early results: we offered immediate possibility for therapy to the high-risk patient-group, in the course of which we could record accelerated healing dynamics, and besides this the movement restrictiveness of the patients also decreased, thus we could measure also the psychic contentment.
The late results - after one year: No need for major amputation, less than 40% recidiv trophic ulcer (generally we use plastic plaster again). In this period we diagnosed one stroke, and one colon cancer.
Discussion: According to our conclusions, the pilot screening was succsessful, as it detected in more than 50% of the patients deformations, to which earlier no importance has been attached. We regard our initial results as the first step to a nationwide screening program to be carried out in 21 centres. We are even currently carrying on negotiations concerning the possibilities of joining the National Health Programs - as in Hungary there are 600.000 people with diabetes and at least 15% of them suffer from some kind of trophic disorders.

Taspoglutide, a novel human once-weekly GLP-1 analogue, induces ß-cell proliferation and protects from cytokine- and lipotoxicity-induced apoptosis

H. Wang[1], M. Prummer[2], S. Sewing[1], S. Uhles[1], C. Migliorini[1], D. Bosco[3], C.B. Wollheim[4], E. Sebokova[1]
[1] *F. Hoffmann-La Roche Ltd, Metabolic and Vascular Diseases, Basel, Switzerland*
[2] *F. Hoffmann-La Roche Ltd, Discovery Technologies, Basel, Switzerland*
[3] *University Medical Center, Department of Surgery, Geneva, Switzerland*
[4] *University Medical Center, Department of Cell Physiology and Metabolism, Geneva, Switzerland*

Aims: Glucagon-like peptide-1 (GLP-1) has protective effects on pancreatic ß cells. To test this hypothesis for taspoglutide, a human once-weekly GLP-1 analogue, its *in vitro* effects on insulin secretion, ß-cell proliferation and apoptosis were investigated and compared to native human GLP-1.
Methods: Acute effects of taspoglutide on insulin secretion in rat insulinoma (INS-1E) cells and human islets were studied under basal (2.8 mM) and high (16.7 mM) glucose concentrations. The effect on proliferation was assessed by EdU incorporation after 48 h exposure of murine pancreatic ß cells (MIN6) or rat islets in culture with taspoglutide. INS-1E cells or dispersed human islets were used to examine the effects of taspoglutide (10 nM) on apoptosis (quantified by TUNEL/DAPI or insulin staining using high-content screening) induced by cytokines (recombinant human IL1ß: 1 ng/ml + IFNgamma: 5 ng/ml + TNFalpha: 5 ng/ml, in 6 h culture) or lipotoxity (0.5 mM palmitate in 24 h culture).
Results: In INS-1E cells, taspoglutide dose-dependently increased glucose-stimulated insulin secretion without affecting basal secretion. An increase of 10.6% ($p<0.05$) was demonstrated at only 1 pM taspoglutide, and a larger increase of 177.7% ($p<0.001$) was seen at 100 nM. Proliferation of MIN6 cells was increased dose-dependently by taspoglutide, with almost a 4-fold increase at 100 nM (3.9±1.7; 8.3±1.4, 12.1±1.5, 13.5±2.9, and 14.2±1.8% at 0, 0.1, 1, 10, and 100 nM respectively; $p<0.001$). Taspoglutide almost totally abolished cytokine-induced apoptosis in INS-1E cells (Control 0.5±0.2; Cytokines: 2.2±0.4; Taspoglutide + Cytokines: 0.6±0.2%, $p<0.001$), and prevented lipotoxicity–induced apoptosis in INS-1E cells (Control: 0.5±0.2; Palmitate: 8.1±4.6; Taspoglutide + Palmitate: 0.5±0.2%, $p<0.001$). Comparable effects on ß–cell proliferation and protection from cytokine- and lipotoxicity-induced apoptosis were seen with human GLP-1 at the same concentrations. The protective effect of taspoglutide on cell proliferation and apoptosis was confirmed in dispersed rat and human islets.
Conclusion: Similar to human GLP-1, taspoglutide exerts multiple ß-cell protective effects including enhancement of insulin secretion, promotion of ß-cell proliferation, and prevention of apoptosis.

Chronic administration of the glucagon-like peptide 1 analog, liraglutide, delays the onset of diabetes and lowers triglycerides in a novel model of type 2 diabetes, the UCD-T2DM rat

B. Cummings[1], J. Graham[1], K. Stanhope[1], S. Griffen[2], C. Nilsson[3], L.B. Knudsen[3], K. Raun[3], P.J. Havel[1]
[1] *University of California Davis, Molecular Biosciences Vet Med, Davis, USA*
[2] *Bristol-Myers Squibb Co., Discovery Medicine & Clinical Pharmacology, Princeton, USA*
[3] *Novo Nordisk A/S, Pharmacological Research 1, Maaloev, Denmark*

Aims: Due to the increasing prevalence of type 2 diabetes (T2DM), there is a need to identify T2DM prevention strategies. We have investigated the efficacy of liraglutide, a human GLP-1 analog, to prevent or delay T2DM in UCD-T2DM rats, a model of polygenic obese T2DM that is more similar in etiology to T2DM in humans than other existing rodent models.
Methods: At 2 months of age, rats were divided into three groups: control, liraglutide and food restricted (n=32). Rats received liraglutide (0.2 mg/kg) or vehicle injections BID for up to 10 months. Restricted rats were food restricted to equalize body weights to liraglutide rats. Non-fasting blood glucose was measured weekly to determine diabetes onset (<200 mg/dl). At 6 months of age 16 animals from each group were euthanized for tissue analyses.
Results: Energy intake and body weight at 4 months of age were lower in liraglutide and restricted compared with control rats: (control: 103±3kcal/d, 618±6g; restricted: 80±1kcal/d, 544±5g; liraglutide: 89±2kcal/d, 549±6g, P<0.0001). Greater energy intake in liraglutide compared with restricted rats, despite identical weight gain suggests that liraglutide increases energy expenditure. Compared with control, restricted and liraglutide delayed diabetes onset by ~2 and ~3 mo, respectively (P<0.01). Mean ages of T2DM onset were: control 4.9±0.5, restricted 6.9±0.5, and liraglutide 7.8±0.5 months. By 6.5 months of age, only 3/32 liraglutide animals had become diabetic, whereas 12/32 restricted and 26/32 control animals were diabetic. Thus, liraglutide delayed diabetes onset compared with the control and restricted groups (P<0.05). At 6 months of age, fasting plasma glucose and HbA1c concentrations were higher in control (180±27 mg/dl; 9.1±0.6%) compared with both liraglutide (119±8 mg/dl; 5.5±0.4%) and restricted (121±5; 4.9±0.2%) animals (P<0.001). Plasma TG was reduced in liraglutide treated (93±5mg/dl) compared with either control (137±10mg/dl) or restricted (175±16mg/dl) animals (P<0.05). Fasting plasma insulin at 4 months of age was lower in liraglutide (1.4±0.1ng/ml) treated compared with either control (2.9±0.2ng/ml) or restricted (2.6±0.2ng/ml) animals (P<0.001). After excluding animals that had become diabetic and started losing weight, liver TG content and total white adipose tissue weights were significantly lower in liraglutide (13.2±1.1mg/g liver, 74±4g, n=14) and restricted (13.0±1.7mg/g liver, 81±5g, n=14) compared to control (23.0±1.4mg/g liver, 98±4g, n=6) animals (P<0.01).
Conclusion: Liraglutide delays the onset of T2DM in UCD-T2DM rats and the delay likely involves effects on food intake, weight gain and energy and lipid metabolism. We are currently investigating other potential mechanisms including effects on islet morphology and function.

Liraglutide, a once-daily human GLP-1 analogue, reduces systolic blood pressure within 2 weeks in patients with type 2 diabetes

V. Fonseca[1], A. Falahati[2], M. Zychma[3], S. Madsbad[4], J. Plutzky[5]
[1] *Tulane University Health Sciences Center, Endocrinology, New Orleans, USA*
[2] *Novo Nordisk, Biostatistics, Bagsvaerd, Denmark*
[3] *Novo Nordisk, International Medical Affairs, Warsaw, Poland*
[4] *University Hospital, Endocrinology, Hvidovre, Denmark*
[5] *Brigham and Women's Hospital, Vascular Disease Prevention Program, Boston, USA*

Aims: Six large phase 3 clinical trials in patients with type 2 diabetes (T2D) have shown that the once-daily human GLP-1 receptor agonist liraglutide is effective in controlling glycaemia, as measured by HbA_{1c} reductions of 1.0–1.5%, while simultaneously reducing mean body weight by approximately 3 kg and systolic blood pressure (SBP) by 2.7–6.6 mmHg (min, max baseline SBP, mmHg: 128/76-134/81). Our aim was to study the effect of liraglutide on SBP by quartile of baseline SBP.
Methods: A meta-analysis across the six phase 3 liraglutide clinical trials (the Liraglutide Effect and Action in Diabetes (LEAD) programme) was carried out. Patients treated with liraglutide 1.2 mg (n=896), liraglutide 1.8 mg (n=1362) or placebo (n=520) were included in the analysis. Mean SBP changes from baseline were analysed using an ANCOVA model adjusted for trial, baseline SBP and baseline SBP quartile. The investigators were not given specific instructions on lowering blood pressure with medication during the trials.
Results: Baseline SBP in all treatment groups was similar. Overall, significant reductions from baseline in SBP were seen with liraglutide 1.2 mg (2.5 mmHg, p=0.0030) and liraglutide 1.8 mg (2.6 mmHg, p=0.0008) but not with placebo (-0.2 mmHg, p=0.7828). To investigate the longitudinal effect on SBP from baseline to week 26 repeated measure analysis with a model adjusted for baseline SBP quartile was used. The effect of baseline SBP quartile was significant (p<0.0001). At first visit after 2 weeks of treatment with liraglutide 1.2 mg or liraglutide 1.8 mg SBP was reduced by 3.0 mmHg and 2.6 mmHg, respectively, before any significant weight loss occurred. These reductions were maintained over 26 weeks. Thus, after 26 weeks of treatment SBP reductions of 2.7 mmHg and 2.6 mmHg with liraglutide 1.2 mg and liraglutide 1.8 mg, respectively, were observed. In patients receiving placebo SBP was reduced by 0.8 mmHg and 0.9 mmHg after 2 and 26 weeks, respectively. The greatest SBP reductions (-11.4 mmHg) were seen in the quartile with highest baseline SBP (Table).
Conclusions: Patients with T2D often have elevated blood pressure, which exacerbates CV risk. Treatment with liraglutide reduces SBP within 2 weeks, preceding any significant weight change. This effect on SBP was sustained over time and was enhanced in patients with baseline hypertension. Liraglutide may, therefore, have a beneficial effect on CV risk, especially in patients with high SBP.

	Liraglutide 1.2 mg Delta SBP	Liraglutide 1.8 mg Delta SBP	Placebo Delta SBP
Q4: 140<SBP≤190<sbp< />	-11.4 (1.2)	-11.4 (1.0)	-7.7 (1.3)

Effects of exenatide compared to glibenclamide on glycaemic control and on insulin resistance in type 2 diabetic patients with metformin therapy

G. Derosa[1], A.F.G. Cicero[1], P.D. Ragonesi[1], S.A.T. Salvadeo[1], I. Ferrari[1], F. Querci[1], I.G. Franzetti[1], G. Gadaleta[1], L. Ciccarelli[1], M.N. Piccinni[1], A. D'Angelo[1], R. Fogari[1]
[1] *University of Pavia, Department of Internal Medicine and Therapeutics, Pavia, Italy*

Aims: Our study aimed to compare the effect of Exenatide (Ex) vs Glibenclamide (Gl) on glycemic control and on insulin resistance related-parameters in type 2 diabetic patients taking metformin.
Methods: Ninety-eight type 2 diabetic patients with uncontrolled type 2 diabetes (HbA1c > 8 %) were randomised to Ex 5 mg b.i.d. or Gl 2.5 mg t.i.d. and titrated after 1 month to Ex 10 mg b.i.d. or Gl 5 mg t.i.d. They were resulted intolerant to metformin at maximum dosage (3000 mg/day) and were taking various different doses (1000-2000 mg/day). The treatment period had a 9 months duration. We evaluated BMI, HbA1c, FPG, PPG, FPI, Homa index and collected plasma samples of retinol-binding protein-4 (RBP-4), and resistin at baseline, and after 9 months.
Results: Ninety-one patients completed the study (43 in Ex and 48 in Gl group). BMI was significantly reduced by Ex, but not by Gl (from 28.3±1.2 to 26.6±0.8 Kg/m^2, p< 0.05, and from 28.4±1.3 to 28.1±1.2 Kg/m^2, ns vs baseline, p< 0.05 vs Ex, respectively). HbA1c was decreased by 1.1±0.05 % (p< 0.01), and by 1.3±0.04 % (p< 0.01); FPG was reduced by 24±3 mg/dl (p< 0.01), and by 25±4 mg/dl (p< 0.01); PPG was decreased by 41±6 mg/dl (p< 0.01), and by 42±7 mg/dl (p< 0.01), in Ex and Gl group, respectively. FPI was decreased by 4.8±0.4 mU/ml (p< 0.05) in Ex group, and was increased by 1.1±0.07 mU/ml in Gl group (ns vs baseline, p< 0.05 vs Ex). Homa index was reduced by 2.5±0.7 (p< 0.05), and by 0.8±0.1 (ns vs baseline, p< 0.05 vs Ex), in Ex and Gl group, respectively. RBP-4 was decreased by 15.3±3.9 mg/ml (p< 0.05), and by 3.9±0.8 mg/ml (ns vs baseline, p< 0.05 vs Ex), in Ex and Gl group, respectively; resistin was reduced by 1.1±0.4 ng/ml (p< 0.05), and by 0.2±0.01 ng/ml (ns vs baseline, p< 0.05 vs Ex), in Ex and Gl group, respectively. There was a significant correlation between BMI value decrease and RBP-4 decrease (r= 0.63, p< 0.01), and resistin (r= 0.59, p< 0.01).
Conclusion: Ex and Gl improved diabetes control when added to metformin, but only Ex improved insulin resistance related-parameters. The RBP-4, and resistin reduction seems to be related to weight loss.

D-0910

Impact of liraglutide on reaching target HbA1c without weight gain or hypoglycaemia, versus other T2D therapies

B. Zinman[1], J. Buse[2], A. Falahati[3], A. Moses[4], S. Gough[5]
[1] *Mt. Sinai Hospital, Leadership Sinai Centre for Diabetes, Toronto, Canada*
[2] *University of North Carolina Medical School, Endocrinology and Metabolism, Chapel Hill, USA*
[3] *Novo Nordisk, Biostatistics, Bagsvaerd, Denmark*
[4] *Novo Nordisk, Clinical Development, Princeton, USA*
[5] *University of Birmingham, Endocrinology, Birmingham, United Kingdom*

Aims: We conducted a post-hoc meta-analysis of the LEAD (Liraglutide Effect and Action in Diabetes) studies comparing the once-daily human GLP-1 analogue liraglutide with other T2D therapies, to determine how many patients achieved HbA_{1C}<7.0% as a single endpoint or the clinically relevant composite endpoint of: HbA_{1c}<7.0% + no major or minor hypoglycaemia and no weight gain.
Methods: The 6 phase 3 LEAD randomised controlled trials compared liraglutide as follows: liraglutide vs glimepiride (GLM) as monotherapy; liraglutide +metformin (MET) vs GLM+MET; liraglutide +GLM vs rosiglitazone (ROS)+GLM; liraglutide +ROS+MET vs placebo +ROS+MET; liraglutide +MET+GLM vs insulin glargine +MET+GLM; liraglutide +MET and/or GLM vs exenatide +MET and/or GLM. For this meta-analysis, data analysis was ITT, LOCF, and baseline-adjusted.
Results: At 26 weeks, more patients in the liraglutide 1.8 mg group reached HbA_{1c}<7% (66%) and the composite endpoint (42%) (Table). Odds ratios (ORs) for reaching single or composite endpoint were significantly greater for liraglutide 1.8 mg (p<0.05 vs all comparators) and liraglutide 1.2 mg (p<0.05 vs ROS, GLM, and placebo).

Conclusion: The composite endpoint reflects three clinically relevant outcomes in T2D (HbA_{1c}, weight control and hypoglycaemia). With the GLP-1 agonist liraglutide, the odds of reaching the composite endpoint (and also the odds of reaching HbA_{1c}<7%) were significantly increased.

D-0911

Mechanism of protraction for liraglutide, the once-daily human GLP-1 analog

L. Bjerre Knudsen[1], P.F. Nielsen[1], D.B. Steensgaard[1], P. Bloch[1], J. Lau[1], H. Agersoe[1]
[1] Novo Nordisk A/S, Biology&Pharmacology Mgt, Maaloev, Denmark

Liraglutide is a once-daily human GLP-1 analog that has been developed for the treatment of type 2 diabetes and obesity. Liraglutide has a unique structure with a simple fatty acid and a spacer attached covalently to the peptide backbone (C16-gamma-Glu-Lys26,Arg34GLP-1(7-37)) that provides both delayed absorption and long plasma half-life. The mechanism for the protraction is based on app. 99% binding to albumin, providing the long plasma half-life, and heptamer formation in the formulation, providing a delayed absorption. Also, DPP(Di-Peptidyl Peptidase)-IV stability is obtained. We designed a series of analogs of liraglutide that provides insight into the mechanism of protraction by investigating the importance of the length of the fatty acid. The pharmacokinetic profiles were measured in pigs. DPP-IV stability was measured by mass spectroscopy. Binding to albumin was measured indirectly, by adding increasing amounts of albumin to a GLP-1 receptor binding assay. Multimer formation was assessed by circular dicroism spectroscopy. Decreasing the length of the fatty acid decreased half-life after s.c administration (16, 5.1 and 0.8h) and Tmax (7, 1.3 and 0.9h), as well as half-life after i.v. administration (10, 1.7 and 0.3 h) for liraglutide (C16), C11- and C10-analogs, respectively. Stability towards degradation by the DPP-IV enzyme correlated with the length of the fatty acid. The half-life for DPP-IV degradation in vitro was 2.4 min. for GLP-1, and 937, 383, 156 and 108 min. for liraglutide, C14-, C12-, C10-analogs, respectively. Binding to albumin decreased with the length of the fatty acid, measured as the shift in receptor activation by addition of 4% albumin (45, 45, 41, 14 for liraglutide, C14, C12, C10). The un-acylated analog did not bind to albumin. The apparent K_d for multimer formation in the formulations increased by decreasing fatty acid length. $K_{d,app}$ was <0.1 µmol/l for liraglutide, and 2, 10 and 50 µmol/l for C14, C12 and C10, respectively. In conclusion, the protraction mechanism for liraglutide includes albumin binding, heptamer formation and DPP-IV stability, resulting in delayed absorption and long plasma half-life, allowing once-daily dosing in humans.

D-0912

Liraglutide, the once-daily human GLP-1 analogue, administered as monotherapy or SU combination over 52 weeks provides effective glycaemic control in Japanese patients with type 2 diabetes

Y. Seino[1], M.F. Rasmussen[2], Y. Katayama[3], K. Kaku[4]
[1] Kansai Denryoku Hospital, Division of Endocrinology, Osaka, Japan
[2] Novo Nordisk, Medical & Science GLP-1, Bagsvaerd, Denmark
[3] Novo Nordisk Pharma, Medical Science Affairs Department, Tokyo, Japan
[4] Kawasaki Medical School, Division of Diabetes and Endocrinology, Okayama, Japan

Aims: The efficacy and safety of the once-daily human GLP-1 analogue liraglutide was investigated in Japanese patients with type 2 diabetes (T2D) in two large Phase 3 trials.
Methods: Trial A: liraglutide 0.9 mg (*n*=268) vs glibenclamide (glib) 1.25–2.5 mg (*n*=139), both as monotherapy. Trial B: liraglutide 0.6 or 0.9 mg combined with an SU vs SU monotherapy (all groups *n*=88). Trials were 24-week double-blind, followed by 28 weeks unblinded.
Results: Trial A: After 52 weeks HbA_{1c} decreased from baseline by -1.48% with liraglutide vs -0.95% with glib (difference, -0.49%). Percentage reaching HbA_{1c} <7.0% was greater for liraglutide (36.9%) vs glib (18.2%). Trial B: HbA_{1c} decreased from baseline by -1.09% and -1.30% with liraglutide 0.6 and 0.9 mg, and by -0.06% with SU (difference: liraglutide 0.6 mg vs SU, -0.96%; liraglutide 0.9 mg vs SU, -1.37%). More patients reached HbA_{1c} <7.0% with liraglutide (0.6 mg: 30.6%, 0.9 mg: 56.8%) vs SU (6.8%). Mean PG and PG increments from FPG and 7-point profiles were lower with liraglutide in both trials. Beta-cell function (measured as pro-insulin/insulin and pro-insulin/C-peptide) was improved with liraglutide in both trials vs baseline. Liraglutide was weight neutral in both trials, despite improved glycaemic control. In both trials, more GI AEs were reported with liraglutide vs SU therapy in the first 4 weeks but were at comparator levels after week 4. No major hypoglycaemic events were reported. Trial A: 0.7 minor + symptoms only hypoglycaemic episodes/ patient year reported with liraglutide vs 3.8 with glib. Trial B: rates were similar with liraglutide 0.6 mg, 0.9 mg and SU (3.1, 3.7 and 3.0 episodes/patient year). However, from 24 to 52 weeks, rates with liraglutide were lower vs SU. In both trials, approx. 15% of liraglutide-treated patients developed liraglutide antibodies. Antibodies did not influence HbA_{1c}; mean decrease in both trials was similar in patients with antibodies vs. total cohort.
Conclusion: Once-daily liraglutide either as monotherapy or in combination with an SU provides effective and sustained glycaemic control without weight gain compared with SU therapy, in addition to low rates of hypoglycaemia. Both trials demonstrate improved beta-cell function with liraglutide in Japanese patients with T2D.

ND, not determined.								

Methods: For the monotherapy analysis, data from 2 clinical trials were pooled, and analyses were performed on the cohort of 147 patients not on an antihyperglycemic agent at screening and with a common baseline HbA_{1c} of 7.5%–10%. For the add-on to metformin analysis, data from 2 other clinical trials were pooled, and analyses were performed on the cohort of 852 patients on metformin =1500 mg/day and with a common baseline HbA_{1c} of 7%–10%. In each cohort, change from baseline in HbA_{1c}, fasting plasma glucose (FPG), HOMA-ß and proinsulin-to-insulin (P/I) ratio were analyzed over time (through 2 years). Additionally, 2-hour post-meal glucose (PMG) was analyzed in the monotherapy cohort. Data following initiation of an additional antihyperglycemic agent (used as glycemic rescue therapy in some studies) were treated as missing. Missing data were not imputed.
Results: For the pooled monotherapy cohort, mean baseline age was 53 years and duration of type 2 diabetes was 4.9 years. After 2 years, sitagliptin monotherapy decreased mean HbA_{1c}, FPG, and 2-hour PMG from baseline values of 8.5% (n = 147), 187 mg/dL (n = 147), and 261 mg/dL (n = 100) to 6.9% (n = 32), 132 mg/dL (n = 32), and 175 mg/dL (n = 32), respectively. HOMA-ß was increased from 47% (n = 103) at baseline to 69% (n = 36) and P/I ratio improved from 0.54 (n = 99) to 0.26 (n = 34) after 2 years with sitagliptin. For the pooled add-on to metformin cohort, mean baseline age was 56 years and duration of type 2 diabetes was 6.5 years. After 2 years, the addition of sitagliptin to ongoing metformin therapy decreased mean HbA_{1c} and FPG from baseline values of 8.0% (n = 852) and 173 mg/dL (n = 851) to 6.9% (n = 347) and 141 mg/dL (n = 345), respectively. HOMA-ß was increased from 47% (n = 730) from baseline to 61% (n = 357) and P/I ratio improved from 0.36 (n = 715) to 0.29 (n = 357) at 2 years. Treatment with sitagliptin was generally well tolerated over 2 years in each of the 4 clinical trials from which the pooled populations were drawn.
Conclusion: Substantial improvements in glycemic control and ß-cell function were observed with sitagliptin both as monotherapy and as add-on therapy to metformin in patients with type 2 diabetes over 2 years.

D-0914

Combination alogliptin plus pioglitazone treatment in patients with type 2 diabetes receiving metformin

R. DeFronzo[1], C.F. Burant[2], P. Fleck[3], C. Wilson[4], Q. Mekki[5], R.E. Pratley[6]
[1] *University of Texas Health Sciences Center, Diabetes and Metabolism, San Antonio, USA*
[2] *University of Michigan, Internal Medicine, Ann Arbor, USA*
[3] *Takeda Global Research & Development Center Inc., Clinical Science, Lake Forest, USA*
[4] *Takeda Global Research & Development Center Inc., Analytical Science, Lake Forest, USA*
[5] *Takeda Global Research & Development Center Inc., Biological Science, Lake Forest, USA*
[6] *University of Vermont, Diabetes and Metabolism, Burlington, USA*

Aims: To assess the efficacy and safety of alogliptin (ALO) combined with pioglitazone (PIO) in patients with type 2 diabetes inadequately controlled on metformin monotherapy.
Methods: Treatment arms in this randomized, double-blind, placebo-controlled, 26-week study were placebo, ALO alone (12.5 or 25 mg qd), PIO alone (15, 30, or 45 mg qd), and the combinations of each ALO dose with each PIO dose. The primary analyses compared PIO monotherapy (all doses pooled; n = 387) with ALO 12.5 mg plus any dose of PIO (n = 390) or ALO 25 mg plus any dose of PIO (n = 390).
Results: Overall mean baseline A1C and BMI were 8.49%, 8.50%, and 8.54% and 31.1, 31.4, and 31.1 kg/m^2 for the PIO, ALO 12.5 + PIO, and ALO 25 +PIO groups, respectively. Decreases from baseline in mean A1C levels at Week 26 in subjects treated with ALO 12.5 + PIO or ALO 25 + PIO vs PIO alone were 1.43%, 1.42%, and 0.89%, respectively. In the overall analysis, each of the individual combination therapy arms had significantly greater efficacy at lowering A1C than either component monotherapy. When analyzed by subgroups of baseline A1C, subjects receiving either of the combination therapies achieved significantly larger decreases from baseline in A1C at Week 26 vs subjects receiving PIO alone (Table); in all 3 groups, subjects with higher baseline values had larger decreases. A significantly (P<0.001) higher percentage of subjects in both the ALO 12.5 + PIO (55%) and ALO 25 + PIO (56%) groups achieved A1C levels of ≤7.0% compared with PIO alone (30.5%). Indicators of pancreatic islet function, specifically HOMA ß-cell function, showed a statistically significant improvement in subjects receiving either combination therapy vs those receiving PIO alone (P<0.01). Some evidence of a synergistic effect was apparent with either ALO + PIO group vs PIO alone, particularly with ALO 25 + PIO; least squares (LS) mean changes from baseline in HOMA-ß were 5.1 for PIO alone, 18.2 for ALO 12.5 + PIO, and 22.2 for ALO 25 + PIO. The LS mean change in weight was 1.49, 1.81, and 1.87 kg for PIO alone, A12.5 + PIO, and A25 + PIO, respectively. Weight gain was not associated with peripheral edema. The percentages of subjects experiencing study drug-related AEs were similar across the treatment groupings: 19%, 20%, and 22% in PIO alone, ALO 12.5 + PIO, and ALO 25 + PIO, respectively. The percentage of subjects who discontinued the study due to AEs did not increase with combination therapy (ALO 12.5 + PIO, 2.1%; ALO 25 + PIO, 1.5%) vs PIO alone (2.8%).
Conclusions: ALO combined with PIO was well tolerated and produced statistically significant reductions in A1C compared with PIO alone.
Table. LS Mean Changes from Baseline at Week 26

	PIO alone	ALO 12.5 mg + PIO	ALO 25 mg + PIO
Baseline A1C <8.5%	-0.66% (n=196)	**-1.12% (n=188) <0.001***	**-1.08% (n=177) <0.001***
Baseline A1C >/=8.5%	-1.09% (n=180)	**-1.74% (n=197) <0.001***	**-1.74% (n=200) <0.001***
FPG, mg/dL	-28.3	-45.2	-44.2

Problems in blood glucose self management among insulin treated diabetes patients in the context of non-adherence to recommended testing frequency

O. Mast[1], P. Evans[2], A. Antonow[2], J. Weiner[2], K. Giorgi-Vigo[3], U. Schmidt[1]
[1] *Roche Diagnostics GmbH, Global Reimbursement, Mannheim, Germany*
[2] *IPSOS, MediaCT, Minneapolis, USA*
[3] *Roche Diagnostics, Market Intelligence, Indianapolis, USA*

Aims: Tight glycemic control is demanding in every day life of people with diabetes (PwD). Non-adherence to recommended self-monitoring of blood glucose (SMBG) is one of the consequences. The survey aimed to describe the level of non-adherence and identify problem areas that could be targets for improving adherence.
Methods: 150/152 structured telephone interviews with insulin-using PwDs were performed in the Netherlands (NL) / Denmark (DK). The questionnaire covered a broad spectrum of known barriers to proper insulin therapy and

SMBG - grouped into 11 categories. Patients were categorized into either flexible (they adjust insulin doses on their own) or fixed insulin therapy. Non-adherence (NAD) was defined in three ways: derived NAD (less frequent than recommended or self-rating NAD below 6 on a 1-7 rating scale (7=full adherence)) and guideline NAD (less than the 2009 ADA-guideline recommended frequency of 3 tests per day for patients on flexible insulin therapy). Shapley values were calculated to analyze the contribution of problem categories to SMBG non-adherence.

Results: Average age was 52.4/48.3 years with mean 15.4/12.7 years since diagnosis of diabetes. The overall satisfaction with diabetes management (top 3 points on 7 point scale) was 92/91%. Self-rated NAD with insulin therapy was 12 / 11%. 41/48% of PwDs in NL/DK were on Flexible insulin therapy, of which 41/33% are Guideline NAD. Among Guideline NAD, 60/54% test only once a day and 40/46% test twice a day. Derived NAD with SMBG was 39 / 30% (flexible) and 44/27% (fixed). The most prevalent problem with SMBG among insulin-using patients were test strip handling issues (88/82%), followed by time/situation (69/58%), educated decision making (47/25%), pain (45/35%), discreetness (40/26%), motivation (39/6%), coding (36/71%), safe waste-handling (31/30%), sense for need of testing (30/28%), cost (22/5%), glucose meter (17/18%).

Ranking of problems by impact on NAD (Shapley values, declining order): test strip handling, safe waste-handling, pain, time/situation, coding, educated decision making. The remaining categories scored distinctly lower.

Discussion: Optimal glycemic control with insulin relies on the adherence to recommended insulin injections and corresponding SMBG. Adherence to SMBG however is a challenge to a large share of patients – despite high satisfaction with diabetes management and good adherence to insulin therapy. Test strip handling (strip contamination, storage, temperature, expiry, etc.) and lifestyle alignment (time / situation) were most frequently mentioned problems. Differences between countries indicate that solutions need to consider specifics of health care systems and mentality as well.

D-0916

Cost-effectiveness analysis of self-monitoring of blood glucose in patients with type 2 diabetes mellitus in a tertiary care hospital in Bangladesh

S.H. Habib[1], S. Saha[1], S. Akter[2], A.K. Azad Khan[1]
[1] BADAS, Health Economics Unit, Dhaka, Bangladesh
[2] BIRDEM, Dept of Biochemistry & Cell Biology, Dhaka, Bangladesh

Background & aims: Self-monitoring of blood glucose (SMBG) is considered a cornerstone of diabetes care and widely recommended. The cost-effectiveness of SMBG is still sometimes disputed and is controversial in a developing country. The study was taken to determine whether SMBG is associated with better glycemic control in patients with type 2 diabetes (T2DM) and whether it is economically cost-effective.

Methods: Four hundred T2DM patients were selected purposively, followed up in BIRDEM the central Diabetic Hospital in Bangladesh. Of them, 200 practiced SMBG regularly (visited 5 times) and other 200 were irregular (visited<2 times). In 1 yr follow-up, we ascertained a) the proportion performing SMBG b) SMBG frequency c) associates of SMBG use & frequency & $HbA1_c$ & d) SMBG cost.

Results: The Mean±SD age were 58±9 yrs and median $HbA1_c$ 7.5%. 30% were diet treated, 60% were taking OHAs & 10% were on insulin with or without OHA. There were no significant differences in fasting plasma glucose (FPG) or HbA_{1c} between the user groups at entry (P>0.001), but at the end FPG or HbA_{1c} found to be significantly higher in the group who didn't practice SMBG regularly (P=0.09). Patients were further divided into four groups based on frequency of testing:1) never (group 1, 9%), 2) less than one time per week (group 2, 21%), 3) one or more time per week and less than one time per day (group 3, 60%) & 4) one or more time per day (group 4, 10%). Univariate analyses of SMBG frequency showed in comparison with group 1, subjects in group 3 were younger (49.7 ± 7.3 vs. 63 ± 9.5 years; P=0.004), had shorter diabetes duration (median 2.9 [interquartile range 0.8-7 [1.4-10.0]; P=0.004), however, these patients also had a lower median HbA_{1c} (6.3 vs. 7.8%; P=0.001) and higher proportions exercised (8.2 vs. 6.1%; P=0.010), attended diabetes OPD (34.5 vs. 23.6%; P<0.001). The average annual cost per patient was US$ 172. A glucometer added US$ 50 per patient per year. SMBG costs for diet and OHA-treated patients were almost similar (US$ 141 & US$ 153 per patient, respectively, P=0.83) but lower than the US$ 221 for insulin-treated patients (P<0.001). The direct health care costs (excluding glucometer) averaged US$ 93 & US$ 252 for the regular & irregular SMBG user groups respectively. The 200 who attended five or more follow up were significantly younger, had shorter diabetes duration, better glycemic control, fewer diabetes complications (P<0.001). The proportion of the longitudinal cohort using SMBG increased over time (trend P<0.001), from 51% at entry to 67% at third follow up (P<0.001), before leveling off to 78% at fifth follow up (P=0.001 vs. baseline).

Conclusion: Intensive blood glucose control in T2DM patients, who used SMBG significantly initially increased treatment costs in a diminishing marginal rate but substantially reduced the cost of complications. Timely management by SMBG frequently was both clinically astute & cost effective.

[3] TaiDoc Technology Corp., TeleHealth Business Group, Taipei, Taiwan
[4] Changhua Christian Hospital, Diabetes Education Center, Changhua, Taiwan
[5] Chang Jong Christian University, Department of Nursing, Tainan, Taiwan

Aims: Many studies have sought to evaluate whether the use of self-monitoring of blood glucose (SMBG) positively affects diabetic care in assessing glycemia. There are multiple sources of error including the population studied, the mode of treatments, durations of the trial, and study designs, all the issues affect the evaluation of conclusion in each trial. Aim of this study was to investigate the improvement of HbA1c in diabetic patients of more than 3 months intervention of SMBG with stable health educational control.

Methods: 164 patients (88 men, 76 women, 6 Type 1 DM, 158 Type 2 DM) were enrolled consecutively into the trial from December 2007 to December 2008. Subjects were followed up more than 3 months. Web-based TeleHealth System was provided for communication between subjects and physicians, and for management of blood glucose values. Primary outcome parameter was the change of HbA1c between baseline and follow-up end point. Primary outcome criterion was tested by a one-sided t-test for non-inferiority. Secondary outcome parameters were other metabolic markers as total cholesterol, triglyceride, LDL, HDL and creatinine. The daily frequencies and measuring time points were also recorded and analyzed.

Results: There are no statistical differences in the 164 subjects for demographic parameters and drug treatments. However, significant difference was demonstrated for the primary outcome in the change of HbA1c and the mean HbA1c for enrolled subjects was improved from 7.64±1.31 to 7.38±1.26 (P = 0.045). There were no statistically significant differences for all secondary metabolic markers. The distribution of average daily frequencies for the use of SMBG was 25% for 1 time/day, 46% for 1-2 times/day, 19% for 2-3 times/day, and merely 10% for 3-6 times/day. The distribution of pre-meal measuring time points was 29.18% before breakfast, 18.78% before lunch, and 25.98% before dinner. The distribution of post-meal measuring time points was 26% after breakfast, 21.77% after lunch, and 40.66% after dinner. Obviously, the most available times for measuring blood glucose are before breakfast and after dinner, and it indicated that patients preferred to measure blood glucose at home rather than outside such as work place. Some patients were concerned if colleagues or friends knew about his diabetes and would influence the social relationship or work performance.

Conclusion: SMBG is good method to allow diabetic patients to relate events in their daily life and treatment regimen to glycemic results. Frequencies for the use of SMBG vary directly with the intensity of treatment, and the consistent communication between diabetic patients and physicians is essential to effective implementation of self-monitoring and maintenance of patient motivation. Our study indicates that intensive care in using SMBG is necessary for the improvement of glycemia.

Effect of SMBG-based Diabetes Self-Management Education (DSME) on glycemic control in type 2 diabetes with oral antidiabetic agents

K.H. Sim[1], S.Y. Kim[1], K.Y. Kim[2], M.S. Hwang[3], Y.H. Sung[3]
[1] Samgsung Medical Center, Diabetes Education Unit, Seoul, Korea
[2] Samgsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea
[3] Samgsung Medical Center, Research Institute for Clinical Nursing Science, Seoul, Korea

Backgrounds: The goal of Diabetes Education is to optimize metabolic control. Self-monitoring of blood glucose(SMBG) is an important educational tool for achieving glycemic control. The aim of the study was to evaluate the effect of self-monitoring of blood glucose(SMBG)-based Diabetes Self-Management Education(DSME) on glycemic control in type 2 diabetes with oral antidiabetic agents
Methods: This study was designed to compare changes in glycemic control in SMBG-based DSME group(n=65) versus control group(n=65). Data were obtained from medical records of type 2 diabetic patients treated with oral antidiabetic agents and HbA1c $\geq$ 7.0% who received their education at a samsung Medical diabetes center in Korea from June 2006 to June 2007. All participants completed Diabetes Self-Management Education(DSME) defined as informational intervention of lifestyle habits and reinforcement of educational Monthly News letter delivered by the diabetes nurse educator. SMBG-based DSME group requested to measure blood glucose 7 times a day for a week and to record their diary and received counseling with a focus on diet and lifestyle during the education. Assessments were conducted baseline, 3, 6 and 12 months. HbA1c was used as an index of glycemic control.
Results: Baseline of HbA1c was not different between the SMBG-based DSME group and control group (SMBG-based DSME group 8.34± 1.53% vs. control group 7.82± 0.83%). 12 months later, the level of HbA1c was reduced by 1.28±1.68% SMBG-based DSME group(end point 7.07± 0.91%) and 0.49±1.05% in the control group(end point 7.34±1.12%) and achieved the goal of glycemic control (IDF goal: HbA1c< 6.5%) (SMBG-based DSME group 27.69% vs. control group 20.0%). A repeated measures analysis of variance was also carried out on the four values (at baseline, 3 months, 6 months and 12months) and found a significant decrease in HbA1c level over time(P<0.0001), a significant effect of Time* Group interaction (P =0.0128), but no significant effect of group.
Conclusion: SMBG-based DSME for patients with type 2 diabetes with oral antidiabetic agents was effective in improving glycemic control and maintaining long-term glycemic control.

Self-monitoring of blood glucose improved both the glycaemic control and 10-year coronary heart disease risk profile of Afro-Caribbean type 2 diabetic patients in Trinidad and Tobago

C. Ezenwaka[1], A. Dimgba[2], F. Okali[2], T. Skinner[1], R. Extavour[1], M. Rodriguez[1], V. Davis[2], A. Spencer[2], V. Davis[2], H. Mayer[1], A. Jones-LeCointe[1]
[1] The University of the West Indies, Unit of Pathology & Microbiology, St Augustine Trinidad, Trinidad and Tobago
[2] Tobago Regional Health Authority, Medicine, Tobago, Trinidad and Tobago

Background and aim: The debate on the overall benefits of self-monitoring of blood glucose in type 2 diabetic patients is still continuing. We assessed the difference in glycaemic control and coronary heart disease (CHD) risk levels of Afro-Caribbean patients provided with facilities for self-monitoring of blood glucose and their counterparts without such facilities.
Methods: Sixty-one patients who had no prior experience in using glucometers were studied as intervention (n=30) and control (n=31) groups. The intervention group was trained on self-monitoring of blood glucose and documentation. At baseline, blood pressure (BP), anthropometric indices and fasting blood glucose of all patients were measured. Subsequently, the intervention patients were provided with free glucometers, testing strips and advised to self-monitor their fasting and postprandial blood glucose every other day for six months. The 10-year CHD risk levels were determined with the United Kingdom Prospective Diabetes Study-derived risk engine calculator.
Results: The age, diabetes duration, BP and anthropometric indices were similar in the two groups (all, p>0.05). The majority of the patients were unemployed or retired females with only primary education. After three months, the HbA1c levels of the control patients remained unchanged (7.8±0.3 vs. 7.9±0.4%, P>0.05) whereas the HbA1c levels of the intervention patients reduced significantly from the baseline at three (9.6±0.3 vs. 7.8±0.3%, p<0.001) and six (9.6±0.4 vs. 7.5±0.3%, p<0.001) months. Interestingly, while the 10-year CHD risk level of the control group remained unchanged after three months, that of intervention group was remarkably reduced from the baseline level at three and to nearly one half after six months (7.4±1.3 vs. 4.5±0.9%, p<0.05).
Conclusion: Provision of facilities for self-monitoring of blood glucose in Afro-Caribbean type 2 diabetic patients significantly improved both their glycaemic control and CHD risk profile. Type 2 diabetic patients of African origin will benefit from inclusion of glucose meters and testing strips in their health care package.

The self-measurement of home blood pressure contributes to controlling mean clinic blood pressure levels below 130/80 mmHg in diabetic-hypertensive patients with their agreement

N. Kato[1], M. Kato[1]
[1] Kato Clinic, Internal Medicine, Tokyo, Japan

Background and aims: We treat approximately 900 outpatients/month, of whom 79% have diabetes, and 47% of them have hypertension. The clinic BP in outpatients has been significantly decreasing in recent years. The mean clinic BP was 129 /70 mmHg in 2003 and 123/68 mmHg in 2007 (unpaired t-test vs 2003, p<0.001). This is assumed to be attributable to the fact that we have been strongly recommending patients to measure home BP. In recent years, most patients have measured home BP and tried to control it.We investigated the effect of the self-measurement of home BP.
Materials and methods: We lent BP monitors and recorders to patients who had discontinued or had not undergone hypertension treatment. The data they measured by themselves was accumulated in PC. Referring to data on morning BP, we selected an antihypertensive drug or increased its dose each time when they visited clinic, with the objective of achieving an optimal BP of 125/80 mmHg or a target BP of <135/85 mmHg. We also instructed the remaining diabetic patients concomitantly having hypertension to measure home BP using their own BP monitors and record it in their notebooks (notebook-using patients). We tried to control their BP, referring to results when they visited. To achieve the same target BP, all the hypertensive patients were required to measure home BP in the morning and evening. The data accumulated in PC was reported to each patient.
Results: The study started from 2002. 33 diabetic patients (14 male, 42%) could accumulate data for 6 months or longer. A comparison of patients backgrounds between the HOMED-BP study and notebook-using (257) was - age: 58±8 / 65±10 years respectively (vs. HOMED-BP study, p<0.0001); BMI: 26±5 / 25±4 kg/m^2 (p=0.2196); diabetes treatment duration: 8±8 / 10±8 years (p=0.0491)(Mean±SD); current clinic BP: 122±14/68±8 and 128±14/68±10 mmHg (p=0.0202 and p=0.6674) (clinic BP at the start of the study: 156±15 /88±12 mmHg; and morning BP: 157±12 /91±10 mmHg); and the number of antihypertensive drugs used: 3±1 and 1.8±0.8 (p<0.0001).
Conclusion: When anti-hypertensive medications were administered to diabetic patients with hypertension in reference to home BP data, the target attainment rates of both home and clinic BP largely increased.This suggests that if physicians select an appropriate anti-hypertensive medication and control its dose, referring to home BP, it is possible to decrease BP in many diabetic patients with their agreement. Hypertension may cause macroangiopathy, including myocardial infarction and cerebral infarction, and worsen diabetic retinopathy and diabetic nephropathy. However, it is very difficult for all people with diabetes to achieve these targets, and the target attainment rate in Japan is not high.The self-measurement of home BP does not put any burden on patients, excluding the purchase of BP monitor, so it is assumed to greatly contribute to medicoeconomics.

Variation of capillary glycemia and blood pressure of people with type 2 diabetes after joining a program of physical activity for diabetes

C.E.G. Reis[1], G.F. Mendes[2], F.D. Moreira[2], A.O.P. Protzek[3], A.S.M. Silva[2], J. Dullius[4]

[1] *Federal University of Viçosa, Department of Nutrition and Health, Viçosa, Brazil*

[2] *Federal University of Brasília, Doce DESAFIO, Brasília, Brazil*

[3] *Federal University of Brasília, School of Medicine, Brasília, Brazil*

[4] *Federal University of Brasília, School of Physical Education, Brasília, Brazil*

Aims: To observe the changes in capillary blood glucose and blood pressure of type 2 diabetic individuals of both sexes, after entering a program of physical activities geared to diabetics.

Methods: The program is assisted by a team in the areas of exercises, education, nutrition, medicine, nursery. The activities consisted of monitoring 3x per week, in the afternoon, with 2h in duration each, where in each meeting, the self-monitoring of blood glucose is done in a fed state. Activities included physical monitoring, lectures, and guidelines on treatment. We analyzed 22 type 2 diabetic individuals aged average of 56±9 years and average time of diabetes diagnosis 9±6 years, requiring a minimum presence of 60% in the activities of the program (30 lessons) and correct completion of the chips. To measure capillary blood glucose were used glucometers (One Touch and Roche) under the observation of monitors, and measurement of systemic blood pressure (SBP) was performed by trained personnel with the columns of mercury sphygmomanometers. We collected the data of glycemia and SBP to compare results. To compare the variables was applied paired student t-test with significance level $p<0.01$. All subjects gave written informed consent. This investigation was approved by the institutional review boards of the University of Brasília, Brazil.

Results: There were no significant changes in relation to SBP, comparing both the systolic and diastolic separately (both p=0.27), average initial and final 131/82mmHg and 133/80mmHg. Glycemia was significantly reduced ($p = 0.007$). The mean initial blood glucose was 177±99mg/dl, decreasing to 144±35mg/dl at end of program, totaling an average decrease of 33 mg/dl which represents 18.64%. There was 3 people with higher loss of 100mg/dl, and the maximum was 312mg/dl.

Discussion/conclusion: It is known that poor of glycemic control is an important predictor of many chronic complications of diabetes mellitus, and strategies for changing behavior are fundamental to the improvement of the metabolic system. Education programs in diabetes assume paramount importance in the work of awareness in the treatment of disease. More research is needed to develop interventions effective in maintaining long-term glycemic control.

Diabetes prevention and control: public education initiatives in the U.S.

J. Gallivan[1]

[1] *NIDDK/NIH, National Diabetes Education Program, Betheda MD, USA*

The National Diabetes Education Program is a government funded program sponsored by the U.S. Department of Health and Human Services. NDEP has over 200 partner organizations that work at national, state and local levels. NDEP was established to improve diabetes awareness and control in the U.S. in 1997. In 2001, based on the results of the Diabetes Prevention Program (DPP), NDEP added a diabetes prevention initiative.

NDEP develops and implements evidence-based public education initiatives by translating clinical research into effective public education messages, materials and campaigns. NDEP conducts quantitative and qualitative research. Results of the NDEP 2006 and 2008 public surveys provide information on public awareness of factors influencing diabetes awareness, diabetes control and influences on one's perception of risk for diabetes. Qualitative research done through the use of focus groups with targeted populations is used for guiding program development. All program components are subject to evaluation, and are updated with new evidence.

Addressing health disparities is a core goal of NDEP. Core materials are adapted for up to 20 audiences. Resources are also age appropriate, with an emphasis on children, adolescents and older adults and their families.

NDEP's Control Your Diabetes. For Life. campaign focuses on providing, and the importance of, comprehensive diabetes care. The campaign was based on the findings of the Diabetes Control and Complications Trial and is updated regularly. This campaign includes resources for consumers, families and health care professionals.

NDEP's diabetes prevention campaign, Small Steps. Big Rewards. Prevent Type 2 Diabetes, is designed to reach the 57 million Americans at risk for diabetes and is based on the intervention used in DPP. Resources include a toolkit for healthcare professionals to help consumers with lowering their risk through lifestyle changes and modest weight loss, and community guides for implementing prevention programs for various audiences.

Findings from recent clinical trials and new clinical standards will be summarized and how these results are changing the NDEP public education initiatives will be presented.

A new initiative, Support Behavior Change, is focused on helping with the behavior/lifestyle change efforts of people with diabetes and at risk for diabetes, and their families. It will also support health care providers and organizations in helping those who want to change their behavior. NDEP is assembling an inventory of existing and useful tools and programs that target various behaviors.

Using a participatory process to enhance effectiveness of diabetes awareness campaign in the Philippines

J. Hernandez[1], I. Boyose-Nolasco[1], J. Villafuerte[2], E. Pasquier[3], P. Guimet[3], C. Vasseur[4], O. Fabre[4]

[1] *Handicap International Philippines Program, Diabetes Project, Davao City, Philippines*

[2] *City Government of Davao, City Health Office, Davao City, Philippines*

[3] *Handicap International France, Technical Resources Division, Davao City, Philippines*

[4] *Handicap International Philippines Program, Head Office, Makati, Philippines*

Introduction: The call to action on diabetes resonates around the world as late diagnosis of diabetes continues to challenge diabetes management. Response to this global call can be enhanced with the use of the community-based participatory process through the P-Process steps in strategic health communications. This has been widely used in family planning, maternal health, child survival, HIV/AIDS, and other infectious diseases such as malaria and tuberculosis. The Handicap International team in the Philippines believes that the same planning approach can be applied to a non-communicable disease like diabetes to initiate positive change in an effective and culturally acceptable manner.

Objective: To determine the benefits of a community-based participatory process in enhancing the effectiveness of a diabetes awareness campaign in the Philippines.

Methods: The process began with the joint analysis of the situation and the audience through dialogues with the partners and focus group discussions with persons at risk of developing diabetes. To develop the strategic design, a multi-stakeholder working group was organized with group members coming from health professionals, community health workers, people with diabetes, communication specialists and professional artists. Together, a strategy was built; messages and materials on screening were further developed and then pretested. To implement the campaign, community health workers underwent capacity-building workshops and action planning sessions.

To measure the results of the campaign, the numbers of screened patients were counted from the screening registries in the community health centres. After five months of implementation, strategies were improved.

Results: Practice-based evidence on the effectiveness of community-based participatory strategy for diabetes awareness campaigns: a step-by-step road map that allows stakeholders to work together on a campaign with measurable impact on the target audience.

Increase by 60% in the number of people who availed screening services in the project areas between the first and second half of 2008.

Conclusions: With many stakeholders on diabetes education who popularize the symptoms of diabetes and healthy lifestyle, a community-based participatory process is effective in identifying interventions where scarce resources can be appropriated and wasteful duplication of efforts reduced.

The added value of this process is that it also facilitated quality partnership building and enabled local partners to have a sense of ownership of the project. Local ownership is critical to sustainability of community-based interventions.

Barriers to healthy behaviors for people with type 2 diabetes: what role do patient out-of-pocket costs play?

C.J. Longo[1]
[1] McMaster University, School of Business, Hamilton, Canada

Published US research shows that patient compliance with recommended healthy behaviors is greater when external funding sources reduce out-of-pocket costs (OOPC) for diabetes supplies, and is associated with improved health outcomes. However, for people with diabetes, research was not identified that directly investigated the influence of financial barriers on healthy behaviors in largely publicly funded healthcare systems.

Aims: This current research project investigates patients' financial barriers associated with diabetes care in a Canadian setting in order to determine the influence of these barriers on healthy behaviors.

Methods: We conducted in-depth face-to-face interviews with 14 adults (25-73 yrs; 57% female) from the Hamilton, Ontario area, with type 2 diabetes (diagnosed at least one year earlier). Detailed questions were asked about OOPC and the respondents' compliance with the following recommended health behaviors: exercising regularly; healthy eating; attending family physician and specialist visits; glucose monitoring; and medication compliance. A 10-point Likert scale was used to quantify respondents' perceptions of the impact of OOPC on these behaviors, with 0 being not at all and 10 being severe.

Results: Thirty-six percent of respondents reported moderate to severe financial barriers to complying with recommended healthy behaviors (rating 5-10). Those respondents who reported these higher scores for financial barriers typically had either no or inadequate financial coverage through employer-sponsored or public programs. We observed that the majority of our sample population (64%) found financial barriers associated with patient OOPC of minimal concern (ratings of 1-4). However, some individuals provided detailed commentary raising concerns about their inability to continue these health behaviors in the absence of existing external financial support.

Conclusion: Respondents stated financial barriers are associated with the magnitude of OOPC, and typically these costs are mitigated by both employer-sponsored and publicly funded programs for diabetes care. This highlights the importance of these funded programs and the risks associated with their retrenchment. Future research that explicitly considers the impact of a loss of external financial support on patients' healthy behaviors may prove to be an important adjunct to the existing research on OOPC and its relationship to health outcomes.

Activation of lysosomes by intracellular triacylglycerol accumulation contributes to the increased oxidative stress in liver in NAFLD

M. Cahova[1], O. Oliarnyk[1], H. Dankova[1], L. Kazdova[1]
[1] Institute of Clinical and Experimental Medicine, Department of Metabolism Of Diabetes, Prague, Czech Republic

Aims: Hepatic steatosis represents a risk factor for the development of serious complications. This study was designed to test the hypothesis that processes associated with intracellular TAG cycling contribute to increased susceptibility of fatty liver to further stress factors. Special attention was paid to the regulation of TAG breakdown.

Methods: Hepatic steatosis was induced by 2-week high-fat diet (HFD, 69 cal% as lard) administration to male Wistar rats (300±15 g). Individual lipases were identified according to their pH optimum. Phagolysosome (PhL) fraction was prepared from liver homogenate by differential centrifugation. mRNA expression was measured by RT-PCR. LAL protein expression was quantified by immunodetection.

Results: Lysosomal lipase (LAL) was the only lipase that was able to cleave endogenous liver TAG. LAL activity was regulated according to the nutritional status at the level of mRNA synthesis (fasting 33.6±7.3; fed state 6.8±0.9 pg cDNA/ml). Beside this, in the situation of intracellular TAG accumulation we described an additional mechanism of LAL activation independent of mRNA or protein synthesis. LAL is functional only in lysosomes activated by substrate ingestion (PhL) that can be separated by centrifugation. In fatty liver the increased amount of intracellular fat droplets makes their contact with lysosomes more frequent and the probability of PhL formation increases. In accordance with this presumption we found an increased LAL activity (11±1 vs 29±4 nmol FFA.mg^{-1}.60 min^{-1}) and protein expression (4,5±1 vs 11,2±1,2 arb. units) in phagolysosomal fraction in HFD group. Moreover, the PhL from fatty liver exhibited increased fragility measured by the release of lysosomal glucuronidase (GU) into cytosol *in vivo* (33±2 vs 60±6 μmol.mg^{-1}) and during incubation *in vitro* (5,4±0,9 vs 13±2,2 μmol.mg^{-1}). Indicators of oxidative stress were significantly higher in homogenates from fatty liver (CD 31.5±1.2 vs 41.5±1.8 nmol.mg^{-1}; TBARS 1.4±0.1 vs 2.1±0.25 nmol.mg^{-1}; GSH 15.5±0.9 vs 11.5 μmol.mg^{-1}). Dexamethasone (5 mg/kg per day, 4 doses) significantly increased TAG accumulation in liver, depressed LAL activity (8.5±0.08 nmol FFA.mg^{-1}.60 min^{-1}), decreased fragility of lysosomes (GU release *in vivo* 12.8±2.3; *in vitro* 5.6±1.1 μmol.mg^{-1}) and ameliorated oxidative stress parameters (TBARS: 0.89±0.1 nmol.mg^{-1}).

Conclusion: In steatosis degradation of liver TAG realised by LAL is stimulated and requires formation of phagolysosomes. It may contribute to the alterations in mitochondrial function (described in steatotic liver) via 1) supplying excess of fatty acids for oxidation and 2) deterioration of mitochondrial membrane by released lysosomal enzymes, both resulting in increased ROS production. The importance of alterations of lysosome "state" induced by TAG accumulation in liver in the induction of oxidative stress is supported by the effect of dexamethasone.

The effect of telmisartan on insulin-stimulated selected plasma adipocytokine levels in patients with metabolic syndrome

P. Wohl[1], E. Kruinová[1], S. Kratochvílová[1], M. Hill[2], P. Mlejnek[3], M. Pravenec[4], T. Pelikánová[1]
[1] Institute of Clinical and Experimental Medicine, Diabetes center, Prague, Czech Republic
[2] Institute of Endocrinology, Department of Biochemistry, Prague, Czech Republic
[3] Academy of Science, Department of Physiology, Prague, Czech Republic
[4] Academy of Science, Deparment of Physiology, Prague, Czech Republic

Aims: Telmisartan is suggested as modulator of lipid and glucose metabolism. The underlying mechanisms are still unclear. The aim of our study was to test the effect of telmisartan (T) on selected plasma adipocytokine concentrations during acutely-induced hyperinsulinemia.

Methods: 12 patients with impaired glucose tolerance or impaired fasting glucose were enrolled in randomized, placebo-controlled, cross-over study of 3 weeks treatment with telmisartan (160 mg/d) or placebo (P). At the end of each treatment period the glucose disposal rate (M) was estimated by one-step hyperinsulinemic euglycemic clamp (120 minutes; 1 mU.kg $^{-1}$.min $^{-1}$; 5 mmol/l). Before and during the clamp (0, 120 minutes) plasma levels of fatty acid binding protein (A-FABP), high-molecular adiponectin (HMW), total adiponectin, visfatin, retinol-binding protein (RPB-4) were evaluated by ELISA.

Results: Compared to placebo, treatment with T increased insulin-stimulated total adiponectin concentrations during the clamp ($p<0.05$), however basal concentrations have not been changed. T has no effect on HMW adiponectin, A-FABP, visfatin and RPB-4. We have not found effect of T on insulin sensitivity, M was comparable between T and P periods.

	T		P	
Time	0 min.	120 min.	0 min.	120 min.
Adiponectin (ug/ml)	6,53±0,8	7,51±0,9	6,41±0,8	6,01±0,9
HMW adiponectin (ug/ml)	3,55±1,8	3,59±1,9	3,64±2,4	3,25±2,1
Visfatin (ng/ml)	8,48±8,5	8,51±5,4	8,40±7,9	9,34±10
A-FABP (ng/ml)	22,8±10	22,27±9	24,15±10	25,31±12
RBP- 4 (ug/ml)	44,26±20	39,24±23	43,30±17	39,77±15

Conclusion: We conclude that 3-week intervention with telmisartan increases plasma total adiponectin during acutely-induced hyperinsulinemia, while HMW adiponectin, visfatin, A-FABP and RPB-4 are not affected. The results support the hypothesis, that the increase in plasma adiponectin might be involved in the metabolic effects of telmisartan in patients with metabolic syndrome. (IGA *NR9359-3/2007).*

Deletion of adipose differentiation related protein (ADRP) prevents lipid accumulation in knockout mice

Y.K. Lee[1], K.T. Dalen[2], A. Kimmel[1], C. Londos[1]
[1] *National Institutes of Health, National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, USA*
[2] *Institute of Basic Medical Science Faculty of Medicine University of Oslo, Department of Nutrition, Oslo, Norway*

All cells package neutral lipids (triacylglycerol and cholesterylesters) in storage droplets surrounded by a phospholipid monolayer into which are embedded at least one member of the PAT protein family (perilipin, ADRP, Tip47, S3-12 and LSDP5). These proteins serve to protect the lipid contents from lipases and thus, sequester fatty acids which may induce insulin resistance. The lipid droplets are essential for storage of lipids utilized for cellular energy, membrane synthesis and steroid production. Excessive cellular triglycerol storage is commonly associated with obesity and it is a well-known risk factor in the development of obesity-related metabolic complications such as insulin resistance, type 2 diabetes, cardiovascular disease, and abnormal lipid metabolism. Perilipin is a well-characterized member of the PAT family proteins, with expression largely limited to adipose cell whereas other PAT proteins such as ADRP are ubiquitous. The objective of this study was to generate an ADRP knockout mouse. To our knowledge, this is the first mouse model of an ADRP knockout mouse. Chan et al. reported inactivation of part the ADRP gene in mice that exhibited a limited phenotype with only marginal reduction of hepatic lipids, but there was no effect to the plasma lipid profile, adipocyte differentiation, and fat mass. By contrast, our ADRP knockout mouse exhibits a total lack of ADRP, and a dramatically reduced (by 30%) fat mass such as epididymal and inguinal fat pads ($p<0.001$). A better understanding of the molecular pathophysiological mechanisms of lipid droplet-associated proteins with functional links to metabolic complications can lead to the discovery of new therapeutic molecular targets for the treatment of metabolic disorders.

Acute angiotensin II type 1 receptor blockade induces an increase in adiponectin in healthy subjects

E. Krusinova[1], P. Wohl[1], S. Kratochvilova[1], J. Kopecky jr.[1], H. Kahleova[1], P. Mlejnek[2], M. Pravenec[2], L. Kazdova[1], T. Pelikanova[1]
[1] *Institute for Clinical and Experimental Medicine, Diabetes Center, Prague, Czech Republic*
[2] *Academy of Sciences of the Czech Republic, Institute of Physiology, Prague, Czech Republic*

Background and aims: Decreased adiponectin concentrations in metabolic syndrome and diabetes are widely acknowledged. Angiotensin II type 1 receptor blockade is supposed to enhance insulin sensitivity. However the underlying mechanisms, eg. effect on adiponectin levels, have not been clarified in humans till now. The aims of our study were: a) to assess plasma concentrations of total and high-molecular weight (HMW) adiponectin and its expression in subcutaneous adipose tissue and b) to evaluate their responses to acutely induced hyperinsulinaemia and angiotensin receptor blockade in healthy subjects.
Methods: 12 healthy men underwent: 1) hyperinsulinaemic (1 $mU.kg^{-1}.min^{-1}$) euglycaemic (5 $mmol.l^{-1}$) clamp (HEC); 2) HEC after administration of losartan 200 mg (AT-HEC) and 3) saline 0,9% infusion as a volume control (SAL). At baseline (0 min) and at the end of the particular intervention (240 min) blood samples were taken for assessment of total and HMW adiponectin in plasma (HEC/AT-HEC/SAL) and a needle biopsy of abdominal subcutaneous adipose tissue (HEC/AT-HEC) was performed. Tissue samples were further processed for real-time PCR to estimate relative expression of adiponectin.
Results: Insulin sensitivity estimated as metabolic clearance rate of glucose (MCR) was not influenced by angiotensin receptor blockade (HEC vs. AT-HEC: 10.81±0.77 vs. 11.46±1.16 $ml.kg^{-1}.min^{-1}$; ns). Plasma concentrations of HMW adiponectin declined during both HEC and SAL ($p<0.05$; ANOVA), changes in total plasma adiponectin during HEC and SAL were not significant. Compared to other interventions, during AT-HEC significant increases in both total and HMW adiponectin were detected ($p<0.05$; resp. $p<0.01$; ANOVA). Relative expression of adiponectin in subcutaneous adipose tissue did not show any changes during HEC, whereas during AT-HEC an increase in expression was observed ($p<0.05$; ANOVA).
Conclusion: The increase in total and HMW adiponectin, as well as its increased expression after acute losartan administration, might represent one of the mechanisms by which the angiotensin receptor blockade influences insulin sensitivity. Acute hyperinsulinaemia had no significant impact on plasma adiponectin or its expression. The decline in HMW adiponectin during hyperinsulinemia can be explained by haemodilution during the clamp. Table: Plasma concentrations of total and HMW adiponectin and its relative expression (adiponectin mRNA/cyclophilin mRNA). Data expressed as mean±SEM.

p-adiponectin [µg/ml]	HEC		AT-HEC		SAL

Combined effects of atorvastatin and metformin on glucose-induced variations of endothelial function in patients with newly diagnosed diabetes mellitus

K. Koniari[1], D. Tousoulis[1], C. Antoniades[1], A. Nikolopoulou[1], M. Noutsou[2], N. Papageorgiou[1], K. Makris[1], K. Marinou[1], C. Stefanadis[1]
[1] *Hippocratio Hospital University of Athens, Cardiology, Athens, Greece*
[2] *Hippocratio Hospital University of Athens, Diabetes Center, Athens, Greece*

Aims: Statin treatment has been suggested to improve survival in patients with atherosclerosis, but their effects on the glucose-induced variations of endothelial function are unknown.We examined the effect of atorvastatin when administered on top of conventional anti-diabetic treatment or diet, on glucose-induce variations of endothelial function, in patients with newly diagnosed diabetes mellitus type 2 (DM).
Methods: Seventy subjects with newly diagnosed DM were randomised to receive metformin 850mg/d (M, n=17), metformin850mg/d+atorvastatin 10mg (M+A, n=16), atorvastatin 10mg/d with dietary instructions (A+D, n=18) or diet only (D, n=19). All subjects underwent glucose loading (75g oral glucose) at baseline and after 12 weeks of treatment. Blood samples were obtained at baseline and 3 hours post-loading, while endothelium-dependent dilation (EDD- by gauge-strain plethysmography) was evaluated at baseline and every 1h.
Results: At baseline, EDD was reduced after glucose loading in the overall population (from 86.2±5.1% to 60.7±2.5% at 1h $p<0.001$ vs baseline, 54.7±2.3% at 2h $p<0.001$ vs baseline and 75.5±2.8% at 3h, $p<0.05$ vs baseline). Diet slightly prevented the glucose-induced reduction of EDD at 3h (from 80.4±7.1% to 63.2±4.7% $p<0.05$ at 1h, 62.0±5.0% $p<0.05$ at 2h and 76.2±6.5% p=NS at 3h). A similar effect was observed in M group (from 88.8±5.6% to 58.9±6.5% at 1h $p<0.001$, 52.6±4.8% at 2h $p<0.001$ and 75.4±3.6% at 3h p=NS). There was no benefit in A+D group (from 85.7±4.8% to 56.2±4.1% $p<0.001$ at 1h, 53.6±4.6% $p<0.001$ at 2h and 71.7±5.7% p=NS at 3h) or in M+A (from 73.3±4.7% to 62.2±3.6% $p<0.001$ at 1h, 55.6±5.6% at 2h and 55.6±5.6% p=NS at 3h).
Discussion/conclusions: Glucose loading significantly affects endothelial function. Three months treatment with atorvastatin alone or in combination with metformin failed to further improve the response of endothelial function.

Role of stress in the development of type 2 diabetes mellitus

S.V. Madhu[1], A. Siddiqui[1], N.G. Desai[2], S.B. Sharma[3]
[1] University College of Medical Sciences, Department of Medicine Division of Endocrinology & Metabolism, Delhi, India
[2] Institute of Human Behaviour & Allied Sciences, Department of Psychiatry, Delhi, India
[3] University College of Medical Sciences, Department of Biochemistry, Delhi, India

Aim: To study whether chronic environmental stress is associated with abnormalties in Glucose tolerance, Insulin sensitivity and Pancreatic beta cell function.
Methods: Stress scale questionnaires - Presumptive Stressful Life Events Scale (PSLES), Perceived Stress Scale (PSS) and Sense of Coherence (SOC) - were administered to 232 Normal Glucose Tolerance (NGT) and 123 Newly Detected Diabetes Mellitus (NDDM) subjects. Study subjects were recruited on the basis of standard WHO criteria following a 75 gram oral glucose tolerance test (OGTT) conducted in 1921 apparently healthy subjects comprising relatives of diabetic patients and other healthy volunteers. Clinical parameters like body mass index (BMI), waist, waist hip ratio (WHR), systolic blood pressure (SBP) and diastolic blood pressure (DBP) were recorded in all. Fasting serum insulin and lipids were performed in all cases. Insulin resistance and ß-cell function were determined by the method of homoeostasis model assessment (HOMA). All parameters were compared in NDDM and NGT subjects in a case control design.
Results: All clinical (BMI, waist, WHR, SBP, DBP), biochemical (serum total-, high density lipoprotein-, low density lipoprotein-, very low density lipoprotein-cholesterol, and triglycerides) and insulin resistance (HOMA-IR) parameters were significantly higher and pancreatic ß-cell function (HOMA-ß) parameters were significantly lower in NDDM subjects as compared to NGT.
Stress questionnaire scores were significantly higher in NDDM subjects as compared to NGT ($p<0.05$) with respect to PSLES-lifetime (577.20± 146.67 vs 420.55±119), PSLES-1 yr (99.98±73.40 vs 41.26±44.12) as well as PSS (19.4±6.39 vs 12.22±5.64) indicating higher prevalence of stress in them. SOC scores (23.63±4.37 vs 25.60±4.70) were lower in the NDDM group suggesting that NDDM subjects did not cope as well as NGT subjects with stress.
Conclusion: The results of the present study indicate that NDDM subjects display higher chronic environmental stress and poor stress coping. It would appear that chronic stress leads to a higher central obesity, greater insulin resistance and Diabetes Mellitus.

Evaluation of insulin resistance in first degree relatives of type 2 diabetes mellitus patients in population from Colombia

A. Villegas Perrasse[1], N.G. Natalia Gallego Lopera[1], L.F. Liliana Franco Hincapié[1], M.P. Maria Victoria Parra[1], C.D. Constanza Duque Veléz[1], J.O. Juan Pablo Otalvaro[1], A.R. Andres Ruiz Linares[2], G.B. Gabriel Bedoya Berrio[2]
[1] Universidad de Antioquia, Endocrinología, Medellín, Colombia
[2] Universidad de Antioquia, Genetica Molecular, Medellín, Colombia

Introduction: Family history of type 2 diabetes (DM2) is a major risk for DM2 in youth. We assessed the effect the variants in four genes with relatively small effects may contribute to the etiology of diabetes. Homeostasis model assessment (HOMA) is a method for assessing *B*-cell function and insulin resistance (IR) from basal (fasting) glucose and insulin.
Objective: To evaluate the impact of family history of DM2 on insulin secretion relative to insulin sensitivity in healthy youth and to assess the association between the polymorphisms ID 45 and -866G/A of the gene uncoupling protein 2 (*UCP2)*, -55C/T of the gene *UCP3*, -2548GA of the gene *Leptin* and SNP19 of the gene *Calpaine* in a Colombian population.
Methods: A total of 186 men and women aged 20-40 years with (60) and without (126) a family history of DM2. Enzymatic methods were used to measure glucose, total and HDL cholesterol and triglycerides in each sample. Serum insulin was measured by radioimmunoassay.
All participants were interviewed. The study comprised measurement of anthropometric parameters: weight, height, body mass index (BMI), blood pressure, waist and abdomen circumferences and waist to hip ratio. Each sample was genotyped for 5 polymorphisms in UCP 2 and 3, Leptin and Calpaine genes by PCR and PCR-RFLP.
Comparison between people with and without a family history of DM2 was made using two-tailed Student's *t* test for continuous variables. Pearson or Spearman correlation analysis was used. Single associations were evaluated by chi-square test. The IR, the state beta cell function (%B) and insulin sensitivity (%S) was calculated with HOMA v2.2.
Results: Cholesterol LDL (92 vs. 101 mg/dl, P= 0.033), waist circumferences (81 vs. 86 cm, P= 0.015), waist to hip ratio (0.81 vs. 0.84, P= 0.043), body mass index (22 vs. 26 Kg/m^2, P= 0.001), weight (63 vs. 69 kg, P= 0.009), plasma glucose (82 vs. 88 mg/dl, P= 0.001) and triglycerides (99 vs. 148 mg/dl, P= 0.001) were lower in people without versus with family history of diabetes. The alleles were in Hardy-weinberg equilibrium. The ID genotype subjects for ID45 (UCP2) had significantly higher fasting HDL cholesterol concentrations and so on in the GG genotype subjects for -2548GA (Leptin) had higher fasting total and LDL cholesterol concentrations and they had higher BMI; the DD genotype subjects for SNP 19 (Calpaine) had higher fasting total cholesterol and insulin concentrations.
Conclusion: Family history of DM2 is associated with alterations in metabolic parameters in youth with a positive family history, and suggests that many of the determinants are genetic. Some alleles of UCP 2, Leptin and Calpaine genes confer risk of DM2 in a Colombian population. The cut-off point for the homeostasis model (HOMA) was 1.8.

The association between objective and surrogate measures of insulin sensitivity and beta cell function in adolescents

A. Macintosh[1], B. Wicklow[1], K. Wittmeier[1], E. Sellers[2], H. Dean[2], J. McGavock[1]
[1] Manitoba Institute of Child Health, Pediatrics and Child Health, Winnipeg, Canada
[2] University of Manitoba, Pediatrics and Child Health, Winnipeg, Canada

Background: A reduction in both insulin sensitivity (Si) and the acute insulin response to a glucose challenge (AIR) precede the development of type 2 diabetes (T2DM). As direct measurements of these variables are labour intensive and associated with a risk of hypoglycemia, epidemiological studies of youth frequently rely on surrogate fasting or post-prandial measures to estimate Si and AIR. The aim of this study was therefore to assess the validity of surrogate measures of Si and AIR with direct measures in a cohort of adolescents with normal glucose tolerance.
Methods: We recruited 78 youth to participate in a cross sectional study of modifiable determinants of Si in youth, who were all screened for glucose tolerance. Si and AIR were assessed directly using Bergman's frequently sampled intravenous glucose tolerance test (IVGTT). Surrogate measures included a frequently sampled (15,30,60,90,120 min) insulin response to a two-hour 75g oral glucose tolerance test (OGTT) and the homeostasis model of insulin resistance and beta cell function (HOMA-IR and HOMA-B).
Results: We studied 65 overweight (BMI Z score: 1.9 ± 0.5) and 15 healthy weight (BMI Z score: 0.2 ± 0.6) adolescents aged 13-18yrs (mean 16± 2 yrs). Both HOMA ($r = -0.53$, $p < 0.01$) and OGTT-derived ($r = -0.52$, $p < 0.01$) measures of insulin sensitivity were significantly associated with IVGTT-derived values. In contrast, the disposition index was not associated with the insulin response at 15 and 30 minutes during an OGTT or HOMA-B. Variables that predicted Si and the area under the curve during an OGTT included percent body fat, waist circumference, hepatic triglyceride content and maximal oxygen uptake.
Conclusions: Surrogate estimates of Si obtained from fasting and frequently sampled OGTT are closely associated with values obtained from Bergman's IVGTT and may be considered useful for epidemiological studies of youth. In contrast surrogate measures of beta cell function from fasting or post-prandial insulin levels are less valid in adolescents.

[4] *Steno Diabetic Centre, Steno Diabetic Centre, Copenhagen, Denmark*

[5] *Copenhagen University, Department of International Health, Copenhagen, Denmark*

Introduction: Those born with low birth weight have a greater propensity to develop diabetes, a reason why glucose intolerance, insulin insensitivity & metabolic syndrome are increased in India.

Aims: To assess baseline characteristics of young rural South Indian males with low & normal birth weight on:

A. Insulin resistance as assessed by the hyperinsulinemic euglycemic clamp and other indices.

B. Body composition by DEXA and Bio-impedance.

C. Energy expenditure by indirect calorimetry & Actiheart.

Method: Subjects- 100, young rural males born at term from rural South India.

- Inclusion criteria: Healthy Males aged 18 to 22 years & fully attained puberty.
- Exclusion criteria: Diabetes, strenuous exercise, any medications, BMI >25 kg/m2, major organ disease.

Subjects are brought to hospital fasting & were examined. After informed consent, Anthropometry was assessed. Hyperinsulinemic euglycemic clamps combined with IVGTT & indirect calorimetry were done. Insulin secretion was measured using first phase insulin response. Insulinogenic index, M-value & disposition index were calculated. Resting and total energy expenditure were measured using indirect calorimetry and Actiheart. Body composition was measured using DEXA (Hologic).

Results: Analysis revealed: BMI: 19.13(±2.75), HOMA: 0.92(±1.16), 1/HOMA: 1.97(±1.44), QUICKI: 0.42(±0.06), McAuley's index: 11.33(±2.77). Glucose infusion rate during insulin stimulation (M value): 10.92(±3.78) mg/min/kg. Fat Free mass: 43.38(±5.39).

insulin sensitivity indicator (M value) correlated negatively with BMI(r: -0.28), waist circumference (r: -0.39), Total energy expenditure(r= -0.21), Total Cholesterol(r= -0.24), LDL(r= -0.26), Dry Lean weight(r= -0.27) and Truncal fat(r= -0.34).

Birth weight correlated positively with Basal (r=0.24 with p=0.008) and Activity associated energy expenditure(r= 0.17 with p=0.04).

Subjects were divided into quintiles on the basis of birth weight. Those with very low birth weight (VLBW<2kg) lagged behind in final height, compared to subjects with normal birth weight (NBW>3kg) [p=0.046]. Fat free mass assessed by DEXA was less in LBW subjects (2-2.2kg) compared with NBW subjects (p=0.029). Fasting insulin was higher in VLBW subjects compared to Borderline LBW (2.2-2.5kg) and NBW subjects (p values of 0.01 and 0.005 respectively).

Discussion/conclusion: This is the first study where indirect and direct determinations of body composition and insulin sensitivity were performed simultaneously in young lean healthy adult Asian Indians.

Insulin resistance indices were significantly related to glucose uptake, fasting insulin levels and the M-value being most tightly associated.

Data on energy expenditure obtained from the Actiheart indirect calorimetry showed a positive correlation between birth weight and energy spent.

Subjects in the lowest quintile had hyperinsulinemia more significant when compared those in the Normal and borderline low birth weight quintiles.

What if everyone were Chinese? The convoluted effects of ethnicity on type 2 diabetes in Canada

C. Robinson1, Y. Shi[1], H. Morrison[1], M. Abdel-Motagally[1], L. Vardy[1]

[1] *Public Health Agency of Canada, Centre for Chronic Disease Prevention and Control, Ottawa, Canada*

Aims: Canada's multi-ethnic make-up provides certain advantages when it comes to analyzing the effect of ethnicity on type 2 diabetes (T2DM). Canada represents not only a diverse set of racial groups, but also a Westernized obesogenic environment. This diversity makes it possible to directly compare the prevalence of type 2 diabetes among Caucasians and other major ethnic groups, controlling for BMI and other confounders.

Methods: Self-reported data from the 2003/04 and 2005/06 Canadian Community Health Survey were pooled to increase the sample size for subgroup stratification and restricted to those aged 40 years and older (n= 148,446). The unweighted sample included 127,315 Caucasians; 1,825 Blacks; 6,702 East and Southeast Asians; 1,718 Aboriginals; 3,202 South Asians; 866 West Asians and Arabs; and 836 Latin Americans. Those with physician-diagnosed diabetes were further verified to exclude gestational diabetes and possible type 1 diabetes using an algorithm previous developed by Statistics Canada. The adjusted odds ratios for type 2 diabetes, adjusted for various confounders such as age, sex, body mass index (BMI) and family income, were then examined using logistic regression with Caucasian ethnicity as the reference group. Measures of variance and statistical significance were determined using bootstrap estimation.

Results: Before adjustment, crude prevalence of diabetes by ethnicity showed 7.5% for Caucasians; 10.7% for Blacks; 6.8% for East and Southeast Asians; 12.7% for Aboriginals; 13.6% for South Asians; 3.3% for West Asians/Arabs; and 6.1% for Latin Americans in adults 40 years of age and over. Compared to Caucasians, odds ratios for diabetes, adjusted for age and sex, were 2.3 (95% CI: 1.9-2.8) for Aboriginals, and 2.3 (95% CI: 1.8-2.9) for South Asians. Adjusted for age, sex and BMI, odds ratios were 1.8 (95% CI: 1.3-2.5) for Blacks, 1.7 (95% CI: 1.4-2.1) for East and Southeast Asians, 1.9 (95% CI: 1.6-2.4) for Aboriginals and 3.0 (95% CI: 2.4-3.8) for South Asians.

Conclusions: Compared to Caucasians, the crude prevalence of self-reported diabetes is high among South Asians, Aboriginals and Blacks, but relatively low for East and Southeast Asians. After adjusting for confounders such as BMI and age, Chinese and other Southeast Asians have similar diabetes risk as Blacks and Aboriginals. South Asians were the ethnic group with the highest risk for type 2 diabetes, after controlling for confounding factors.

HOMA does not identify insulin resistance in cohorts with a high prevalence of pre-diabetes: a study of Black Africans and African Americans

M. Luercio[1], M. Ricks[1], O. Imoisili[1], A. Sumner[1]

[1] *National Institute of Health, NIDDK, Bethesda, USA*

Insulin resistance can be accurately determined from the insulin sensitivity index (S_I) with data from frequently sampled intravenous glucose tolerance tests (FSIGT). However, FSIGT are time consuming and expensive. As an alternative, homeostasis model assessment (HOMA) is an inexpensive way to measure insulin resistance. HOMA is calculated using the product of fasting glucose and fasting insulin. HOMA is founded on the principle that fasting insulin levels are increased in the presence of insulin resistance. However, ß-cell failure can lead to low fasting insulin levels. Therefore, in pre-diabetes, which is characterized by both insulin resistance and ß-cell failure, HOMA could be inappropriately low. Using S_I as the reference, our goal was to determine if HOMA accurately measures insulin resistance in a cohort with a high prevalence of pre-diabetes. Sixteen Black Africans (BA) (75% male, age 38±8y (mean±SD), BMI 27.2±3.8 kg/m^2) were matched by sex, age and BMI to 16 African Americans (AA). All pairs had oral glucose tolerance tests (OGTT) and FSIGT. Insulin resistance was measured by HOMA and S_I. ß-cell secretion was determined by the acute change in insulin response to glucose (AIRg) during the FSIGT. BA had a higher rate of pre-diabetes than AA. S_I did not differ between BA and AA, but BA had

lower HOMA and lower AIRg (Results in Table). In conclusion, S_I was similar for BA and AA, but HOMA was significantly lower in BA. Therefore, HOMA did not reflect insulin resistance in BA. The cause for the inappropriately low HOMA in BA appears to be ß-cell failure. Evidence of ß-cell failure in BA was their high rate of pre-diabetes and low AIRg. Our data suggest HOMA should be used with caution in cohorts with a high prevalence of pre-diabetes and ß-cell failure.

Metabolic Characteristics			
Variable	Black Africans	African Americans	*P*-Value
Pre-diabetes (%)	50	6	<0.05
S_I	3.81±1.88	3.54±2.51	0.96
HOMA	1.02±1.40	1.60±0.62	<0.01
AIRg	606±255	1130±960	<0.01

[3] *Institut National de la Santé et de la Recherche Médicale, U780, Paris, France*
[4] *Institut National de la Santé et de la Recherche Médicale, ERI20, Paris, France*
[5] *Institut National de la Santé et de la Recherche Médicale, ERI20 U780, Paris, France*

Aims: Tea consumption is associated with a reduced risk for type 2 diabetes in some cohort studies, but this association has not been confirmed in others, and its effect on glucose disturbances remains inconclusive. We examined the long-term effect of tea consumption with incident type 2 diabetes in a cohort of French women.
Methods: The E3N Cohort Study included 69,532 French women, 41 to 72 years, without diabetes at baseline. Tea consumption was assessed in 1993, and we documented 1415 validated incident cases of diabetes during a mean follow- up of 11 years. Hazard ratios (HRs) for diabetes and 95% confidence intervals (CIs) were estimated for each category of tea consumption compared with no intake by using Cox proportional hazards regression models with age as the timescale, and simultaneous adjustment for potential confounders.
Results: At baseline, tea consumers were younger, leaner, more physically active. Consumption of tea was also positively associated with dietary fiber intake, and inversely associated with energy intake, fat intake, caffeine intake, and magnesium intake. Addition of sugar and milk decreased with increasing tea consumption. In age-adjusted models, the hazards ratio for diabetes in the highest category of tea consumption (=3 cups/daily) was 0.68 (95% CI: 0.58-0.80; $p < 0.001$) in comparison with no daily tea consumption. The inverse association was independent of multiple confounders [0.77 (0.65-0.89; $p < 0.001$)], but no longer statistically significant after further adjustment for body mass index as a time-dependent variable [0.89 (0.76-1.05, $p = 0.46$)].
Discussion/conclusion: Our data do not support a protective effect of tea consumption for diabetes. However, in the present study it was not possible to discriminate the type of tea consumed (green or black), and evidence suggests that different types of tea might play distinct roles on the risk of diabetes. Tea consumption was inversely associated with body mass index at baseline, which suggests that any potential protective effect of tea would be mediated by its impact on body weight. Further studies, discriminating the type of tea consumed are necessary to elucidate the role of tea on diabetes risk.

Introduction: Monogenic forms of diabetes include up to 2 % of all diabetes cases, but the exact epidemiology is not known. Direct prevalence of monogenic diabetes (MDM) can be calculated only with help of a nation-wide diabetes registry. This is available for children with diabetes in some countries including Slovakia, and can be used for calculation of early-onset monogenic diabetes, i.e. neonatal diabetes. In case of MODY, the registries for adults are absent in majority of countries. Therefore, only the frequency of MODY subtypes can be calculated.
Aim: of this study was to establish the epidemiology of selected forms of MDM, particularly the prevalence of Permanent Neonatal DM (PNDM) and frequency of the Maturity Onset Diabetes of the Young (MODY) subtypes.
Methods: Prevalence of PNDM was calculated using the Slovak National Registry of children with diabetes and Slovak demographic data, and updated to the end of 2007. Patients with MODY were actively searched in the diabetes outpatient clinics throughout Slovakia, using the MODY clinical diagnostic criteria (Ellard et al, 2008). The relevant genes responsible for PNDM (KCNJ11, ABCC8 and insulin gene) and for MODY (genes for GCK, HNF1A, HNF1B and HNF4A) were analyzed using the direct sequencing technique in the UK (PNDM) and Slovakia (MODY), respectively.
Results: Based on Slovak National Registry, nine patients with PNDM were identified. The PNDM incidence in Slovakia reached 1 case in 209,566 live births. Seven living patients with PNDM have different etiology of their MDM (four have KCNJ11 mutations, two have insulin gene mutations and one an ABCC8 mutation). Since 2004, in 86 families (319 patients) fulfilling the clinical diagnostic criteria for MODY, 24 probands and 56 family relatives had a mutation in GCK gene; 21 probands and 29 of their family had a mutation in HNF1A gene, and in one family (2 pts) a mutation in the gene for HNF4A was identified. No HNF1B mutation carriers were found.
Conclusions: The true, registry-based prevalence of PNDM in Slovakia is 1 case to 209,566 live births. Of the MODY subtypes, the most prevalent are *GCK* mutations (28% of MODY), followed by HNF1A (24%) and HNF4A mutations (1%). MODY-X families account up to 47%. Following the international estimate for MDM (2% of all diabetes cases), in 324,914 patients with diabetes in Slovakia, more than 6,500 patients should have monogenic etiology of their diabetes. This is a great challenge for the health care system, as majority of them should undergo a pharmacogenomics driven change in treatment (i.e. switch from insulin to sulphonylurea and/or diet only).

Diabetes is a risk factor for cancer specific mortality

S. Ioacara[1], C. Ionescu-Tirgoviste[1], R. Lichiardopol[1], D. Cheta[1], S. Sabau[2], C. Tiu[3]

[1] "N. Paulescu" Institute of Diabetes Nutrition and, Diabetes 1, Bucharest, Romania

[2] Hokkaido Tokai University, Statistics, Saporo, Japan

[3] "University" Hospital, Neurology, Bucharest, Romania

Aims: The well-known mitogenic effect of insulin raised some questions about its influence on cancer risk. We investigate the diabetes impact on cancer specific mortality.

Methods: We included 25760 consecutive subjects, 46% males, attending "I. Pavel" Diabetes Center, Bucharest, Romania; inclusion date was the first diabetes consultation during 2001. The follow-up was based on diabetes receipts and yearly follow-up with National Death Registry until 31st December 2007. The primary end-point was cancer specific mortality based on death certificate (ICD10 coding). Age-standardized mortality rates (ASMR) using European Standard Population as reference and Cox regression analysis adjusted for diabetes duration at inclusion were performed to correct for age biases.

Results: The mean age at diabetes onset was 38.8±17.3 years in T1DM, 58.3±10.2 years in OAD-treated T2DM (T2DMo), p<0.001 vs T1DM and 53.1±10.8 years in insulin treated T2DM (T2DMi), p<0.001 vs. T1DM. The mean diabetes duration at inclusion was 11.5±9.2 years in T1DM, 5.4±6.3 years in T2DMo (p<0.001 vs T1DM) and 8.2±7.3 years in T2DMi (p<0.001 vs. T1DM). The mean age at death was 66.9±11.7 years in T1DM, 73.3±8.8 years in T2DMo (p<0.001 vs T1DM) and 70.7±9.3 years in T2DMi (p<0.001 vs. T1DM).

During 5.99±1.69 years of follow-up (154251 person-years) there were 1014 (3.9%) cancer specific deaths; cancer ASMR = 16.01‰ in T2DMo, 25.51‰ in T2DMi and 18.46‰ in T1DM. Cancer ASMR in 2004 (mid-follow-up) for general population of Bucharest (official data) was 10.79‰. Considering the high "dilution" of our subjects within general population (~2 millions) we calculated standardized mortality ratios: 1.48 in T2DMo, 2.36 in T2DMi and 1.71 in T1DM.

Adjusted Cox regression analysis showed a cancer mortality risk associated with age at inclusion (hazard ratio 1.055 95%CI 1.044-1.066, p<0.001), masculine gender (HR 1.366 95%CI 1.152-1.621, p<0.001 vs. females) and both T1DM (HR 1.845 95%CI 1.275-2.671, p<0.001, vs. T2DMo) and T2DMi (HR 1.626 95%CI 1.329-1.99, p<0.001 vs. T2DMo).

Conclusions: We confirm previous reports regarding higher cancer mortality associated with diabetes, especially in T2DMi and T1DM. Although adjusted Cox regression analysis showed a significant hazard ratio for T1DM (HR 1.8) and T2DMi (HR 1.6) compared with T2DMo, we can only speculate that this is due to insulin presence in the treatment or due to a more severe (beta cell) insulin deficiency.

Dysglycaemia in an urban Fulani population of Nigeria

A.E. Ohwovoriole[1], A. Sabir[2]

[1] College of Medicine University of Lagos, Department of Medicine, Lagos, Nigeria

[2] Usman DanFodio University Teaching Hospital, Department of Medicine, Sokoto, Nigeria

The Fulani are a normally nomadic people known for covering great distances on foot with a resulting lean physique and presumably low risk for diabetes mellitus. However, with modernization some Fulani have adopted sedentary lifestyles, western diet and white collar occupations which are some of the risk factors for diabetes mellitus and related non-communicable diseases.

Objective: To determine the prevalence and correlates of dysglycaemia in an urban Fulani ethnic group of Nigeria.

Research design and methods: Three hundred and eighty-nine urban Fulani dwellers were recruited using a multi-stage sampling technique. Using a modification of the WHO STEPS instrument, information on socio-demographic and anthropometric data were obtained. Casual or fasting plasma glucose was obtained in all subjects while OGTT was performed in a randomly selected group of 48 subjects. Dysglycaemia or glucose intolerance was defined using WHO criteria as the presence of diabetes mellitus, impaired fasting glycaemia (IFG) or impaired glucose tolerance (IGT).

Results: Of the 389 subjects studied, 190 (48.8%) were females while 199 (51.2%) subjects were males (χ^2=5.43, p>0.05). The mean (SD) age of the sample population was 39.3 (14.2) years with the males [42.0 (13.8) years] being significantly older than the females [36.4 (14.1) years, p< 0.05]. The male subjects had significantly higher mean weight, height, waist circumference, WHR and blood pressures but the women had higher but not statistically significant mean BMI (p=0.108). Eighteen subjects (4.6%) had previously undiagnosed type 2 diabetes mellitus while 37 (16.9%) of the subjects who had FPG done had IFG. Of the 48 subjects who had OGTT, seven (14.6 %) subjects had impaired glucose tolerance. The mean (SD) age, BMI, waist circumference and blood pressures of subjects with dysglycaemia were significantly higher than those in subjects with normoglycaemia (p<0.05).

Conclusions: The study shows a high prevalence of over 15% of dysglycaemia in this urban Fulani population of Northern Nigeria, much higher than most previously reported rates from Nigeria. The major modifiable risk factors for dysglycaemia in this study was obesity. The results underline the need to increase public screening and to emphasize the value of lifestyle modification toward traditional African lifestyle.

Mortality in type 1 diabetes mellitus in Moscow county

A. Dreval[1], I. Misnikova[1], Y. Kovaleva[1]

[1] Moscow Region Research Clinical Institute, Endocrinology, Moscow, Russia

Aim: of the study was to analyze life duration, life expectancy, survival rate and causes of death in patients with type 1 diabetes mellitus (T1DM) of Moscow county.

Materials and methods: Data for 10 781 T1DM patients who live in Moscow County is in diabetes mellitus register. During the 2003-2007 period 713 deaths were observed (6,61%). Life duration, life expectancy and causes of death were examined by dividing the cohort into three groups by onset of T1DM. Survival analyses by the Kaplan-Meier method was also used. Statistical analysis was made using standard program.

Results: Mean life duration was 49,61±1,63 yrs (males - 46,497±1,496, females 53,85±1,51) the mean life duration at onset T1DM <10 yrs - 34,99±8,25 yrs, 11-20 yrs - 36,25±1,93 yrs, 21-25 yrs- 44,19±3,97. Life expectancy difference at age 40 between T1DM patients and non-diabetics was greater in women than in men (15,56 and 11,41 yrs). Life-analyses by the Kaplan-Meier method indicated cumulative survival rates of 99,3% at 5 years (2003-2007 yrs). With onset T1DM ≤25 yrs major causes of death were chronic renal failure -30,16%, heart failure- 7,92%, cerebral vascular diseases - 5,42%, acute diabetic complications-2,56 %.

Conclusion: Mean life duration depends on age at onset of T1DM and it is longer if T1DM was diagnosed at age > 25 yrs than at age < 10 yrs. Chronic renal failure is the main cause of death associated with T1DM (30,16%).

Links between risk factors and adverse pregnancy outcomes among Utah mothers with gestational diabetes

F. Tavake-Pasi[1], I. Nash[2], K. Lui[3], B. Ralls[4], W. Stinner[5], R.C. Bullough[4], C. Rasmussen[6]

[1] National Tongan American Society, Executive Director, Salt Lake City, USA

[2] National Tongan American Society, Education Director, Salt Lake City, USA

[3] National Tongan American Society, President, Salt Lake City, USA

[4] Utah Department of Health, Utah Diabetes Prevention and Control Program, Salt Lake City, USA

[5] Utah State University, Professor Emeritus, Logan, USA

[6] Exodus Health Care, Medical Department, Magna, USA

Aims: The excess risk of gestational diabetes mellitus (GDM) and its related adverse pregnancy outcomes are well known. Key risk factors for GDM include pre-pregnancy weight status, age, parity, and racial/ethnic minority status. This study examines the extent to which each of these four risk factors is associated with an adverse outcome among Utah mothers with GDM.

Methods: Utah birth records (2007) were used to identify the most commonly listed complications of GDM: pregnancy-induced hypertension (PIH), having a C-section delivery, and having a macrosomic infant. Analyses were limited to singleton births to mothers with GDM (N=1,680). Descriptive analyses were

used to examine the prevalence of risk factors among mothers with GDM as well as the relationships between each risk factor and pregnancy outcome. Logistic regression was used to identify the extent to which each of the four risk factors had the greatest effect on increasing the odds for each adverse outcome. Month of entry into prenatal care was controlled.

Results: Nearly one-third (32.7%) of GDM pregnancies ended with a C-section delivery. About nine percent of mothers had PIH and a macrosomic infant (8.9% and 9.4%, respectively). Not unexpectedly, being obese (having a BMI of 30) had the greatest impact on odds for all three adverse outcomes. Most notably, obesity nearly tripled the odds (2.7 times) of having a C-section delivery (p<.001). Obesity doubled (2.2 times) the odds of PIH (p<.01). Obesity increased the odds of having a macrosomic infant by 50% (1.5 times), but the effect was not statistically significant.

Discussion: Pre-pregnancy obesity is a known risk factor for GDM. Among Utah mothers with GDM, obesity prior to pregnancy increased the risk of adverse pregnancy outcomes. These effects were maintained even with other risk factors (age, parity, and minority status) controlled.

C-sections can lead to longer hospital stays for mothers, and increased risk of breathing problems and lower Apgar scores for infants. PIH is a leading cause of fetal complications, and uncontrolled PIH can have potentially fatal effects for mother and infant. More public health efforts to increase women's awareness of the importance of being at a healthy weight prior to becoming pregnant are needed.

NT-proBNP versus proteinuria in predicting cardiac events in patients with diabetes mellitus

M. Resl[1], S. Neuhold[2], R. Pacher[2], M. Hülsmann[2], A. Luger[1], M. Clodi[3]

[1] *Medical University of Vienna, Department of Endocrinology and Metabolism, Vienna, Austria*

[2] *Medical University of Vienna, Department of Cardiology, Vienna, Austria*

[3] *Kaiser Franz Joseph Hospital, First Department of Medicine, Vienna, Austria*

Aims: Cardiovascular disease is the main cause of morbidity and mortality in patients with diabetes mellitus. Albuminuria has been so far considered the best independent risk factor for cardiovascular events in patients with diabetes. Recently, special attention has focused on the cardiac hormone B-type natriuretic peptide (BNP). Therefore we aimed to compare the predictive values of N-terminal pro-BNP (NT-proBNP) and proteinuria for short-term cardiac events in diabetic patients.

Methods: In a prospective observational study we recruited 1080 patients with diabetes mellitus. NT-proBNP, renal function and lipid status were measured at baseline. Proteinuria was defined as urinary albumin/creatinine ratio > 30 mg/g. Patients were followed during a mean observation period of 9.6 months, 48 patients reached the defined endpoint (unplanned hospitalization due to a cardiac event).

Results: The mean duration of diabetes was 15 ± 12 years and mean HbA1c was 7.5 ± 3.1%. At baseline, 23.06% of the patients presented proteinuria, and 35.7% had plasma NT-proBNP values above 125 pg/ml. 48 patients reached the defined endpoint. Multiple Cox regression analysis including age, gender, duration of diabetes and HbA1c revealed that NT-proBNP was a better predictor of the defined endpoint than proteinuria (Hazard ratio 1.001; CI 1.001-1.001 p< 0.0001). These results are confirmed by receiver operating characteristics with an AUC of 0.89 (CI 0.747- 0.872 p<0.0001) for NT-proBNP compared with an AUC of 0.674 (CI 0.523-0.75 p<0.0001) for proteinuria.

Conclusion: NT-proBNP seems to be the better predictor of the upcoming short-term cardiac event in patients with diabetes mellitus.

Serum cystatin C and risk factors for cardiovascular disease in type 2 diabetic patients with metabolic syndrome

G. Sartore[1], E. Ragazzi[2], F. Piarulli[1], R. Marin[1], S. Burlina[1], C. Cosma[1], M. Zaninotto[3], M. Plebani[3], E. Manzato[1], D. Fedele[1], A. Lapolla[1]

[1] *University of Padova, Department of Medical and Surgical Sciences, Padova, Italy*

[2] *University of Padova, Department of Pharmacology and Anesthesiology, Padova, Italy*

[3] *Azienda Ospedaliera, Department of Laboratory Medicine, Padova, Italy*

Aims: Cystatin C, a cysteine proteinase inhibitor, is associated with progressively unfavorable lipid and lipoprotein concentrations and with metabolic syndrome (MS), and it can enhance cardiovascular risk prediction in different populations, independently of traditional cardiovascular risk factors, although not all authors agree. This study was carried out to determine the relationship between cystatin C, diabetes, MS components and risk factors for cardiovascular disease, in type 2 diabetic patients with MS.

Methods: To analyze possible links and determinants of cystatin C, simple and multiple regression analyses were performed on metabolic parameters measured in 50 type 2 diabetic patients: waist circumference, HbA1c, HOMA, creatinine, uricemia, uricuria, microalbuminuria and eGFR, triglycerides, HDL cholesterol, LDL cholesterol, oxidized LDL, and small LDL particles. Principal component analysis (PCA) was also used to characterize the overall behaviour and interrelationships among the metabolic parameters.

Results: Cystatin C concentrations of type 2 diabetic patients were significantly higher compared with healthy subjects (1.01±0.23 *vs* 0.73±0.17 mg/L, respectively, p<0.0001). With simple regression analysis, significant correlation was found only between cystatin C *vs* plasma creatinine (r= 0.7148, p<0.0001), eGFR (r=-0.7166, p<0.0001) and uricemia (r=0.3328, p<0.02). Stepwise forward multiple regression analysis, considering cystatin C as dependent variable, showed a significant contribution only from plasma creatinine (coefficient±SE: 0.0055±0.0020, p=0.0059) and eGFR (-0.0077±0.0020, p=0.0012). The correlation coefficient of the model was r=0.7849 (p<0.0001). All the remaining variables, except for uricuria, which gave a coefficient close to being significant (0.0270±0.0150, p=0.08), were not significant contributors to the regression. Considering PCA analysis, it can be argued that cystatin C is strictly positively related to plasma creatinine, confirming what was found with linear regression analysis. Some positive links were found also between cystatin C and waist circumference, as well as triglycerides, HOMA, LDL cholesterol, oxidized LDL and small LDL particles, while a negative link was found between cystatin C and eGFR, uricuria, and HDL cholesterol. No relationship was found with microalbuminuria and HbA1c.

Conclusion: Our study shows that cystatin C concentrations are higher in type 2 diabetic patients with MS and are associated with parameters of renal function, lipid profile and lipoprotein abnormalities. The correlation between cystatin C and other components of MS may suggest a common etiological factor, where cystatin C could have a role as a promising marker of renal function and metabolic syndrome.

N-terminal pro-brain natriuretic peptide(NTproBNP) as a marker for diabetic complications independent of ischemic heart disease (IHD) or heart failure

R. Komi[1], M. Abe[1], M. Kumagai[2], K. Hamano[1]

[1] *Shonan Kamakura General Hospital, Dept of Diabetes and Endocrinology, Kamakura, Japan*

[2] *University of Tokyo, Dept of Diabetes and Metabolism, Tokyo, Japan*

Aims: It is important to establish a biochemical marker that allows early diagnosis of ischemic heart disease (IHD) including silent myocardial ischemia and diabetic cardiomyopathy specific to diabetes. We conducted the present study to assess whether there is a link between NTproBNP and diabetic complications in type 2 diabetes.

Research design and methods: We enrolled 105 subjects (age 64.8±1.0 years, the duration of diabetes 10.8±1.0 years, HbA1c 8.1±0.2% (mean±SE)). NTproBNP was measured by ECLusys pro BNP. Medical records, laboratory and echocardiographic data were collected simultaneously.

Results: NTproBNP levels were 242.4±37.3 (mean±SE, 5.6 to 2234.0) pg/mL. Log-transformed NTproBNP (log (NTproBNP)) was positively correlated

with age, serum creatinine, left atrial diameter (p<0.0001), and left ventricular diastolic diameter (LVDd) (p=0.01), left ventricular systolic diameter (LVDs) (p=0.03) and left ventricular mass (LVmass) (p=0.0006). Log(NTproBNP) was negatively correlated with eGFR (modified MDRD) (p<0.0001). Log(NTproBNP) was significantly elevated in the subgroup with IHD (41 cases) (p<0.0001) and it tended to increase with the additional comorbidity of macroangiopathy. After adjustment for eGFR, age and HbA1c, log (NTproBNP) remained an independent indicator of prior IHD (p<0.05). When subgroups without overt heart failure (defined as LVEF>40%;89 cases) or without history of IHD were analyzed, similar results were obtained.

Conclusion: Our data suggest that NTproBNP may reflect left ventricular function in diabetes independent of prior heart disease, NTproBNP might therefore serve as a marker for incipient cardiac complications such as SMI or diabetic cardiomyopathy and there is a possibility that NTproBNP may reflect non-cardiac complications irrespective of the history of IHD or heart failure.

[4] *Chu Basse-terre, Service De Cardiologie, Basse-terre, Guadeloupe*

[5] *Chu De Martinique, Service De Cardiologie, Fort-de-france, Martinique*

Adiponectin (Ad) is a protein secreted by adipose tissue. Decreased plasma levels of adiponectin have been associated with obesity-related disorders including type 2 diabetes (T2D) and arteriosclerosis. The adiponectin-encoding gene, *ADIPOQ*, is localized on chromosome 3q27 within the region which was identified as susceptibility locus for T2D and metabolic syndrome. Ethnic differences in these associations have been suggested.

Aims: The aims of the study were to determine the frequency of adiponectin multimers and of four variants of *ADIPOQ* and to quantify their associations with prevalent coronary artery disease (CAD) in Carbbean subjects of African and South Indian descent (Afro-Caribbeans (AC) and Indians).

Methods: In a cross sectional study conducted in the French West Indies University, we studied 274 T2D volunteers from the hospital departments of Endocrinology and Cardiology. Coronary artery disease was defined on the basis of a history of angina pectoris, acute myocardial infarction, coronary bypass surgery or coronary angioplasty. Circulating total and multimer adiponectin, High molecular weight (HMW), middle molecular weight (MMW) and low molecular weight (LMW) were assayed by ELISA kit. Genomic DNA was extracted and four single nucleotide polymorphisms (SNPs) of Ad gene were genotyped: +45TG, +276GT, -11391AG and rs182052. ANCOVA, Pearson correlation tests, logistic regression were used.

Results: Among the 274 T2D subjects, 104 had prevalent CAD (among whom 75 myocardial infarctions). Indian subjects had significantly lower body mass index and HDL-C levels and significantly higher waist to hip ratio and triglycerides levels compared to ACs. Total Ad levels were significantly lower in those with CAD than in the others (6.7 *v* 8.6, *P=0.03*). Ethnic differences in total Ad, adiponectin multimers and HMW/total Ad ratio were noted. Among the 4 SNPs studied in the adiponectin gene, we found associations with prevalent CAD only for the SNP +45TG. The frequency of carriers of the minor allele 45G (GG/TG) was significantly higher in subjects with CAD (22% *v* 11%, *P=0.01)* than in those without CAD, with differences in ethnic groups. After adjustment for ethnic groups and other covariates, the adjusted OR of CAD was 3.3 (1.2 - 8.8), *P=0.04)* for carrying the 45G minor allele.

Conclusion: In addition to anthropometric parameters and lipid differences between subjects of South Indian and African descents, adiponectin levels and 45 TG SNP could contribute to the difference in cardiovascular risk between these ethnic groups.

Associations of aminotransferase activities with cardio-metabolic risk factors - implications for clinical practice

N. Abdella[1], O.A. Mojiminiyi[2], M. Al Arouj[3], A. Ben Nakhi[3]

[1] *Faculty of Medicine Kuwait University, Medicine, Kuwait, Kuwait*

[2] *Faculty of Medicine Kuwait University, Pathology, Kuwait, Kuwait*

[3] *DASMAN Diabetes Center, Diabetes, Kuwait, Kuwait*

Increasing prevalence of obesity has made non-alcoholic fatty liver disease (NAFLD) a major health problem that is found in association with increased cardio-metabolic risk. Aminotransferase (aspartate aminotransferase (AST), alanine aminotransferase (ALT)) concentrations have been shown to be associated with indices of obesity and may reflect NAFLD. This study explores the associations of ALT and AST with indices of obesity, adipokines, insulin resistance and components of the metabolic syndrome in an alcohol free normoglycemic population with negative medication history and hepatitis screen. Anthropometric measurements and fasting adiponectin, leptin, leptin receptor, insulin, glucose, high-sensitivity C-reactive protein (hs-CRP) and lipid profile were measured in 429 (155M, 274F) subjects. Univariate regression and multivariate logistic regression analyses were used to relate the aminotransferases with indices of obesity, adipokines as well as with the degree of adiposity (BMI≤25, 25.1 - 29.9 or ≥30), insulin resistance (homeostasis model assessment (HOMA-IR ≤2 or >2)) and the number of the criteria of the metabolic syndrome (MS) (International Diabetes Federation (IDF) criteria). 89 (21%) of subjects were classified as MS positive. All the study subjects had normal ALT and AST but gender dimorphism was noted with males having higher mean ALT (27.7 IU/L) and AST (23.5 IU/L) than females (17.4 and 20.0 IU/L respectively). ALT and AST showed stepwise increase with increasing categories of obesity, insulin resistance and the number of criteria of the metabolic syndrome. ALT showed significant correlations with age (r = 0.13), indices of obesity (r = 0.32 for BMI; r= 0.36 for waist circumference), beta cell function (%B) (r= 0.14) insulin (r= 0.18), HOMA-IR (r= 0.27), triglycerides (r= 0.24), hs-CRP (r= 0.25) and inverse correlations with adiponectin (r= -0.29), insulin sensitivity (%S) (r= -0.27) and HDL-cholesterol (r= -0.25). AST showed similar correlations. Adiponectin, HOMA-IR, %B and %S retained their significance after partial correlation analysis correcting for indices of obesity. In logistic regression models adjusting for age and sex, subjects in the 4th quartiles of ALT (odds ratio (OR) 3.8 (95% CI 1.3–10.9) and AST (OR 2.5 (95% CI 1.1–5.7) had significant risk of MS compared with those in the 1st quartile. We conclude that aminotransferases are significantly associated with cardiometabolic risk factors and should be included in routine laboratory risk assessment. As concern is growing about NAFLD, not only because it is a common liver disorder, but also because it is one of the leading causes of chronic liver disease, laboratories may need to lower the upper normal reference limits to facilitate earlier detection of obesity-associated increases in aminostransferases.

The expression of CD16 or toll-like receptor (TLR) 4 on peripheral CD14+ monocytes in subjects with various stages of glucose tolerance or in patients with coronary artery disease

Y. Aso[1], K. Hara[1], M. Suetsugu[1], T. Inukai[1]

[1] *Dokkyo Medical University Koshigaya Hospital, Internal Medicine, Koshigaya, Japan*

Monocytes are involved in the pathogenesis of inflammatory disease. The CD14+16+ or Toll-like receptor (TLR) 4+ monocytes may play a significant role in the pathogenesis of insulin resistance or atherosclerosis. We investigated the relationship between the expression of CD16 or TLR4 on peripheral CD14+ monocytes and the disease severity in subjects with different stages of glucose metabolism or in patients with coronary artery disease (CAD). We studied 40 male subjects with various stages of glucose tolerance [10 subjects with normal glucose tolerance (NGT), 10 with impaired glucose tolerance (IGT), and 20 with type 2 diabetes (DM)], and 35 male patients with CAD. The expression of CD16 and TLR4 on peripheral monocytes was measured using flow cytometry. In 40 subjects with various stages of glucose tolerance, the number of CD16+ monocytes was significantly higher in subjects with DM than in those with NGT (32.2% vs. 4.6%, P<0.01). The number of TLR4+ monocytes was significantly higher in subjects with metabolic syndrome than in those without

metabolic syndrome (4.9% vs. 1.9%, P=0.0016). In 35 patients with CAD, the number of CD16+ monocytes correlated positively with waist circumference, hemoglobin A1c, and triglyceride. The number of CD16+ monocytes was significantly higher in CAD patients with than without metabolic syndrome (23.6% vs. 7.9%, P=0.0093). The number of CD16+ monocytes was higher in CAD patients with 3-vessel disease than in those with 1- or 2-vessel disease. In conclusion, both CD16+ and TLR4+ monocytes are associated with the components of metabolic syndrome, irrespective of the presence or absence of CAD. Furthermore, the number of CD16+ monocytes may reflect the disease severity in patients with CAD.

Promoter polymorphism of the matrix metalloproteinase 3 gene in diabetes mellitus patients and risk of coronary artery disease in an Iranian subjects

M. Seifi[1], S. Fallah[1], M. Firoozrai[1]
[1] Iran University of Medical Sciences, Biochemistry, Tehran, Iran

Aims: Matrix metalloproteinase-3 (MMP3) -1612 5A/6A gene polymorphism has an effect on MMP3 expression which leads to low promoter activity 6A6A, intermediate promoter activity 5A6A and high promoter activity 5A5A genotypes, have been shown to be associated with coronary artery diseases (CAD) (e.g., coronary stenosis, myocardial infarction, coronary artery calcification, etc.). The aim of our study was to estimate the functional polymorphism in MMP3 gene in diabetes mellitus patients and test the hypothesis that this polymorphism in diabetes mellitus patients might be predictor of susceptibility to coronary artery disease.
Methods: Ninety-five CAD patients and one hundred three healthy control subjects were included in this study. MMP3 genotypes were determined by polymerase chain reaction and restriction fragment length polymorphism.
Results: Significant differences between cases and controls were observed for MMP3 genotype frequencies (X^2=14.606, p = 0.001). The 6A allele was less frequently seen in the control group, compared to the disease group (80.79 vs. 71%, 6A/6A+5A/6A vs. 5A/5A, *P*=0.001).
Conclusion: We for first time indicated that MMP3 -1612 5A/6A polymorphism is involved in diabetes mellitus and is a genetic susceptibility factor for CAD in diabetes mellitus.

[5] Inst of Molecular and Clinical Medicine, Dept of Nephrology, Gothenburg, Sweden

Background and aims: Insulin resistance occurs early in the development of type 2 diabetes. An altered balance in the autonomic nervous system may contribute. The aim of this study was to evaluate the autonomic nervous system in healthy first-degree relatives of type 2 diabetes patients and healthy controls and assess the relationship to insulin resistance.
Subjects and methods: 23 healthy individuals with first-degree relatives with type 2 diabetes (R) were compared with 24 control subjects without a family history of diabetes (C). The groups were matched for age, BMI and sex. A hyperinsulinemic, euglycaemic clamp (56 mU/min/m^2) and an oral glucose tolerance test (75 g glucose) were performed. Analysis of heart rate variability (HRV) during rest, controlled breathing, an orthostatic manoeuvre and a standardised physical stress (cold pressor test, CPT), was used to assess the activity of the autonomic nervous system.
Results: Insulin sensitivity, reflected by the M-value, was similar in the two groups. HbA1c, fasting blood glucose and serum insulin did not differ significantly between the groups. HRV did not differ significantly between the R and C groups. There were significant negative associations between insulin sensitivity and low-frequency (LF) spectral power as well as low frequency/high frequency (LF/HF) spectral power ratio in the basal state (r= -0.34, p=0.028 and r= -0.34, p=0.026, respectively), during controlled breathing
(r= -0.44, p=0.003 and r= -0.45, p=0.002), during CPT (r= -0.35, p=0.026 and r= -0.37, p=0.019) and during and after tilt (r= -0.37, p=0.016 and r= -0.40, p=0.008, r= - 0.31, p=0.036 and r= -0.33, p=0.031). Furthermore, insulin sensitivity was significantly and positively associated with high-frequency (HF) power during CPT r=0.33, p=0.036). When all subjects were divided into two groups by insulin sensitivity (mean M-value), LF power and LF/HF ratio was significantly higher in the low M-value group during controlled breathing (p=0.004 and 0.003, respectively) and tilt (p=0.012 and 0.012, respectively).
Conclusion: An altered balance of the parasympathetic and sympathetic nervous activity, mainly explained by attenuated parasympathetic activity, was related to insulin resistance, but no difference was found between subjects with first-degree relatives with type 2 diabetes and control subjects without a family history of diabetes.

Gastric emptying measured by C13-CO2-octanoate breath-test: Lessons from clinical use in 259 patients with type 1 diabetes mellitus and 52 patients with type 2 diabetes mellitus.

B.L. Becker[1], S. Schminkel[1], E. Rehring[2], M.A. Nauck[1]
[1] Diabeteszentrum, Internal Medicine and Diabetology, Bad Lauterberg, Germany
[2] Diabetologische Schwerpunktpraxis, Diabetology, Ilsede, Germany

Aims: Retardation of gastric emptying up to complete gastroparesis is known as one of the most challenging complications of diabetes mellitus. Since 2001 the method of measuring gastric emptying by means of the C^{13}-CO_2-octanoate breath test is established at the center for treatment of diabetes in Bad Lauterberg, Germany. In the latter we try to evaluate the diagnostic value and the indications for this type of diagnostic procedure.
Methods: From 2005 until 2007 all patients (n=354) who had a measurement of gastric emptying were identified and analysed. In case of repeated measurements the latest test was chosen. 259 patients with T1DM and 52

patients with T2DM were included and the results of C^{13}-CO_2-octanoate breath tests were compared with the results of 25 healthy subjects. 25 tests performed in patients with diabetes other than T1DM or T2DM or patients with operatively changed anatomy of upper gastrointestinal tract were excluded. A delayed gastric emptying was diagnosed when the one-sided upper 90 % confidence interval (mean + 1.605 SD) of gastric half emptying time of the healthy control group was exceeded. Clinical characteristics of patients with delay of gastric emptying and unaffected individuals were compared (ANOVA). Indications for testing gastric emptying time were analysed by chi-square-test.

Results: C^{13}-CO_2-octanoate breath test was performed much oftener in patients with T1DM than in subjects with T2DM (reference: all treated patients; 259/2339 vs. 52/4672, $p < 0.0001$). The probability of delayed gastric emptying was 17/259 in T1DM (6.6%) and 5/52 in T2DM (9,6%). Main indications for testing were postprandial hypoglycaemia (n=44) and unexplained excursions of blood glucose (n=146) in T1DM and gastrointestinal discomfort (n=19) in T2DM. Patients with delayed gastric emptying and T1DM had more elevated $A1_c$ levels (8.65 vs. 7.78), a faster resting heart rate (82.9 vs. 74.4 min^{-1}; p=0.009) and a lower systolic blood pressure (120.2 vs. 135.4 mmHg; p=0.004).

Patients with T2DM and delayed gastric emptying had more episodes of self reported hypoglycaemia per week (4.5 vs. 0.85; p=0.007).

Dicussion: Delay of gastric emptying is extremely rare even in a collection of highly pre-selected patients with diabetes (approximately twice the expectation). The diagnostic procedure is mostly performed due to unsatisfying stability of blood glucose levels in subjects with type 1 diabetes mellitus, in type 2 diabetes mellitus mostly because of abdominal discomfort. Patients with delayed gastric emptying and type 1 diabetes mellitus show poorer control of $A1_c$ and a higher resting heart rate as a hint for cardiac autonomic neuropathy. The rate of hypoglycaemia increases in patients with delayed gastric emptying and type 2 diabetes mellitus.

Short-term spectral analysis of heart rate variability could predict subclinical cardiovascular disease in type 2 diabetes mellitus

J. Kim[1], Y.H. Ku[1], E.K. Park[1], H.R. Kwon[1], H.G. Seok[1], K.W. Min[1], K.A. Han[1], H.J. Kim[2], K.S. Park[2], B.K. Koo[1]
[1] Seoul Eulji Hospital, Internal Medicine, Seoul, Korea
[2] Daejeon Eulji Hospital, Internal Medicine, Daejeon, Korea

Aim: Cardiac autonomic neuropathy (CAN) in diabetes is associated with increased mortality. We investigated correlations of CAN with subclinical atherosclerosis and myocardial perfusion in Type 2 diabetes.

Methods: Two hundred patients (aged 60 ± 11 years, 67 males and 133 females) with type 2 DM were enrolled in this cross sectional study. We assessed total CAN scores from 5 tests (heart rate response to Valsalva maneuver, deep breathing, and standing: blood pressure response to standing, and sustained handgrip). We also determined powers in total- (TP), low- (LF), and high-frequency (HF) bands and standard deviations of all N-N intervals (SDNN), which are derived from all intervals between adjacent QRS complexes, from short-term (5 minutes) spectral analysis of heart rate variability (HRV). The augmentation index (AI), subendocardial viability ratio (SEVR), brachial artery pulse wave velocity (PWV), and ankle-brachial index (ABI) were evaluated from central and peripheral pulse waveform, and carotid intima media thickness (IMT) from carotid sonography. Definite to severe CAN was defined as individuals with CAN score of 2 or more by Ewing's classification.

Results: Mean HbA1c was 8.3 ± 1.8 % and mean duration of diabetes was 12.3 ± 7.8 years. 17.2 % of the participants had definite to severe CAN. The AI, SEVR, PWV, ABI and IMT were not different between individuals with and without CAN. Total CAN scores were significantly correlated with SDNN and TP from spectral analysis of HRV ($g = -0.261$, $P < 0.002$ and $g = -0.275$, $P = 0.001$, respectively). Total CAN scores did not show any associations with these CVD parameters. On the other hand, the SDNN ($g = 0.278$, $P < 0.001$), LF ($g = 0.230$, $P < 0.001$), and TP ($g = 0.308$, $P < 0.001$) were associated with subendocardial viability ratio (SEVR), which remained still significant after adjustment for other CVD risk factors such as age, blood pressure, and LDL-cholesterol.

Conclusion: The indices of HRV from spectral analysis were associated with the SEVR, an estimate of myocardial perfusion relative to cardiac workload, but not with reactivity and thickness in the macrovasculature, expressed as AI, PWV, ABI and IMT.

Comparison of somatic tests - modified Neuropathy Disability Score, and a new simple instrument for autonomic dysfunction - Neuropad® for early diagnosis of diabetic neuropathy

Z. Kamenov[1], J. Petrova[2], V. Christov[1]
[1] Clinic of Endocrinology, Medical University, Sofia, Bulgaria
[2] Clinic of Neurology, Medical University, Sofia, Bulgaria

Diabetic neuropathy (DN) is the most common late diabetic complication. Somatic and autonomic DN usually develop simultaneously, but autonomic DN is rarely diagnosed in the everyday clinical practice because the tests are time-consuming and there are no simple devices and score systems like in the case of somatic DN. The aim of this study was to compare a new simple test for sudomotor dysfunction – Neuropad – to the somatic diagnostic complex of modified Neuropathy Disability Score (NDS), shown to be predictive for diabetic foot at risk for developing diabetic ulcers.

Patients and methods: In this cross-sectional study participated 264 consecutive (M/F = 126/138) people with DM type 1/2 (61/203), mean age of 55.4 ± 12.0 years and duration of DM of 9.3 ± 7.1 years, excluding other reasons for neuropathy and interfering drugs. The patients underwent testing with modified NDS and the new instrument. Neuropad was stacked on both soles 1-2 cm distally of the point between metatarsal heads I-II. After 10 minutes, the color change of the indicator was read and the patients were divided in 3 groups: normal (complete change from blue to pink = 0 points), borderline (mottled blue/pink color = 1point), abnormal (no color change – the test remain blue = 2 points).

Results: Both, Neuropad and NDS differentiated and stratified people and feet at risk. The groups selected by Neuropad differed significantly in their results for the four tests of NDS separately and in aggregate. Most important determinants for pathological NDS and Neuropad responses were age, diabetes duration and presence of microvascular complications. Most sensitive for detecting DN were the aggregate NDS = 1, followed by Achilles reflexes, vibration perception (128 Hz Rydel-Seiffer tuning fork) and Neuropad. Compared to the markers for presence of somatic DN (NDS = 1) and for foot at risk (NDS = 6) Neuropad showed sensitivity = 77.5 and 84.8%, specificity = 58.3 and 38.7%, positive = 94.9 and 62.8% and negative = 20.6 and 67.6% predictive value respectively.

Conclusions: Early screening for diabetic neuropathy must cover somatic and autonomic disturbances. Neuropad is a new test, sensitive and appropriate for everyday clinical use for detecting DN and identification of diabetic foot at risk.

Psychological process and psychometric study of diabetic and non-diabetic men undergoing penile prosthesis surgery for erectile dysfunction

S. Kovesh Shaheb[1], C.T. Garcia Alvarez[2], B. Fabre[2], M. Mendoza[2], R. Fragas[2]
[1] University of Havana, Philosophy, Ciudad de la Habana, Cuba
[2] National Institute of Endocrinology, Diabetes, Ciudad de la Habana, Cuba

This study comprises the results of 100 diabetic and non diabetic men studied during the period 2006- 2008, who had penile surgery for erectile dysfunction, as a part of the National Project in Havana, Cuba.

The main obejctive of the national project was to find out the efficacy, safety and satisfaction among men with penile prosthesis and their partners. This National Study afforded our group a different approach to the same patients from the point of view of psychology and psychometrics.

Aims: To know body representations, anxiety, depression and characteristics of the psychological processes, particularly in reference to the satisfaction with the surgical therapy, and to study the effects of these psychological processes on the bodies of patients and their partners.

Methods: In depth interviews with patients and their partners were conducted and multiple psychological tests were administered, among them: Anxiety test of Catell; MMPI test of Hathaway and MacKinely; Somatic test-Body symbolism of Wilfrd A. Cassell (Cuban Version by C.T. Garcia) and in depth case studies.

Results: 25 % of the men had Diabetes as a Diagnosis. The majority of them had normal results from the Psychometrics tests. Neverthless, 40% of them had psychological conflicts with body symbolism, particularly with vaginal representation. Some of them showed psychological repression, as an example, in front of the card depicting a vagina, they responded, "this is a butterfly", "it is an insect", "it is a flower","this is a dark and dangerous place". In addition a subgroup of the partners, demonstrated conflicts with their partners after the penile surgery and their dissatisfaction with the surgery.

Conclusions: Studies of psychological aspects and the partner relationships as well as psychological counselling were very helpful to improve the satisfaction of patients with diabetes who underwent penile prosthesis surgery for erectile dysfunction. The psychological counselling contributed a great deal to the well being of the patients with diabetes and their partners.

Prevalence of impotence among men with diabetes mellitus in Jos, North-central Nigeria

F. Puepet[1], A. Uloko[2], I. Akogu[3]
[1] University of Jos, Dept of Medicine, Jos, Nigeria
[2] Ado Bayero University, Dept of Medicine, Kano, Nigeria
[3] Diabetes Screening and Care Foundation, Diabetes Education, Jos, Nigeria

Background: Impotence is a common problem in diabetes. It has been reported that about 50% of men with diabetes eventually become impotent. Impotence in diabetes is particularly distressing as it is usually irreversible but libido is commonly preserved. However, in our experience few men attending the diabetes clinic ask for help for impotence and even fewer are being treated.
Objective: To determine the prevalence of impotence in a male diabetic population and to examine how many had asked for help for their problem.
Methods: Four hundred and fifty six consecutive male patients aged 20-70 years attending the Diabetes clinic of the Diabetes Screening and Care center, Jos, North-central Nigeria were administered a questionnaire. This addressed issues such as whether or not they had erectile dysfunction, whether they would like treatment and whether or not they had ever asked for medical help in the past. Their glycaemic status, presence of proteinuria (including microalbuminuria) and of retinopathy (background or advanced) and hypertension were recorded from the patients' case notes.
Results: The prevalence of impotence was 49.3%, and it increased with age. The prevalence of proteinuria was 11.4% and retinopathy was 24.6%. One hundred and forty(62.2%) had concomitant hypertension and were on treatment. Of the 225 patients with impotence, 34(15%) had DM duration < 1year, majority (47.4%) had duration of DM between 5 and 15 years and 23.4% had duration > 15years. Over 80% were treated for DM with Oral antidiabetic agents only, while less than 20% were insulin treated. The mean HbA1c of the entire population was 8.7±2.6%, while that of patients with impotence was 9.2 ± 3.5%. All the patients with proteinuria and 72% of those with advanced retinopathy had Impotence. Two hundred and seven (92%) of patients with impotence wanted treatment; 128 had never asked for treatment (56% for embarrassment, 30% for ignorance of availability, 9% had no reason); 126 had consulted different Doctors for treatment; 72 (32%) knew impotence was a complication of Diabetes; 81(36%) had sought traditional (native) treatment.
Conclusion: The prevalence of impotence in this population of Diabetics is high and reluctance to report the problem and ignorance about available treatment is common. Available treatment for impotence in Diabetes is not very effective and is too expensive for the Nigerian Diabetic male population. Clearly, extra resources will have to be found if more impotent men are to be treated within the Health Service.

Stratification of risk factors in diabetic patients by a new test for sudomotor dysfunction - Neuropad

Z. Kamenov[1], J. Petrova[2], V. Christov[1]
[1] Clinic of Endocrinology, Medical University, Sofia, Bulgaria
[2] Clinic of Neurology, Medical University, Sofia, Bulgaria

Diabetic neuropathy (DN) begins insidiously and engages somatic and autonomic nerve functions. The global spread of diabetes (DM) and the importance of early therapeutic intervention determine the need of simple, inexpensive and sensitive methods for diagnosis of diabetic complications in the general practice.
Aim: of this study was to investigate the value of a new instrument – the plaster Neuropad in identification and stratification of diabetic patients at different micro- and macrovascular risk.
Patients and methods: In this cross-sectional study participated 264 consecutive inpatients (M/F=126/138) with DM type 1/2 (61/203), mean age of 55.4±12.0 years and duration of DM of 9.3±7.1 years. According to hospital records personal data file for every patient was created including: anthropometric data; FPG and HbA1c; presence of micro-(retino-, nephro-, neuropathy), and macrovascular (arterial hypertension, coronary-and brain vascular disease (CHD/BVD), dyslipidemia) complications. Neuropad was stacked on both soles 1-2 cm distally of the point between metatarsal heads I-II. After 10 minutes the color change of the indicator was read and the patients were divided in 3 groups: normal (complete change from blue to pink=0 points), borderline (mottled blue/pink color=1), abnormal (no color change – the test remain blue=2). The groups were compared and the adjusted for age and gender Odds ratios were calculated.
Results: are presented on the tables. *-p<0.05; **-p<0.01; ***-p<0.001.

Groups, differentiated by Neuropad						
Group	2	p for 2/1 groups	1	p for 1/0 groups	0	p for 0/2 groups

Cardiac autonomic neuropathy in type 2 diabetes patient with microalbuminuria

T. Akhobadze[1], R. Kurashvili[2], L. Dzneladze[3], M. Dundua[2], L. Tsutskiridze[2]
[1] Georgian Diabetes Center, Department of Cardiology, Tbilisi, Georgia
[2] Georgian Diabetes Center, Georgian Diabetes Center, Tbilisi, Georgia
[3] National Center of Therapy, Department of Cardiology, Tbilisi, Georgia

Background and aims: Prevalence of microalbuminuria (MA) and cardiac autonomic neuropathy (CAN) increases together with the increase in diabetes duration (DD); they are considered to be significant risk factors for cardiovascular events in type 2 diabetic (T2DM) patients (pts). Our aim was to assess CAN, heart rate variability (HRV), QTc interval dispersion (QTcd), silent myocardial ischemia (SMI), non-dipper phenomenon in T2DM with microalbuminuria.
Materials and methods: We supervised 2 groups (Gr): Gr.1-without (n=52, 23m/29f, mean age 52.6±13.1 yrs) and Gr.2 with MA (albumin excretion rate 30-300 mg/l, n=50, 26m/24f, mean age 54.3±9.7 yrs). In all pts 24-h ambulatory ECG and BP monitoring were performed. Time domain HVR parameters and SMI episodes were assessed on Holter ECG. QTcd was measured on surface ECG. CAN severity was evaluated using Evings 5 - standard tests (severe CAN-scores 7-10, moderate- 4-6, mild- 2-3, no CAN - 0-1). Mean 24-h BP was measured on ABPM. DD, HbA1c, plasma lipids were also assessed.
Results: Pts with MA (mg/l) have significantly higher 24-h BP, than those without MA (139.5±19.3 vs 131.1±16.2, p=0.018). There were more non-dippers in Gr.2, than in Gr.1 (24% vs, 13.4%). HRV parameters: SDNN (0.096±0.037 vs 0.127±0.032 msec, p= 0.000) and Triangular index (26.5±6.3 vs 34.8±8.1 p=0.000) were significant by lower; QTcd was longer (48.7±9.7 vs 38.5±11.7 msec, p=0.000), and SMI episodes were more frequent in Gr.2, than in Gr.1 (32% vs 21.1%). CAN prevalence was: severe-9.1% (Gr.1), 16 % (Gr.2); moderate - 25% (Gr.1), 42% (Gr.2); mild - 36.5% (Gr.1), 36% Gr.2; no CAN-28.8% (Gr.1), 6% (Gr.2). Severe and moderate CAN were more frequent in MA pts. DD was

significantly longer in Gr.2 (11.3±3.6 vs 6.7±2.9yrs, p=0.000). HbA1c values did not differ between the groups (7.9±0.13 vs 7.3±0.12% p=0.181).
Conclusion: Pts with MA showed association between DD, BP and CAN parameters. CAN plays important role in hypertension and non-dipper phenomenon development, and HRV decrease in diabetes. Pts with MA need more detailed investigation to reveal cardiovascular risk and timely initiate preventive measures.

[6] *University Clinic, University Center, Frankfurt, Germany*
[7] *Gemeinschaftsklinikum, Koblenz-Mayen, Koblenz, Germany*
[8] *KH Hellersdorf, Krankenhaus Hellersdorf, Berlin, Germany*
[9] *Abt. Endokrinologie, Innere Medizin Universität, Rostock, Germany*
[10] *Innere Medizin, Klinikum Schwerin, Schwerin, Germany*
[11] *Diabeteszentrum, Christl. KH Quakenbrück, Quakenbrück, Germany*
[12] *Institut für Epidemiologie, Universität Ulm, Ulm, Germany*

Background and aims: Intensified insulin therapy (MIT) and insulin pump therapy (CSII) are well established options for insulin substitution in type 1 diabetics. The estimated number of insulin pump users in Germany is about 44 000, but less is known about their social and clinical data. Most of them are treated by physicians who have only few patients on CSII. So data on pump therapy under real-life-conditions in large multicenter databases are rare (DPV-Science Initiative).
Results: By March 2009, data on 11 872 adult subjects with type 1 diabetes were available for analysis: mean age 36,8±0,2 years, range 18-89 years, gender ratio 51% males and 49% females, mean age at onset of diabetes 20.6±0,1 years, mean diabetes duration 16,2±0,1 years.
8746 patients (73,7%) used multiple daily injections, while 3126 (26,3%) used CSII. Diabetes duration was longer in pump patients (20,3 vs14,7 years, p<0.0001), and more women opted for CSII (57 vs 46%, p<0,0001). Daily insulin requirement was lower in CSII (45,2±0,4 Units compared to 53,6±0,3 Units, p<0,0001). 54 % of subjects on MIT used insulin analogs, compared to 74 % of CSII patients (p<0,0001). Mean HbA1c was 7,8 % in CSII patients and 8,0 % in MIT (p<0,05), this difference was still present after adjustment for age, duration of diabetes, gender, insulin dose, insulin preparation, degree of overweight and center heterogeneity. In addition, the rate of severe hypoglycaemic episodes was slightly lower in CSII (29,6 vs 36,6 events per 100 patients-years, p=0,06) compared to MIT patients. However CSII patients were slightly more overweight with a BMI of 25.9 kg/m^2 compared to 24.9 kg/m^2 in MIT patients (p<0,0001).
Conclusion: Updated results (March 2009, DPV) are: In CSII patients, insulin requirement is significantly lower, metabolic control (HbA1c) is significantly better and BMI is slightly higher compared to MIT. In Germany medical insurance companies usually reimburse insulin pump therapy on the basis of improvement of HbA1c-levels. Therefore the German Diabetes Technology Group (AGDT, subgroup of the German Diabetes Society) starts a nationwide insulin pump registry (epidemiological data and 91 questions about diabetes progress and therapy) to document the global and individual benefit of CSII. Also a certification for insulin pump centers will improve quality in education and treatment of patients using CSII therapy and may facilitate reimbursement by health insurance.

Hypoglycaemia in type 1 diabetic patients treated with CSII during driving - results of continuous glucose monitoring

J. Broz[1], V. Donicova[2], M. Andel[3]
[1] *Charles University, 3rd Medical Faculty, 2nd Dep Int Med*
[2] *Human Care, Outpatient unit, Kosice, Slovakia*
[3] *Charles University 3rd medical faculty, 2nd Dep Int Med, Prague, Czech Republic*

Aims: Hypoglycaemic episode during driving could cause a fatal accident. Using continuos glucose monitoring in type 1 diabetic patients, we wanted to determine the glycaemic excursions during periods of driving.
Methods: We monitored 21 patients with type 1 diabetes mellitus treated with CSII (6 female, 15 men), duration of disease 11,2 ± 5,4 year, duration of treatment 4,2± 1,87 year. Each patient wore CGMS for 3-5 working days during his normal activity and was not alowed to see actual glycaemic values. Patients were asked to record all important events (such as insulin injection, exercise, meals, working periods) including periods of a car driving. After CMGS use, continuous glucose profiles were reviewed to identify glycaemic excursion during periods of car driving, with a special interest in hypoglycaemic episodes (values under 3,5 mmol/l) and periods of glycaemia under 4,5 mmol/l with considerable risk of hypoglycaemia.
Results: We evaluated 4761 min (79 hours 21 min) of driving, an average 79,2 ± 37,8 per day and patient. Patients recorded 4 symptomatic episodes while driving. We found 11 episodes of asymptomatic hypoglycaemia, all in 4 patients. Total time of driving with glycaemia under 3,5 was 52 min (1,1 %), with glycaemia under 4,5 mmol/l it was 256 min (5,4 % of total driving time).
Conclusion: Risk of hypoglycaemia even in well experienced patients with type 1 diabetes mellitus treated with CSII during driving is considerable and should be regularly adressed in education.

Differences in long-term metabolic control and BMI in children with type 1 diabetes on insulin pumps stratified by age and sex

E. Pytka[1], R. Barnes[1], A. Bossy[1], N. Dumouchel[1]
[1] *MUHC- Montreal Children's Hospital, Diabetes Division, Montreal, Canada*

Aim: There is conflicting evidence of long-term sustained improvement in A1C among children with type 1 diabetes (T1D) using insulin pumps, and whether outcomes differ with gender, age and prior metabolic control. This practice audit follows a previous evaluation of annual change in A1C and BMI z-score from baseline among patients at our centre, and attempts to assess for differing outcomes based on age, sex and prepump A1C.
Methods: Practice audit of patients whose pumps were initiated from 2000-2008 at our centre. Inclusion: pump initiation > 18 months post T1D diagnosis; > 1 yr follow-up; > 2 A1C tests in the 6-12 months pre-pump at our centre. Of 122 pump patients, 40 (60% males) were eligible for analysis. Mean age and diabetes duration at pump start were 10.8 yrs and 4.8 yrs respectively; mean follow-up was 4.2 years. Data was stratified by sex, prepump A1C and BMI z-score. Intention-to-treat analysis was performed using a paired T-test and to compute 95% confidence intervals (95CI).
Results: A1C showed a statistically and clinically significant sustained improvement across all years of a 7-year follow-up for the cohort, with a mean change of -1.0 (95CI: -1.3, -0.7). Children with a prepump A1C >8.7% significantly decreased their mean A1C by -1.1 (95CI: -1.4, -0.8), while there was no significant change for those with a pre-pump A1C <8.7%. Mean A1C decreased -1.1% (95CI: -1.5, -0.7) in children <11 yr irrespective of gender. Older children (>11 yr) decreased A1C by -0.7 (95CI: -0.2,-1.1). In older males (>11 yr) mean A1C decreased by -1.0 (95CI: -1.5, -0.5). Older girls (the smallest sub-group), showed a trend towards a first-year decrease in A1C that did not reach statistical significance, and which was not sustained. There was no significant change in BMI z-score except in older boys whose BMI z-score increased +0.37 (+0.18, +0.55). Five children (12.5%) discontinued pump use for the following reasons: allergy to catheter dressing (1); poor adherence / frequent ketosis (2); defective device not replaced (1); lost device (1).
Discussion/conclusion: In general, insulin pump users at our centre showed a clinically and statistically significant improvement in metabolic control which was sustained over 7 years of pump use without a significant change in BMI z-score. However, these improvements were not sustained across all ages and genders. Greater improvements were associated with higher A1C and younger age (<11 yr) pre-pump, irrespective of gender. In younger children, pump

use was associated with a clinically and statistically significantly, sustained improvement in A1C that was "weight neutral." Improved metabolic control in older males was associated with a statistically significant increase in BMI z-score. Older females showed no significant change in either A1C or BMI z-score. Future research will compare these outcomes to patients not started on pumps, matched for age, sex and diabetes duration

DM2 patients on insulin therapy can achieve the same weight loss as patients not on insulin while simultaneously improving diabetes control

P. Moreira-Cali[1], S.A. Gezan[2]
[1] *Diabetes & Nutrition Education Center, Diabetes, Gainesville, USA*
[2] *University of Florida, Statistics, Gainesville, USA*

Introduction: It is generally accepted that DM2 patients on insulin therapy gain weight and, although tighter glucose control improves A1c, it usually leads to concurrent increase in weight. We conducted a retrospective 18 month study of DM2 patients referred for DM education, comparing the diabetes control (A1c) and weight change of patients on insulin with patients not on insulin. We postulated that if diabetic patients receive effective education through Medical Nutrition Therapy (MNT) and diabetes self management skills, diabetes control can be achieved by patients on insulin, without the undesirable weight gain.
Materials: A total of 1,141 adult patients with DM2 were studied, 23% on insulin and 77% not on insulin. Half of the patients not on insulin didn't take any hypoglycemic medication. The mean initial A1c was 8.9% and 7.5% for the group on and not on insulin, respectively. 56% were female, 44% male; 78% Caucasian, 15% African American, 6% Hispanic. Only 20% of the patients had previous DM education, mean age was 61 and 86% were overweight.
Methods: Patients received individual education by a clinical dietician/ diabetes educator, including carbohydrate counting using the exchange system, with insulin to carbohydrate ratio for patients on rapid acting insulin. A carbohydrate distribution of 45-60 grams per meals and 15-30 grams per snacks was suggested, and a 500 kcal deficit was applied to the meal plans of overweight patients. Insulin was adjusted as needed. Patients were to record FBS and 2 hours pp glucose, increase physical activity, and keep follow-up every 3 months. A repeated measures statistical analysis was performed considering the variables A1c and weight over 18 months, while controlling for dropout rate.
Results: A statistically significant and consistent decrease in A1c was observed over the 18 months for both groups studied ($p < 0.001$). The average A1c compared to initial was 7.4, 7.0, 7.1, 6.9 and 6.7 mg/dl for the insulin group and 6.5, 6.4, 6.3, 6.3, and 6.2mg/dl for the non insulin group, at 3, 6, 9, 12 and 18 months, respectively. The statistical analysis for weight also showed a significant and consistent decrease for both groups over time (p-value < 0.001), indicating that there was no difference in the average weight loss, nor in the pattern of loss, for either group of patients. The average drop in weight was 2.3, 3.6, 4.4, 4.9 and 6.6 kg for the patients on insulin and 4.5 5.6, 6.1, 6.4 and 6.4 kg for the patients not on insulin, at 3, 6, 9, 12 and 18 months, respectively. The dropout rate was similar for both groups.
Conclusion: This study demonstrates that a significant reduction in A1c can be achieved in DM2 patients on insulin therapy, without undesirable weight gain. Individual MNT is as effective in promoting good diabetes control and weight loss in DM2 patients on insulin, as it is in patients not on insulin therapy.

Treatment experience and satisfaction of type 2 diabetic patients treated with a basal-bolus regimen using insulins glargine or detemir as basal insulin: results from the LIVE-COM study

J. Moock[1], F. Hessel[2], T. Kohlmann[1]
[1] *University of Greifswald, Institute for Community Medicine, Greifswald, Germany*
[2] *Sanofi-Aventis Germany, Health economics and outcome research, Berlin, Germany*

Objectives: Patient-reported outcome (PRO) measures can be used to examine whether drug differences other than clinical aspects have an impact on outcomes that may be important to patients. Although basal insulins glargine (GLA) or detemir (DET) appear to have similar clinical efficacy for treatment of type 2 diabetes (T2D), there are several differences between these two regimens that could affect outcomes from a patient's perspective. The purpose of this study was to compare treatment experiences (TE) and treatment satisfaction (TS) associated with insulin administration in T2D patients treated with either GLA or DET in a basal-bolus regimen for at least 6 months.
Methods: The study "Long Acting Insulin Glargine versus Insulin Detemir Cost Comparison in Germany" (LIVE-COM) was a non-interventional, cross-sectional, retrospective study performed between April and September 2008 in 138 randomly selected centers of primary care physicians in Germany. The study enrolled 1731 T2D patients with statutory health insurance status who were eligible for documentation when either treated with GLA (n=1150) or DET (n=581) as part of a basal-bolus regimen for at least 6 months prior to documentation. Patients completed the Insulin Treatment Experience Questionnaire (ITEQ), a new condition-specific instrument assessing TE and TS, and the Diabetes Treatment Satisfaction Questionnaire (DTSQs). To examine differences between the two treatment groups, independent *t*-test were used. Further, differences between groups were examined with general linear models (GLMs), adjusting for sociodemographic (gender, age) and diabetes-related characteristics (duration of diabetes, BMI, HbA1c, risk factors), respectively.
Results: Patients' characteristics for GLA (47% female) and DET (51% female) groups were (mean ± SD): age: 66±10/65±10 yrs., BMI: 31.3±5.8/32.7±6.2 kg/m^2, HbA1c: 7.5%±1.2/7.7%±1.2, fasting blood glucose: 142±47.7/149±49.0 mg/dl. Diabetes duration (> 10 yrs.: GLA 60%, DET 59%), onset of first insulin therapy (> 5 yrs.: GLA 62%, DET 64%), diabetic complications and risk factors were equally distributed in both groups. Treatment experiences and satisfaction analyses were conducted with data from 1,718 per protocol patients (GLA: 1,141; DET: 577). ITEQ subscales (sleep, diabetes control, weight control), ITEQ total score differed between insulin groups and were clearly better ($p< 0.05$) in GLA group (ITEQ total score: 68.6±12.7 vs. 66.7±13.9, p=0.004). Differences in DTSQs total score failed to reach statistical significance (28.8±5.9 vs. 28.2±5.8, p=0.064) Results of the GLMs indicate that differences between the insulin groups were stable after adjustment.
Conclusions: Under real life conditions, our results indicate that glargine was associated with significant higher treatment experiences as well as treatment satisfaction compared to detemir among T2D patients treated in a basal-bolus regimen.

Lower treatment costs with insulin glargine compared to insulin detemir as part of a basal-bolus regimen in type 2 diabetes: results of the LIVE-COM study in Germany

W. Landgraf[1], T. Kohlmann[2], R. Holle[3], K.-H. Theobald[1], R.A. Bierwirth[4], W. Landgraf[5]
[1] *Sanofi-Aventis Deutschland GmbH, Medical Affairs, Berlin, Germany*
[2] *University of Greifswald, Institute of Community Medicine, Greifswald, Germany*
[3] *Helmholtz Centre Munich, National Research Center for Environmental Health, Neuherberg, Germany*
[4] *Elisabeth Hospital, Diabetes Center, Essen, Germany*
[5] *University of Dresden, Department of Medicine III, Dresden, Germany*

Aims: The basal insulin analogs glargine (GLA) and detemir (DET) are recommended drugs in main national and international guidelines for the treatment of diabetes. In addition to clinical aspects the economic impact of

such basal insulin analogs on healthcare expenditures is of importance. The aim of this study was to compare resource utilization and costs incurred by a basal-bolus insulin regimen in type 2 diabetes (T2D) patients using either GLAR or DET from the perspective of the Statutory Health Insurance (SHI) in Germany under real-life conditions.

Methods: LIVE-COM was a non-interventional, cross-sectional, retrospective study performed between April and September 2008 in randomly selected primary care practices in Germany. T2D patients with SHI status were eligible for documentation if aged ≥18 years and either using GLAR or DET as part of a basal-bolus regimen for ≥6 months prior to documentation. The primary objective was to compare mean direct diabetes-specific treatment costs (DTC) between GLAR and DET groups over 6 months. DTC comprised antidiabetic medication (insulins, OADs), needles, self-monitoring of blood glucose (test strips, lancets), and hypokits to treat severe hypoglycaemia. Mean costs were adjusted for relevant influencing factors by analysis of covariance (ANCOVA).

Results: LIVE-COM enrolled 1731 T2D patients (GLA, 1150; DET, 581) from 138 primary care practices. Patient characteristics for GLA (53% male) and DET (49% male) groups were (mean±SD): age (66.0±10.7 vs. 64.7±10.1 years; p<0.01), BMI (31.3±5.8 vs. 32.7±6.2 kg/m^2; p<0.01), HbA1c (7.5±1.2 vs. 7.7±1.2; p<0.01), and fasting blood glucose (140±46 vs. 148±48 mg/dl; p<0.01). Diabetes duration (>10 years: 60 vs. 59%; ns), onset of first insulin therapy (>5 years: 61.6 vs 64.4%; ns), and number of diabetic complications and risk factors (3.0±1.7 vs. 2.9±1.6; ns) were similarly distributed in both groups. Adjusted mean DTC per patient and 6 months were lower for GLA compared to DET group (€ 932 vs.1060; p<0.01). Adjusted average DTC savings per patient were 128 € (95% CI: [90, 167]; p<0.01). Adjusted mean single costs for GLA and DET groups were: basal insulin € 223 vs. 246 (p<0.01), bolus insulin € 241 vs. 289 (p<0.01), needles € 67 vs. 80 (p<0.01), test strips € 347 vs. 393 (p<0.01), lancets € 14 vs. 16 (ns), OADs € 37 vs. 36 (ns), and hypokits € 2 vs. 1 (ns). Mean daily total insulin dose of 27.7/40.3 U (basal/bolus) was found to be lower for GLA group compared to 32.1/47.1 U for DET group (p<0.01). GLA patients had fewer basal insulin injections per day (1.1 vs. 1.3; p<0.01) and required also less test strips (3.2 vs. 3.6; p<0.01). Reported hypolycaemic events, hospitalization rates and frequency of physician contacts did not differ between GLA and DET groups.

Conclusion: Under real-life conditions, a glargine vs.detemir based basal-bolus regimen was associated with lower costs of diabetes care from the SHI perspective in a head-to-head comparison in T2D patients.

Dose response of recombinant human hyaluronidase effects on pharmacokinetics of regular human insulin and insulin lispro following SC injection

D. Vaughn[1], D. Muchmore[2], L. Gee[3], E. Ludington[3]
[1] Halozyme Therapeutics Inc., Research and Development, San Diego CA, USA
[2] Halozyme Therapeutics Inc., Endocrinology Clinical Development, San Diego CA, USA
[3] Halozyme Therapeutics Inc., Clinical Development, San Diego CA, USA

Aims: Recombinant human hyaluronidase (rHuPH20) is a locally and transiently acting enzyme that catalyzes depolymerization of hyaluronan, thus reducing the barrier to local bulk fluid flow and increasing the permeation of coinjected drugs. In the case of insulin, rHuPH20 results in acceleration of pharmacokinetic (PK) and glucodynamic (GD) responses for both regular human insulin and insulin lispro, resulting in an "ultrafast" insulin profile. This euglycemic clamp study compares the PK and GD responses to SC regular human insulin (regular) ± coinjected recombinant human hyaluronidase across a range of concentrations of rHuPH20.

Materials and methods: Separate cohorts of 4 healthy adult volunteers fasted for 10 h prior to receiving either 3 U or 12 U of regular human insulin or 1.5 U or 6 U of insulin lispro at time 0. Each subject received all 6 concentrations of rHuPH20 during 6 separate clamp visits; rHuPH20 concentrations employed were 0, 1.25, 5, 10, 20 and 80 µg/mL for regular and 0, 0.08, 0.32, 1.25, 5, and 20 µg/mL for lispro. Subjects had their glucose regulated to a value 90% of spontaneous fasting level with a variable rate glucose infusion. Samples were collected for PK at frequent intervals (24 samples over 8 h).

Results: All subjects completed the 6 clamp procedures, and PK data are presented for both insulin doses. PK parameters were analyzed using an ANOVA model with fixed effects for dose (i.e., 3 U insulin, 12 U insulin, 1.5 U Lispro and 6 U Lispro) and PH20 concentration. An unstructured covariance matrix among repeated observations for each subject was assumed. Coadministration with rHuPH20:

- increased the geometric mean peak insulin concentration (Cmax), at PH20 concentrations = 0.3 µg/mL with full effect obtained by 5 µg PH20/mL.
- increased geometric mean early insulin exposure (AUC from 0 to 30 minutes), at all PH20 concentrations with full effect obtained by 1.25 µg PH20/mL.
- shortened time of offset (Late $t_{50\%}$), at all PH20 concentrations with full effect obtained at the highest level tested, 80 µg PH20/mL.
- slightly increased total bioavailability (AUClast) overall, although the effect did not reach significance for any dose relative to control, with the full effect obtained by 5 µg PH20/mL.

Conclusions: rHuPH20 is a potent permeation enhancer, enhancing insulin over a wide concentration range 0.08 to 80 µg/mL, with an optimum effect at or about 5 µg/mL.

D-0965

Treatment of impaired glucose tolerance with buccal spray insulin: a novel approach

N. Napoli[1], A. Palermo[1], A. Lauria[1], G. Beretta[1], S. Manfrini[1], P. Pozzilli[1]
[1] Università Campus Bio-Medico, Endocrinology and Diabetes, Rome, Italy

Background and aim: Postprandial hyperglycaemia is the consequence of a reduced first phase insulin response after a meal. This condition has been associated with an increased risk of cardiovascular events and mortality. Subjects with postprandial hyperglycaemia often present with co-morbidities such as dyslipidaemia, hypertension, abdominal obesity, microalbuminuria, endothelial dysfunction and markers of visceral inflammation. Normalization of the first phase insulin response using fast acting insulin is an attractive option. The objective of this phase II study was to investigate the efficacy and safety of treatment with buccal spray insulin (Oral-lyn™)on post-prandial plasma glucose and insulin levels in subjects with impaired glucose tolerance (IGT).

Methods: A total of 20 Caucasian subjects, mean age 48.7 ±14.3 SD years, a body mass index of 32± 6 Kg/m2, 13 females and 7 males, with confirmed IGT were included in the study. Subjects were randomized to take 4, 6 or 12 Oral-lyn™ puffs, split in two equal doses each, one before and the second 30 minutes after a standard 75 g oral glucose tolerance test (OGTT). Glucose excursions and insulin levels were measured at baseline and 30, 60, 90, 120, 180 min following OGTT.

Results: There were no significant differences in plasma glucose levels during OGTT with 4 or 6 puffs compared to OGTTs performed without insulin administration. Treatment with 12 Oral-lyn™ puffs (equal to 12 IU) was followed by a significant 29.6% decrease in mean plasma glucose at two-hours (from 175.3± 14.0 to 124.0±39.1 mg/dl), and a 26.8% decrease at three-hours (from 124.7±50.5 to 91.3±26.0 mg/dl), altogether p=0.01. Considering all time points of the OGTT up to 180 min, there was a mean reduction of 15.8% in plasma glucose levels. There was a trend for increased insulin (µU/L) levels at all time measurements. Finally, no adverse events were observed in the course of the OGTT and, most relevant, no hypoglycaemic episodes were reported at any time-points by the participating subjects.

Discussion/conclusion: This proof of concept study demonstrates that treatment with buccal spray insulin is a simple and valuable treatment for reducing postprandial hyperglycaemia in obese subjects with IGT. Importantly, this treatment is safe and none of the study subjects experienced hypoglycaemia. Therefore, the use of insulin administered through an alternative route such as the buccal mucosa can represent a novel approach for treatment of postprandial hyperglycaemia.

Study of oral administration of insulin in a hydrogel form to a non-diabetic and diabetic rodents

E. Smolko[1], J.H. Lombardo[1], C. Gonzalez[2], F.M. Lombardo[2], R. Hipp[3], E. Lombardo[4]

[1] Comision Nacional de Energia Atomica, I+D, Buenos Aires, Argentina

[2] Buenos Aires Univ., School of Medicine Dept of Pharmacology, Buenos Aires, Argentina

[3] CONAE, Gerencia Aplicaciones, Buenos Aires, Argentina

[4] Mater Dei, Sanatorio, Buenos Aires, Argentina

Objective: To evaluate the effect of a new insulin preparation in hydrogel form, in diabetic and non diabetic rodents.

Method: A new hydrogel form containing rapid acting insulin was tested through four different experiments in rodents (Wistar rats and Balb/C mice) by oral administration. Diabetes was induced by STZ. The new formulation was designed to allow the delivery of insulin in a sustained form, avoiding serum peaks, as cylindrical pellets of 3 mm diameter, containing 3IU/cm. The amount of insulin administered by mouth was 4 IU/kg of body weight. Hydrogel pellets mainly consist of an aqueous solution of an acrylic monomer polymerized by gamma radiation.

The four experiments were carried out as follows:

a. administration of oral insulin to non-diabetic mice
b. administration of oral insulin seized in hydrogel form to non-diabetic mice,
c. administration of oral insulin seized in hydrogel form to diabetic rats and
d. like c) with food every 6 hours.

Results: The experiments show that in a lineal plot of glycemia (Gl) in mg/ml versus time in min, exp.(a) shows a constancy of Gl in 100 in a period of 200 min and exp(b) shows a decrease of Gl to nearly 50 in 30 min and normalization after that time. In exp. (c) Gl starts at 350 decreasing steadily to less than 20 for a period of 20 hrs. Finally exp(d) shows a decrease from around a Gl value of 500 that could be controlled by systematic oral administration of insulin with food.

Administration of insulin in hydrogels to non-diabetic mice displays significantly glycemic control when comparing experiments b) and a).

When insulin is administered to diabetic rats as in hydrogel form, it showed a quick reduction of glycemia up to hypoglycemic levels, lasting more than 20 hours. In the case of administration of insulin in hydrogel with food, the control of glycemia was smoother and gentler and can be controlled by the amount of drug seized into the polymer.

Conclusion: Administration of insulin as a long lasting oral hydrogel preparation markedly reduced glycemic level in the studied rodent models.

Incidence of perinatal complications in women with gestational diabetes controlled with diet who do not perform self blood glucose monitoring

L. Zajdenverg[1], A. Lázaro[1], M. Rodacki[1], J.E. Oliveira[1]

[1] Federal University of Rio de Janeiro, Endocrinology, Rio de janeiro, Brazil

Introduction: Appropriate therapy for gestational diabetes mellitus (GDM) can decrease fetal and maternal morbidity. However, there is still no consensus if it is necessary to treat those women with "mild" GDM. GDM treatment consists of diet, self blood glucose monitoring (SBGM) and insulin if necessary. Because of limited resources in Brazil, many women whith GDM can not afford SBGM. Those who control diabetes only with diet are frequently just monitored through weekly laboratory tests and ultrasound.

Objective: The goal is to identify which patient who is on diet, without self monitoring, had a higher incidence of complications, in order to identified those who need more rigorous treatment.

Methods: It was performed a retrospective study through review of medical records from women diagnosed with GDM followed in a Brazilian public maternity between 1999 and 2005. GDM diagnoses were made based on the American Diabetes Assotiacion criteria. Those who needed to use insulin were excluded from the analyses. The risk variables were age, parity, mean fasting plasma glucose (FPG), mean post prandial plasma glucose (PPG), gestational age of GDM diagnostic (GA), prior history of gestational diabetes, weight gain after second trimester of pregnancy, pre-pregnancy body mass index (BMI), family history of diabetes and prior history of gestational diabetes. It was applied Student t-test for mean comparison of the continuous risk variables and Pearson Chi-Square for categorical risk variables.

Results: The sample is composed of 72 women, 44 cases (61%) do not develop complications. One case with twins was excluded. There were no maternal complications in our sample. The main fetal and neonatal complications were: hypoglycemia (12 cases), large for gestational age (12 cases), congenital malformations (4 cases), neonatal infection (4 cases), hyperbilirubinemia (4 cases), prematurity (1 case), coagulation disorder (1case), polycythemia (1case), hemangioma (1case). Pregestational BMI showed a significant association with perinatal risk (26.8 ±4.9 kg/m^2 vs 31.6 ±5.4 kg/m^2)($p < 0.05$). Patients who developed perinatal complications did not differ from women without complications in age (31.1 ± 5.7years vs 31.3 ± 5.0 years), parity (2.8 ± 1.8 vs 2, 9 ± 1.4), mean FPG (92.6± 11.3 mg/dL vs 101.9 ± 33.7mg/dL), mean PPG (111.7 ± 24.3mg/dL vs 110.8 ± 32.5 mg/dL), GA at GDM diagnosis (27.1± 5.2 weeks vs 25.9 ± 6.9 weeks) and weight gain (8.4 ± 4.7 kg vs 7.8 ± 4.4 kg). Family history of diabetes and prior history of gestational diabetes weren´t associated with worst outcomes.

Conclusion: We concluded that obesity may be a marker of risk of perinatal complications that more features of decompensated diabetes in women with mild GDM. Therefore, we must be more aware of the possibility of unfavorable outcomes in this group of women and encourage as far as possible the implementation of SMBG.

Comparative study of three insulin schedules in pregnant insulin-treated diabetic women

J. Lang[1], L. Valdes[2], B.R. Rodriguez[2], O. Santana[2], O. Zaldivar[2], B.E. Herrera[2], M. Granda[2], A. Santurio[2], A.M. Marquez[1]

[1] National Institute of Endocrinology, Diabetes and Pregnancy Central Service, Ciudad de la Habana, Cuba

[2] Ramon Gonzalez Coro Hospital, Diabetes and Pregnancy Central Service, Ciudad de la Habana, Cuba

Aim: To compare the effects on metabolic control, maternal and perinatal outcomes of 3 intensive insulin treatment schedules in pregnant insulin-treated diabetic women. The acquired information will allow individualizing the management of the diabetic pregnant women and to optimise the availability of different insulin preparations.

Study design: 84 pregnant women with pregestational diabetes requiring insulin treatment were included in one of 3 schedules of insulin treatment in the Central Service of Diabetes & Pregnancy, Havana, Cuba. In the 3 schedules, regular insulin (Actrapid HM Novo Nordisk) was used before breakfast, lunch and dinner; the difference was in the fourth dose of insulin: regular insulin at 3:00 a.m.(4-6 Units), intermediate insulin (Insulatard HM Novo Nordisk) at 10 pm. (1/4 of the daily dose), and intermediate insulin at 6 pm. (1/3 of the daily dose). The initial total daily dose was calculated according with the type of diabetes and initial degree of metabolic control. The effectiveness of metabolic control was measured by glycemic profiles (3 am, 7 am, 10 am, 2 pm, 8 pm), average value of Hb A1c and maternal weight gain.

Results: The achievement of adequate metabolic control through pregnancy was similar in the 3 therapeutic groups. Glycemia in different moments of the day showed the lowest values of fasting glycemia (7 am) in the users of intermediate insulin at 10 pm., the lowest values of glycemia at 3 a.m. with intermediate insulin at 6 p.m. and the highest values of glycemia at 3 a.m. with regular insulin at this hour. The highest frequency of hypoglycaemia was found in the users of intermediate insulin at 6 p.m. The 3 shedules showed similar results in maternal and perinatal outcomes.

Conclusion: The 3 schedules of intensive insulin treatment gave the desired maternal and perinatal outcomes. The method of intermediate insulin at 10 p.m. provides more acceptable glycemic values, although give longer hospital stay.

HbA1c, fasting, postprandial glycemia and infants' birth weight in patients with type 1 diabetes

N. Asatiani[1], R. Kurashvili[1], E. Shelestova[1], M. Dundua[1], K. Paghava[1], M. Hod[2], S. Smirnov[3], V. Vlasov[3], L. Tsutskiridze[1]

[1] *Georgian Diabetes Center, Clinical care, Tbilisi, Georgia*

[2] *Rabin Medical Center, Dept. of Obstetrics and Gynecology, Tel-Aviv, Israel*

[3] *Novo Nordisk, A/S, Copenhagen, Denmark*

Aim: of the present work was to reveal correlation between glycemia indices in pregnant patients with type 1 diabetes mellitus (T1DM) and their infants' birth weight (IBW).

Methods: Totally, 178 pregnant women with T1DM were enrolled in the study (mean age - 27±7yrs; diabetes duration – 11.2± 5.4yrs). Patients with nephropathy were excluded. Strict metabolic control was maintained and fetal surveillance was performed throughout the pregnancies. Data obtained for home-blood glucose monitoring (five-point profiles), postprandial (PG), fasting (FG), mean blood glucose (MG) were analysed. Healthy infants were born to diabetic mothers at 38-40 week of gestation. According to the IBW, the patients were divided into 2 groups (GR): GR.1, n=127, IBW < 4 000g;Gr. 2, n=51, IBW >4 000g.

Results: HbA1c (%), PG, FG and MG (mg/dl) levels were statistically higher in GR.2, than in Gr.1: HbA1c (7.2 ±1.38 vs 6.1± 1.71, P<0.001), PG (168.1± 17.1 vs 110.4± 14.7, P=0.000), FG (136.5 ±15.8 vs 102.5± 13.4, P=0.000), MG (155.2 ±12.17;vs 104.7± 12.1, P=0.000). Pre-pregnancy BMI (kg/m2) indices were higher in Gr.2, than in Gr.1 (27.2± 0.58 vs 22.5± 0.62, P<0.001). Strong correlation was observed between IBW and PG (r-0.882; P=0.000), IBW and HbA1c (r-0.794;P=0.04), IBW and MG (r-0.703;P=0.012) for Gr.1, and between IBW and PG (r-0.814; P=0.000), IBW and pre-pregnancy BMI (r-0.866; P=0.001) for Gr.2.

Summary: IBW strongly correlates with PG, MG and HbA1c in the pregnant patients with T1DM. Pre-pregnancy BMI>26kg/m2 and postprandial glycemia levels of >160mg/dl may predict fetal macrosomia.

What do we know of gestational diabetes ? (medicine based on the evidence)

L. Valdes[1], O. Santana[1], B.R. Rodriguez[1], A. Santurio[1], J. Lang[2], A. Marquez-Guillen[2]

[1] *Ramon Gonzalez Coro Hospital, Central Service of Diabetes and Pregnancy, Ciudad de la Habana, Cuba*

[2] *National Institute of Endocrinology, Central Service of Diabetes and Pregnancy, Ciudad de la Habana, Cuba*

Aim: Since Miller in 1946 reported a perinatal mortality 4 times greater than normal in women that developed Diabetes later on, there are many publications that still discuss proceeding diagnosis and repercussion of the Gestational Diabetes.

Patients and method: We analyze our experience from 1968-2007 with 2 238 Gestational Diabetics regarding frequency, used diagnosis, factors of risk in our population, repercussion on maternal and perinatal morbi-mortality and other variables of importance.

Results: The frequency of Gestational Diabetes in our population is 4,5%. As for maternal and perinatal morbi-mortality it has been superior significantly to that reported by our institution for population without selecting. The risk factors more frequently detected in our population have been: a.- maternal age = or > 30 years old, b.- corporal overweight > 26,0 (BMI) and c.- diabetic relatives or 1erst line. As screening we have used the fasting glycemic value = or > 80 mg/dl (4,4 mmol/L). The diagnostic method used has been the oGTT one advised by WHO, because we don`t detect differences with coming from J. O`Sullivan. The control approach "good" during pregnancy it has been fasting glycemic value = or < 94 mg/dl (5,2 mmol/L) and post-prandial 2 hours = or < 114 mg/dl (6,3 mmol/L). The frequency of glucose intolerance of variable intensity post childbirth has been 23% at 6 years of the event.

Conclusion: The biggest risk in Gestational Diabetes consists of underestimating it.

Diabetic women in fertile age: gynaecological, obstetric and contraception history

J. Lang[1], L. Castelo[1], M. Vera[1], L. Valdes[2], B.R. Rodriguez[2], O. Santana[2], O. Zaldivar[2], B.E. Herrera[2], A. Marquez-Guillen[1]

[1] *National Institute of Endocrinology, Diabetes and Pregnancy Central Service, Ciudad de la Habana, Cuba*

[2] *Ramon Gonzalez Coro Hospital, Diabetes and Pregnancy Central Service, Ciudad de la Habana, Cuba*

Background and aims: It is well established the necessity to obtain strict metabolic control before conception in order to reduce the frequency of congenital malformations in newborns of women with diabetes. In expectance of these metabolic conditions, the same as the presence of complications that dissuade pregnancy require adequate contraceptive use and efficient diabetological and sexual education.

Materials and methods: With the aim to know gynaecological, obstetric and contraception history, we interviewed all the women with diabetes in fertile age (14-45 years old) from 2 primary care areas of Havana City, Cuba: 65 patients, 19 type 1DM and 46 type 2 DM. We make a questionnaire designed with this purpose (pregnancies, deliveries, abortions, macrosomics, underweight newborns, congenital malformations, perinatal deaths, previous and actual use of contraception), gynaecological examination and vaginal smear.

Results: The half of the women had gynaecological problems, mainly vaginal discharge (leucorrea); the most frequent germ was Candida albicans. The frequency of pregnancies and newborns was significantly higher in women with type 2DM, compared with type 1. There was a high frequency of macrosomic newborns (23,5% vs. 5%) and congenital malformations (13,9% vs. 2,1%) in group of women with diabetes, compared with general population attended in Ramon Gonzalez Coro Hospital. There were not statistical differences of the gynaecological and obstetric history with previous investigations in the not diabetic women. There were 23 sterilized women (35,4%). Another frequent contraceptive method was the intrauterine device (21,5%). Near one third of the total group did not use any contraceptive method at the moment of the study (21 women for 32,3%).

Conclusion: We confirm deficient policy in the contraceptive control of the women with diabetes in reproductive age, with inadequate education to the patient with diabetes and her family in topics as pregnancy and sexuality.

Gestational diabetes (GDM) and excessive gestational weight gain both have significant implications for the health of mother and child.

Aim: To compare patterns of gestational weight gain between women with GDM and women without GDM (controls).

Methods: Data were collected on maternal and neonatal outcomes by detailed retrospective reviews of medical records in women who delivered between January and December 2007 at the Centre Mère-Enfant, Laval University Medical Center (Quebec, Canada). Analysis included 165 women (40 GDM and 125 controls) for whom gestational weight gain was calculated by the difference between maternal weight measured at delivery, or at the last prenatal visit (≥37th week), and pre-pregnancy self-reported weight. Weight gain rate was also calculated for the entire pregnancy. Gestational weight gain was compared to the recommendations by the Institute of Medicine (IOM). GDM women were diagnosed and treated according to the Canadian Diabetes Association guidelines.

Results: Women with GDM had a significantly higher pre-pregnancy body mass index (BMI) compared to controls (28.6±8.1 vs. 23.7±4.5 kg/m^2, p<0.001). Total gestational weight gain was not significantly different in

GDM women compared to controls (13.4±5.4 vs. 15.4±5.4 kg, p=0.12). The proportion of women exceeding IOM recommendations was not significantly different in GDM compared to controls (40% vs. 50%, χ^2=1.13, p=0.56). Total gestational weight gain was positively associated with child birth weight (r=0.25, p=0.002) and women exceeding IOM recommendations delivered significantly heavier babies compared to women within or below IOM recommendations (3666.4±403.5 vs. 3530.4±348.1 and 3351.7±328.1 g respectively, p=0.001). A trend for a lower weight gain rate was observed in women with GDM compared to controls during the entire pregnancy (0.36±0.15 vs. 0.41±0.14 kg/wk, p=0.06). First trimester weight gain was not different in GDM compared to control women (2.27±2.65 vs. 1.51±2.26 kg, p=0.26). In contrast, weight gain was significantly lower in GDM compared to controls in the second (4.08±2.32 vs. 4.90±1.86 kg, p=0.03) and in the third trimester (3.19±2.14 vs. 5.44±2.44 kg, p<0.0001). Second and third trimester weight gain were both positively associated with child birth weight (r=0.23, p=0.006 and r=0.23, p=0.004 respectively). No association was found in the first trimester. Gestational weight gain was a significant predictor of elevated child birth weight independently of the presence of GDM (r^2=0.07, p=0.001).
Conclusion: GDM women are characterized by an elevated pre-pregnancy BMI and lower weight gain in the second and third trimester compared to women without GDM. Women exceeding current weight gain recommendations delivered heavier babies independently of GDM.

D-0973

Gestational Diabetes Mellitus(GDM): we need to revise the standard criteria for diagnosis - Indian experience

S. Gupta[1]
[1] *Diabetes Care and Research Centre Pvt. Ltd., Diabetology, Ramdaspeth Nagpur, India*

Aim: To study the clinical profile of women with glucose intolerance of varying degree during pregnancy & to evaluate whether we need to reduce the cut off values given in Carpenter & Coustan & ADA criteria for diagnosis of GDM. [i.e.100 g OGTT – F 95, 1hr 180, 2hr 155, 3hr 140 mg%, if any 2 values are abnormal.]
Material and method: 781 pregnancies with glucose intolerance of varying degree were divided as – GDM (as above) and Decreased Gestational Glucose Tolerance [DGGT– if two hours BG is between 120-155mg% or if any one value is abnormal in OGTT]. All cases were treated with diet & /or insulin to achieve fasting BG < 90 mg% & 2hr PPBG < 120 mg% and followed till delivery. Age, Anthropometry measures, Family History(F/H), Bad Obstetric history (BOH), Insulin Requirement were compared with the fetal out come and is observed as below.
Results: TOTAL GDM DGGT
781 493 (63.1 %) 288 (36.8 %)
Mean Age (years) 28.8 ± 3.96 28.4 ± 4.07
Weeks of Diagnosis 24.6 ± 8.5 24.9 ± 7.4
Pre Pregnancy BMI (Kg/m2) 23.9 ± 4.0 23.4 ± 3.5
Positive Family History 332 (67.3 %) 175 (60.7 %)
Bad Obstetric History (BOH) 211 (42.7 %) 131 (45.4 %)
Patients on Insulin at Full Term 300 (60.8 %) 82 (28.4 %)
Fetal outcome:
Macrosomia 27 (5.47 %) 12 (4.1 %)
Neonatal Hypoglycemia 60(12.1 %) 14 (4.8 %)
Hyperbilirubinemia 24 (4.8 %) 11 (3.8 %)
Fetal Loss 33 (6.6 %) 11 (3.8 %)
The difference between mean age, pre pregnancy weight, body mass index & weeks of diagnosis of glucose intolerance in 2 groups were statistically not significant. 63.1 % were GDM while 36.8 % had DGGT. 60.8 % of GDM women & 28.4 % of DGGT women required insulin to achieve euglycemia for pregnancy. 42.7 % of GDM & 45.4 % of DGGT women had past history of BOH, the incidence of which reduced to 6.6 % & 3.8 % respectively.
Conclusion: If we follow the standard criteria for diagnosis of GDM, 36.8% of pregnancies would have remained undiagnosed & untreated for glucose intolerance. Due to aggressive management we could reduce the incidence of fetal loss from 45.4 % to 3.8 % in DGGT group as that of GDM. We recommend that all women with 2hr. value of OGTT more than 120mg%, but not GDM by standard diagnostic criteria, should be categorized as, "Decreased Gestational Glucose Tolerance (DGGT)", to achieve better fetal outcome.

Effect of a community-based lifestyle intervention on physical activity and diet in pregnant women

A. Hui[1], *S. Ludwig*[1], *P. Gardiner*[2], *G. Sevenhuysen*[3], *H. Dean*[4], *E. Sellers*[4], *E. Bruce*[5], *M. Morris*[6], *G. Shen*[1]
[1] *University of Manitoba, Internal Medicine, Winnipeg, Canada*
[2] *University of Manitoba, Physical Education, Winnipeg, Canada*
[3] *University of Manitoba, Human Nutritional Sciences, Winnipeg, Canada*
[4] *University of Manitoba, Pediatrics, Winnipeg, Canada*
[5] *University of Manitoba, Community Health Sciences, Winnipeg, Canada*
[6] *University of Manitoba, Obstetrics and Gynecology, Winnipeg, Canada*

Obesity is a modifiable risk factor for type 2 diabetes. Maternal obesity is associated with future obesity and type 2 diabetes in mothers and their offspring. We conducted a community-based lifestyle intervention for pregnant women in Winnipeg. Pregnant women (<20 weeks of pregnancy) were recruited with assistance from the Healthy Start for Mom & Me Prenatal and Postnatal Program, and randomized into Intervention (IG) and Control Groups (CG). Participants in the IG received instructed group and home exercises for 3-5 times/week, and computerized Food Choice Map dietary counseling. Participants in both groups received 2 surveys for activity and diet at baseline and 2 months after enrolment (post-intervention), and a post-partum visit. A total of 131 women completed the program (67 in the IG, 64 in the CG). No significant difference was detected in age, ethnicity, family income, pre-pregnant weight, baseline physical activity index and nutritional intakes between the groups. Self-reported physical activity at post-intervention was greater than that of IG at baseline (p<0.001), but not in the CG. Fat intake by participants in the IG at post-intervention was lower than that in the CG (p<0.05). Excessive weight gain during pregnancy was found in 29% of the IG and 48% of the CG (p=0.10). Prevalence of gestational diabetes, the requirement for delivery procedures and macrosomia were 6%, 10% and 19% in the CG, and were 2%, 5% and 12% in the IG (not statistically significant). The results suggest that lifestyle intervention during pregnancy effectively improved activity and diet, and potentially decreases excessive weight gain in pregnant women (supported by Lawson Foundation and CIHR).

Prevalence of gestational diabetes mellitus and maternal height

P. Karatodorova[1], *K. Hristozov*[1], *B. Zvetanova*[1], *V. Chobanova*[1], *N. Usheva*[2]
[1] *Medical University, Department of Endocrinology and Metabolic Diseases, Varna, Bulgaria*
[2] *Medical University, Department of Social Medicine and Health Care Organization, Varna, Bulgaria*

Background: Short maternal stature is one of the reported factors associated with increased prevalence of gestational diabetes mellitus (GDM) in different ethnic groups.
Aim: To find out the prevalence of GDM in a sample of Bulgarian women according to their height and to analyze the association between maternal stature and gestational diabetes.
Methods: We studied a sample including 189 consecutive pregnant women who underwent 2-h 75-g OGTT as a part of universal screening program (for GDM diagnosis WHO-1999-criteria were applied) and 18 additional patients with out-of-screening diagnosed GDM. At enrollment, after signing a written informed consent approved by the Local Ethic Committee, a standardized questionnaire was completed, an anthropometry (weight, height) obtained, plasma glucose at 0', 60', 120' was measured using glucose-oxidase method.
Results: We found 11,6% prevalence of GDM (22 women) in the whole sample of 189 screened women. All 189 women are stratified into five groups according to intervals of maternal height and a prevalence of GDM in each group is determined: < 155cm (50%); 155-159cm (13,3%); 160-164cm (12,7%); 165-169cm (10,6%), > 170cm (7,4%). Then all pregnant women are stratified into two groups: with GDM (22 from the screening and 18 out-of-screening) and a second group with healthy women (N=167). Study population details (GDM women vs. healthy) are as follows: age (30,3±5,2 vs. 28,6±4,3; p=0,05); gestational weeks (27,6±5,7 vs. 27,8±3,7; p=0,5); pre-pregnancy BMI (26,1±6,0 vs. 22,5±5,0; p<0,0001); height (1,62±0,06 vs. 1,65±0,05; p=0,008). Pearson correlation coefficients for maternal height with fasting, 1-h and 2-h plasma glucose are -0,13 (p=0,05), -0,14 (p=0,04), -0,2 (p=0,005), respectively.

Discussion: Maternal height is significantly lower in GDM women. Consistent with this finding, the prevalence of GDM increased with decreasing stature being highest in the interval with lowest height. Maternal stature shows inverse weak significant relation with 1-h and 2-h post-load glycaemia. The role of short maternal stature as another possible risk factor for GDM should be explored further.

A structured diabetes self-management education program in Hong Kong: Process and outcome evaluation

E.C.Y. Kan[1], W.M.W. Cheng[2], M.P.H. Mok[3], J.Y.M. Kwan[4], A.Y.S. Leung[5], A.T.Y. Shiu[6]

[1] *Alice Ho Miu Ling Nethersole Hospital, Medicine, Hong Kong, Hong Kong China*
[2] *Queen Elizabeth Hospital, Medicine, Hong Kong, Hong Kong China*
[3] *United Christian Hospital, Medicine, Hong Kong, Hong Kong China*
[4] *Our Lady Maryknoll Hospital, Medicine, Hong Kong, Hong Kong China*
[5] *Yan Chai Hospital, Medicine, Hong Kong, Hong Kong China*
[6] *Chinese University of Hong Kong, Nethersole School of Nursing, Hong Kong, Hong Kong China*

Background: A structured diabetes self-management education (DSME) program using patient empowerment approach was developed, implemented and evaluated by the Association of Hong Kong Diabetes Nurses (AHKDN). Based on the Michigan Empowerment Model and education strategies appropriate for Chinese culture, AHKDN developed the structured program with a teaching kit which contains: a set of slides with scripts, a log book and a hand book. Four diabetes nurses implemented the program (three 4-weekly sessions) in 4 diabetes centers. This paper reports the process and outcome evaluation of the program.
Methods: A single, embedded case study design (with 8 embedded units representing main data sources) was employed to evaluate the program. All units together provided a comprehensive evaluation of the case using multiple-triangulation. The patients (n=40), facilitators (n=4) and observers (n=10) contributed to the three samples of participants of the study. Data collection methods included audio-taping of the education process, reflective diary written by facilitators and observers, questionnaires and scales administration, home-work by patients, glycaemic levels measurements, and focus-group interviews with the three samples. In line with the case study design, there were two stages of data analysis – within-unit and cross-units analyses.
Results: Key findings of within-unit analysis show that patients, facilitators and observers were highly satisfied (mean score=70-100%) with the program. Patients showed high engagement (score>90%@session). Every patient set diabetes goals (mean no.=2.8) and performed SMBG (mean days=8.5). Patients showed significant improvement in i) diabetes specific psychosocial self-efficacy, ii) diabetes knowledge (gain by 28%), and iii) A1c levels (reduction by 0.5%). In cross-unit analysis, the converged themes confirm important insights on the implementation of DSME: i) content – practical and accurate information, peer sharing, support and role modeling, and opportunity to practice and receive feedback are important, ii) method - multiple education strategies, home work assignments and goal setting are useful to enable patients' participation, interaction and experimentation with DSM; iii) by whom – program facilitators should have a good mastery of DSME, problem solving and group facilitation skills, and willingness to work as equal partners with patients.
Conclusions: This is the first structured DSME program tested among Chinese type 2 diabetic patients (> 650,000) in Hong Kong. Findings show that the program, an attempt to apply patient empowerment with Chinese patients, is successful in improving self-efficacy, self-management behavior and glycaemic control.
AHKDN will continue to advocate and promote high quality DSME in Hong Kong.

Chinese patients' perceptions of diabetes self-management education: a case study of a patient empowerment program

A.T.Y. Shiu[1], E.C.Y. Kan[2], W.M.W. Cheng[3], M.P.H. Mok[4], J.Y.M. Kwan[5], A.Y.S. Leung[6]

[1] *The Chinese University of Hong Kong, The Nethersole School of Nursing, Hong Kong SAR, China*
[2] *Alice Ho Miu Ling Nethersole Hospital, Diabetes Education Centre, Hong Kong SAR, China*
[3] *Queen Elizabeth Hospital, Diabetes Education Centre, Hong Kong SAR, China*
[4] *United Christian Hospital, Diabetes Education Centre, Hong Kong SAR, China*
[5] *Our Lady of Maryknoll Hospital, Diabetes Education Centre, Hong Kong SAR, China*
[6] *Yan Chai Hospital, Diabetes Education Centre, Hong Kong SAR, China*

Aim: This paper reports patients' perceptions of diabetes self-management (DSM) education, which were part of the findings of a case study that evaluated the education process of a patient empowerment program undertaken in Hong Kong.
Methods: A single, embedded case study design was employed to evaluate a patient empowerment program. It was designed with three-monthly sessions (n = 8 hours). Four courses of the program were each facilitated by one diabetes nurse (facilitators, n = 4) to a group of 10 patients (n = 40) with type 2 diabetes. The program was observed by 9 diabetes nurses and one doctor (observers). The facilitators, patients and observers contributed to the three samples of participants of the case study. Eight embedded units of analysis together provided a comprehensive evaluation of the case using multiple-triangulation. Data collection methods included audio-taping of the education process, reflective diary written by facilitators and observers, questionnaires and scales administration, work-books recorded by patients, A1c levels retrieved from patient records, and focus-group interviews with the three samples. There were two stages of data analysis – within-unit and cross-units analyses. This paper focuses on one of the units – patient focus-group interview data. The interview was attended by a sub-sample of 8 patients who were participants of one of the courses, using convenience sampling method. The interview, taped and transcribed verbatim, was facilitated by one of the researchers using a semi-structured guide.
Results: Thematic analysis of patients' focus-group data yields two categories: (1) perceptions of abilities required for DSM, and (2) perceptions of the empowerment program. The first category has four subcategories: diabetes-specific medical knowledge and skills, perseverance and internal motivation, coping with negative emotion and stress, and obtaining support from family and health professionals.The second category has four subcategories: the facilitator's professional expertise, experiential learning, peer input and collaborative learning, and length and content of the program. Findings from the eight units of analysis converge and validate each other that the program was implemented in line with the philosophy of patient empowerment.
Conclusion: Limited investigation has been directed to examine Chinese patient perceptions of the abilities required for DSM and their experience of such education process. The strength and limitation of this study will be discussed. Implications of our findings for facilitating empowerment programs in diabetes and other chronic care specialties will be discussed.

Evaluation of a multidisciplinary diabetes school for people with type 2 diabetes in an out-patient clinic in Denmark

B. Hansen[1]

[1] *Aarhus University Hospital, Medical Department, Aarhus C, Denmark*

Background: A published review (Deakin T el al, 2006) showed that patient-centred group education based on the principles of the empowerment philosophy resulted in improved health and HbA1c. In Denmark there has never been an evaluation of group education and therefore this randomised control study was conducted.
Method: Two different group education programmes were evaluated: programme A (10 hours) and programme B (14 hours including cooking and exercise). The two programmes were identical apart from cooking and exercise and were patient-centred and based on the empowerment philosophy.

The diabetes team doing the group education consisted of diabetes nurse specialist, dietician, chiropodist, physiotherapist and general practitioner (GP). The participants had individual consultations by the diabetes team including the diabetologist. At baseline and after half a year the participants completed validated questionnaires: Problem Areas in Diabetes Scale (PAID), Perceived Competence in Diabetes (PCD) and Treatment Self-Regulation Questionnaire (TSRQ). Demographic data, BMI, medication and blood tests were recorded.
Along with group education multiple risk factor interventions were made.
Results: 100 people with type 2 diabetes were referred from GPs. 90 (47 women) were included: 45 in programme A and 45 in programme B, mean age 59 years and duration of diabetes 45,2 months.
8,2 months after interventions there was a significant reduction ($p<0,001$) in PAID scale, HbA1c and blood pressure. PCD increased ($p<0,001$). Significantly more people were on lipid lowering medication, antiplatelet agents, insulin treatment and all were eating a healthy diet.
Programme A and B had the same effect on outcomes.
Conclusion: Multidisciplinary group education based on the empowerment philosophy and patient-centred education involving the person with diabetes actively combined with optimized dietetic and medical treatment resulted in significantly less problems in relation to living with diabetes and people felt empowered. These changes might translate into less diabetic complications and improvements in quality of life for people with type 2 diabetes.
The results are in accordance with the results in the above-mentioned review.

Patient involvement in diabetes medication discussions: the effects of an educational intervention for UK nurse prescribers.

A. Sibley[1], S. Latter[1], T.C. Skinner[2], S. Craddock[3]
[1] University of Southampton, Health Sciences, Southampton, United Kingdom
[2] University of Western Australia, Combined Universities Centre for Rural Health, Geraldton, Australia
[3] Portsmouth Hospitals NHS Trust, Queen Alexandra Hospital Diabetes Centre, Portsmouth, United Kingdom

Background: Better patient outcomes are reported when professionals engage in patient-centred care (Stewart et al 2000). As an important element of patient-centred care, provider-patient communication studies have indicated that routine medication discussions can lack depth and breadth (Stevenson et al 2000). Recently, UK guidance has recommended an increase in patient involvement during consultations to address non-adherence to medications (NICE 2009) and nurse prescribers have an important opportunity to promote patient involvement in their consultations with patients. However, evidence indicates that consultations are characterised by professionals' domination of medication discussions and one-way information giving (Shiu 2006; Latter et al 2007; Richard & Lussier 2007).
Aim: This paper presents results from an evaluation of an educational intervention for nurse prescribers to improve patient-centred medication discussion for people with diabetes. The paper draws on findings from a larger study funded by Diabetes UK (Latter, Sibley et al, 2009).
Methods: To assess changes in consultation participation, consultation audio-recordings were collected before and after (1 week, 3 months, 6 months) the nurse prescribers took part in an educational intervention. The intervention aimed to develop nurse prescribers' skills in patient-centred communication to support their exploration of patients' medication beliefs in practice. A consultation content assessment tool (MEDICODE: Richard & Lussier 2006) was used to examine levels of participation during routine prescribing consultations. Using a validated list of medication discussion themes, MEDICODE can quantitatively assess levels of consultation participation using two measures: the Preponderance of Initiative (POI) and Dialogue Ratio (DR).
Results: 154 consultation audio-recordings, from 14 nurse prescribers, provided 620 different instances of medication discussion. Across all discussion themes, the POI shifted significantly from the nurse prescriber to a shared initiative with the patient at all post-intervention time-points ($p<0.0001$). The DR did not change post-intervention. Assessments of POI & DR at the individual discussion theme level will be examined and post-intervention qualitative interviews with the nurse prescribers provide further insights about the intervention.
Discussion: The findings suggest a substantial move toward increased patient initiative during medication discussions following the educational intervention. At baseline, nurses were already engaging patients in dialogue, this may account for the lack of change in DR. The theoretical framework of the educational intervention offers potential to invoke a shift in health professionals' consultations towards a more patient-centred and empowering approach.

Delivering successful diabetes self-management education across diverse cultures

J. Denton[1], T.M. Cleary[1]
[1] Diabetes Auckland, Supporting charity, Auckland, New Zealand

Auckland is New Zealand's largest city with a multi-cultural population that includes 11.1% Maori, 14.4% Pacific Islanders and 18.9% Asian people. It is estimated that almost half of the Asian population are from the South Asian nations.
Obesity, diabetes, and heart disease are rife, especially in these groups where numbers of Type 2 Diabetes are forecast to increase by 130-150%, (1996 – 2011). Language and cultural differences for Maori, Pacific and Asian people mean that often these groups do not access relevant health information delivered through conventional channels.
In recent years New Zealand's education for Type 2 diabetes has moved from secondary to primary care and there are many providers of Diabetes Self Management Education (DSME) utilising various programs.
Diabetes Auckland has been delivering successful Diabetes Self Management Education (*Healthy Living with Diabetes*) for many years and recently has tailored versions specifically for Maori, Pacific and Asian people. Careful selection of appropriate venues and incorporation of important cultural and spiritual customs (e.g. greetings, prayers, meeting closure) provides a comfortable environment that removes barriers to attendance. Visual food resources relevant to each culture are used throughout the food sessions.
Diabetes Auckland's presenters have a long history of independent diabetes education and now offer DSME under contract to a local Primary Health Organisation. In 2005 existing programs were re-designed to provide delivery that incorporates the principles of self-management, particularly action planning and problem–solving, as per the Stanford model. Further revisions, primarily of facilitation style, have followed by comparing the existing program to relevant education standards documented in the research literature.
The *Healthy Living with Diabetes* course is multi-session. Revision of material from each previous session occurs at the start of each new session, allowing integration and deepening of new knowledge. The sessions are jointly facilitated by a nurse and dietitian/nutritionist. One of these co-facilitators is drawn from the cultural group concerned.
Given that many participants speak English as a second language, a large number of visual and tactile resources are utilised and nutrition issues, including practical label-reading, have a high priority, providing approximately 40% of the content.
Analysis of attendance and retention data indicates that the program succeeds in reaching Auckland's unique cultural mix.

Educating older adults with diabetes

A. Knip[1], A. Mawji[1], M. Gurbin[1], J. Belle-Brown[2]
[1] Grand Bend Community Health Centre, Diabetes Program, Grand Bend, Canada
[2] University of Western Ontario, Research, London, Canada

Aims: The purpose of this study was to qualitatively explore the perceptions, ideas, and experiences of clients with diabetes, over the age of 65 years, participating in a diabetes education program using a Conversation Map Tool™. These themes, accompanied by quotes from the transcripts, were presented to the fourth researcher, an expert in qualitative methods, for data verification.
Methods: Four Conversation Map™ group sessions were conducted at a Community Health Centre. Each group had six participants. Thirteen clients over the age of 65 years were recruited within one month following the completion of the Conversation Map Tool™. Participants were recruited as follows: four participants from Group one, three participants from Group two, two participants from Group three, and four participants from Group four. Participants reflected a maximum variation sample on several dimensions.

Participants ranged from having new diagnosis of Type 2 diabetes to living with diabetes for thirty years. Diabetes management ranged from lifestyle intervention to insulin administration. Participants' ages ranged from 65 to 82 years. Data was collected using individual interview with open-ended questions and probes. The interviews were audio taped and transcribed verbatim. The researchers then reviewed the transcripts for accuracy and completeness. Three researchers then independently read the transcripts looking for key words and themes. The team met to review their analysis and to identify the themes. These themes accompanied by quotes were then reviewed by a fourth researcher for data verification.

Results: Each group had six participants. Two predominant themes emerged from the data analysis. The first theme pertained to participants' perceptions of diabetes. Diabetes required life long learning and understanding the importance of self-care behaviors to manage diabetes. The second theme that emerged pertained to participants' learning during the Conversation Map™ session. Group learning occurred as a result of listening to others' experiences, sharing stories, and encouragement from others. Participants valued the Map, ease of use and lessons learned. Participants commented that a smaller group size and having individual maps along with large map might have facilitated their learning.

Conclusions: The Conversation Map™ was an effective tool to facilitate learning in older adults with Type 2 diabetes. Teaching older adults in a group setting utilized educator resources more efficiently while still maintaining a high quality of service. This qualitative study highlighted the effectiveness and benefits of group learning for older adults. This study provides support for further research using the Conversation Map tool in the younger adult population.

Multidisciplinary workshops for parents of preschool children with diabetes

M. Grubic[1], I. Gregurincic[1], J. Ille[1], J. Radanovic[1]
[1] University Hospital Zagreb, Department of Pediatrics, Zagreb, Croatia

Object: It is well known that parents of preschool children with diabetes have to deal with complex physiological and psychosocial needs of their children. Therefore we organized workshops to help them cope more effectively with diabetes regimen in order to improve glycaemic control and to enhance the psychological well being of families.

Method: Workshops were delivered in five small groups of 10 to 15 parents by a team of a pediatrician, diabetes nurse specialist and psychologist. There were two sessions each of 2 hours, in which three topics were addressed: adjusting insulin dose in special situations, providing special diet and managing behavior and adjustment difficulties in children.

37 mothers and 18 fathers completed two comparable versions of The Diabetes Knowledge Scales before and after the workshops. The parents perception of the improvement of their well being was evaluated by a questionnaire made for this purpose.

Results: Diabetes-related knowledge of parents increased significantly ($t=3,28$, $p<0.01$). After the workshop sessions all parents perceived themselves as less anxious and more confident about managing the diabetes of their children.

Conclusion: Structured muldisciplinary workshops are useful in improving diabetes-related knowledge, as well as the well being of parents. Interventions should be delivered by professionals with varying expertise who can deal with the special needs of each target group. Follow-up research is indicated to evaluate how often workshops are needed to maintain the improvements we found.

Determinants of childhood and adolescent overweight and obesity in school going children in Karachi

A. Rizwan[1], J. Hatcher[1], J. Akhter[1], T. Jafar[1], S. Awan[1], A. Fahim[1]
[1] Aga Khan University, Medicine, Karachi, Pakistan

Aims: To determine the risk factors for overweight and obesity in school going children, with emphasis on canteen food consumption.

Methods: In 2007, we surveyed four private and two public schools. Data on the childrens' sociodemographic variables, dietary habits and physical activity patterns at the school, home and elsewhere were recorded, as well as their physical measurements (height, weight, anthropometry, presence of acanthosis nigricans). Multiple logistic regression was applied to assess the significance of each risk factor for primary outcome of overweight or obesity.

Results: Of the total of 530 children approached, 434 consented to enroll, of whom 14.1% were overweight or obese using the International Obesity Task Force Criteria: 13.8% boys and 14.4% girls ($p=0.84$). Of the non overweight non obese children, 159[42.6%] had waist size $\geq$ 71 cm, as compared to the 58 [95%] of overweight or obese children with waist size $\geq$ 71cm ($p< 0.05$). Acanthosis was documented in 12.4% children. Of the overweight or obese individuals, 27[44.3%] were documented to have acanthosis, while 34 [55.5%] were not. In the case of non overweight or non obese individuals, 27 [7.2%] had acanthosis, while 346 [92.8%] did not ($p<0.05$). Children bringing lunch and soft drinks from the canteen had significantly greater odds of overweight or obesity ([OR] 1.84, 95% [CI] 1.21, 3.45). Snacking while watching television and fast food visits more frequently than twice a week raised the odds of overweight or obesity by more than threefold ([OR] 3.32, 95% [CI] 3.23,4.79) and ([OR] 3.14, 95%[CI] 2.42,11.25], respectively. *The duration* of activity of $<$ 35 minutes versus $>$ 35 minutes per physical education [PE] class placed the child at greater odds of overweight or obesity ([OR] 2.84, 95% [CI] 1.27, 3.01), whereas the weekly *frequency* of PE classes did not achieve significance.

Discussion/conclusion: The school is well placed to initiate public health measures to prevent the epidemic of overweight and obesity in children that has evolved in the West. Children displaying acanthosis, a physical marker of insulin resistance representing a pre diabetic state, is a group requiring counseling for more rigorous and prompt institution of lifestyle modification. Despite facilities for physical education being available at the school, it was the duration of active participation per class that was associated with obesity, highlighting the need for better supervision by the coach. Efforts are required to educate children and their families about potentially modifiable high-risk behaviors, such as canteen food, eating during television watching, and engaging in physical activity at home and school, associated with overweight and obesity.

Let's ask the experts! An experience with focus groups of diabetic adolescents to improve follow-up

M. Castellsague[1], L. Perrenoud[1], C. Bussien[1], V. Schwitzgebel[1], M. Caflisch[1]
[1] Hopitaux Universitaires de Geneve, Departement de Pediatrie, Geneva, Switzerland

Introduction: Adolescence is often a crucial time for young diabetic patients. Adherence to treatment gets difficult and pubertal changes have a major impact on the control of their diabetes. This could also be observed among the diabetic adolescents seen at our outpatient clinic. We are seeking new strategies to improve this situation.

Aims and methods: Knowing the importance of participatory proceedings when taking care of young people, we proposed to work in focus groups (twice 10 adolescents) to allow them to express their needs. In order to develop new strategies, we created mixed groups including professionals, parents and adolescents.

Results: In the different focus groups the adolescents pointed out three major needs: 1. They want to be recognised as experts for their disease. They concretely suggested to be introduced to newly diagnosed diabetic children to share their experiences. They declared their availability for babysitting for diabetic infants through a mailing list. 2. They expressed their need to be motivated with new challenges to improve their compliance to treatment. They wished more opportunities to get in touch with other young diabetic people. 3. They considered the consultations boring and too repetitive and they want a change in the content.

Professionals and parents expressed also their needs which were compatible with the considerations of the adolescents, they mainly mentioned motivation and autonomy as being major difficulties.

Discussion: Based on the different propositions we partially modified our consultations and included a common breakfast, where they could meet each other for a time of discussion during their annual check-up. The adherence to this project was excellent (only two refused out of 30 adolescents). The discussions concerned important problems they have to deal with alcohol consumption, the aim of annual check-ups, difficulties to deal with parents and teachers worries concerning their diabetes. Following their wishes we organised also evening meetings with their friends and we are producing a movie explaining life with

type 1 diabetes. The interactions between younger and older adolescents are often a starting point for attitude changes or initiation of a new treatment, i.e. change from injections to pump. 90% of the participants said that they have learned something out of these discussions; 93% prefer this setting compared to individual consultations.

Conclusions: Our project was based on the empowerment of young people, confirmed by their wish to be considered as experts. When professionals look for new strategies to improve the situation of diabetic adolescents, it seems to be very effective to include them from the beginning in the process of change. Adolescents, parents and professionals have been able to develop different innovative strategies of follow up.

[6] *Hospital Puerta de Hierro, Cirugía, Madrid, Spain*
[7] *National Institutes of Health, NIDDK (DDB), Bethesda (MD), USA*

Aims: The orphan human Bombesin Receptor Subtype-3 (hBRS-3) is a member of the bombesin family, which is highly expressed in skeletal and cardiac muscle, brain and other several tissues. This G-protein receptor is implicated in energy metabolism, motility and tumor growth; although its function in physiological and pathological states remains unknown, BRS-3-knock-out mouse model develop obesity, hypertension and unbalanced glucose metabolism, suggesting a role of BRS-3 in glucose homeostasis. Here we explored the hBRS-3 gene expression level in the skeletal muscle of Type-1 (T1D) and Type-2 (T2D) diabetic and Obese patients (OB), compared to that in Normal subjects.

Methods: Pieces of skeletal muscle (120 mg) were obtained -previous informed consent given- from T1D (1F/2M; age: 74 ±1 yr; fasting plasma glucose: 129 ± 1 mg/dl; cholesterol: 146 ± 5 mg/dl; triglycerides: 165 ± 6 mg/dl), T2D (2F; 70 ± 9 yr; 126 ± 6 mg/dl; 148 ± 45 mg/dl; 167 ± 87 mg/dl), OB (1F/2M; 49 ± 6 yr; 130 ± 5 mg/dl; 206 ± 12 mg/dl; 172 ± 48 mg/dl; BMI: 46 ± 3 kg/m^2) patients and Normal (6F/1M; 44 ± 6 yr; 94 ± 2 mg/dl) subjects undergoing surgery performed with different purposes than that of this work. hBRS-3 gene expression -by RT-PCR- was studied; for each muscle sample, the hBRS-3 mRNA value was normalized with that of the housekeeping gene, 18s, and expressed as $2^{-?ct}$.

Results: In the muscle of T1D patients, hBRS-3 mRNA level was much lower (12.2 ± 1.1 times down-regulated, $p<0.0001$; range: 6.2-21.7) than Normal (range: 0.7-1.5). OB patients also showed a decreased ($p<0.0001$) muscle hBRS-3 gene expression, the value representing 5.6 ± 0.8 times down-regulated (range: 3.3-5.9) compared to Normal; and the same was detected in the muscle of the T2D group, where the level of hBRS-3 mRNA was 6.9 ± 0.9 times down-regulated (range: 5.8-7.5) respect Normal; the gene expression value of hBRS-3 in the T2D group was similar in magnitude to that in the muscle of OB patients. Although compared to Normal subjects the three groups of patients studied, T2D, T1D and OB, showed a significantly reduced muscle hBRS-3 mRNA, the value in T1D was much lower ($p<0.01$) than those respectively detected in T2D and OB patients (T1D: 2.0 ± 0.6 times down-regulated overall mean T2D and OB).

Conclusion: These novel findings demonstrate a direct link between hBRS-3 expression and human diabetes and obesity, which opens for the future the possibility to use this receptor as a molecular target in the treatment of each of these pathologies.

[9] *Helsinki University Central Hospital, Obesity Research Unit, Helsinki, Finland*
[10] *Karolinska University Hospital, Obesity Unit, Huddinge, Sweden*

Aims: Prediabetes has an estimated prevalence in the US of more than 20% and predicts the development of type 2 diabetes. Liraglutide reduces HbA_{1c} by 1.0–1.5%, weight by 2–3 kg and systolic blood pressure (SBP) by 2–6 mmHg at doses up to 1.8 mg in patients with type 2 diabetes. This double-blind, placebo-controlled trial with open-label orlistat comparator investigated the effect of liraglutide doses up to 3.0 mg in obese non-diabetic subjects. The primary outcome was body weight. This abstract focuses on secondary outcomes prediabetes status and SBP.

Methods: Subjects (18–65 years, BMI 30–40 kg/m^2), of whom 175 had prediabetes based on 2003 ADA guidelines, were randomized equally to 1 of 4 liraglutide doses (1.2, 1.8, 2.4 or 3.0 mg OD s.c.), placebo OD s.c. or orlistat (120 mg 3x daily orally) for 20 weeks. Prediabetes was defined as IGT or IFG (IGT: 2h glucose 140–199 mg/dL in OGTT; IFG: FPG 110–125 mg/dL). Subjects were advised to reduce daily energy intake by 500 kcal and to increase physical activity. www.clinicaltrials.gov ID: NCT00422058.

Results: In the ITT population (561 of 564 randomized subjects) using LOCF, estimated mean placebo-subtracted weight loss from randomization was 2.1 kg [95% CI 0.6-3.6] (liraglutide 1.2 mg) to 4.4 kg [2.9-6.0] (3.0 mg). Mean weight loss with liraglutide 3.0 mg was 7.2 kg. Total weight loss from screening, including 2-week run-in, ranged from 4.1 ± 3.9 kg (placebo) to 9.1 ± 5.2 kg (liraglutide 3.0 mg, Table). Prediabetes incidence over 20 weeks was reduced by about 90% with liraglutide 1.8–3.0 mg. In a post hoc analysis, liraglutide-treated subjects had significantly greater odds of having normal glucose tolerance at Week 20 compared to placebo or orlistat ($p<0.01$ all doses). The number of subjects needed to be treated to prevent one case of prediabetes was 3–6 with liraglutide 1.2–3.0 mg, compared to 24 with orlistat. Estimated mean placebo-subtracted change in SBP was -1.6 mmHg [-5.6; 2.5] (liraglutide 1.2 mg) to -4.7 mmHg [-8.7; -0.7] (liraglutide 2.4 mg; $p<0.02$).
Compared to placebo, more events of nausea and vomiting of mild to moderate intensity occurred with liraglutide, mostly within the first 4–6 weeks. 11 (3%) liraglutide-treated subjects withdrew due to these events.

Conclusion: Liraglutide 1.2–3.0 mg once daily for 20 weeks produced weight loss, reversed existing prediabetes and reduced SBP in obese subjects. Treatment with liraglutide may have the potential to delay the onset of type 2 diabetes.

Contribution of the myostatin gene polymorphisms to normal variation in lean mass and fat mass in Chinese male offspring nuclear families

H. Yue[1], J. He[2], S. Wu[1], Z. Zhang[2]
[1] Shanghai Jiao Tong University Affiliated Sixth People's Hospital, The Department of Endocrinology and Metabolism Shanghai Clinical Center for Diabe,
[2] Shanghai Jiao Tong University Affiliated Sixth People's Hospital, The Department of Osteoporosis Bone Metabolic Disease and Genetics Research Unit Shanghai Jiao Tong University Affiliated Sixth People's Hospital., Shanghai, China

Objective: Myostatin is a TGF-beta family member that is a negative regulator of skeletal muscle growth. Our previous studies suggested that the genetic polymorphisms in *myostatin* likely play a role in attainment of peak BMD in Chinese women, furthermore, +2278G>A, which is detected by direct sequencing, had significant within-family association with BMI in Chinese female nuclear families using quantitative transmission disequilibrium test (QTDT). However, no study has been performed on the genetic association of *myostatin* gene polymorphisms and related traits variation in Chinese male nuclear families. Our study is aimed to investigate the association of *myostatin* gene polymorphisms and lean mass (LM) and/or fat mass (FM) variation in Chinese men.
Methods: We have recruited 400 male nuclear families from 2004 to 2007, composed of 1215 individuals with at least one male child whose age is between 18- 44 years (mean age 30±6). The studied single nucleotide polymorphisms (SNPs) are tag-SNPs, which are located within the *myostatin* gene were selected from NCBI Gene Bank Databases (http://www.ncbi.nlm.nih.gov/sites/entrez) and International HapMap Project (http://www.hapmap.org/cgi-perl/gbrowse/hapmap3_B36), respectively. We performed to genotype the three tag-SNPs (rs2293284, +2278G>A, rs3791783) in *myostatin* by TaqMan and further tested whether these SNPs were associated with body lean mass and fat mass variation at the arms, legs, trunk, total and BMI in our 400 Chinese male offspring nuclear families using QTDT, respectively. Fat mass and lean mass were measured by dual-energy X-ray absorptiometry (DXA) on a GE-LUNAR prodigy (U.S.A.). Raw body lean mass and fat mass were adjusted by age as covariates.
Results: Using QTDT, we found significant within-family association between fat mass variation and rs3791783 at trunk (p<0.001). Moreover, subsequent permutation 1000 tests were in agreement with the finding (p<0.001). However, the other two SNPs had no significant within-family association with Body lean mass and fat mass at any body site. Moreover, for within-family association, significant associations were found between haplotype AGG, AAA and TGG and the trunk fat mass, respectively (all p<0.001).
Conclusions: These results suggested, for the first time, that genetic polymorphisms in *myostatin* have an effect on normal variation in fat mass in Chinese male, and *myostatin* gene may be a candidate for the genetic determination of body fat mass in Chinese men.

Prevalence of diabetes in Santhals, a tribal population of Bangladesh and India

M.A. Sayeed[1], A. Banu[2], S. Sayeed[2], H. Mahtab[3], P.A. Khanam[3], T. Begum[3], R. Amin[4], A.K. Azad Khan[3]
[1] Ibrahim Medical College, Community Medicine, Dhaka, Bangladesh
[2] Institue of Nutrition and Food Science, Clinical Nutrition, Dhaka, Bangladesh
[3] BIRDEM, Epidemiology, Dhaka, Bangladesh
[4] BIRDEM, Gynae and Obs, Dhaka, Bangladesh

Background and aims: Santhals are considered as the third largest tribe in a combined territory of Bangladesh and India. They are non-Aryan and indigenous population, living in the forests and maintain livelihood by hunting and gathering. Deforestation forced them to change their livelihood to fishing and cultivation. They are at risk for developing obesity and Type 2 diabetes (T2DM), impaired fasting glucose (IFG) observed in other aborigines. There is no published document so far citing health status of Santhals. We address some biophysical characteristics and prevalence of T2DM, IFG, and systolic and diastolic hypertension (sHTN, dHTN).
Subjects and methods: We purposively selected 10 villages in the remote Manda thana under Nougaon district, inhabited by Santhals. We discussed with tribal leaders. They agreed to volunteer. All subjects of age 20y or more were eligible. Investigations included social status, height, weight, waist, hip, blood pressure (SBP, DBP), fasting blood glucose (FBG) and lipids (total cholesterol (chol), Triglycerides (TG)). Body mass index (BMI = wt kg/ht msq.) and waist-to-hip ratio (WHR) were calculated. ADA diagnostic criteria were used for T2DM and IFG. For sHTN and dHTN, the cut off values were >135 and >85mmHg, respectively.
Results: A total of 1047 (m/f = 421/626) subjects volunteered. Their mean (SD) age was 39.2 (14.7)y. The mean (SD) values for BMI, WHR and FBG were 18.9 (2.3), 0.85 (0.06) and 4.7 (0.68) mmol/l, respectively. Their SBP was 127 (22) and DBP was 80 (12) mmHg. For chol and TG, the values were 152 (31) and 99 (40) mg/dl, respectively. The crude prevalence of T2DM was 3.1% (m v. f = 2.5 v. 3.5%) and IFG was 7.9% (m v. f = 8.1 v. 7.7%). T2DM and IFG showed no difference between men and women. They had high prevalence sHTN (24.4%) and dHTN (24.6%). Though men had significantly higher BMI and WHR the women had significantly higher sHTN (16.2 v. 29.9%; p<0.001)) and dHTN (18.3 v. 28.9%; p<0.001).
Conclusions: This study is the first to report the prevalence of diabetes and hypertension in the Santhals. The observed characteristics and the prevalence of diabetes and hypertension will help determining the change or trend in future. It is not clear why there was lower prevalence of diabetes and very high prevalence of hypertension with minimal obesity. Possibly, high salt intake might be cause of hypertension. Their poor earning with strenuous physical labor forced them to take large amount of rice and table salt as they can not afford pulse or vegetables, not mentioning costly fish or meat. More study is needed to confirm this for the prevention of hypertension in the Santhals.

High-fat and low-fat meals modulated gastric mucosa transcriptome

M. De Giorgio[1], M. Yoshioka[1], J. St-Amand[1]
[1] CHUQ-CHUL, CREMO Functional Genomics Laboratory, Québec, Canada

The ineffective short-term control of feeding behaviour compromises energy homeostasis regulation and can lead to obesity and its metabolic complications, such as type 2 diabetes. The gastro-intestinal tract secretes several satiating and appetitive peptides. However, except for ghrelin, little is known about the stomach peptides contribution to the acute regulation of energy intake. In the attempt to identify new gastric signals that can acutely influence food intake, we used the serial analysis of gene expression (SAGE) method for the transcription profiling of stomach mucosa in 7 groups of mice: fasting; and sacrificed 30 minutes, 1 hour, 3 hours after a low-fat (LF30m, LF1h, LF3h) or high-fat (HF30m, HF1h, HF3h) *ad libitum* meal. From a total of 56381 SAGE tag species detected, 39 genes have been differentially modulated by LF and HF meals compared to fasting, including 12 mRNAs coding for digestive enzymes and 10 novel transcripts. Although the basic stomach gene profile did not undergo substantial variations, both LF and HF meals influenced the transcription. This study represents the first global analysis of stomach transcriptome as induced by different nutritional stimuli. Further studies including the characterization of novel genes may help to identify new targets for the therapy of obesity.

Hexosamine biosynthetic pathway regulates adipogenic gene expressions during 3T3-L1 adipocyte differentiation

T.J. Hsieh[1], T. Lin[1], P.C. Hsieh[1], S.J. Shin[1]
[1] *Kaohsiung Medical University, Department of Medical Genetics, Kaohsiung, Taiwan*

Introduction: Obesity is characterized as increasing adipose tissue which results in adipokines secretion and involves in development of metabolic complications. However, regulation of adipocyte differentiation and adipokines secretion still need further clarification. O-linked N acetyl- glucosamine (O-GlcNAc) modification has been implicated in regulation of signaling pathway, cell function and gene expression in several cell types. Hexosamine biosynthetic pathway (HBP) generates the sugar nucleotide UDP-GlcNAc, which is the donor for O-GlcNAc modification of nucleocytoplasmic proteins.
Aim: of this study is to investigate the role of HBP and protein O-GlcNAc modification on the regulation of adipocyte differentiation and related gene expression.
Methods: 3T3-L1 preadipocytes were cultured with induction media containing high glucose (25mM), insulin (0.32mM), dexamethasone (1mM) and isobutylmethylxanthine (0.5mM) for 8 hours, 1, 2, 3, 4, and 6 days. Then, the O-GlcNAc modification proteins were detected by O-GlcNAc Western Blot Detection Kit. Messenger RNAs of SREBP-1, C/EBPs, PPAR-gamma, S3-12, perilipin, adipophilin, adiponectin, visfatin, apelin, retinol-binding protein 4 and angiotensinogen were measured by real-time PCR. The mature adipocytes were identified by Oil-Red Staining. Azaserine (AZA) was used to block the HBP key enzyme GFAT-1.
Results: Our results demonstrate that the O-GlcNAc modified proteins are increased in the process of 3T3-L1 preadipocyte differentiation. SREBP-1, C/EBPs, PPAR-gamma, S3-12, perilipin, adipophilin, adiponectin, visfatin, apelin, retinol-binding protein 4 and angiotensinogen mRNAs are increased in mature adipocytes. However, blocking HBP by AZA prevents the differentiation of 3T3-L1 cells and mRNA overexpression of the above adipogenic genes.
Conclusion: The results suggest that HBP activation and change of protein O-GlcNAc modification maybe a novel pathway mediating adipocyte differentiation and lipid formation.

3111T/C clock gene polymorphism is associated with metabolic changes in Brazilian obese children and adolescents

M. Moreira Zanquetta[1], C.Y.M. Nicolau[1], E.S.T. Frazzatto[1], I.C. Guazzelli[1], M.L.C.C. Giannella[1], S.M.F. Villares[1]
[1] *HCFMUSP, Laboratory of Human Nutrition and Metabolic Disease LIM-2 5, São Paulo, Brazil*

Aims: Dysregulation of intrinsic circadian rhythmicity seems to play a role in the development of obesity and Metabolic Syndrome (MS). Functional 3111T/C single nucleotide polymorphism (SNP) of the (*Circadian locomotor output cycles kaput*) *CLOCK* gene, located in the 3'-UTR, may have a part in the genetic susceptibility to metabolic alterations involved in these pathologies. The aim of the present study was to investigate whether the 3111T/C SNP could be associated with metabolic changes that are seen in states of obesity and MS, in Brazilian obese children and adolescents (OCA).
Methods: Study subjects consisted of 312 OCA (BMI = p95th), 36.8% boys, aged 10.6±1.2 years, 46.4% pubescent, BMI 30.1±0.4 kg/m^2, ZscoreBMI 2.3±0.01, representing the two genotypes for 3111T/C SNP: TC+TT (Tx) group and CC group. The presence of 3111T/C SNP alelles was evaluated by Real Time PCR, using TaqMan primers and probes. Fasting serum levels of glucose, insulin and leptin were measured. HOMA%B and HOMA%S were calculated to evaluate insulin secretion and insulin sensitivity respectively, using calculations obtained from www.ox.ac.uk website. MS was defined using the International Diabetes Foundation (IDF) criteria. Statistical analyses were performed using t test and two types of regression analysis.
Results: Allele frequencies in OCA were 92% of Tx and 8% of CC. Genotype distributions did not deviate from Hardy-Weinberg expectations. Anthropometric measures were not altered between genotypes. Insulin and leptin levels were higher in CC individuals when compared with allele T carriers (insulin: CC- 20.1±2.2 vs Tx- 16.9±0.6 mUI/ml, P<0.05; leptin: CC- 56.8±6.4 vs Tx- 41.4±1.7 ng/ml, P<0.02). HOMA%B was also higher in CC children (CC- 185.8±12.5 vs Tx- 159.3±3.9, P<0.05) and HOMA%S was not changed in groups, although it showed a tendency to be higher in Tx subjects. Correlations of minor allele C with insulin secretion and insulin levels were found after performing multiple linear regression analysis, adjusted to ZIMC and presence of SNP (ß=-0.09, P=0.026 and ß=-0.13, P=0.024, respectively). Using the IDF criteria in OCA, it was observed that 16.7% were classified as having MS. Logistic multinomial regression analysis was performed with MS results adjusted to ZIMC and puberty, and showed that CC subjects have higher risk for MS than Tx carriers (Exp(ß): 2.6; IC 95%: 1.0-6.76; P=0.045).
Conclusions: Although 3111T/C polymorphism is poorly present in Brazilian obese children and adolescents' population, it seems that presence of T allele is more protective to develop insulin resistance and MS. The results suggest that 3111T/C SNP has a relevant association with metabolic changes related to obesity and MS in Brazilian OCA.

Depot-specific expression of the transcription factor, T-Box 5, in human adipose tissue

K.E. Pinnick[1], M.J. Neville[1], F. Karpe[1]
[1] *University of Oxford, Oxford Centre for Diabetes Endocrinology and Metabolism, Oxford, United Kingdom*

Aims: Upper body adipose tissue (AT) has been associated with an increased risk of cardiovascular disease and diabetes while lower body AT appears to be "metabolically-protective". At the cellular level, regional AT depots display distinct functional characteristics and vary in terms of their adipogenic and proliferative capacity. Preliminary data using transcriptional profiling of human abdominal and gluteal AT identified T-Box 5 (TBX5), a transcription factor implicated in the regulation of cellular proliferation and differentiation, as a very differentially expressed gene. The aim of this study was to investigate the expression of TBX5 in different regional AT depots, isolated preadipocytes and during adipogenesis.
Methods: Paired abdominal-gluteal subcutaneous AT biopsies were obtained from lean (BMI=23.5±0.3kg/m^2, n=20) and obese (BMI=33.6±1.2kg/m^2, n=20) subjects from the Oxford Biobank. Additionally, preadipocytes were isolated from abdominal (n=9) and gluteal (n=5) AT biopsies from healthy volunteers. Preadipocytes were cultured in adipogenic media for 14 days to induce adipocyte maturation and were harvested during adipogenesis. Total RNA was extracted from biopsies and cells and real-time PCR was performed. Expression values were calculated by the efficiency-corrected Ct model and were normalized to housekeeping genes.
Results: TBX5 expression was higher in abdominal AT (1.00±0.04) than gluteal AT (0.66±0.06; P<0.001). Female subjects (n=20) displayed elevated abdominal (0.97±0.05) and gluteal (0.80±0.08) TBX5 expression compared to male subjects (abdominal, 0.79±0.04; gluteal, 0.36±0.04; n=20, P<0.05) and TBX5 expression was higher in lean females (0.99±0.11, n=10) than obese females (0.60±0.07, n=10; P<0.01). Gluteal TBX5 expression was negatively correlated with BMI (r= -0.48; P<0.05) and waist circumference (r= -0.62; P<0.001). Isolated preadipocytes displayed striking depot-specific differences in TBX5 expression which were retained after 2-3 passages (abdominal, 0.76±0.10; gluteal, 0.06±0.03; P<0.001). The expression of TBX5 was not altered during differentiation and at day 14 similar abdominal-gluteal differences were apparent (abdominal, 0.63±0.08; gluteal 0.05±0.02; P<0.001).
Conclusions: TBX5 displays depot-specific differences in expression in whole human AT and specifically in isolated preadipocytes. This may impact on regional adipocyte biology through the differential regulation of downstream targets. The finding that abdominal-gluteal differences in TBX5 expression were retained during culture supports the view that preadipocytes from different regional depots are inherently distinct.

Acarbose improves hypoglycemia after gastric bypass surgery by decreasing postprandial exaggerated insulin and glucagon-like peptide 1 response

J.P. Valderas[1], L. Rubio[1], F. Pollak[1], M. Escalona[1], A. Maiz[1]
[1] *Pontificia Universidad Catolica de Chile, Nutrition Diabetes and Metabolism, Santiago, Chile*

Introduction: Postprandial hypoglycemia after Roux-en-Y gastric bypass (RYGB) is a severe complication of this surgery with unknown prevalence. Acarbose, an alpha-glucosidase inhibitor (AGI), is empirically employed in its treatment. Several studies have shown that AGIs increase the postprandial levels of glucagon-like peptide 1 (GLP-1) in normal and diabetic subjects. This fact is very important, because the GLP-1 increase is one of the factors involved in the physiopathology of hyperinsulinemic hypoglycemia.
Objective: Assess the effects of acarbose on glucose, insulin and GLP-1 plasma levels in patients with hypoglycemia post RYGB or dumping syndrome.
Methods: 8 patients were studied fasting and 30, 60, 90, 120 and 180 minutes after the intake of standard liquid meal (STM) (Ensure Plus®; 355 Kcal; 13 g protein; 50 g carbohydrate; 11 g fat). The test was repeated the following week with oral administration of 100 mg of acarbose (Glucobay ®) 15 minutes before the STM. We measured plasma levels of glucose (glucose oxidase), insulin (RIA) and GLP-1 (ELISA). Data are expressed as mean ± standard error of the mean (SEM). Area under the curve (AUC) was calculated by trapezoidal method. The Kolgomorov-Smirnov test was used to assess normality. Parametric and non-parametric paired test were used to compare values. P value < 0.5 was considered significant.
Results: 6 patients had a symptomatic hypoglycemia during the test (glucose level $<$ 55 mg/dl) associated to exaggerated insulin and GLP-1 response. Acarbose ingestion avoided hypoglycemia in 5 patients with a significant increase of glucose levels at 90' and 120' and a significant decrease at 15' and 30'. Acarbose ingestion decreased AUC_{0-180} for serum insulin and GLP-1 levels at 15'.
Conclusions: Acarbose avoided hypoglycemia post RYGB, decreasing the hyperinsulinemic response produced by the carbohydrate intake. This was associated to a decrease in the earlier GLP-1 secretion, in contrast to non operated subjects. This finding could be explained by the reduction of glucose load in the jejunum, the main stimulus for GLP-1 secretion, produced by the alpha-glucosidase inhibition.Therefore, acarbose is a safe option in the treatment of this condition.

Value (mean ± SEM)	Without acarbose	With acarbose
Plasma glucose (mg/dl) at 15'	182.9 ± 7.5	134.0 ± 10.9
Plasma glucose (mg/dl) at 30'	153.3 ± 11.7	121.5 ± 11.5
Plasma glucose (mg/dl) at 90'	52.2 ± 6.9	65.7 ± 3.9
Plasma glucose (mg/dl) at 120'	62.3 ± 3.2	73.2 ± 3.5
AUC_{0-180} for serum insulin (µU per ml per min) (mean ± SD)	13,008 ± 6,612	7,668 ± 4,587
GLP-1 levels (ng/dl) at 15'	647 ± 277	305 ± 62

Incidence of diabetes in Scottish children 1984 to 2003

S. Scottish Study Group for the Care of Diabetes in the Young[1], A. McKillop-Smith[1], P. Royle[1], M. Cox[2], N. Waugh[1]
[1] *University of Aberdeen, Department of Public Health, Aberdeen, United Kingdom*
[2] *University of St Andrews, Department of Geography, St Andrews, United Kingdom*

Previous studies of the incidence of diabetes in Scottish children have shown: a rise in incidence from 10 per 100,000 in 1968, to 18 in 1976, to 26 in 1993. The incidence was higher in rural areas, and lower in less affluent urban ones. The aim of this study was to bring the incidence data up to date, and to examine urban/rural and socio-economic variations.
Methods: The SSGCDY maintains a register based on reporting of new cases by paediatricians and physicians. The main method of validation against an independent source is hospital discharge data. Feedback of expected versus reported numbers to paediatricians and physicians also acts as a prompt to completeness. A new urban/rural classification which incorporates both settlement size and remoteness was used. A new composite index of socio-economic status was used.
Results: Incidence has continued to rise, by around 2.6% a year over the period 1984 to 2003. Incidence is higher in remote areas. There is seasonal variation in older age groups. The excess in remote areas appears to be seasonal, applying only in the winter peaks. The average age at onset has dropped by about 7 months. Less variation by socio-economic status was seen than in previous studies.
Conclusion: The incidence of type 1 diabetes in Scottish children aged under 15 reached 35 per 100,000 in 2003, making it one of the highest in the world.

[4] *Assurance maladie, Service médical national RSI, Saint Denis, France*
[6] *Cemka-Eval, Etudes médicales, Bourg-la-Reine, France*

Aims: National cross-sectional studies of people with diabetes were undertaken in France in 2001 and 2007 to describe the health, quality of care, quality of life, educational needs of people with diabetes and the cost of diabetes care.
Methods: In 2007, a random sample of 8926 adults was drawn from the French medical insurance system (covering 75% of the population) among people who were reimbursed from at least 3 deliveries of oral hypoglycaemic agents (OHA) or insulin during the past 12 months. All medical reimbursements and hospital data were extracted for 3 years. Three surveys were undertaken: patient short phone interview and mailed-questionnaire (47% and 48% response rates), and a mailed questionnaire to their medical doctors (62% response rate). Data were weighted for the sample design and characteristics of non-respondents. The 2007 data were compared to the similar 2001 data.
Results: Type 2 diabetes accounted for 92% of all cases. In people with type 2 diabetes, mean age was 66 yrs, mean diabetes duration was 11 yrs, 19% were born abroad, and socioeconomic characteristics were lower than those of the general population in all age-groups. Based on patient reports, obesity was frequent (41%, +7 points since 2001), as well as overweight (39%, -3 points). Based on provider reports, only 15% of people had HbA1c>8% (41%>7%), 49% had blood pressure>130/80mmHg and 18% LDL cholesterol≥1.30g/l. Glycemic control (mean HbA1c 7.1%; -0.3 % since 2001), blood pressure (mean 134/77mmHg; -3/2mmHg) and LDL (mean 1.06g/l; -0.18g/l) control improved over 6 yrs, in all age and sex groups. OHA and antihypertensive treatments were more frequently used: metformin +12 points; combination of OHAs +3 points; combination of insulin and OHA +4 points; statins +24 points; ARBs +17 points; diuretics +12 points. Estimates of diagnosed diabetes complications were somewhat higher in 2007 compared to 2001, which was mostly due to improved screening and treatment: coronary revascularisation +5 points; opthalmologic laser treatment +3 points; frequency of foot risk classification +12 points. Based on reimbursements, an eye fundus exam was performed over a 1 or 2 year time period, respectively, in 52% and 70% of people; and urine albumin in 28% and 44%, respectively. A podiatric exam was performed during the past 12 months in 20% or 66% of people, according to, respectively, patients or doctors. General practitioners provided care for 82% of people without referral to a specialist.
Conclusion: In France, national objectives were to reach the level of 80% of people with diabetes receiving adequate care in 2008: several indicators fall well below this level in 2007. However, many improvements have been monitored over the past 6 years.

Decreasing stroke rates among Albertans with and without diabetes, 2003-2007

S.H. Simpson[1], M.D. Hill[2], S.U. Balko[3], G. Hugel[3], J.A. Johnson[4]
[1] University of Alberta, Faculty of Pharmacy & Pharmaceutical Sciences, Edmonton, Canada
[2] University of Calgary, Faculty of Medicine, Calgary, Canada
[3] Institute of Health Economics, Alberta Diabetes Surveillance System, Edmonton, Canada
[4] University of Alberta, School of Public Health Sciences, Edmonton, Canada

Aim: Stroke has a major impact on the individual and our health care system. Diabetes is an established risk factor for ischemic stroke and also appears to increase the risk of hemorrhagic stroke. This time-series analysis compared population-based rates of acute ischemic strokes (AIS), transient ischemic attacks (TIA), and hemorrhagic strokes between Alberta residents with and without diabetes.

Methods: Administrative databases from Alberta Health and Wellness were used to identify hospitalizations with a most responsible diagnosis of stroke for all Alberta residents >=20 years old between 2003 and 2007. Alberta is one of ten provincial jurisdictions in Canada with a population of approximately 3.4 million people living in diverse regions. The Canadian National Diabetes Surveillance System algorithm was used to identify people with diabetes. The pathological type of stroke was grouped into three categories: AIS (ICD-9 codes 362.3, 433, 434 & 436 [excluding 433.X0 and 434.X0]; ICD-10 codes H34.1, I63 & I64), TIA (ICD-9 code 435; ICD-10 codes G45, G45.0, G45.1-G45.3, G45.8 & G45.9), and hemorrhagic stroke (ICD-9 codes 430 or 431; ICD-10 codes I60 or I61). Annual age- and sex-standardized rates for each stroke type were compared between Albertans with and without diabetes across the observation period (2003-2007).

Results: The annual age- and sex-standardized rates (per 10,000 people) by type and diabetes status are presented in the following table.

	2003	2004	2005	2006	2007
AIS					
Diabetes	18.3	15.2	15.5	15.9	13.1
No Diabetes	7.1	6.9	6.6	6.4	6.6
TIA					
Diabetes	6.3	6.2	6.5	5.1	5.4
No Diabetes	3.5	3.6	3.4	2.9	2.7
Hemorrhagic Stroke					
Diabetes	3.0	1.9	2.5	2.0	2.0
No Diabetes	1.6	1.4	1.5	1.4	1.4

The age- and sex-standardized rate ratio between diabetes and no diabetes fell from 2.59 in 2003 to 1.99 in 2007 for AIS and from 1.96 in 2003 to 1.39 in 2007 for hemorrhagic stroke. The rate ratio for TIA increased from 1.80 in 2003 to 2.04 in 2007.

Discussion: Stroke rates declined for all Albertans over the observation period of 2003-2007. Within all stroke types, people with diabetes had consistently higher rates compared to those without diabetes. This difference appears to be slowly closing over time for AIS and hemorrhagic stroke; however, it appears to be widening for TIAs.

Life expectancy following diagnosis of type 2 diabetes

K. Chikkaveerappa[1], K. Jones[1], D.B. Jones[1]
[1] Arrowepark Hospital, Diabetes and Endocrine, Wirral, United Kingdom

Introduction: Patients with type 2 diabetes are known to have reduced life span compared to non diabetic population. The cause of death in the majority of the patients with type 2 diabetes is cardiovascular disease. Recommendations from international societies call for tighter control of glycaemia, blood pressure and lipids to reduce mortality and morbidity from diabetes. However recent studies have raised the issue of what should be the "ideal" blood glucose control to reduce the mortality in these patients.

Aims: To compare life expectancy of a cohort of patients with type 2 diabetes in years from diagnosis with that of non diabetic general population of the same age.

Methods: A review of all deaths on the Wirral of patients with type 2 diabetes between 1st January to 31st December 2006 was undertaken. There were total number of 3864 deaths during this time, 1999 men and 1865 women. In order to study the effects of diabetes on life expectancy, we have determined the mean number of years from diagnosis to time of death for all these patients.

We have used this data to construct a survival curve of years of life lived until death from the year of diagnosis of diabetes for males and females. These figures have been subsequently compared with the expectation of life of individuals of the general population of the same age as at the age of diagnosis. These figures were identified in the interim life tables produced by the Office of National Statistics in the United Kingdom.

Results: Study of life expectancy of deceased 3864 type 2 diabetic patients demonstrates a dramatic reduction in life span compared to that of non diabetic population. This is particularly marked in men and in patients diagnosed below the age of 70 years.

Men diagnosed at the age of 50 years have an approximately 12 year reduction in life expectancy; those diagnosed at the age of 70 have a 6 year reduction in life expectancy.

For women there is a 15 year reduction in life expectancy for those diagnosed at the age of 50 and a 6 year reduction in life expectancy if diagnosed at the age of 70.

The difference in women is partly due to an increased expectation of life in women in the non-diabetic population.

Conclusions: It is clear from our study that type 2 diabetes is associated with a very significantly reduced life expectancy. This reduction is particularly marked for men and those diagnosed below the age of 60.

In the population studied it is also found that there has been a downward trend in lipid values and also blood pressure readings during this period but there has been no improvement in glycaemic control.

Despite increased attention to cardiovascular risk factors in diabetes, there is little evidence to date that this is reflected in the prolonged survival in these patients. There remains a large deficit of years lost in both men and women with type 2 diabetes.

Epidemiology of diabetes mellitus and metabolic syndrome: Beijing scenario

N. Jin[1], J. Dou[1], J. Li[1], Y. Kang[1], S. Yan[1], J. Lu[1]
[1] Chinese PLA General Hospital, Endocrinology, Beijing, China

Aims: To provide the epidemiologic profile of diabetes mellitus and metabolic syndrome in Beijing and to contribute to the prevention and control of these diseases.

Methods: A community-based survey was carried out in Beijing from Sept. to Nov., 2007. Using a stratified cluster random sampling method, 3522 individuals from urban, peri-urban and rural areas were selected as study subjects. Diagnostic criteria for diabetes mellitus and metabolic syndrome were those recommended by WHO and IDF.

Results: The age-standardized prevalence of diabetes was 10.15% (self-reported 5.02% vs undiagnosed 5.13%) and was 10.97%, 11.95% and 6.86% among urban, peri-urban and rural populations respectively ($p<0.01$ when comparing the prevalence of self-reported diabetes among rural area with those among urban or peri-urban areas, while no statistic difference was found when comparing prevalence of undiagnosed diabetes among different areas). The age-standardized prevalence of IGT was 9.84% and was similar among different areas (10.52%, 9.68% and 9.27% among urban, peri-urban and rural areas respectively, $p=0.33$). The age-standardized prevalence of metabolic syndrome was 20.39% and tended to be higher among peri-urban population (20.19%,26.32% and 21.26% among men from urban, peri-urban and rural areas respectively, $p=0.02$; 16.09%, 21.55% and 20.85% among women from different areas respectively, $p=0.06$).

Conclusion: Diabetes and metabolic syndrome are very common in Beijing and probably rising in both incidence and prevalence. Residents in peri-urban and rural areas, with a low rate of awareness, are at equal or even higher risk of developing diabetes and metabolic syndrome when compared with their counterparts living in urban. Our study might underscore the urgency for development of public health strategies which must cover urban, peri-urban and rural communities.

Baseline characteristics of people with Type 2 diabetes on insulin in Japan compared to the global population: data from the Cardiovascular Risk evaluation in people with Type 2 diabetes mellitus on insulin therapy (CREDIT) study

R. Kawamori[1], K. Node[2], T. Hanafusa[3], Y. Atsumi[4], Y. Oka[5]
[1] *Juntendo University School of Medicine, Medicine Metabolism & Endocrinology, Tokyo, Japan*
[2] *Saga University, Faculty of Medicine Department of Cardiovascular&Renal Medicine, Saga, Japan*
[3] *Osaka Medical College, Medical Faculty Division of Medicine, Osaka, Japan*
[4] *Saiseikai Central Hospital, Division of Diabetes & Endocrinology, Tokyo, Japan*
[5] *Tohoku University Graduate School of Medicine, Department of Medical Sciences, Sendai, Japan*

Aims: The Cardiovascular Risk evaluation in people with Type 2 diabetes mellitus (T2DM) on insulin therapy (CREDIT) study is evaluating the effect of glycemic control on the risk of cardiovascular events. Here we report the baseline characteristics of Japanese people in the CREDIT study, comparing the results with those of the global population.
Methods: CREDIT is an ongoing, 314-centre, international, non-interventional prospective cohort study, with a 4-year follow-up. Inclusion criteria are as follows: age greater than 40 years, time from diagnosis of T2DM to insulin initiation greater than 1 year, duration of insulin treatment 1-6 months. Study sites were randomly selected from 12 participating countries in North America, Europe and Asia. Baseline data within 1 year before and 1 month after insulin initiation were collected.
Results: There were more patients exhibiting HbA1c>10.0 at baseline in the Japanese population than in the global one (Table). Fewer T2DM people in Japan used basal insulin and the dose was lower than in the global population. A lower percentage of Japanese T2DM people displayed macrovascular disease and renal failure. Reno-cardiovascular risk factors such as hypertension, obesity, and family history of cardiovascular disease were also lower.
Conclusion: The CREDIT baseline data reveal differences between the Japanese and global T2DM population: Japanese people have poorer glycemic control and use basal insulin less frequently and at a lower dose. As the study progresses, it will be of interest to see if adequate regimen changes will lead to better glycemic control in the Japanese population.

Baseline characteristics	Japan (n=511)	Global (n=3031)
Male (%)	63.8	51.0
Body mass index	23.9±4.0	29.3±6.3
HbA1c>10% population (%)	51.6	35.8
Insulin regimen (%) Basal alone	6.3	51.6
Short-acting alone	24.5	7.3
Insulin dose (IU/day) Basal alone	7.2±2.9	14.7±9.4
OADs use (%) Biguanides	29.0	71.2
a-glucosidase inhibitors	34.6	11.9
Macrovascular disease (%)	25.1	34.1
Family history of cardiovascular disease (%)	11.5	25.9
Hypertension (%)	47.6	68.7
Renal failure (%)	15.3	37.9
Concomitant therapy (%) statin	31.9	51.5
ARB, ACEI	35.6	69.0

Effect of glitazones on cancer mortality in type 2 diabetes

S. Bowker[1], Y. Yasui[1], P. Veugelers[1], S.H. Simpson[2], J.A. Johnson[1]
[1] *University of Alberta, School of Public Health, Edmonton, Canada*
[2] *University of Alberta, Department of Pharmacy, Edmonton, Canada*

Aims: Numerous studies have observed an association between type 2 diabetes (T2DM) and cancer, with recent reports suggesting a modulating role of antidiabetic therapy. There is little epidemiologic information, however, exploring the effect of the glitazones and cancer mortality in T2DM. We hypothesized a decreased risk of cancer mortality associated with glitazones use, compared to sulfonylurea monotherapy use.
Methods: This was a population-based retrospective cohort study using administrative data from Saskatchewan Health. We identified new users of metformin or sulfonylureas from January 1, 2000 to December 31, 2005, with follow-up until death, departure from the province, or December 31, 2006. We compared cancer mortality between glitazone users (plus metformin), metformin and sulfonylurea combination users, metformin monotherapy users, and sulfonylurea monotherapy users (reference group). A time-varying Cox analysis was used to estimate the hazard ratio (HR) of cancer mortality, accounting for oral antidiabetic therapy, insulin therapy, age, sex, and chronic disease score (CDS). Exposure to oral antidiabetic therapies was defined by use of each agent (i.e., yes/no) within 1-year time windows. We examined the dose-response gradient for insulin exposure. Firstly, we created a count of insulin dispensations for each 1-year time window. Cumulative insulin exposure/year was then calculated by summing insulin counts at the end of each year and dividing by the person years of insulin use since insulin index. We stratified the cumulative insulin exposure level into high, low, and no exposure to insulin.
Results: We identified 20,448 new users of metformin or sulfonylureas during the index period, with an average (SD) follow-up of 3.5 (1.8) years. The mean age for the cohort was 61.3 (14.3) years and 53.8% were men. Unadjusted cancer mortality was 9.8% (154/1,577) for sulfonylurea monotherapy users and 1.3% (43/3,365) for glitazone (plus metformin) users ($p < 0.0001$). After adjusting for age, sex, CDS, and insulin use, glitazone (plus metformin) users had a significantly lower risk of cancer mortality compared with the sulfonylurea monotherapy cohort (HR: 0.42, 95% CI: 0.24 – 0.72; p=0.002). The adjusted HRs (95% CI) for insulin use were 1.33 (0.83 – 2.13) and 7.08 (5.27 – 9.51) for <12 and 12 cumulative insulin dispensations/year, respectively, compared to those using no insulin.
Conclusion: These findings add further support that antidiabetic therapies may play a role in the relationship between type 2 diabetes and cancer outcomes. Our results suggest that patients with type 2 diabetes exposed to glitazones had a significantly decreased risk of cancer mortality compared to patients exposed to sulfonylurea monotherapy. It is uncertain whether this decreased risk is related to a protective effect of glitazones or a toxic effect of sulfonylureas.

[11] *Centre Marc Sankale, Centre du diabete, Dakar, Senegal*

Background: Unlike in the past, it is now accepted that Africa is not exempt from the worldwide epidemic of diabetes mellitus (DM). Country-related socio-demographic characteristics of DM have been reported but no region-wide data are available.
Aim: To describe the socio-demographic features of persons with diabetes in selected countries in sub-Saharan Africa.
Methods: NovoNordisk Diabcare Middle Africa was aimed at collecting basic data about diabetes in six African countries: Cameroun, Ghana, Kenya, Nigeria, Senegal and Tanzania. Each of the centres in the participating countries contributed data they had available for every third diabetic patient obtained by interview, examination of clinical records and HBA_1c measurement at time of data collection. The results of the survey were pooled at the national and continental levels. This communication is a report of the aspects of the pooled

continental data dealing with gender, age, ethnicity, type and duration of DM in the populations studied.

Results: Thirty-one centres in the six countries enrolled 2711 patients. Availability of required information varied from 2533 (93.4%) for age at diagnosis, to 2670 (98.5%) for type of diabetes. About 97% of the patients were Africans while the rest were Arabic (1.9%), Indians (0.5%) or others (0.3%). Region-wide, type 1 and type 2 diabetes respectively accounted for 9.1% and 88.1% of all cases, with T1DM varying from 4.6% to 15.3% among the countries. There was a preponderance of women in all the countries: women 60.9% and men 39.1%. The mean (SD) age of the patients at survey was 53.8 (13.5) years with the mean ages in all the six countries being similar. The mean age at diagnosis of DM was 46.3 (13.6) years with a mean range at diagnosis of 43.5 to 49.2 years. The mean duration of diabetes was 7.5(6.0) across the continent with a wide range of 1-38 years.

Conclusion: There appears to be a preponderance of women with diabetes across Africa. Whether this is artificial or real will need further studies. The duration of diabetes is rather short. The proportion of Type 1 to Type 2 DM appears similar to occurrences in other continents, while age at diagnosis is somewhat lower than reported from elsewhere.

Community-based weight reduction campaign in Japan, named "3-3 challenge in Kato city"

A. Kaneta[1], M. Domichi[1], K. Okazaki[1], N. Sakane[1]
[1] Kyoto Medical Center, Department of Preventive Medicine, Kyoto, Japan

Aims: The prevalence of type 2 diabetes is increasing in Japan, so the development of the diabetes prevention program is one of the urgent health issues. Obesity or overweight is known to be one of the major factors for the incidence of diabetes. Thus, the effective weight losing program in the community is strongly needed from a public health perspective. The aim of this study is to evaluate the effectiveness and feasibility of a community-based weight reduction campaign.

Methods: This is a public health campaign held at Kato city with a population of 40,000. General goal of this program was to lose 3kg in 3 months, the title of the campaign "3-3 challenge" was named after this goal. Campaign started in October 2008 and ended in February 2009. During this period, 39 shops in Kato city supported the campaign in various ways. This campaign also included a weight reduction program. A total of 394 community-dwelling people with a body mass index over 23, ranging in age from 20 to 74 years, were registered through public information paper or website of Kato city. In this program, applicants were recommended to weigh themselves twice per day, once in the morning before breakfast and once in the evening after dinner. They were also advised to fill in a daily weight chart and draw the line graph of weight for 3 months. All the participants received leaflets of tips for safe and effective weight loss. In addition, part of the participants who wished (n=140) attended a two-hour group session in October. By the beginning of February, participants reported their final weight in the mail. In March, the public health office of city held a health fair including a briefing session on the result of the program and an award ceremony with the mayor for participants.

Results: Three hundred and eight subjects (male 37%, mean age 52±11 years, mean BMI 26.4±2.8 kg/m^2) completed the program. The dropout rate was 22%. At the end of the program, the mean weight loss from the baseline, was 2.3±2.3kg. A hundred and one subjects (33%) achieved weight loss more than 3 kg. A hundred and fifty three subjects (50%) achieved weight loss more than 3% of the weight. Eighty four subjects (27%) achieved weight loss more than 5% of the weight. In a subgroup analysis, participants with group lesson lost more weight than those without group lesson (2.7±2.4kg vs. 1.9±2.2kg, $p<0.01$). The dropout rate was lower in participants with group lesson than those without group lesson (10 % vs. 28%, $p<0.01$).

Conclusion: These findings suggest that this program is effective and feasible for overweight participants to lose weight in the community setting. This campaign also seemed to foster momentum of health in Kato city. This accomplishment of weight reduction can make some contribution to prevent type 2 diabetes in overweight Japanese.

BMI may not predict the incidence of diabetes in Asian-Indian subjects: a five year follow-up study from Bangladesh

A. Hussain[1], A.K. Azad Khan[2], M.A. Sayeed[2], S.A. Asghar[3]
[1] Institute of General Practice and Community Medicine, International Health, Oslo, Norway
[2] Bangladesh Institute of Research and Rehabilitation in Diabetes Endocrine & Metabolic Disorders (BIRDEM) Dhaka Bangladesh, Research, Dhaka, Bangladesh
[3] Inst of General Practice and Community Medicine/ Dept. of International Health University of Oslo, International Health, Oslo, Norway

Aims: Incidence rates and risk of obesity for type 2 diabetes in lean populations are not well documented. Therefore the purpose of the study was to determine the incidence of type 2 diabetes and to examine the effect of relative changes in obesity (BMI, WHR and waist) measures on diabetes incidence.

Methods: Population based longitudinal study (1999 – 2004) in Bangladesh with clinical, anthropometric and biochemical measurements in 2011 non-diabetic adults aged 20 and above at baseline were followed for five years.

Results: The overall 5 year cumulative incidence of diabetes was 16.4 per 1000 person-years. Those with impaired fasting glucose (5,6 – 6,9 mmol/L) had an incidence rate of 49,2 per 1000 person-years adjusted for age and sex. Significant increase was observed for BMI, waist, WHR, Systolic BP and fasting blood glucose levels. Obesity measures (BMI or WHR) did not show any significant association with the incident cases of diabetes in the adjusted model but waist >85 cm was associated (RR of 2.2 [95% CI 1,3 – 4,0]) in the adjusted model. Relative changes in BMI either by gaining or losing weight by more than 5% from the initial values was significantly associated with the incident cases of diabetes in the age group 41-50 (RR 3.4 [95% CI 1.5 – 7.5]) controlling for age and gender. Other factors of significance were age more than 30 and systolic blood pressure more than 140 mmHg (RR 2,1 [95% CI 1,3 -3,4]) and impaired fasting glucose at base line (>5,5 – 6,0 mmol/L) was strongly associated with the incident cases of diabetes (RR 4,9 [95% CI 3,7 – 6,7]). Risk factors for the relative change in WHR, waist, systolic BP and diastolic BP by gender were all statistically different.

Discussions/conclusions: Incidence of diabetes is increasing at an alarming rate in the rural population of Bangladesh, described as a nutritionally marginalized or lean population. Preventive measures to decrease the incidence of diabetes by reducing body weight in this population, is less likely to make any impact. Further, our data suggest that reducing weight in a lean population (low BMI) may essentially indicate an increased risk for the development of diabetes. Targeted intervention in those with impaired fasting blood glucose will expectedly reduce the incident cases. Dissimilar risk factors by gender and other essential features like waist and blood pressure may be incorporated in the intervention programmes.

Relationship between overweight children and components of the metabolic syndrome among 6-14 years old Argentinean school children

V. Hirschler[1], G. Maccallini[2], C. Aranda[2]
[1] Hospital Durand, Nutrition, Buenos Aires, Argentina
[2] Hospital Durand, Laboratory, Buenos Aires, Argentina

Background: Argentina has experienced marked increases in the prevalence of childhood overweight/obesity (OW/OB) over the last few decades; however, there are few data about this problem from school children in this country.

Objectives: We examined 1) the distribution of the mean values of lipids, glucose, and HOMA-IR according to the presence of OW/OB, age, and sex and, 2) the association between metabolic syndrome (MS) and OW/OB, Tanner, gender, and HOMA-IR.

Methods: Data were collected cross-sectionally from 10 elementary schools between April 2006 and March 2008. BMI, waist circumference, blood pressure, fasting lipids, insulin, glucose and Tanner were obtained. Children were divided for analysis in groups according to age (6-9 years and 10-14 years) and gender. Criteria analogous to ATPIII were used for children as IDF definition was proposed only for children over 10 y. MS was defined as the presence of $\geq$3 of the following 5 conditions: (1) abdominal obesity (waist circumference$\geq$90th), (2) triglycerides >110 mg/dL, (3) HDL-C <40 mg/dL, (4) blood pressure $\geq$90th (5) glucose >100 mg/dL.

Results: Over 1009 children (508 m) aged 9.4±2.0y were evaluated. 165 (16.4%) were OB (≥95th percentile), and 166 (16.5%) OW (85-95th). Twenty five (2.5%) were severely OB (BMI≥99th). Most of the children (62%) were pre-pubertal (Tanner 1: 613/979). There was not a significant difference in the prevalence of OW/OB between genders. Differences in BMI and waist circumference increased with age in both genders ($p<0.001$). Mean systolic blood pressure was higher in OW/OB children in both age groups and genders. Triglycerides, insulin, and HOMA-IR were higher ($p<0.001$) and HDL-C lower ($p<0.001$) in OW/OB in both age groups and genders. However mean levels of total cholesterol were only significantly higher among 6-9 year old OW/OB girls. There was not a significant difference in glucose levels between any of the groups. The risk factors of central obesity (279/989; 28.2%) and low HDL-C (199/1009; 19.7%) were common, while hypertension (86/999; 8.6%) and impaired fasting glucose (8/1008; 0.8%) were infrequent. The prevalence of MS was 5.6% overall, 32% in severely OB, 16.4% in OW/OB and 0.4% in normal weight children. The prevalence of one or more component of the MS was 45.8% overall, and was significantly higher in OW/OB (81.8%) than in normal weight (28.3%). The prevalence of two or more components of the MS was 17.8% overall, 44.5% in OW/OB and 4.9% in normal weight ($p<0.001$). None had the 5 components of the MS. Multiple logistic regression showed that BMI (OR 1.39; 95% CI 1.27-1.51), and HOMA-IR (OR 1.88; 95% CI 1.10-3.23) were significantly associated with MS adjusted by gender and Tanner. When Tanner was replaced by age, results did not change.
Conclusions: A substantial number of OW/OB children have the MS. HOMA-IR, and BMI were strong predictors of MS in children suggesting that OW/OB school children are at a higher risk for future metabolic and cardiovascular disease.

An evidence informed diabetes curriculum to prepare exercise professionals for delivering culturally relevant pre-diabetes physical activity interventions

C. Rowan[1], M. Riddell[1], V. Jamnik[1], P. Ritvo[1], A. Salmon[2], N. Gledhill[1]
[1] York University, Physical Activity and Chronic Disease Unit Diabetes Section Faculty of Health School of Kinesiology and Health Science, Toronto, Canada
[2] Ontario Ministry of Health Promotion, Toronto, Canada

Aims: In preparation for a pre-diabetes detection and physical activity (PA) intervention program, we developed a curriculum to prepare fitness professionals to deliver culturally relevant pre-diabetes PA interventions to high-risk target populations. The curriculum is a comprehensive resource on diabetes, pre-diabetes detection, behaviour change methods and culturally relevant PA options to reduce the incidence of type 2 diabetes.
Methods: The curriculum was developed after careful review of scientific literature and clinical recommendations from prominent diabetes associations throughout North America. It is targeted at highly qualified fitness professionals - Certified Exercise Physiologists. The following populations are known to have an elevated risk for type 2 diabetes; South Asian, Aboriginal, African/Caribbean, and East Asian. We identified culturally-relevant PA activities via established contacts within these targeted communities. Special care was taken to quantify the exercise intensity of the culturally-specific activities to calibrate them to known effective PA intervention prescriptions.
Results: The curriculum provides essential diabetes information and highlights the role of lifestyle modification in the prevention/delay of type 2 diabetes. The section on behaviour change provides culturally specific PA recommendations and considerations for pre-diabetes screening, while drawing on methods that integrate key constructs from stages of change, self efficacy and motivational interviewing models. The behaviour change tools were customized with input from the culturally-based community contacts in each high risk sub-group, emphasizing use of appropriate language and awareness of culture-specific barriers and facilitators to PA participation.
Discussion/conclusion: This curriculum provides fitness professionals with the essential information and tools to implement culturally relevant PA based diabetes prevention interventions in high-risk sub-populations to reduce the incidence of type 2 diabetes.

Providing diabetes care during a military conflict: Learnings and consequences for emergency preparedness

L. Tsutskiridze[1], R. Kurashvili[1], G. Kurashvili[1], E. Shelestova[1], H. Wenzel[2]
[1] Georgian Union of Diabetes and Endocrine Associations, Endocrinology dept., Tbilisi, Georgia
[2] Consultant in health economics, Endocrinology dept., Mannheim, Germany

As a consequence of the military conflict in August 2008 about 130,000 people have been displaced and were accommodated in IDP camps, collective centres and host families. In October about 86,995 IDPs were located in Tbilisi and 46,061 were scattered in different regions. In Gori town there were 6,681 IDPs of which 2,250 resided in tent camps, 2,370 in host families and 2,061 in 28 collective centres (Ministry of Refugees and Accommodation of Georgia). Prevalence of diabetes (DM) and various thyroid pathologies is very high in this population. In those with known DM very high glycemia levels were found; they were caused by a severe stress, and the fact that due to psycho-social and economic conditions patients are unable to adhere to treatment. A large number of fresh cases of type 2/type 1 DM was registered as well; the latter is especially high in children and adolescents. Up to 1,000 persons were consulted/investigated during two actions; fresh cases of DM were revealed in 2% of persons. The operating requirements for caring for those people went beyond the existing resources. Because the flow of refugees occurred without warning, no risk management was possible. In the framework of the emergency management our institute was trying to get support. Using a network of different organisations and personal relationships the provision could be provided. Glucometers and strips could be delivered to all people with DM; they were donated by the international organization "Insulin for Life" and industry. Such actions will be carried out in future and GUDEAS with its partners will actively participate in them.

Recreational poly-drug use is prevalent amongst people with type 1 diabetes and may be associated with poor glycaemic control – preliminary results from an Australia-wide survey

P. Lee[1], J.R. Greenfield[1], K. Gilbert[2], L.V. Campbell[1]
[1] Garvan Institute of Medical Research, Department of Endocrinology, Sydney NSW, Australia
[2] The Type 1 Diabetes Network Inc., Sydney, NSW, Australia

Designer drugs have gained increasing popularity during 'rave' parties. Based on the National Drug Strategy Home Survey, 38% of the Australian population over 14 years had used illicit drugs at least once in their lifetime[1]. The prevalence of illicit drug use amongst people with type 1 diabetes is poorly documented. Despite case-reports of life-threatening diabetic ketoacidosis (DKA) complicating drug use in people with type 1 diabetes[2], little is known regarding effects of designer drugs on people with type 1 diabetes[3,4].
Aim: To determine the prevalence, pattern and impact of recreational drug use amongst people with type 1 diabetes in Australia.
Methods: Through radio broadcast and online/hospital advertising, people with type 1 diabetes in Australia were invited to participate in an online survey regarding drug use. Ten questions encompassing demographic details and pattern of drug use were posted.
Results: Of 204 (F=129, mean age: 31±2 years) respondents, 77% had used recreational drugs at least once in their lifetime and 56% had used drugs within the last month. Two-thirds of users were poly-drug users (>3 drugs within last year) and one in five drug-users reported daily drug use. The six most common drugs used were cannabis (87%), "Ecstasy" (62%), "Speed" (53%), cocaine (40%), "Ice" (16%) and ketamine (10%). Nine respondents reported DKA following illicit drug use. Drug-users (N=157, F=71) were similar in age to non-users (30±2 vs 33±3 years old, p=NS) but were significantly more likely to smoke tobacco (33% vs 8%, $p<0.01$). Ninety-four per cent of non-drug users knew their last HbA1c compared to 85 % of drug users ($p<0.05$). HbA1c tended to be higher amongst drug users than non-users (8.1±2.1 vs 7.4±1.1%, p=0.07). Two-thirds of drug users had informed their partners about their drug use, while only 10% had informed their family doctors &/or diabetologists. Fifteen per cent of drug users had told no one about their drug use.
Conclusions: More than 1/2 of the people with type 1 diabetes in our survey had used recreational drugs in the last month, with 2/3 using >3 drugs in the past year. Only one in ten people had informed their health professionals about

their drug use. Recreational drug use may be associated with worse glycaemic control & higher risk of DKA. Health care professionals should be aware of this under-recognised health issue amongst their patients with type 1 diabetes.

The influence of weight perception on weight management and dietary behaviors in overweight and obese people with diabetes

B. Ekezue[1], E. Platonova[2]
[1] UNC Charlotte, Health Services Research, Charlotte, USA
[2] UNC Charlotte, Health Administration, Charlotte, USA

Objectives: Extensive evidence exists on the risks associated with excess weight and chronic diseases, which should provide motivation for weight management in people with diabetes. Studies have also suggested that weight perceptions influence weight management behaviors and may affect efforts aimed at effective weight control in the diabetic population. Hence, this study's objective is to understand how misperceived weight status influences weight control and dietary behaviors in overweight/obese people with diabetes.
Methods: The study population comprised people with diabetes who are overweight/obese and 16 years or older. Three waves of NHANES data from 2001-2006 were used. Self-reported data and biometric measurements of 1,586 participants were obtained. The outcome variables are; an attempt to lose weight, intentional weight loss, physical activity level, and dietary fiber intake. The explanatory variables include demographic factors, family history, and misperception of weight, defined as discordance between study participant's body mass index and self-reported weight status.
Results: Misperceived weight status was more prevalent in overweight participants (77%) compared to obese participants (23%) especially among overweight males (62%) compared to overweight females (38%). Using multivariate logistic regression, we found males had over three times the odds of misperceiving their weight (OR 3.6, CI 2.2-6.0) compared with overweight females. In addition, being overweight (OR 14.4, 8.6-23.8), being a widow, having low education level, and having income $75,000 and above were significantly associated with misperceived weight ($P<0.05$). Overweight participants who misperceived their weight were less likely to attempt to lose weight (OR 0.31 CI 0.14-0.64). While misperception of weight was not associated with dietary fiber intake, the results show racial, gender and income differences in dietary fiber intake. Females were more likely to have higher dietary fiber intake compared to males, Blacks were more likely to have higher dietary fiber intake compared to Whites. Low family income (<$20,000) was a significant indicator of low dietary fiber intake.
Conclusion: The study shows that misperception of weight negatively influences the motivation to lose weight especially in males and overweight people with diabetes. Targeted weight management interventions that focus on modifying weight perceptions may be necessary to achieve effective weight control behaviors in overweight people with diabetes.

Insight into people living with type 2 diabetes: a global survey of patients and physicians

J.M. Ekoé[1], I. Iliopoulos[2], M. Drolet[2], N. Nasseri[2]
[1] University of Montreal, Medicine, Montreal, Canada
[2] Merck Frosst, Montreal Group, Montreal, Canada

Aims: To survey people living with type 2 diabetes and physicians from 8 countries (North America, Europe and Asia) on issues related to the disease and its management.
Methods: 1200 randomly selected patients with type 2 diabetes (35 years and over) and 360 physicians (endocrinologists and diabetologists) were surveyed during three weeks using face-to-face interviews or via telephone. The interviews lasted 20-25 minutes for patients and 15-20 minutes for physicians. One standardized questionnaire used for all interviews addressed the following issues: misconceptions, awareness about diabetes, impact of diabetes on daily life and diabetes treatment.
Results: 68% of patienst had been living with diabetes for over 5 years and 42% for over 10 years. Physicians estimated that an average of 75% of their patients had type 2 diabetes. The majority of patients (72%) of patients believed that earlier diagnosis and treatment may have slowed down their disease progression.46% of patients believed that they were living with symptoms for at least 6 months before being diagnosed with the disease. The majority of patients checked their blood glucose at least once a week (55%). Only 40 % of the youngest (under 45) checked their blood glucose levels at least once a week compared to 67% of the oldest group (75 and over). Checking blood glucose levels at least once a day was recommended by the majority of pysicians. A high percentage of physicians (60%) and patients (63%) underestimated the global prevalence of diabetes. Only 28% of patients agreed that diabetes is as severe a disease as HIV and breast cancer. Less than half of physicians believed that diabetes is responsible for a similar loss of lives each year as HIV (45%) and breast cancer (35%). Many physicians (82%) believed that diabetes has a significant impact on their patients' daily lives. 97% of physicians agreed that diabetes affected their patients' dietary choices without any good metabolic control (39%). Weight gain and hypoglycemia were the main obstacles for treatment for both patients and physicians; Other concerns were disease progression (84%), complications (82%) and inadequate blood glucose control (72%). Diabetes was felt as seriously altering the quality of life, mostly for the younger patients (under 45). Some differences were found between countries.
Conclusions: Type 2 diabetes has a great negative impact on lives of patients in different parts of the world. Its daily management is a real burden. Medication, dietary habits, weight gain, hypoglycemia and long term complications were the main concerns. However, the worldwide magnitude of diabetes and its impact on health were underestimated both by patients and physicians in this survey.

D-1010

Social and economic consequences to women because of diabetes in self or in family in Bangladesh

A. Ali[1], S.H. Habib[2], S. Saha[2], H. Mahtab[1], A.K. Azad Khan[1]
[1] BADAS, BADAS Secretariat, Dhaka, Bangladesh
[2] BADAS, Health Economics Unit, Dhaka, Bangladesh

Background & aims: People living with chronic diseases like diabetes are especially facing an increasing demand for long-term continuous health care services, leading to increased burden of health care expenses specially among women. BIRDEM data showed that total no of registered diabetic women was 8639 in 2005. Among those 43.9% was from rural, 48.9% was from urban and 5.9% from sub-urban area. 44677 patients were supported by the Social welfare dept and getting medicine and treatment free of cost. Among them female constituted about 62.3%, Juvenile constituted 7.7%. Literacy rate among those women were very negligible. They belong to a very poor socio-economic class. Family earning was less than US $ 42.85. Most of the women were housewife and dependent. The present study was undertaken to observe social and economic consequences to women because of diabetes in self or family in Bangladesh.
Methods: The survey was conducted on 100 women, 25 women who have diabetes and 25 women from diabetic family (either husband or any other member of the family have diabetes) from a tertiary hospital, 25 women who have diabetes and 25 women from diabetic family from sub-urban area.
Results: Twenty three percent believes that it's a communicable disease, 78% can read & write their name, 3% don't go for health care due to lack of awareness and misbelieves, 7% don't get access to the care due to religious restrictions, 74% are from identified poor socioeconomic group, 87% are housewife and dependent, 67% is suffering from financial crisis due to productivity loss, 56% are facing changed behavior of husband and mental stress, 51% reported that dependency on elder son (who is earning) & relatives are increasing, 72% children are depriving either from education or

family emotional attachment, 12% remain unmarried due to diabetes, 9% got divorced due to diabetes herself. Sometimes an unmarried girl is not taken as a wife simply because she has diabetes. When one of the members of the family becomes disabled due to diabetes the whole burden has to be borne by the woman herself. Outpatients cost for diabetes care is the cost per patient was found to be 0.50 US$ for medical care, 7.94 US$ for investigations, 0.76 US$ for health education and nutrition, 0.18 US$ for supporting/overhead services. If complications develop during the onset of disease then it substantially increases the cost of complication as well as care. Uncontrolled foot ulcer and uncontrolled blood glucose costs on an average of US$ 443.60 per patient & US$ 138.08 per patient individually.

Conclusion: Diabetes in women affects the productivity and due to loss of productivity she has to be a burden financially. Bangladeshi diabetic women suffer from a great deal of social, psychological and economic burden which need to be addressed by special attention.

"Going Back to School": giving at-risk families new HOPE

J. Denton[1], T.M. Cleary[1], D. Frost[1]
[1] Diabetes Auckland, Supporting charity, Auckland, New Zealand

New Zealand is a multi-cultural society with 14.1% Maori, and 6.2% Pacific Islanders. Obesity, diabetes, and heart disease are rife, especially amongst these groups, and Type 2 Diabetes is forecast to rise 130-150%, (1996–2011). Language and cultural differences for Maori and Pacific people mean that often they do not access relevant health information delivered through conventional channels. Facilitating lifestyle-change specifically for Maori and Pacific people is a challenge requiring additional skills.

HOPE – "Healthy Options = Positive Eating" was designed by an NGO in Auckland and is delivered to both Maori and Pacific students and parents/caregivers in at-risk areas.

The program has two elements that set it apart:

- increased traction because parents and children receive similar information at the same time;
- a unique combination of physical activity, practice in cooking traditional foods in a healthier way and experiential learning being continually interwoven across the course's multiple sessions.

Aim: The Aim of this program is to encourage families to learn "together" so as to adapt to and adopt enduring healthier lifestyles.

Method: Students participate in a school health-awareness program fostering healthy living. The HOPE initiative then provides the same information for associated parents/caregivers, delivered in a manner appropriate to their understanding. Children are welcomed at the parent program, thus enabling families to learn together. The Presenter of this program is of the same ethnicity as those attending.

The social marketing strategy employed has been devised to encourage creation of a suitable environment to facilitate lifestyle-change based on shared trust and understanding. Behaviour-change is maximised by integrating clear understanding, appropriate changes in attitudes and development of attendees' practical commitment to employ new approaches to nutrition and physical activity.

The HOPE course consists of five sessions during which the family progressively integrates learning into daily life. On completion a one-month is issued to embed the new learning. Then a graduation celebration is held providing opportunity to share the positive experiences gained. HOPE empowers and thereby creates action to reduce obesity, heart disease and diabetes.

Outcome: Three HOPE courses were delivered in 2008, with the initial pilot being subject to careful independent evaluation. HOPE is proving to be a very effective vehicle to stimulate sustained behaviour-change across whole families and filtering on through their community networks.

[9] *Mount Sinai Hospital, Medicine, Toronto, Canada*

Aim: To compare glycemic control in patients with private drug insurance and unencumbered access to any oral hypoglycemic agents (OHA) with that in patients who only have access to OHAs approved by their provincial formulary reimbursement program.
Methods: Patients with type 2 diabetes mellitus (T2DM) and glycated haemoglobin (A1C) levels above the 2003 Canadian Diabetes Association guidelines-recommended target of 6.0-7.0% were enrolled in a glycemic treatment optimization program (Time 2 Do More) between March 2006 and September 2007 from the offices of 331 primary care practitioners across 9 Canadian provinces. Four clinic visits aimed at tightening glycemic control were scheduled over 12 months.
Results: Of the 5280 subjects (mean age 60.6±11.9 years), 73% had some form of private coverage while 27% only had public coverage - a ratio mandated by the study design. Subjects with access to private insurance were younger (mean age 58.9±11.6 years vs 65.9±11.3 years for private vs public only; P<0.001). Target A1C≤7.0% attainment increased with consecutive visits (0%, 37.7%, 44.0% and 48.5% for private; 0%, 39.3%, 43.0% and 46.7% for public) but A1C≤7.0% achievement ratios were indiscernible between the groups. The median 12-month A1C for the private and public only coverage groups were 7.1% (IQR, 6.6%-7.8%) and 7.1% (IQR, 6.6%-7.9%) respectively. At visit 4, 48.5% of those with private coverage and 46.7% of those with public insurance achieved the A1C≤7.0% goal (P=0.36). Comparisons of the last measured A1C data (last observation carried forward; LOCF) against baseline A1C show that 73.1% of the subjects with decreased A1C levels vs. 68.6% of those with increased A1C levels had private coverage (P<0.005). Although fasting plasma glucose (FPG) improved with consecutive visits, <50% of all subjects attained the recommended ≤7.0 mmol/L goal after 12 months of treatment (18.5%, 35.9%, 39.9% and 43.4% for private; 19.8%, 34.8%, 38.6% and 39.8% for public).
Conclusions: While A1C decreases were linked with greater private coverage, overall A1C changes were indistinguishable between the two groups. Our results suggest that in Canada, differential insurance coverage did not appreciably influence short term glycemic target attainment in this prospective epidemiologic evaluation of patients with T2DM. Further analyses are required to explain these findings. Given that >50% of these patients still demonstrate an A1C above target, other causes for this care gap must be sought.

Fibrocalculous pancreatic diabetes - a case presentation

O. Adesina[1], R.T. Ikem[2], B.A. Kolawole[2], D.O. Soyoye[2], O.J. Adebayo[2]
[1] *Federal Medical Centre Abeokuta, Medicine, Abeokuta Ogun State, Nigeria*
[2] *Obafemi Awolowo University Teaching Hospital, Medicine, Ile Ife Osun State, Nigeria*

Objective: To highlight the clinical features of Fibrocalculous pancreatic diabetes and the problems associated with diabetes management in a resource challenged environment.
An 18 year old farmhand was admitted with 3 months history of polyuria, polydipsia and weight loss. He has had history of recurrent abdominal pains.
He is a secondary school dropout, the second of his mother's three children in a polygamous family with 18 children. Father is a farmer.
Examination revealed a young man who was small for age, wasted, dehydrated, with fluffy hair and pale. Weight: 39Kg, Height: 1.5M, BMI: 16.4Kg/m^2, waist circumference: 66cm. The rectum was filled with normal coloured stool containing partially digested rice and beans grains.
The Random blood glucose at presentation was unrecordably high with ketonuria of 3+. He was subsequently managed as a case of diabetic ketoacidosis.
Abdominal X-ray revealed pancreatic calcifications while serum proteins showed hypoalbuminaemia.
He had great difficulty in procuring medications while in hospital. He was counseled on diabetes, hypoglycaemia, foot care and the need for compliance with medications. He was discharged on the 11th day but was subsequently lost to follow-up.
Conclusion: Fibrocalculous pancreatic diabetes is still being seen in Nigeria where its treatment, as it obtains for the treatment of other forms of diabetes, is burdensome economically to the individual.
Keywords: secondary diabetes, access to drugs and technologies.

Accessing insight: visual impairment and diabetes technologies

J. Jesso[1]
[1] *North Vancouver, Canada*

Jennifer Jesso will facilitate discussion and hands-on demonstrations about experiences using diabetes technologies with a visual impairment.
Participants will:
- learn about visual impairments and their effect on vision,
- understand how impaired vision affects the use of diabetes technologies,
- gain insight into how people with visual impairments use diabetes technologies,
- learn easy-to-implement suggestions on educating people with visual impairments in the use of diabetes technologies,
- hear Jennifer's personal experiences with diabetes technologies, and
- hear (and identify!) suggestions for improvements in product design and accessibility.

Jennifer is a professional in the field of visual impairments who has had type 1 diabetes for 18 years and has been legally blind since birth, and manages her diabetes with an insulin pump.

Type 1 diabetes in "have" children in India: experience and future of the insulin pump therapy program in the state of Karnataka, India - successes, failures and social engineering

M. Ramarajan[1], B. Naik[1], A. Sharda[1]
[1] *SAMATVAM: Endocrinology Diabetes Center, Endocrinology & Diabetes, Bangalore, India*

India is a 'continent' of striking extremes and contrasts: ancient to ultra modern, very rich to abjectly poor, highly intelligent to totally illiterate etc, and thus socially justified health care projects must reach out to all sections of society. Our Insulin Pump Project (IPP) was started in 2002; 1st Certified Insulin Pump Project in India; 8 Certified Pump Trainers – CPTs; 3 of them themselves having T1DM and were the initial pump users (1 doctor, 1 diabetes educator, 1 volunteer – computer engineer); primary credit for the continued success of our IPP goes to this volunteer T1DM – CPT (he initiates and troubleshoots pump and runs FREE 24 x7 x 365 helpline); because of the commitment, talent and compassion of this one volunteer serving our group, despite 20 eminent endocrinologists and hundreds of physician diabetologists in our state, 90% of the total pump prescriptions in our state come from our own practice of 2 endocrinologists.
Program: Patients initiated = 36 (T1DM 30, T2DM 5, 2 DM 1); Offered Pump in Clinic = 30; Pump sought by patients = 6; Drop outs = 4 + 1. Reasons for going on pump: Recurrent severe hypoglycemia = 8; Wide fluctuations in BG levels = 20; Suboptimal DM control = 17; Micro / Macro vascular complications = 4; Compromised life style =18; Young children, infants and neonates = 3; Eating disorders = 0; Pronounced dawn phenomenon = 6; Needle phobia = 1; Pregnancy - preconception = 1; Ketosis prone = 1; Competitive athletes = 0. Age at DM diagnosis= 3 to 28 years; duration of diabetes = 0 to 32 years; age at pump initiation= 3 to 45 years; number of years on pump= 1 to 7; number of basal rates per day=4 average; number of boluses per day=4 average. Complications – problems on pump: Severe hypoglycemia = 0; Metabolic deterioration DKA= 0; Site infection / recurrent = 4; Site irritation / scarring = 6; Site failure / cannula occlusion= 6; Body image problem= 2; Insulin omission= 2; Diabetes burnout= 1.
Conclusions: Insulin pump therapy is being increasingly accepted in India - a heterogeneous developing country. Indications, difficulties and limitations are similar to those experienced in more affluent societies. Increased awareness and education of physicians and patients necessary for wider usage and benefits. Technology improvements and cost reduction (refurbished pumps, lower cost disposables) will facilitate.
Man, machine and money: all important.

Anti-diabetic effect of aqueous extract of Tapinanthus butungii in male sprague-dawley rats

A.A. Osinubi[1], G.O. Ajayi[2], A.E. Adesiyun[3]
[1] *College of Medicine of the University of Lagos, Department of Anatomy College of Medecine, Lagos, Nigeria*
[2] *University of Lagos, Department of Pharmacognosy Faculty of Pharmacy, Lagos, Nigeria*
[3] *University of Lagos, Department of Clinical Pharmacy & Biopharmacy Faculty of Pharmacy, Lagos, Nigeria*

Background and aim: The prevalence of diabetes mellitus has risen exponentially in the last decade and an increasing number of people are using herbal supplements. Despite significant achievements in treatment modalities and preventive measures, the prevalence of diabetes and its complications have risen astronomically in the last decade. There is therefore a continued need for new and more effective therapies. Our aim was to evaluate the anti-diabetic effects of aqueous extract of fresh green leaves of Tapinanthus butungii in the rat.
Materials and methods: Young adult, male Sprague-Dawley rats weighing 180-200 g were used. Diabetes mellitus was induced in the group of diabetic test rats by intraperitoneal injections of alloxan (150 mg/kg). Hyperglycemic state was induced by administration of subcutaneous injections of 50% Dextrose in water (4 g/kg). Single doses of aqueous leaf extract of Tapinanthus butungii (200, 300 or 400 mg/kg p.o.) were administered to normoglycemic, hyperglycemic and diabetic rats. The hypoglycemic, anti-hyperglycemic and anti-diabetic effects of these single doses were compared with those of glibenclamide (10 mg/kg), chlorpropamide (250 mg/kg), insulin lente (0.1 I.U./kg) and distilled water (2 ml/kg). Blood glucose levels were estimated before treatment, 0h, 1h, 2h, 4h, 8h, 10h and 12h after administration of extract
Results: Aqueous leaf extract of Tapinanthus butungii produced significant dose-dependent reductions ($p < 0.05$-0.001) in the blood glucose concentrations of normoglycemic, hyperglycemic and diabetic rats comparable to glibenclamide, chlorpropamide and insulin lente.
Conclusion: These results suggest that the leaf extract of Tapinanthus butungii has strong and remarkable anti-glycemic property, and is therefore a potential anti-diabetic drug.

Medicinal plants used to treat diabetes in the south-western regions of Bangladesh

M. Mollik[1], R. Jahan[1], T.K. Paul[1], M.S. Hossan[1], H. Reza[1], F. Rehana[1], M. Rahmatullah[1]
[1] *University of Development Alternative, Biotechnology & Genetic Engineering, Dhaka, Bangladesh*

Diabetes mellitus (DM), particularly type 2 DM is a disease that affects a considerable segment of the population worldwide. The disease is characterized by abnormal insulin secretion with concomitant hyperglycemia and alterations in carbohydrate and lipid metabolism. The disease is also prevalent in Bangladesh, where the vast majority of the rural population relies on medicinal plants administered by traditional medicinal practitioners (Kavirajes) for control of this disease. As the available allopathic medicines are not able to cure DM (they merely control hyperglycemia and secondary syndromes of DM), it is always interesting to find out novel sources of treatment for any potential curative effect. The aim of this study was to conduct an ethnomedicinal survey amongst the Kavirajes of the south-western districts of Bangladesh, which fall under Khulna division, to learn more about plants used to treat DM. It is to be noted that because of the long tradition of alternative medicine in Bangladesh, the Kavirajes possess considerable expertise on medicinal plants, which knowledge is passed from generation to generation. Interviews were conducted with the help of a semi-structured questionnaire and plant species as pointed out by the Kavirajes were pressed on the field, brought and identified at the Bangladesh National Herbarium, where voucher specimens were also deposited. It was observed that 17 plant species were used to treat DM. These plant species (with family names given in parentheses) included Carica papaya (Caricaceae), Coccinia grandis (Cucurbitaceae), Trichosanthes kirilowii (Cucurbitaceae), Cassia occidentalis (Fabaceae), Ficus hispida (Moraceae), Psidium guajava (Myrtaceae), Syzygium cumini (Myrtaceae), Phragmites australis (Poaceae), Coix lacryma-jobi (Poaceae), Heritiera fomes (Sterculiaceae), Cinnamomum tamala (Lauraceae), Mirabilis jalapa (Nyctaginaceae), Scoparia dulcis (Scrophulariaceae), Murraya koenigii (Rutaceae), Glycosmis pentaphylla (Rutaceae), Morinda citrifolia (Rubiaceae), and Drynaria quercifolia (Polypodiaceae). Scientific studies on extracts of whole plants or plant parts have already established the hypoglycemic potential of Trichosanthes kirilowii, Psidium guajava, Coix lacryma-jobi, Scoparia dulcis, Murraya koenigii, and Syzygium cumini. It is expected that more scientific studies will be able to find out novel pharmacological constituents in the above-mentioned plant species, which can prove to be of considerable importance in treating DM.

[8] *Iran University of Medical Sciences, ENT - Head & Neck Surgery Department and Research Center, Tehran, Iran*

[9] *Rabe Rashidi Institute Tabriz, Department of Biotechnology, Tabriz, Iran*

Aim: Most of the treatments proposed for the diabetic foot have a partial effect in ulcer improvement and amputation rate; so more effective treatments are essential. The aim of the present study was to show safety and efficacy of Semelil (ANGIPARS™) as a new phytotherapeutic candidate for wound healing.

Methods: In experimental studies acute toxicity, genotoxicity (Comet assay), sub-acute Toxicity, mutagenic properties (Ames test, dominant lethal mutation in germ cells, chromosomal aberration, embryo toxic & teratogenic properties and allergic effects were evaluated. Then in clinical studies The Maximum Tolerated Dose (MTD) and Possible Dose Limiting Toxicities (DLTs) were determined. Then randomized controlled clinical trials for efficacy of intravenous, oral and topical routes of this herbal extract in diabetic foot ulcers were done.

Results: According to preclinical studies, Semelil had no severe acute or chronic toxicity and it was recommended for clinical trials. No toxicity or major side effects were observed up to daily dose of 10ml of this drug. Semelil by intravenous route is more effective than standard therapy without any side effects ($p<0.05$). This herbal extract by oral (Improvement ratio (%) 87.847 ± 10.95) and combination of oral and topical route (Mean improvement ratio (%) 84.380 ± 3.521) is more effective ($p<0.05$) than standard therapy (Mean improvement ratio (%) 25.092 ± 14.54) without any side effects.

Conclusion: The absence of any significant side effect indicates that ANGIPARS™ could well become a part of routine therapy for diabetic foot ulcers. However, further studies with greater sample size are necessary.

Herbal drug for the management of diabetic complications

S.B. Sharma[1], U. Rani[2], R. Kumari[1]

[1] *UCMS & GTB Hospital, Biochemistry, Dehli, India*

[2] *UCMS & GTB Hospital, Pathology, Dehli, India*

Aim: To study the pharmacological potential of anti- diabetic compound (FIIc) purified from fruit-pulp of Eugenia jambolana (EJ) in diabetic rats.

Methods: Chromatographic purification of aqueous extract of EJ yielded pharmacological active compound FIIc. Homogeneity of FIIc was confirmed by HPLC. Effect of FIIc was studied against diabetes induced macro vascular and micro vascular complications.

Results: FIIc resulted significant fall ($p< 0.001$) in FBG and Glycosylated Hb (51.5%) in SD after 15 day Tt. Plasma insulin levels were significantly increased ($p< 0.001$). In vitro studies showed 3 fold increase in insulin levels. FIIc significantly improve the altered metabolism by increasing ($p< 0.001$) the activity of key enzymes of glycolysis and decreasing ($p< 0.001$) the glyconeogenesis. After Tt, liver and muscle glycogen content increased by 55 & 51 % respectively. FIIc showed its significant anti thrombotic effect by significantly improving the levels of VCAM-1 and fibrinogen along with NO levels. Oxidative stress parameters were significantly improved after Tt with FIIc. Atherogenesis indices were also significantly normalized. FIIc significantly improved ($p< 0.001$) the kidney function tests (blood urea, creatinine, microalbuminurea). Renal hypertrophy, which was observed in diabetic rats, decreased significantly along with improvement in histomorphological changes.

Conclusion: FIIc has potent antihyperglycemic and antihyperlipidemic activity. It is pancreatic as well as extrapancreatic in action. It has attenuated the early stages of diabetes induced macro and micro vascular complications.

Synergistic effect of ferulic acid on glucose uptake activity in L6 myotubes

P.K. Prabhakar[1], M. Doble[1]

[1] *IIT Madras Chennai, Biotechnology, Tamil Nadu, India*

Diabetes mellitus is a chronic disorder characterized by increased blood glucose level and the cause is insufficient or inefficient insulin response. There are 20.8 million children and adults in the United States who have diabetes and it cause about 5% of all deaths globally each year. Ferulic acid a phenolics physiochemical present in the plant cell wall providing rigidity. In animal and in vitro studies suggests that ferulic acid may have direct antitumor activity against breast cancer and liver cancer. We have used the nonradioisotope, enzymatic method for 2DG uptake assay. This paper understands the effect and the mechanism of action of ferulic acid in L6 myotubes. The study reveals that ferulic acid has enhancing effect on glucose uptake in a time- and dose-dependent manner. The 4 hour incubation with 25 µM ferulic acid shows approx 2.97- fold increase in glucose uptake. Ferulic acid has a synergistic effect in combination with metformin or THZ with a maximum 2DG uptake increased by 4.98- and 5.11- fold of the base value (without the drugs or the natural products) respectively. At molecular level, elevated levels of the expression of GLUT4 (2.78-fold) and PI3K (2.07-fold) genes were observed with ferulic acid. The studies indicate that chlorogenic acid enhances glucose uptake by increasing GLUT4 expression via PI3K dependent pathway, which is in line with glucose uptake. The effect of ferulic acid on the ATP: AMP and ATP: ADP ratio also been studied. Collectively, our findings suggest that the phytochemicals can replace the commercial drugs in part, which could lead to a reduction in toxicity and side effects of the commercial oral drugs.

Prevalence and traditional management of diabetes mellitus in the Guinean urban and rural areas

K. Oulare[1], M. Donzo[2], F. Keita[2], A.D. Diallo[2], W. Bah[2], M. Traore[2], M.S. Traore[1], F.B. Magassouba[1], A.M. Balde[1]

[1] *Research and Valorisation Center on Medicinal Plants, Phamacognosy, Dubreka, Guinea*

[2] *University Julius Nyerere of Kankan, Biology, Kankan, Guinea*

Aims: To determine the prevalence of diabetes mellitus in urban and rural areas in Guinea. To evaluate the use of traditional medicine in the treatment of diabetes.

Methods: A transversal study was conducted through 510 inhabitants of both urban and rural areas. An ethnobotanical investigation was carried out by the Research and Valorisation Centre of Medicinal Plants of Dubreka (Guinea) on the basis of validated questionnaires.

Results and discussion: The prevalence of diabetes mellitus was quiet higher in the urban area of Siguiri (13,70% ; 34/248) than that of the rural area in Kankan (5,72% ; 15/262). Through an ethnobotanical investigation, 67 traditional healers (8 women and 59 men) were contacted and 28 of indigenous plant species were collected. From these, 23 were botanically determined. The most cited ones being Combretum micranthum G. Don, Xylopia aethiopica (Dunal) A. Rich, Piliostigma thonningii (Schum.) Milne-Redhead. Among these, "Fadakada" a mixture recipe of two plants was selected and submitted to an ethnotherapeutical evaluation in 31 patients. The oral administration of the recipe during 7 days led to a significant decrease (42.29 mg/dl; $p<0.0002$) of the glycemy; any significant side effects were recorded and the clinical signs were improved.

Conclusion: These preliminaries results well supported the traditional antidiabetic use of "Fadakada". Biological; phytochemical and clinical investigations are in progress.

Role of faradism for diabetic foot pain syndrome - a clinical evaluation

Z. Uddin[1], M. Islam[1], S. Islam[2], U. Zaman[3]
[1] *Bangladesh Institute of Health Sciences, Physiotherapy, Dhaka, Bangladesh*
[2] *Bangladesh Institute of Health Sciences, Public Health Disciplines, Dhaka, Bangladesh*
[3] *Center for Rehabilitation of the Paralyzed, Physiotherapy, Dhaka, Bangladesh*

Background and objectives: Faradic current has been used in medical science since the period of early development in electro-analgesia. Foot burning and pain syndromes are common feature of diabetic neuropathy among uncontrolled diabetic patients. Peripheral micro-circulatory problem causes peripheral neuropathy that forms into foot burning sensation and pain. Intermittent faradism (faradic current therapy) causes peripheral vasodilatation, increased muscular pumping activity and enhances soothing effect on nerve endings and hypoalgesia. Aim of our study is to find out the clinical efficacy of faradism for diabetic foot pain syndrome sufferers.
Methods: An experimental clinical study was done among 20 foot burning sufferers. Mean age 55.8 years (SD=11.79), sex ratio, M: F= 7:13. Patients were primarily selected (excluded foot ulcer) and referred to the physiotherapy department by the medical officer. Then they were assessed and explained about the study protocol. After considering ethical issues and inform consent the patients were assessed with the questionnaire sheet. All patients were treated by intermittent faradism for 10 minutes per session for 20 days. Intermittent mode selected as 5-second pulse with 2-second rest. Footbath technique applied for both feet, separately in different plastic bowl as single pole method of each foot immersed under water. Intensity was selected as maximum as individual patient can tolerate. After successfully completed 20 session of treatment they were re-assessed by the questionnaire sheet. Then both data were collected for statistical analysis. Basically we had used the Numeric rating Scale (NRS) of pain; also we had calculated 'pain hours/day' and 'pain days/week' to quantify pain.
Results: Mean state of pain hours per day was; before treatment=18.50 (SD=7.53) and after treatment=9.10 (SD=7.43). Mean state of pain days per week was; before treatment=7.00 (SD=0.00) and after treatment=6.86 (SD=0.54). Mean pain score in NRS was; before treatment=5.37 (SD=1.38) and after treatment=3.16 (SD=1.26).
Conclusions: Faradism applied as foot bath technique is effective for diabetic foot pain syndrome in our small scale, limited study. We need some good quality of RCT type double blind or placebo controlled trial study in a large scale subjects to realize the actual efficacy of faradism in diabetic foot pain syndrome.

Anti-diabetic effect of Korean traditional Baechu (Chinese cabbage) kimchi in a type 2 diabetes model of rats

M.S. Islam[1], H. Choi[2]
[1] *University of KwaZulu-Natal (Westville Campus), Department of Biochemistry, Durban 4000, South Africa*
[2] *Seoul National University, Department of Food and Nutrition, Seoul 151-742, Korea*

Aims: The present study was investigated to study the anti-diabetic effects of Korean traditional Baechu (Chinese cabbage) kimchi in a type 2 diabetes model of rats.
Methods: Five-week-old male SD rats were fed a HF-diet for 2 weeks then divided into 4 groups namely: Normal Control (NC), Diabetic Control (DBC), Kimchi Low (KML, 0.5%), and Kimchi High (KMH, 2.0%) groups. Diabetes was induced by an injection (i.p.) of STZ (40 mg/kg BW) in all groups except the NC group.
Results: After 4 weeks feeding of experimental diets, serum insulin concentrations and pancreatic beta cell functions were increased and HbA1c level was decreased in the kimchi fed groups compared to the DBC group, when significant ($P < 0.05$) difference was observed only in the KMH group for serum insulin concentration. Although lower fasting blood glucose and better glucose tolerance were observed in the KMH group compared to the DBC and KML groups, differences were not significant. Blood glycated hemoglobin (HbA1c), serum lipid profile and liver glycogen were not influenced by kimchi-containing diets.
Conclusion: Data of this study suggest that dietary Baechu kimchi has some anti-diabetic effects even when fed with a HF-containing diet.

Medicinal plants used by alternative medicinal practitioners of Rajshahi district, Bangladesh to treat diabetes and secondary infections

M. Mollik[1], M.T. Islam[1], M.M. Rahman[1], M.J. Islam[1], M.O. Faruque[1], M.M. Hasan[1], R. Jahan[1], M. Rahmatullah[1]
[1] *University of Development Alternative, Biotechnology & Genetic Engineering, Dhaka, Bangladesh*

Diabetes mellitus (DM) and secondary infections arising out from DM are common afflictions affecting millions of people in today's world. The disease is characterized by abnormal insulin secretion and consequent hyperglycemia. Allopathic medicine does not provide a complete cure for the disease. On the other hand, alternative medicinal practitioners in many countries of the world treat this ailment with formulations prepared from plants and these formulations are often claimed to completely cure DM. There is, therefore, at present a world-wide interest in medicinal plants for treatment of DM. In Bangladesh, alternative medicinal practitioners of various districts treat DM with medicinal plants. The formulations and use of plants vary from district to district. The objective of this present study was to conduct an ethnomedicinal survey amongst the alternative medicinal practitioners of Rajshahi district, Bangladesh to collect information on medicinal plants and formulations used to treat DM. Interviews were conducted with the help of a semi-structured questionnaire and plant specimens as pointed out were collected and identified at the Bangladesh National Herbarium. 17 plant species were found to be used to treat DM, while 1 plant species was used to treat secondary infections arising out from DM. The 17 plant species (with family name given in parenthesis) included Mangifera indica (Anacardiaceae), Vinca rosea (Apocynaceae), Cocos nucifera (Arecaceae), Wedelia chinensis (Asteraceae), Coccinia cordifolia (Cucurbitaceae), Caesalpinia bonduc (Fabaceae), Cassia occidentalis (Fabaceae), Tamarindus indica (Fabaceae), Lagerstroemia speciosa (Lythraceae), Punica granatum (Lythraceae), Azadirachta indica (Meliaceae), Stephania japonica (Menispermaceae), Ficus racemosa (Moraceae), Zea mays (Poaceae), Murraya koenigii (Rutaceae), Abroma augusta (Sterculiaceae), and Clerodendrum viscosum (Verbenaceae). The seeds of Swietenia mahagoni (Meliaceae) were administered with the bark of Anthocephalus chinensis (Rubiaceae) and leaves of Cyperus rotundus (Cyperaceae) by the alternative medicinal practitioners to treat secondary infections arising from DM. The above-mentioned plants hold good potential for the treatment of DM since a perusal of the scientific literature showed hypoglycemic activity to be present in extracts of plant parts of a number of the above-mentioned plant species.

[2] *S N Medical College, Physiology, Agra, India*
[3] *Jain Medical Institute, Medicine, Dehradun, India*
[4] *Benares Hindu University, Psychiatry, Varanasi, India*

Aims:
To evaluate the effect of defined yoga exercises in diabetes on glycemic control, blood pressure, lipid profile, BMI, and requirement of oral hypoglycaemic agents and/or Insulin.
Methods: 77 consecutive diabetes mellitus subjects on standard diabetes management were randomly allocated to a yoga group (41 subjects) and a control group (36 subjects).
41 patients in the study group were performing supervised yoga exercise protocol while the controls were not on this supervised protocol.

1. Health rejuvenating exercises (5min)
2. Body posture (asanas)
   a. Surya namaskar/ parmeshwar vandana (3min)
   b. Paschimottanasana (3min)
   c. Ardhamatsyasana (3min)
   d. Uttanadsana (3 min)
   e. Sarwangasana (3min)
   f. Matsyasana (3min)
3. Abdomen exercise (7min)

4. On every alternate day either
    a. Relaxation exercises (Kayotsarga) (30 min) or
    b. Preksha meditation including prayanama and Anupreksha (30min) along with relaxation exercises.

These patients were asked to come for yoga exercises for at least 5 times a week for 3 months duration and were compared with 36 controlled group patients who received standard diabetic therapy without yoga.

Results: Glycemic control in the control group improved, the HbA1c decreasing from 9.16±0.82 to 8.22±1.13, and Fasting blood sugar (FBS) declined from 190.39±29.43 to 172.21±27.13 mg%. In the yoga group these improved,with HbA1c 9.35±1.02 to 8.58±0.97 and FBS from 183.9±39.26± to 150.66±34.21 mg%. The initial values between the 2 groups were not significantly different but the final values in the 2 groups were statistically significantly different ($p<0.05$ for HbA1c and < 0.001 for FBS).

Thus the yoga group showed significant improvement in the mean post treatment levels of HbA1c and FBS both in comparison to the mean pre treatment values as well as in comparison to post treatment control values suggesting a highly beneficial effect of yoga in diabetic management.

Conclusion: Supervised Yoga improves glycaemic control in diabetes and is therefore advisable.

Post marketing surveillance of ANGIPARS

B. Larijani[1], M. Ebrahimi[1], S. Bakhshayeshi[1], R. Heshmat[1]
[1] Tehran University of Medical Sciences, Endocrinology and Metabolism Research centre, Tehran, Iran

Aim: One of the most important complications of diabetes is foot ulcers with a life time risk of 15% among diabetics. With the growing prevalence of diabetes worldwide, its related complications bound to increase, which not only results in major economic consequences for the patients but have a significant burden on public health which highlights the necessity for prevention and timely treatment of diabetic foot ulcers. The main objectives of this study was to evaluate the effect of oral and intravenous application of ANGIPARS, a novel compound applied in treatment of diabetic foot ulcers, on ankle brachial Index (ABI) and toe pressure and wound temperature in diabetic foot ulcers.

Methods: A total of 75 diabetic patients aged between 18-75 with foot ulcer who had no signs of wound infection were enrolled in this study. A basal toe pressure, ABI and wound temperature was measured and routine hematological and biochemistry tests plus erythrocyte sedimentation rate (ESR) and serum creatinine were performed. Six and 12 weeks after simultaneous application of oral and topical forms of ANGIPARS, mentioned parameters were evaluated again and analysis was carried out using standard methods.

Results: The mean age of the participants was 56.77 ± 9.7. The mean surface area of the ulcers were 6.05± 11 cm^2 at the baseline and 1.17 ± 3.5cm^2 after3 month of therapy showing a considerable decrease. A significant rise in ABI ($p<0.05$) was observed after 6 weeks of therapy. No significant changes were observed in toe pressure or wound temperature after 3 months. The results also showed a significant fall in ESR and serum calcium levels. No significant side effects or toxicity was reported by the participants during the course of the study.

Conclusion: This study showed the immense effect and safety of ANGIPARS on treatment of diabetic foot ulcers.

Alternative medicine use and self-care habits in diabetes mellitus

A. Ogbera[1], A. Eregie[2], F. Adeleye[3], S. Chinenye[4]
[1] Lagos State University Teaching Hospital, Medicine, Lagos, Nigeria
[2] University of Benin Teaching Hospital, Medicine, Benin, Nigeria
[3] Lagos State Univeristy Teaching Hospital, Medicine, Lagos, Nigeria
[4] University of PortHarcourt Teaching Hospital, Medicine, Port Harcourt, Nigeria

Aims: Self-care in patients with diabetes mellitus includes self home glucose monitoring (SHGM), drug compliance and use of complementary and alternative therapies (CAM). This study aims to document self-care practices in people with DM.

Methods: This was a cross-sectional questionnaire survey involving 262 patients with DM attending a tertiary care centre in Lagos, Nigeria. Biodata, duration of DM, usage of home glucose monitors and blood pressure monitors, adherence to medications and CAM usage were documented.

Results: There were 165 (63%) females and 97 (37%) males with a total mean age (SD) of 60 (10.7) years. CAM users made up 122 (47%) of the study population. CAM users were significantly older than non-CAM users (61.6 (9) vs 58.3 (11), p= 0.006). The herbal products used included bitter leaf (vernonia amygdalina), aloe vera, garlic, ginger, and native herbs. Optimal blood glucose and blood pressure control were comparable in CAM and non-CAM users. SHGM, drug compliance, insulin usage, educational status and duration of DM were also comparable in both groups.

Discussion/conclusion: CAM utilization is an important facet of self care in our patients with DM that needs to be studied.

Medicinal plants used to treat diabetes in Bogra and Pabna districts of Bangladesh

M. Mollik[1], R. Jahan[1], A.I. Hassan[1], M.S. Hossan[1], B. Agarwala[1], M.N. Hasan[1], M. Rahmatullah[1]
[1] University of Development Alternative, Biotechnology & Genetic Engineering, Dhaka, Bangladesh

Bangladesh is a small country but with a population of more than 150 million. The rural population as well as a segment of the urban population relies on traditional medicinal practitioners (Kavirajes) as their primary health-care providers. It has been estimated that as high as 3.8% of the rural population and a greater percentage of the urban population suffers from diabetes mellitus (DM). They are administered to by the Kavirajes, who depend on various formulations of medicinal plants as treatments. Since DM cannot be cured by modern allopathic medicine, it was of interest to survey the medicinal plants used by the Kavirajes as remedy for this ailment. The objective of the present study was to conduct an ethnomedicinal survey amongst the Kavirajes of two central districts of Bangladesh to know more about the medicinal plants in usage to treat DM. Surveys were conducted through personal interviews and with the help of a semi-structured questionnaire. All plant specimens as pointed out were pressed, dried and brought to the Bangladesh National Herbarium for complete identification and where voucher specimens were also deposited. A total of 22 plant species were obtained from the Kavirajes used in the treatment of DM. These plant species (with family names given in parentheses) included Cassia occidentalis (Fabaceae), Coccinia cordifolia (Cucurbitaceae), Ageratum conyzoides (Asteraceae), Alpinia nigra (Zingiberaceae), Aegle marmelos (Rutaceae), Morinda citrifolia (Rubiaceae), Abroma augusta (Sterculiaceae), Ficus hispida (Moraceae), Pongamia pinnata (Fabaceae), Caesalpinia bonduc (Fabaceae), Phyllanthus emblica (Euphorbiaceae), Azadirachta indica (Meliaceae), Andrographis paniculata (Acanthaceae), Phyllanthus niruri (Euphorbiaceae), Cinnamomum tamala (Lauraceae), Cotula hemisphaerica (Asteraceae), Anthocephalus chinensis (Rubiaceae), Cassia angustifolia (Fabaceae), Syzygium cumini (Myrtaceae), Momordica charantia (Cucurbitaceae), Alstonia scholaris (Apocynaceae), and Ficus benghalensis (Moraceae). Of the plants obtained in the present survey, modern scientific studies have established the hypoglycemic potential of whole plant or plant parts of Coccinia cordifolia, Aegle marmelos, Morinda citrifolia, Pongamia pinnata, Phyllanthus emblica, Azadirachta indica, Andrographis paniculata, Phyllanthus niruri, Syzygium cumini, Momordica charantia, and Ficus benghalensis. Since allopathic medicine has no cure for DM, it is of interest to conduct studies on the anti-diabetic plants found in the present survey for their potential in preventing or curing DM.

Medicinal plants used by alternative medicinal practitioners of Nilphamari, Chuadanga and Magura districts, Bangladesh to treat diabetes mellitus

M. Mollik[1], A.I. Hassan[1], T.K. Paul[1], F.I.S. Enam[1], R. Jahan[1], M. Rahmatullah[1]
[1] University of Development Alternative, Biotechnology & Genetic Engineering, Dhaka, Bangladesh

Diabetes mellitus (DM) is a disease which affects a sizeable segment of the population of Bangladesh. Alternative medicinal practitioners (AMPs) form the primary health-care providers in Bangladesh. They use a variety of medicinal plants to treat DM, which can vary considerable between AMPs of different districts. The objective of this present study was to conduct an ethnomedicinal survey amongst the AMPs of Nilphamari, Chuadanga and Magura districts, Bangladesh to collect information on medicinal plants used to treat DM. The

importance of this type of survey lies in the fact that allopathic medicine has no known cure for DM. As a consequence, there is renewed interest in medicinal plants for isolation of compounds, which can prove effective in treating DM. Interviews were conducted of the AMPs and plant specimens as pointed out be them were collected and identified at the Bangladesh National Herbarium. The names of 20 plant species were collected, which are used by AMPs of these three districts to treat DM. These plant species (with family name given in parenthesis) included Cocos nucifera (Arecaceae), Phoenix sylvestris (Arecaceae), Tecoma gaudichaudi (Bignoniaceae), Carica papaya (Caricaceae), Coccinia cordifolia (Cucurbitaceae), Momordica charantia (Cucurbitaceae), Phyllanthus niruri (Euphorbiaceae), Cajanus cajan (Fabaceae), Cassia occidentalis (Fabaceae), Lagerstroemia speciosa (Lythraceae), Ficus racemosa (Moraceae), Psidium guajava (Myrtaceae), Syzygium cumini (Myrtaceae), Averrhoa carambola (Oxalidaceae), Aegle marmelos (Rutaceae), Citrus grandis (Rutaceae), Capsicum annum (Solanaceae), Abroma augusta (Sterculiaceae), Clerodendrum viscosum (Verbenaceae), and Curcuma longa (Zingiberaceae). A number of these plants are also used by AMPs of other regions of Bangladesh suggesting that the plants could be potentially important for isolation of lead compounds for treatment of DM.

P-1030

Medicinal plants used by the Garo tribe, Bangladesh to treat diabetes mellitus

M. Mollik[1], A.I. Hassan[1], M.B. Foisal[1], I.J. Mukti[1], A.K.M.F. Haque[1], K. Parvin[1], M. Rahmatullah[1]

[1] University of Development Alternative, Biotechnology & Genetic Engineering, Dhaka, Bangladesh

The Garo tribe inhabits the north-central districts of Tangail, Netrakona and Mymensingh districts of Bangladesh. They have their own traditional medicinal practitioners, who use medicinal plants for treatment of their various ailments. Diabetes mellitus (DM) is prevalent amongst the rural and urban population of Bangladesh including tribal people, and this ailment cannot be cured by modern allopathic medicine. The objective of the present study was to conduct an ethnomedicinal survey among the Garo tribal medicinal practitioners to find out about plant species used for treatment of DM. Interviews were conducted of the Garo practitioners with the help of an interpreter, and plant species as pointed out by the practitioners were collected and identified at the Bangladesh National Herbarium. It was observed that a total of 17 plant species were used by Garo practitioners to treat DM. These plant species (with family name given in parenthesis) included Cassia occidentalis (Fabaceae), Tamarindus indica (Fabaceae), Cinnamomum tamala (Lauraceae), Cajanus cajan (Fabaceae), Clerodendrum viscosum (Verbenaceae), Punica granatum (Lythraceae), Abroma augusta (Malvaceae), Syzium cumini (Myrtaceae), Psidium guajava (Myrtaceae), Ficus racemosa (Moraceae), Moringa oleifera (Moringaceae), Manihot esculenta (Euphorbiaceae), Tinospora cordifolia (Menispermaceae), Ocimum sanctum (Lamiaceae), Nymphaea nouchali (Nymphaeaceae), Solanum torvum (Solanaceae), and Achyranthes aspera (Amaranthaceae). It was also observed in the present survey that a high degree of patient satisfaction exists among those receiving medicinal plant treatment for DM. It is also to be noted that a number of the above-mentioned plant species like Tamarindus indica and Syzygium cumini have been reported in scientific studies to possess considerable hypoglycemic potential. The other plant species need to be studied scientifically for their potential to treat DM.

Hypoglycemic effect of aqueous extract of Trichosanthes dioica in normal and diabetic rats

L. Bairy[1], S. Adiga[1], A. Meharban[1], I.S.R. Punita[2]

[1] Kasturba Medical College, Pharmacology, Manipal, India

[2] Manipal College of Pharmaceutical Sciences, Pharmacology, Manipal, India

Background: Trichosanthes dioica is used to treat diabetes mellitus, epilepsy, alopecia, and skin disease in folklore medicine. The extract of leaves of the plant is used in diabetes mellitus but there is no scientific studies reported.
Aims: To study the effect of Trichosanthes dioica on serum glucose level in glucose loaded, normal and hyperglycemic rats.
Settings: Kasturba Medical College, Manipal, Karnataka State, India.
Design:Experimental
Methods and Materials: The aqueous extract of leaves of Trichosanthes dioica were compared with glibenclamide for their influence on fasting blood sugar in glucose loaded, normoglycemic and streptozotocin induced (45mg/kg ip) hyperglycemic rats.
Statistical analysis: The data was analyzed by one way ANOVA followed by Scheffe's post hoc test.
Results: In glucose loaded rats, normal rats and hyperglycemic rats the aqueous extract at both the doses (800mg/kg/p.o and 1600mg/kg/p.o) reduced blood glucose significantly when compared to control but it was not as effective as glibenclamide.
Conclusion: The aqueous extract of Trichosanthes dioica with its beneficial effects on blood sugar could serve as good adjuvant to other oral hypoglycemic agents.

A randomized placebo controlled trial of herbal medicine (Sugaradik) in the treatment of type 2 diabetes

S. Goyal[1], R.P. Agrawal[1], S. Jain[1], A. Chopra[1], R. Dogra[1], N. Sharma[2], N. Gupta[3], V. Agrawal[1], N. Mohta[1]

[1] Diabetes Care & Research Centre, Medicine, Bikaner, India

[2] B.R.Nahta College of Pharmacy, Pharmacy, Mandsaur, India

[3] Jaipur Dental College, Dental, Jaipur, India

Aim: This study was undertaken to evaluate the safety and effectiveness of polyherbal powder (Sugaradik) in achieving glycemic control in newly diagnosed type 2 diabetics.
Methods: Study design: A randomized double blind placebo controlled study. Eighty newly diagnosed patients of type 2 diabetes were selected after meeting inclusion and exclusion criteria. Patients were randomly divided into two groups. One group received drug and other group received placebo bearing a distinctive code number. Anthropometric parameters and HbA_1c were performed initially as well as after 3 months of treatment period. Fasting blood sugar and blood pressure were recorded weekly.
Results: After 3 months of treatment with polyherbal powder (Sugaradik) there was a significant improvement in BMI (24.48±0.64 to 25.44±0.62), systolic blood pressure (136.05±3.30 to 126.42±1.51 mmHg) and fasting blood sugar (233.03±8.81 to 136.16±4.96 mmHg; $p<0.001$). There was a significant reduction in HbA_1c (8.39±0.30 to 6.37±0.10; $p<0.001$). No adverse effects were observed in this trial.
Conclusion: Polyherbal preparation of 10 classic herbs appears to be effective in controlling glycemia. Sugaradik seems to be a safe drug and an effective oral agent in the management of type 2 diabetes.
Statistical methods: Student's 'T' test.

A biochemical investigation of Tulbaghia Violacea's anticoagulant and antidiabetic properties

C. Davison[1], C.L. Frost[1], R.A. Levendal[1]

[1] Nelson Mandela Metropolitan University, Biochemistry and Microbiology, Port Elizabeth, South Africa

Secondary metabolites derived from plants, especially those used by traditional healers, are in the forefront of new drug development to combat diseases such as cancer and diabetes. Garlic is employed in indigenous medicine all over the world for the treatment of a variety of diseases. Dietary garlic has been recognized for its beneficial health effects. In particular, garlic consumption has been correlated with (i) reduction of risk factors for cardiovascular diseases and cancer, (ii) stimulation of immune function, (iii) enhanced detoxification of foreign compounds (iv) hepatoprotection, (v) antimicrobial effect and (vi) antioxidant effect, and most importantly its hypoglycemic and anticoagulant properties. Due to these beneficial properties, garlic and its closely related genera (which includes Tulbaghia Violacea), may be useful as coadjuvant therapy in the treatment of type 2 diabetes and some of its physiological complications. The aim of this study is to determine the anticoagulant and antidiabetic properties of Tulbaghia Violacea. Extraction procedures for both protein and sulfur organic compounds have been performed on the roots, leaves, bulbs, seed and flowers. Platelets were also exposed to the extracts to determine their effects upon platelet aggregation, adhesion and protein secretion. Of the above mentioned extracts, the organic bulb extract has shown

the highest potential at inhibiting platelet aggregation and adhesion. Similarly this extract was able to improve glucose-stimulated insulin secretion in SNI-1 pancreatic ß- cells.

Prevalence and predictors of nonalchoholic fatty liver disease in type 2 diabetic patients

H. Shahbazian[1], J. Hashemi[1], A. Alizadeh[1], M. Samimi[1]
[1] Ahvaz Jundishapour University of Medical Sciences, Diabetes Reaserch center, Ahvaz, Iran

Non-alcoholic fatty liver disease (NAFLD) is common in patients with type 2 diabetes and its clinical diagnosis is based on ultrasonography. The aim of this study was to determine the prevalence of fatty liver and its predictive factor in type 2 diabetes patients reffered to Ahvaz university diabese clinic.
Material and methods: The study was performed on 272 consecutive nonalcohol and hepatitis B and C virus-negative type 2 diabetes patients, attending Ahvaz university diabetes clinic. All of them underwent a complete clinical and biochemical work up, including demographic and anthropometric factors, lipid profiles, fasting plasma glucose, glycated hemoglobin (HbA1c), liver transaminases and alkaline phosphatase. Liver ultrasonography was done for each patient.
Results: Patients' average age was 51±10 years. Sixty-eight percent of patients were female. 189 patients (70%) ultrasonographically diagnosed as NAFLD. Average body mass index (BMI) was higher in NAFLD patients than normal group (28.7±4.6 kg/m2 vs. 25.0±3.8 kg/m2, P=0.00). Among age, gender, duration of diabetes, glylated hemoglobin,serum level of triglyceride, total cholesterol, creatinine, liver enzymes and body mass index (BMI), the best predictor of NAFLD in type 2 diabetic patients was BMI [odds ratio=1.26, 95% CI: 1.16 to 1.37] and serum triglyceride level was the next predicting factor after BMI [odds ratio=1.46, 95% CI: 1.01 to 2.11].
Conclusion: The findings of this study demonstrate that the nonalchoholic fatty liver has high prevalence in type 2 diabetes patients, and BMI and serum triglyceride can be considered as two independent predictors of NAFLD in these patients.

Association between lipid profile and coronary artery disease in type 2 diabetic patients

F. Cañizo-Gomez[1], C. De Gorospe-Perez-Jauregui[1], I. Moreno-Ruiz[1], A. Segura-Galindo[1], T. Gonzalez-Losada[1], B. Silveira Rodriguez[1]
[1] Hospital Infanta Leonor, Endocrinology, Madrid, Spain

Various risk factors act synergistically for the development of macrovascular complications, such coronary artery disease (CAD), in type 2 diabetes mellitus (T2DM) patients. The contributions of risk factors have yet to be clearly identified and quantified, but diabetic dyslipidaemia has specific importance.
Aim: To investigate the association of dislipidaemia with CAD in a T2DM population.
Methods: Cross sectional study in 874 patients with T2DM who visited Montes de Barbanza public health center, a specialized secondary referral center, which provides services to the 31 urban district of Madrid (Pueblo de Vallecas), Spain between April and September 2007 for a routine follow-up. In addition to routine tests, total cholesterol (TCh), HDL-cholesterol (HDL-Ch), and triglycerides (TG) were measured and LDL-cholesterol (LDL-Ch) was calculated (Friedewald) in all of the subjects after an overnight fast. The selected patients were evaluated for presence of CAD using standard techniques. Estimated values of TCh> 240 mg/dl; TG> 150 mg/dl, HDL-Ch< 40 mg/dl and LDL-Ch> 130 mg/dl were considered as abnormal. Multiple regression analysis was done to evaluate the association of CAD with abnormal lipid profile. A level of P<0.05 was considered statistically significant (SPSS, v. 13.0).
Results: The mean age of the study group was 65.6 ± 12.6 years with average duration of diabetes 13.0 ± 10.2; 44% were male and 17% (166 patients) had previous CAD. Data regarding lipid profile showed that out of 166 patients with CAD, TCh >240 mg/dl was seen in 13% of patients, LDL-Ch> 130 mg/dl in 13,1%, HDL< 40 mg/dl in 27,9%, and TG> 150 mg/dl in 17,6%. Regression analysis revealed an association of high TCh (P=0.015) and LDL-Ch (P=0.033), and low HDL-Ch (P=0.001) with CAD.
Conclusions: The present study has shown that the most common lipid abnormality in T2DM patients with CAD of the population studied was low HDL-Ch. Moreover the study showed a strong correlation of low HDL-Ch with CAD. Hence, appropriate preventive and new treatment strategies to increase the HDL-Ch should be considered timely in T2DM patients with CAD.

A study of serum lipoprotein (a) and diabetic nephropathy in Chinese hospitalized type 2 diabetic patients

J. Pan[1], Y. Bao[1], L. Zhang[1], H. Yu[1], W. Jia[1]
[1] Shanghai Jiao Tong University Affiliated Sixth People's Hospital, Endocrinology and Metabolism, Shanghai, China

Aims: To examine the relationship of serum lipoprotein (a) [Lp (a)] and diabetic nephropathy in Chinese hospitalized type 2 diabetes patients.
Methods: A total of 1238 (725 men and 513 women;aged 58.1±13.9 years) hospitalized type 2 diabetic patients were selected based on inclusion criteria. Normoalbuminuria (n=929), microalbuminuria (n=229) and macroalbuminuria (n=80) were defined as urinary albumin excretion rate (UAER) of <30mg/24h, 30mg-300mg/24h and >300mg/24h, respectively. Lipid profile, blood glucose, serum creatinine and hemoglobin A1c (HbA1c) were measured. Glomerular filtration rate (GFR) was estimated by the simplified MDRD equation.
Results: (1) There was no significant difference of serum Lp (a) level among different age groups. (2) Lp (a) of macroalbuminuria group was significantly higher than that of normoalbuminuria and microalbuminuria group (p<0.05). However, no significant difference was observed between patients with normoalbuminuria and microalbuminuria. (3) For quartiles of Lp (a), UAER and GFR showed significant association with Lp (a) (p<0.05). (4) Lp (a) positively correlated with total cholesterol (TC), low density lipoprotein cholesterol (LDL-C) and UAER (r=0.152, 0.169, 0.18, p<0.01) and negatively correlated with GFR (r=-0.061, p<0.01). Significant association with Lp (a) and UAER was shown after adjusting for GFR. (5) Multiple stepwise regression showed systolic pressure, Lp (a), LDL-C, GFR and age were independent risk factors for UAER.
Conclusions: Lp (a) level was associated with the progression of diabetic nephropathy regardless of age, diabetes duration and glycemic control.

Gender-based comparisons of dyslipidemia in urban Indian diabetes patients, with and without metabolic syndrome

S.S. Hoskote[1], S.P. Surana[2], D.B. Shah[2], K. Gala[2], S. Susheja[2], V.R. Iyer[1], N. Gill[2], V. Panikar[2], S.R. Joshi[1]
[1] Joshi Clinic, Endocrinology, Mumbai, India
[2] KJ Somaiya Medical College, Medicine, Mumbai, India

Aim: Dyslipidemia is associated with metabolic syndrome (MS) and diabetes mellitus (DM). The Asian Indian population has a high prevalence of MS and type 2 DM. Data is lacking on the characteristics of dyslipidemia in this population. We studied gender-based differences in various parameters between type 2 DM patients with and without MS.
Methods: In all, 21292 patient records were prospectively analyzed from our clinics in Mumbai. Selected patients were over 20 years of age, had complete records for analysis and did not have type 1 DM or primary dyslipidemia. Patients being treated for hypertension or dyslipidemia were also included. MS was defined using the National Cholesterol Education Program Adult Treatment Panel III criteria. Based on this, a total of 4963 patient records were included. Of these, 3817 patients had DM and MS (1936 males; 1881 females), while 1146 patients had DM but no MS (880 males; 266 females). The Student's t-test was used to compare groups. P<0.05 was taken as significant.

>

Results:

Table 1: Prevalence of MS components

	DM with MS		DM without MS	
	Males	Females	Males	Females
Number	1936	1881	880	266

Levels of lipoprotein (a) in the adult population of the municipality of Maracaibo, Venezuela

V. Bermúdez[1], C. Colmenares[1], E. Rojas[1], D. Rodríguez[1], M. Pirela[1], J. Faría[1], R. Añez[1], L. Suárez[1]
[1] Endocrine-Metabolic Research Center "Dr. Félix Gómez", Faculty of Medicine University of Zulia, Maracaibo, Venezuela

Introduction and objectives: Lipoprotein (a) [Lp (a)] is an independent risk factor for cardiovascular disease. The aim of this study was to determine the levels of Lp (a) in the adult population of Maracaibo Municipality and its relationship to personal and family pathological history.
Materials and methods: A descriptive, transversal study was held on 1335 individuals on which complete clinical history was performed and determined glycaemia, insulin, lipid profile and Lp (a). The normal distribution of the variables was corroborated by the Geary test, and the results expressed as mean ±standard deviation, given as reference values for our population those found between the percentiles 10 and 90.
Results: the population mean of the Lp (a) levels was 27.67 ±14.52 mg/dL (upper limit 28.67 mg/dL; lower limit 26.67 mg/dL, 99% confidence interval) [male (28.14 ±14.79mg/dL) and female (27.10 ±14.19 mg/dL)], with no significant difference (p>0.05). Most of the population, presented concentrations of Lp (a) in a range of 10.70 mg/dL (percentile 10) and 47.39 mg/dL (percentile 90). Individuals with and without family history of angina pectoris showed a mean Lp (a) of 27.71 ±14.60 mg/dL and 24.55 ±8.23 mg/dL (p= 0.02) respectively; vascular disease of the brain: 31.93 ±13.39 mg/dL and 27.63 ±14.55 mg/dL (p <0.01), myocardial infarction: 28.00 ±13.95 mg/dL and 27.36 ± 15.12 mg/dL; high blood pressure: 27.39 ±14.28 mg/dL and 28.34 ±15.10 mg/dL. Patients with and without a personal history of myocardial infarction showed a mean Lp (a) 33.88 ±16.70 mg/dL and 27.62 ±14.51 mg/dL respectively; high blood pressure: 29.31 ±14.67 mg/dL and 27.30 ±14.48 mg/dL; angina pectoris: 24.55 ±8.23 mg/dL and 27.71 ±14.60 mg/dL (p<0034); vascular disease of the brain: 31.93 ±13.39 mg/dL and 27.63 ±14.55 mg/dL.
Conclusions: these results are consistent with international studies which consider the hyperlipoproteinemia (a) where the value exceeds 30mg/dL. We consider extreme values, concentrations of Lp (a) less than 10.70 mg/dL and more than 47.39 mg/dL. We suggest that Lp (a) could play an important role in the incidence of angina pectoris and stroke.

Atherogenic profile in diabetes mellitus - a Nigerian report

A. Ogbera[1], O. Fasanmade[2], S. Chinenye[3], A. Akinlade[1]
[1] Lagos State University Teaching Hospital, Medicine, Lagos, Nigeria
[2] Lagos University Teaching Hospital, Medicine, Lagos, Nigeria
[3] University of Port Harcourt Teaching Hospital, Medicine, Port Harcourt, Nigeria

Aims: Diabetes mellitus (DM) is a disorder that is often associated with cardiovascular events and underlying lipid abnormalities. This report seeks to determine the atherogenic profile of in DM.
Methods: A total of 600 patients with DM aged between 22 – 79 years were evaluated for lipid abnormalities. The anthropometric indices, glycosylated haemoglobin, and pattern of DM treatment were noted. Total cholesterol (TCHOL), triglyceride (TG), high density lipoproteins (HDL) and low density lipoproteins (LDL) cholesterol were measured. Test statistic used included student's t test and X^2.
Results: The mean (SD) age and age range of the study subjects was 58 (10) years and 22-79 years respectively.The ratio of subjects with type 1 to 2 DM was 15:565. The prevalence of lipid abnormalities was 89%. The prevalence of elevated LDL-C, reduced HDL, and elevated TG were 74%, 53%, and 13% respectively. The prevalence of elevated TCHOL/HDL ratio was 56% with a female preponderance. There were notable gender, type of DM and BMI impact on TCHOL and LDL, TG and HDL respectively.
Conclusions: The prevalence of lipid abnormalities of Nigerian patients with DM is high and the pattern of abnormalities differ from what obtains elsewhere.

The efficacy and safety of rosuvastatin therapy in Korean dyslipidemic type 2 diabetes mellitus patients who can not reach the LDL cholesterol target at initial dosage of another LDL lowering agents

S.R. Kim[1], S.S. Lee[1], S.J. Yoo[1], S.K. Kang[1]
[1] Catholic University, Dept. of Internal Medicine, Kyonggi-Do, Korea

Background: Elevated serum cholesterol level induces cardiovascular disorder. Cardiovascular disease is the major cause of morbidity in patients with type 2 diabetes mellitus and hypercholesterolemia. But many type 2 diabetes mellitus patients do not reach the lipid treatment target. Rosuvastatin is 3-hydroxy-3-methylglutaryl coenzyme A (HMG-CoA) reductase inhibitor, whichis highly effective in lowering total and low-density lipoprotein (LDL) cholesterol. This study was designed to evaluate efficacy and safety of 6-week therapy with rosuvastatin in Korean patients with Diabetes mellitus and hypercholesterolemia.
Subjects and Methods: This study was a prospective, non-blinded, open-label, non-comparative phase 4 trial. A total of 181patients with diabetes mellitus and hypercholesterolemia (LDL cholesterol > 100 mg/dL), which can not show the effectiveness at initial dosage of another LDL lowering medicines were included. All patients were randomized to receive rosuvastatin 10 mg once a day for 6 weeks. Efficacy was determined by measuring percent changes of lipid parameter including LDL cholesterol, total cholesterol (TC), triglycerides (TG) and high-density lipoprotein (HDL) cholesterol from baseline at week 6.
Results: After 6 weeks, 10 mg of rosuvastatin significantly reduced LDL cholesterol level from baseline (from 127.37mg/dl to 83.54mg/dl, -33%, p <0.001), but not TC, TG and HDL cholesterol (-21%, 1% and 0%, respectively). 89.9% of patients (n=149) who failed to reduce LDL-cholesterol with another LDL lowering agents, reached LDL-cholesterol goals of NCEP ATP III guideline with rosuvastatin 10mg daily. During medication neither significant adverse events nor discomforts that lead to discontinuation of the drug has been observed.
Conclusion: This study indicates that 10 mg of rosuvastatin produces remarkable reductions in LDL cholesterol without adverse effect in Korean patients with diabetes mellitus and hypercholesterolemia. Rosuvastatin treatment was well tolerated. It should be prescribed to allow most patients to reach their NCEP target level. So, this result suggests that rosuvastatin is an effective drug for lowering LDL cholesterol in type 2 diabetes mellitus with hypercholesterolemia.

Effect of valsartan on circulating adiponectin level in type 2 diabetes mellitus patients with hypertension

S. Chang[1], J.H. Kim[1], E.K. Hong[2], J.M. Yu[2], K.A. Han[3], K.W. Min[3]
[1] The Catholic Univerity of Korea College of Medicine, Dept of Internal Medicine, Seoul, Korea
[2] Hallym University College of Medicine, Dept of Internal Medicine, Seoul, Korea
[3] Eulji University College of Medicine, Dept of Internal Medicine, Seoul, Korea

Aim: Angiotensin II receptor blocker has been shown to have beneficial effect on angiopathy of hypertension and glucose metabolism. Adiponectin is also known to have anti-atherogenic and anti-diabetic effect. We investigated the effect of valsartan on circulating adiponectin level and insulin sensitivity in type 2 diabetic patients with hypertension.
Methods: Total 91 (38 men, 53 women) type 2 diabetes patients with mild to moderate hypertension treated with valsartan 80 mg for 4 weeks. The dose was then raised to 160 mg and treatment was continued another 8 weeks. Blood pressure, circulating adiponectin and metabolic parameters were measured before and after treatment. Homeostatis model of assessment insulin resistance (HOMA-IR) was calculated for insulin sensitivity index.
Results: Valsartan treatment significantly decreased mean blood pressure (P<0.001) and increased circulating adiponectin level (P<0.05). There were no differences in metabolic parameter, including HOMA-IR, fasting glucose, insulin, HbA1c and lipid levels before and after treatment.
Conclusions: Our result indicated that valsartan increases the circulating adiponectin but did not change insulin sensitivity in type 2 diabetic patients with hypertension.

Hypertension characteristic in patients with metabolic syndrome

O.N. Korneeva[1], O.M. Drapkina[1], N.V. Korneev[2]
[1] I.M. Sechenov Moscow Medical Academy, Cardiology, Moscow, Russia
[2] N.N.Burdenko Central Military Clinical Hospital, Functional Diagnostic, Moscow, Russia

Background: Hypertension is feature of the Metabolic Syndrome (MS). However, the characteristics of the 24-hour ambulatory blood pressure monitoring (ABPM) in patients with MS are not so well known. Aim of this study was to investigate the clinical characteristics of hypertension in patients with MS by ABPM.
Methods: We studied 60 subjects with MS according to IDF criteria (36 men, mean age = 48±13 years, BMI = 33±5 kg/m2, waist circumference (men) = 114±11 cm, (women) = 109±10 cm) and 20 control hypertensive lean subjects. History, physical examination, ECG, ABPM, lipids, fasting glucose and insulin measurements were performed. All patients with MS were insulin resistant (mean HOMA-IR = 5.8±3.6). Hypertension were diagnosed in 88.3 % (n=53) patients with MS according to current guidelines. Non-dipping was defined as a less than 10% fall in systolic ABP from day to night. BP variability was evaluated as the standard deviation day and nighttime ABP.
Results: The characteristics of hypertension in patients with MS by ABPM were systolodiastolic hypertension daytime, systolic hypertension nighttime, high pulse pressure (PP), high "pressure-time index" (PTI) day and nighttime and prevalence of non-dipping status. Hypertensive patients with MS compared with control group had higher systolic ABP daytime (p = 0.028); higher PP (p = 0.00005); higher systolic PTI daytime (p = 0.006) and nighttime (p = 0.028); higher BP variability of systolic, diastolic day and nighttime ABP; impaired dipping status with 58% prevalence of non-dippers in hypertensive and normotensive patients with MS (p < 0.012).These results demonstrated possible links between insulin resistance and hypertension.
Conclusions: Our study has shown special characteristics of the ABPM in patients with MS that included high systolic ABP daytime, high PP, high systolic PTI, BP variability and prevalence of non-dippers.

Comparative study of telmisartan, ramipril and combination thereof in diabetes with nephropathy and hypertension

A.K. Gupta[1], D.K. Hazra[1], T.P. Singh[1], R. Bharti[2], P. Prakash[1], P. Agarwal[1], H. Prakash[1], S. Prabhu[1], B. Singh[1], V. Gupta[1]
[1] S N Medical College, Medicine, Agra, India
[2] S N Medical College, Pathology, Agra, India

Aims: To evaluate therapeutic efficacy of ramipril, telmisartan alone and in combination in the control of hypertension, microalbuminuria and overt proteinuria in diabetic nephropathy with hypertension.
Methods: 42 consecutive cases of diabetic nephropathy were selected who had serum creatinine levels < 3 mg% and good hyperglycaemia control and systolic BP between 100 and 210 mmHg, but excluding cases with malignant hypertension and renovascular hypertension.They were were randomized into 3 treatment groups,ramipril,telmisartan and combination therapy,each of which was further subdivided into A and B subgroups on the basis of microalbuminuria and overt proteinuria respectively.Group1 (14 cases) was given Telmisartan 40 mg OD.
Group 2 (12cases) was given Ramipril 10mg BD, and Group 3 (16 cases) was given combination Telmisartan 20mg and Ramipril 5 mg OD.
The cases were assessed for blood pressure, microalbuminuria, overt proteinuria, serum creatinine, blood urea, creatinine clearance, serum sodium, serum potassium, serum uric acid, blood sugar, HbA1c, serum bilirubin, SGPT and SGOT at 8 weeks interval for 24weeks i.e. at 8, 16, and 24 weeks.
Results: Microalbuminuria decreased significantly in all 3 groups 30.1% with Telmisartan, 34.5% with Ramipril and 35.5% with the combination. Overt proteinuria subgroups also showed significant decrease in all the three arms Telmisartan (22.2%), Ramipril (22.2%) and combination (35.5%).These decreases were significantly greater in the combination groups.Significant reduction in systolic blood pressure was also seen:11.38%, 11.44% and 13.16% respectively. Diastolic blood pressure was also reduced in the three groups 8.35%, 9.04% and 11.44% respectively. The decrease in systolic and diastolic BP did not differ significantly between these 3 groups.There were no significant changes in creatinine clearance, serum creatinine, blood urea, uric acid and SGPT (Al T) levels after 24 weeks of treatment in all 3 groups.

Conclusion: Combination therapy with Ramipril and Telmisartan is superior to the individual agents in reduction of both microalbuminuria and overt proteinuria..

Do sympathetic outflow and protein kinase A play any role in the Na+/glucose co-transporter SGLT1 in the salivary gland of diabetic hypertensive rats ?

R. Sabino da Silva[1], A.B.T. Alves-Wagner[1], K. Burgi[1], M.M. Okamoto[1], G.A. Lima[1], H.S. Freitas[1], V.R. Antunes[1], U.F. Machado[1]

[1] Biomedical Sciences Institute - Univ. of São Paulo, Physiology and Biophysics, São Paulo, Brazil

Salivary dysfunction has been described in hypertension and diabetes, and the SGLT1 that carries 2 Na^+:1 glucose:264 water molecules plays a critical role in these diseases. The sympathetic activation leads to interaction of ß-adrenoreceptor with ß-agonists that can activate the protein kinase A to trigger the migration of SGLT1 to plasma membrane. In Wistar Kyoto (WKY), WKY-diabetic (WKY-D), spontaneously hypertensive (SHR) and SHR-diabetic (SHR-D) rats, parotid and submandibular glands were harvested for SGLT1/PKA mRNA and protein analysis. Moreover, the salivary glands sympathetic activity (SGSA) was directly monitored. The SGSA increased in SHR and SHR-D (~300%, $p<0.05$) and decreased in WKY-D (45%, $p<0.05$), when compared to WKY. In salivary glands, the regulation of catalytic subunit of PKA was parallel to the sympathetic activity increase in SHR and SHR-D (~60%, $P<0.001$) and reduction (~30%, $p<0.05$) in WKY-D, compared to WKY rats. Besides, the plasma membrane SGLT1 protein content was increased in SHR and SHR-D (~200%, $p<0.001$) and reduced in WKY-D (~45%, $p<0.05$). However, in salivary gland, compared to WKY, the SGLT1 mRNA was increased (~40%, $p<0.05$) by diabetes and/or hypertension. Furthermore, immunohistochemical analysis showed SGLT1 staining in luminal membrane of ductal cells of diabetic and/or hypertensive rats, which is likely involved with water uptake, reducing the salivary flow. As expected, nonstimulated salivary secretion was reduced (~40%, $p<0.001$) in WKY-D, SHR and SHR-D rats. Together, our data suggest that dysfunction of the sympathetic outflow observed in hypertensive and diabetic state might be strictly related to changes in the SGLT1 protein of salivary glands via PKA and the functional alterations in salivary secretion can be mediated by SGLT1 in luminal membrane of ductal cells.

Prevalence of various forms of cancer in patients with type 2 diabetes mellitus

S. Khutsurauli[1], A. Kurtanidze[1], L. Tsutskiridze[1], R. Kurashvili[1], E. Shelestova[1], G. Kurashvili[1]

[1] Georgian Diabetes Center, Clinical endocrinology, Tbilisi, Georgia

Background and aims: Association between diabetes mellitus (DM) and cancer has long been speculated. Thus, the aim of our work was to prospectively examine association between a history of DM and subsequent risk of cancer in Georgian Public Oncology Center.

Materials and methods: In total we analyzed data for 270 patients (pts) with DM and various forms of cancer (females 139/males131, age range 55-75, DM duration 11±6yrs, BG 10.8±1.8mmol/l). Most frequently observed form was breast cancer (BC). Its incidence particularly increased in postmenopausal women. Data of women aged 55-69 yrs were analyzed. Family history of DM as well as BC was not associated with risk of postmenopausal BC in these pts, though DM in anamnesis enhanced the magnitude of the association of BC family history with postmenopausal BC (relative risk 1.87 vs. 1.36). The 2nd leading cancer form was rectal cancer (RC). Its prevalence was the highest in pts on energy-dense, poor in vegetables and fruit diet, or those leading sedentary life. Highest prevalence of RC was observed in men, aged 55-75 yrs. Pts were in clinical stage 2-T4NoMo; stage 3-pT2N1Mo; stage 3-T2NoMo; stage 2-T3NoMo; stage 3-T3NoMo; stage 2-PtNM; pT3C3NoMoRo. All were smokers. The 3rd position occupied stomach (SC) and pancreas (PC) cancers. SC was particularly located in antrum. Most of them were in clinical stage 3, with T3NoMo. All were smokers. Pts (males 50/females 20) with PC had particularly increased total bilirubin and acid phosphatase levels.

Results: Out of 270 cases of cancer analyzed the share of BC was 38%, RC 28% (males 20%/females 8%), SC 10% (all men), PC 10% (males 7%/females 3%), Sigma cancer 5%, Mediastinal lymphoma 5%, hemangioma 4%.

Conclusions: Patients with DM may be at increased risk of total cancer and cancer in specific sites. Further observation and analyzes are desirable.

Thyroid function tests in women with GDM and pre-gestational diabetes mellitus

H. Shahbazian[1], M. Samimi[1]

[1] Ahvaz Jundishapour University of Medical Sciences, Diabetes research center, Ahvaz, Iran

Diabetes is the most common endocrine dysfunction during pregnancy that can be divided to two groups (GDM, pregestational diabetes mellitus).Pregnant women with diabetes may have coexisting thyroid dysfunction so we decided to study thyroid function tests in GDM and pregestational D.M.

This study is a cross sectional prospective study in a group of 61 pregnant women that referred to endocrine clinic of Golestan Hospital (Ahwaz, Iran). They were between 19 to 47 years old.

From 61 patients, 22 person (36.07%) had GDM and 39 person (63.93%) pregestational D.M. Thyroid dysfunction was detected in 11 person (18%) (4.5% of women with GDM and 25.6% with pregestational D.M).

There was significant difference in thyroid dysfunction between GDM and pregestational D.M. ($p=0.037$)

27.3% of women with GDM and 35.7% of women with pregestational D.M had positive titer of anti TPO Ab, 10% of women with GDM and 12% of women with pregestational D.M had high level of anti Tg Ab.

From 61 patients 21.3% had previous history of thyroid disorder. Thyroid dysfunction was detected in 25% of these patients during pregnancy. There was not significant correlation between previous history of thyroid disease and thyroid dysfunction during pregnancy. ($p=0.311$).

Conclusion: Thyroid dysfunction is prevalent in women with pregestational D.M so thyroid function should be evaluated in these patients during pregnancy. Thyroid dysfunction was not prevalent in women with GDM but 27.3%of them had positive titer of TPO Ab that should be followed in post partum period because of high prevalence of post partum thyroiditis in these.

Evaluation of liver function tests in type 2 diabetes mellitus

R. Kumar Sharma[1], M. Farooq[1], A. Sharma[1], R.P. Kudyar[1]

[1] Govt. Medical College Jammu India, Department of Medecine, Jammu, India

The study titled "Evaluation of Liver Function Tests in Type-2 Diabetes Mellitus" was conducted at Government Medical College, Jammu with a view to: study the pattern of liver function test abnormalities in type-2 diabetic patients, and to determine if the liver function abnormalities had any association with glycemic control.

The study comprised 206 subjects, of which 3 tested positive for viral hepatitis (2 for hepatitis-B and 1 for hepatitis-C viruses). Only 203 subjects were, therefore, included in statistical evaluation of the results.

The mean age of the subjects was 51 ± 7.1 years. The minimum age of the patients in the study group was 34 and the maximum age was 77 years. The study group comprised 97 males and 106 females.

The most prevalent liver function abnormality was elevation in the serum level of ALT (33.5%), followed by GGT (17.7%) and AST (17.1%) in that order. The prevalence of abnormal serum bilirubin (4.43%) and serum alkaline phosphate (4.9%) was only marginal.There was a positive and significant correlation between glycemic control and the liver enzymes viz., ALT, AST and GGT.Fasting plasma glucose was found to be positively and significantly related to the serum levels of the three liver enzymes viz., ALT, AST and GGT.There was a significant and positive correlation between HbA1c and each of the three liver enzymes ALT, AST and GGT. Patients with raised level of serum triglycerides generally had liver function test abnormalities as is borne out by highly significant ($p < 0.001$) positive correlations between serum triglycerides on the one hand and serum levels of ALT and GGT on the other.

Increased body mass index (BMI) also contributed to liver function test abnormalities. Thus, a highly significant ($p < 0.0001$) and positive correlation existed between BMI and the three enzymes ALT, AST and GGT.

Waist circumference, known to be an index of insulin resistance, contributed to liver function test abnormalities. This is borne out by highly significant and positive correlations observed between waist circumference and the three liver enzymes viz., ALT, AST and GGT.
A large majority of patients (90.5%), who had abnormal levels of serum ALT, were on ultrasonography found to have fatty liver suggesting that most patients with type-2 diabetes with abnormal ALT also have fatty liver.
It is concluded from the study that the likelihood of having elevated levels of serum aminotransferases and serum gamma glutamyl-transferase is greater among type-2 diabetics leading to non-alcoholic fatty liver disease. In addition, dyslipidemia, poor glycemic control, increased body mass index and increased waist circumference further contribute to the fatty liver disease.

Anemia is associated with an elevated serum level of high molecular weight adiponectin in patients with type 2 diabetes independently of renal dysfunction – link between high serum adiponectin and increased mortality

Y. Aso[1], K. Hara[1], M. Suetsugu[1], R. Suganuma[1], S. Wakabayashi[1], K. Takebayashi[1], T. Inukai[1]
[1] *Dokkyo Medical University Koshigaya Hospital, Internal Medicine, Koshigaya, Japan*

Objective: In recent, high serum adiponectin is reportedly associated with an increased risk of cardiovascular disease or high mortality in patients with congestive heart failure. Anemia is strongly associated with an adverse outcome and increased mortality in patients with coronary heart disease or diabetic nephropathy. We investigated whether anemia was independently associated with the serum level of high molecular weight (HMW) adiponectin in patients with type 2 diabetes.
Subjects and Methods: We studied 207 type 2 diabetic patients (92 women and 115 men). Anemia was defined as a hemoglobin (Hb) <13.0 g/dl in men and <12.0 g/dl in women. Overt nephropathy (CKD) was defined as clinical proteinuria and /or estimated glomerular filtration rate (eGFR) lower than 60 ml/min for more than 3 months. The diabetic patients were divided into four groups according to the presence or absence of anemia and/or CKD. Serum HMW adiponectin levels were measured by a sandwich enzyme-linked immunosorbent assay.
Results: In all 207 patients with type 2 diabetes, serum total and HMW adiponectin levels were correlated positively with age, the duration of diabetes, HDL cholesterol, urinary albumin, and serum erythropoietin, while there were negative correlations with body mass index, triglyceride, eGFR, Hb, hematocrit, and high sensitivity C-reactive protein. Stepwise regression analysis demonstrated that among a number of significant variables, Hb had the strongest independent influence on HMW adiponectin (b= -0.487, P<0.001). Diabetic patients of both sexes with anemia and CKD had the highest serum levels of HMW adiponectin among the four groups.
Conclusions: Anemia is associated with marked elevation of serum HMW adiponectin levels in diabetic patients who have CKD, and this elevation is independent of renal function.

No conflict of interest

Leukocyte telomere attrition is evident in obese children and is not associated with insulin resistance

O. Al-Attas[1], N.M. Al-Daghri[1], M.S. Alokail[1], A. Bamakhramah[1], S.L. Sabico[1], E.T. De Rosas[1], P.G. McTernan[2]
[1] *King Saud University, Biochemistry, Riyadh, Saudi Arabia*
[2] *University of Warwick, Warwick Medical School, Warwick, United Kingdom*

Aims: Advances in studies of obesity highlight the importance of adipocytokines in the development of insulin resistance which in turn leads to biological senescence. In this study we attempt to determine for the first time associations of telomere length to markers of insulin resistance and obesity in Saudi children.
Methods: 148 subjects (69 boys and 79 girls) participated in this cross-sectional study. General information, anthropometric data and fasting blood samples were collected. Serum glucose and lipid profile was done using routine lab methods. Serum insulin, leptin, adiponectin, resistin, TNF-alpha and aPAI-1 were quantified using customized multiplex assay kits. C-reactive protein and ANG II were quantified using enzyme-linked immunosorbent assays. Leukocyte telomere length was examined by quantitative real time PCR utilizing the IQ cycler.
Results: Mean telomere length of obese children was not significantly different from their lean counterparts. Telomere length was not associated to insulin resistance in both boys and girls. In girls, significant predictors of telomere length were adiponectin level and the waist circumference. Correlation analysis revealed that telomere length is not associated to any of the metabolic parameters measured, including HOMA-IR, indices of obesity, lipid profile and glycemic parameters. Regression analysis revealed that adiponectin and waist circumference predicts 61% of variance in telomere length only in girls ($p < 0.0001$).
Conclusion: Insulin resistance is not associated to telomere length attrition among girls, but is evident among obese boys. Further studies are needed to determine as to whether the length can be used as biomarker for other obesity-related diseases in the same population.

Clinical and laboratory correlates of non-alcoholic steatohepatitis and advanced fibrosis in Brazilian type 2 diabetic patients

N.C. Leite[1], G.F. Salles[1], C.A. Villela-Nogueira[1], A.L.E. Araujo[1], G.F.M. Rezende[1], V.L.N. Pannain[1], A.C. Bottino[1], C.R.L. Cardoso[1]
[1] *Medical School Federal University of Rio de Janeiro, Internal Medicine, Rio de Janeiro, Brazil*

Aims: Increasing evidence suggests that patients with diabetes are at a particularly high risk for presenting non-alcoholic fatty liver disease (NAFLD), especially in its more severe progressive form, non-alcoholic steatohepatitis (NASH). Data regarding the prevalence and the factors associated with NASH in diabetic patients are still scarce. The aim of this study was to investigate in type 2 diabetic patients the prevalence and associated factors of NASH and advanced fibrosis.
Methods: In a cross-sectional study, 180 type 2 diabetic patients were submitted to a complete clinical and laboratory examination. Fasting serum samples were assayed for adiponectin, TNF-alpha, TGF-beta, IL-6, IL-8 and IL-10 (LINCOplex assay). An abdominal ultrasonography (US) for NAFLD detection and grading was performed. Those with abnormal aminotransferases levels or steatosis on US were submitted to liver biopsy. Exclusion criteria were daily alcohol ingestion > 20g, other coexistent liver diseases, the use of well-known hepatotoxic drugs and any contraindication to liver biopsy. Percutaneous liver biopsy was performed using the 14G Bloodline needle. Liver histology was assessed by pathologists who were blinded to the clinical data. The histological grading and staging of NAFLD followed the Kleiner's criteria. Advanced fibrosis was considered for patients with fibrosis stage 2 to 4. Categorical parameters among groups were compared using the Chi-squared test. For continuous parameters Student`s t-test and Mann-Whitney test were applied. Statistical significance was taken as $p < 0.05$.
Results: Among the 67 diabetic patients submitted to liver biopsy, 65.7% were female with a mean age of 54.8 (sd=7.16) years. NASH was identified in 44 (65.7%) and advanced fibrosis in 54 (80.6 %). Older age (p=0.038), high serum triglycerides (p=0.010), low high-density lipoprotein (p=0.012), ast/alt ratio (p=0.022), lower adiponectin levels (p=0.019) as well as adiponectin/TNF-alfa ratio (p=0.014) were associated with diagnosis of NASH. Remarkably, the use of statins was related to a lower prevalence of NASH on liver biopsy (p=0.006). The factors related to advanced fibrosis were weight (p=0.038) adiponectin levels (p=0.011) and adiponectin/TNF-alfa ratio (p=0.001).
Conclusions: Our data indicate that NASH and advanced fibrosis are highly prevalent in type 2 diabetic patients. The lack of association between diabetes related parameters and NASH or advanced fibrosis may suggest that NAFLD in type 2 diabetic patients may follow a progressive course independent of the diabetes itself. The imbalance of the cytokines adiponectin and TNF-alfa ratio may have a role in NAFLD progression in diabetic patients.

Diabetes as a risk factor of colon neoplasms in overweight and obese patients

P. Krasnodebski[1], B. Mrozikiewicz-Rakowska[1], W. Karnafel[1], M. Jasik[1], P. Stelmasiak[1], A. Cacko[1], A. Krakowiecki[1], M. Karlinski[1]

[1] *Medical University of Warsaw, Department of Gastroenterology and Metabolic Dieseases, Warsaw, Poland*

Aims: The aim of the study was to assess the incidence of neoplastic changes in patients with type 2 diabetes, who underwent colonoscopy from May 2005 to December 2006. The relation between incidence of neoplastic changes and anthropometric factors was evaluated.

Materials and methods: Colonoscopy was performed in 282 patients: 57 patients with obesity (35 women and 22 men; mean age 61,8±12,5), 99 with overweight (53 women and 46 men mean age 65,2±14,4). The control group comprised 126 patients (BMI<25) (37 men, 89 women, mean age 60,7±16,7 years). Anthropometric parameters (eg. BMI, WHR, waist circumference) were measured. In patients with macroscopic colorectal lesions, histopathological evaluation was performed. Subsequent statistical analysis involved application of Students' t-test and logistic analysis.

Results: Adenocarcinoma was more frequent (p= 0,01) in patients with type 2 diabetes. The most accurate and statistically significant logistic regression model (that includes all risk factors) confirmed the role of diabetes. Coexistence of diabetes increases 6-fold the risk of colon cancer p=0,02. We did not find positive correlation between the presence of diabetes and colon polyps (p=0,2). Colon polyps were observed more frequently in obese compared to lean (20%; p=0,02) and overweight (25%; p=0,1) patients. We observed increased frequency of colon polyps in patients with obesity independently of age, waist circumference and independently of the presence of diabetes. Obesity increases 1,5-fold the risk of colon polyps.

Conclusion: Diabetes type 2 is important risk factor of colon cancer. Obesity increases the risk of colon polyps independently of age, diabetes or other anthropometric parameters.

Biogenesis of methylglyoxal-adducts is associated with LDL and triglyceride levels: implications for diabetic atherosclerosis

Z. Turk[1], J. Boras[2]

[1] *Vuk Vrhovac University Clinic for Diabetes, Department for Laboratory Medicine, Zagreb, Croatia*

[2] *Vuk Vrhovac University Clinic for Diabetes, Department for Diabetes Complications, Zagreb, Croatia*

Aims: Protein glycation leading to AGEs is enhanced in diabetes by increases in blood glucose per se, and collaterally, by endogenous production of reactive carbonyls. Low weight a-dicarbonyls are formed as glycolytic intermediates during metabolic conversion of glucose and/or during lipid peroxidation. Among AGE precursors, methylglyoxal (MG) is considered as one of the key intermediates. We hypothesized it to be a common product of both carbonyl and oxidative stress, and investigated the MG biogenesis in relation to glycemic and lipid status in diabetic patients.

Methods: Serum and urine MG-adduct content was measured by DELFIA method in 88 diabetic patients and 20 controls. Fasting (FG) and postprandial (PPG) glucose level, HbA1c, glucose profile M-index, LDL and HDL cholesterol, plasma triglyceride and homocysteine levels were determined.

Results: A significant positive relationship was observed between serum level of MG-adducts and LDL (r=0.31 p=0.003) whereas fasting glucose correlated inversely (r= -0.33 p=0.001) as well as postprandial glucose (r= -0.23 p=0.041) and HbA1c (r= -0.22 p=0.036). Similarly, significant correlations were also found between urinary levels of MG-adducts and postprandial glucose (r= -0.28 p=0.023), serum triglycerides (r=0.31 p=0.003), homocysteine (r=0.57 p=0.0007), HDL (r= -0.28 p=0.007) and urine albumin/creatinine ratio (r=0.53 p=0.002). Multiple linear regression was performed using serum or urine MG-adducts as dependent variable and HbA1c, fasting and postprandial glucose, LDL, HDL, triglycerides, serum creatinine, homocysteine and urine albumin/creatinine ratio as independent variables. Of these, only LDL-cholesterol and FG were independently associated with MG-adducts in serum (p<0.00046), whereas urine albumin/creatinine ratio, PPG, HDL and triglycerides were independently associated with urine MG-adducts (p<0.011). Patients with LDL-cholesterol >3.0 mmol/l, had a higher serum level of MG-adducts (616±400 mgEq/ml (range 183-2066) vs 424±237 mgEq/ml (53-1370); p=0.026). In addition, significant correlation between homocysteine and urinary excretion of MG-adducts (r=0.8; p=0.02) was recorded in patients with a history of macrovascular disease.

Conclusion: A highly significant relationship between LDL and MG-adduct production, as well as tight correlation between triglycerides and urinary MG-adduct excretion suggest that lipoxidation and glyceraldehyde-3-phosphate route, along with the glycolytic pathway, might be an important source in MG generation. The glycotoxin methylglyoxal seems to be a common factor linking the two dominant metabolic changes in diabetes, hyperglycemia and intensive lipolysis, with vascular pathobiochemistry of diabetes.

Clinical and biochemical assessment of testosterone deficiency in men with type 2 diabetes

V. Pankiv[1], V. Kashperska[1]

[1] *Centre of Endocrinology, Preventive Endocrinology, Kiev, Ukraine*

Aims: The relationships among type 2 diabetes mellitus, obesity, metabolic syndrome, serum total and free testosterone levels are complex and often confusing to the physician. It is known that BMI is inversely proportional to serum total testosterone concentrations. The aim of our study was to assess the prevalence of testosterone deficiency in men with type 2 diabetes.

Methods: In a cross-sectional study of 255 type 2 diabetic men aged >30 years, total testosterone, BMI, and waist circumference were measured and free testosterone was calculated. Overt hypogonadism was defined as the presence of clinical symptoms of hypogonadism and low testosterone level (total testosterone <8 nmol/l). Borderline hypogonadism was defined as the presence of symptoms and total testosterone of 8–12 nmol/l.

Results and discussion: A low blood testosterone level was common in diabetic men, and a significant proportion of these men had symptoms of hypogonadism. Overt hypogonadism was seen in 17% of men with total testosterone <8 nmol/l. Borderline hypogonadism was found in 25% of men with total testosterone 8–12 nmol/l; 42% of the men had free testosterone <0.255 nmol/l. BMI and waist circumference were both significantly negatively correlated with testosterone levels in men, with the association being stronger for waist circumference.

Conclusion: Testosterone levels are frequently low in men with type 2 diabetes, and the majority of these men have symptoms of hypogonadism. Obesity is associated with low testosterone levels in diabetic men.

P-1054

White blood cells apoptosis and blood immune indexes in patients with diabetes mellitus

T. Saatov[1], Z. Shamansurova[2]

[1] *Biochemistry, Lipids, Tashkent, Uzbekistan*

[2] *Endocrinology, Diabetology, Tashkent, Uzbekistan*

Aims: Immune response alterations in Diabetes Mellitus (DM) were shown in many studies, and explained by different mechanisms by hyperglycemia and insulin deficiency states, and we are proposing that blood white cells apoptosis may be one of the reason. So investigation of the relationship between blood immune indexes and white blood cells apoptosis, glycemia and HbA1c level present the aim of this study.

Methods: In 42 patients with type 2 DM and 12 healthy subjects (HS) fasting blood glucose (FBG), HbA1c level, blood total T cells (CD3), B-cells, T-helpers (CD4), T-suppressors (CD8) were tested, white blood cells apoptosis detected by counting through light microscopy after trypan blue and RH-stain and express as index of apoptosis IA= (apoptotic cells/total cells) x100%.

Results: In patients with DM, FBG and HbA1c were increased 2.1 and 1.7 times compared with HS. Total B-cells was significantly decreased in 1.3 times, CD3 decreased in 1.16 times (NS), CD4 - in 1.13 times (NS), and CD8 - in 1.4 times, P<0.05 and relation CD4/CD8 was decreased in 1.56 times, P<0.05 in DM patients and shown suppression of immune response, whereas blood cells apoptosis expressed as IA was significantly increased in 1.98 times in DM patients in compare with HS. IA shown linkage with FBG, and CD3, CD4, CD8 indexes which permit to view the white blood cells apoptosis as a reason of immune response dropping at the DM.

Conclusion: In DM patients white blood cells apoptosis increased and had linkage with FBG, CD3, CD4, CD8 indexes and viewed as a one of reason of dropping immune response.

P-1055

Correlation of highly sensitive C reactive protein with components of metabolic syndrome

S. Vidyasagar[1], A. Razak[1], M. Varma[1], C.K. Prashanth[1]
[1] Kasturba Medical College, Medicine, Manipal, India

Background: C reactive protein (CRP) is an important marker of proinflammatory state, correlated with cardiovascular and cerebrovascular morbidity. The metabolic syndrome has components that translate into vascular events, and it is well known that CRP can be raised in this syndrome. This study was undertaken to identify which of these components correlates most with CRP levels.
Objective: To study the relationship of CRP with components of metabolic syndrome.
Methodology: The study was carried out in the department of medicine, Kasturba Medical college, Manipal, India between January 2006 to July 2007. Patients with ethnic specific criteria for metabolic syndrome (FBS>110mg/dl, BP>130/85mm Hg, TG>150mg/dl, HDL<50mg/dl in women, <40mg/dl in men, Waist >80cm in women, 90cm in men) were screened for highly sensitive CRP levels by particle enhanced immunoturbidometry. All patients with chronic liver, kidney disease, infections and inflammatory conditions, malignancy were excluded. The data was analysed using SPSS 15 version. Non parametric Mann Whitney U test was used to assess statistical significance.
Results: Out of 91 patients screened, 24 were females, 67 were males, with 90% being more than 40yrs of age. FBS high in 80%, hypertension (HT) in 63%,waist circumference abnormal in 79%,TG high in 74%, low HDL in 45%. The mean CRP was found to be significantly higher in patients with FBS>110mg/dl compared to those without (1.72 vs 0.90,p value of 0.021) and among hypertensives and non hypertensives, (CRP 1.83 vs 1.15, p value of 0.038). The most significant difference was for abnormal waist circumference (WC), CRP being 1.76 compared to 0.72 in those with normal WC (p value of 0.003). However there was no significant difference in groups with and without raised TG (p value 0.834),or patients with low or normal HDL (p value of 0.902). Multiple regression analysis with CRP as dependent variable showed that WC correlated best (p value 0.039) along with hypertension (p value 0.028).
Further analysis was done with division of patients into those with 3, 4 or 5 components of metabolic syndrome. CRP was 1.21, 1.80 and 2.29 respectively, showing that CRP increases with increasing clusters of MS components (p value 0.008).
Conclusion: A positive correlation was found between CRP and components of MS such as central obesity, hypertension, and fasting glucose, with waist circumference correlating best. There is a linear increase in CRP with increasing number of components of MS (p value 0.008). CRP is thus an important surrogate marker for chronic inflammation related to atherosclerosis which may explain its close relationship with components of the metabolic syndrome.

Stroke and insulin resistance in sub-Saharan African patients presenting with first-ever-in lifetime stroke

E. Balti[1], E. Sobngwi[1,2], A.P. Kengne[1,3], L. Fezeu[1], B. Nouthe[1], S. Djiogue[1,4], D. Njamen[1,4], J.C. Mbanya[1]
[1] University of Yaounde 1, National Obesity Centre and HoPiT research Group - Internal Medicine, Yaounde, Cameroon
[2] Newcastle University, Institute of Health and Society, Newcastle, United Kingdom
[3] University of Sydney, The George Institute for International Health, Sydney, Australia
[4] University of Yaounde 1, Faculty of Sciences, Yaounde, Cameroon

Background and purpose: The incidence of cardiovascular diseases is increasing in developing countries. Insulin resistance syndrome is associated with an increased risk of stroke. To assess insulin sensitivity of patients with first stroke episode in hospital setting in Cameroon.
Methods: All patients admitted for first-ever-in-lifetime stroke over a 6-month period were eligible for the study. The 84% participation rate yielded 57/68 patients aged 16-85 years. Fifty seven control subjects were selected to match patients included for age range, sex, and known hypertension and diabetes. We measured fasting serum glucose, insulin, and lipids in controls and in patients between day 3 and 7 following admission.
Insulin sensitivity was assessed using the Quantitative Insulin Check Assay (QUICKI) and the Homeostatic Model Assessment of insulin sensitivity (HOMA).
Results: Fasting insulin level was higher in patients than controls (5.9±5.4 vs. 2.3±3.2 IU/ml, p<0.001). Patients were less sensitive to insulin than controls as measured by QUICKI (0.17±0.04 vs. 0.28±0.12, p<0.001) and HOMA-IR (1.9±2.2 vs. 0.7±1.0, p=0.001). The assessment of lipids showed comparable total cholesterol in patients and controls (172.6±39.5 vs. 175.4±49.7 mg/dl, P=0.75) as were triglycerides (129.4±56.1 vs. 122.4±60.7 mg/dl,P=0.53). HDL-C levels were lower in patients than in controls (37.4±20.6 vs. 50.2±18.0mg/dl; P=0.001), with comparable levels of LDL-cholesterol (109.4±43.0 vs. 100.7±48.8mg/dl, P = 0.32). The LDL-C/HDL-C ratio was higher in patients compared to controls (4.0±3.0 vs. 2.3±1.7, P=0.0001), as well as the total cholesterol / HDL-cholesterol ratio (5.9±3.5 vs. 3.9±1.8, P=0.0001).
Conclusions: Stroke is associated with markers of insulin resistance, low serum levels of HDL and high TC/HDL ratio in this African population. Studies on bigger sample size, and cohort designs are warranted to explore the causal pathways, persistence of these abnormalities and population-specific cut points.

Mannose-binding lectin levels and carotid intima media thickness in diabetic patients

M. Káplár[1], S. Sweni[1], M. Papp[2], L. Oláh[3], T. Magyar[3], J. Hársfalvi[4], G. Paragh[1]
[1] University of Debrecen, I Department of Internal Medicine, Debrecen, Hungary
[2] University of Debrecen, II Department of Internal Medicine, Debrecen, Hungary
[3] University of Debrecen, Department of Neurology, Debrecen, Hungary
[4] University of Debrecen, Clinical Research Center, Debrecen, Hungary

Background: Mannose-binding lectin (MBL), a weak acute phase reactant protein activates the "lectin" pathway of complement system, independent of antibodies and plays an important role in the innate immunity. MBL level has been associated with diabetic nephropathy. Also, MBL has been suggested to be involved in the pathogenesis of micro- and macrovascular complications, and may be used as a prognostic marker for these complications. No study up to date, has investigated the association of MBL level and carotid artery intima media thickness (IMT).
Objectives: To analyze a possible association and role of MBL in pathogenesis of IMT, in diabetic patients.
Materials and methods: Serum MBL levels and IMT were measured in a total of 151 diabetic patients, 76 type1 diabetes (T1D) with mean age 46.0±11.5 years and 75 type 2 diabetes (T2D) with mean age 47.4±8.2 years, and were compared with 118 healthy controls (mean age 45±9.7years).MBL levels were measured by sandwich ELISA technique using murine monoclonal antibodies (HYB131-01, HYB131-01B). IMT on both sides were measured using B mode enlarged images. Data including socio-demographic factors and clinical information for all cases and control subjects was collected and analyzed statistically with Newman-Keuls ANOVA and simple correlation analysis.
Results: Logarithmic MBL levels in T1D was 2.7±0.5 ng/ml; T2D was 2.8±0.5 ng/ml ;in controls was 2.7±0.6 ng/ml and there was no significant difference between either groups (p>0.05). Glucose homeostasis was not different between 2 diabetic groups as shown by HbA1c results (T1D: 8.3±1.7 % and T2D: 8.1±1.6 %). Statistically IMT was significantly higher in diabetics compared to controls (p=0.046). Subgroups of patients with absolute and relative MBL deficiency (<100, <500ng/ml respectively) and high MBL level (>1000ng/ml) were analyzed separately. Patients with MBL >1000, had higher IMT (p=0.04) than patients whose MBL <1000. IMT in T2D was significantly higher than controls (p=0.05). In patients with >1000MBL, IMT in T2D was higher than T1D (p=0.041) and controls (p=0.037). IMT was inversely correlated with MBL in absolute deficient patients, in all diabetics (p=0.006) and T1D (p=0.04).
Conclusion: This is a first study investigating the role of MBL in carotid IMT. IMT was significantly higher in all diabetics and T2D versus controls. Also, in T2D with high MBL levels, IMT was higher than T1D and controls. In absolute deficiency, MBL was inversely correlated with IMT in T1D and whole diabetic population. We conclude that high MBL level and MBL deficiency may play a role in the pathogenesis of macrovascular complications in diabetic patients.

[4] *Escuela Nacional de Ciencias Biologicas IPN, Departameto de Microbiologia, Distrito Federal, Mexico*

Nutritional antioxidants such as pomegranate juice are a source of polyphenols and other antioxidants which can contribute to the reduction of oxidative stress and atherogenesis. When pomegranate juice was provided to apolipoprotein E-deficient mice with advanced atherosclerosis, the lesions were reduced by 17% compared with the placebo. A similar effect in PON1--deficient mice has been reported. However, pomegranate juice has been shown to reduce blood glucose levels and induce PON1 gene expression.

Aims: We created a unique streptozotocin-induced diabetes and diet-induced obese model to determine if pomegranate juice could be a treatment for the control of diabetes and obesity occurring together.

Methods: the model was used to test the effect of pomegranate juice on PON1 activity on the simultaneous occurrence of both diseases. The beneficial effects of pomegranate juice were measured when provided to diet-induced obese mice with streptozotocin-induced diabetes. All animals received an obesigenic diet designed by a nutritionist to include typical Mexican foods. Forty CD1 mice of approximately 20-30 g were rendered diabetic by a single i.p. injection of streptozotocin (80 mg/kg body weight). The control group received water ad libitum while the experimental group received water supplemented with pomegranate juice (12.5 mL/L of water). Immediately post-injection and 1, 2, 3 and 4 months after, mice were killed by decapitation and blood was collected. The blood was allowed to stand for 30 min at 4°C and then centrifuged to obtain serum. Glucose, cholesterol, and triacylglycerol levels were measured by a medical diagnostic kit. PON1 activity was measured by a semiautomated method using paraoxon as substrate. PON-1 gene expression was determined by RT-PCR.

Results: pomegranate juice increased the PON-1 gene expression levels compared to the unsupplemented group in proportion to treatment time. PON1 activity was significantly higher in the last month in the pomegranate juice-supplemented group. Additionally, we found that pomegranate juice significantly reduced blood glucose and cholesterol levels ($p<0.05$).

Discussion/conclusion: Although we did not study atherosclerosis lesions directly, the results suggest that pomegranate juice can be used as a preventive for the control of diabetes and for reducing atherosclerosis.

Sexual dysfunction in women with diabetes mellitus

A. Ogbera[1], S. Chinenye[2], A. Akinlade[1], F. Akingbade[1], T. Senbanjo[1]

[1] *Lagos State University Teaching Hospital, Medicine, Lagos, Nigeria*

[2] *University of Port Harcourt Teaching Hospital, Medicine, Port-Harcourt, Nigeria*

Aims: This report is an attempt to document the prevalence, various aspects of sexual dysfunction (SD), clinical correlates and determinants of SD in Nigerian women with diabetes mellitus (DM).

Methods: A total of 64 married women with DM attending had their sexual function assessed using the Female Sexual Function Index questionnaire. The scores in the six domains were compared with that of 30 age matched women who did not have DM. Psychological status was assessed with the General Health Questionnaire.

Results: The prevalence of SD in women with DM and in the control population was 73% and 43% respectively. The mean (SD) FSF score in the diabetic women-16.5 (10) was significantly lower than that of the control group-21 (8.5), ($P = 0.03$).

Women with DM attempted sex less frequently than the control group. Poor mental health status was noted more in the DM (30%) than in the control group (16%) and this was found to be related to SD. However the duration of DM had a significant relationship to the presence of SD ($P=0.002$).

Discussion: Sexual problems are more frequent in women with DM than those without DM, and determinants of SD include duration of diabetes illness and poor mental health.

Occurence of coeliac disease in children and adolescents with type 1 diabetes mellitus

M. Gordeladze[1], T. Parulava[1], I. Manjavidze[1], R. Kurasvili[2], L. Tsutskiridze[2], E. Shelestova[2]

[1] *Pediatric Hospital of State Medical University, Endocrinology dept., Tbilisi, Georgia*

[2] *Georgian Diabetes Center, Clinical care, Tbilisi, Georgia*

Background and Aims: The prevalence of Coeliac disease (CD) in children with autoimmune disorders (AD) greatly exceeds the prevalence in general population. Type 1 diabetes (T1DM) is one of the AD which has been described as associated to gluten sensitive enteropathy (1.1-10%). CD in diabetic kids is usually asymptomatic and untreated and may lead to unexplained hyperglycemia, blood glucose swings, growth failure, and weight loss. The aim of the study was to determine the prevalence of CD in children and adolescents with DMT1 in Georgia.

Materials and Methods: Totally, 32 patients (pts), (age range 1.6-15 yrs, males 17/ females 15) with T1DM and without signs of malabsorption were tested for antigliadin test (IgA and IgG AGA) and to tissue transglutaminase (IgA and IgG TTG). Pts were divided into 3 groups (Gr): Gr.1 (n=5) at T1DM onset; Gr. 2 (n=17) diabetes duration 2-7yrs, HbA1c >8% (9.3±1.1); Gr. 3 (n=10) same diabetes duration, HbA1c<7.5% (6.7±0.6). All pts were on intensive insulin therapy (HM insulins).

Results: IgA AGA was positive in 3 cases. IgA TTG was present in 5 pts. Using internationally accepted criteria, CD was diagnosed in 4 pts (12.5%)-1 from Gr.1, 3 from Gr. 2, none from Gr. 3.

Conclusions: 1. The TTG antibody test is more sensitive than AgA. 2. CD in diabetic pts is frequently asymptomatic and detected only through antibody screening. 3. Our study confirms the prevalence of CD in children and adolescents with T1DM, and that CD influences glycemic and metabolic control. 4. Children with T1DM should be screened for CD routinely.

The investigation of the molecular effects of diabetes mellitus on rat testis tissue and treatment effect of ascorbic acid on diabetes mellitus

S. Ergun[1], D. Guldag[1], N. Kamaci[1], O. Bozkurt[1], M. Dincer Bilgin[2], F. Severcan[1]

[1] *Middle East Technical University, Department of Biology, Ankara, Turkey*

[2] *Adnan Menderes University Faculty of Medicine, Department of Biophysics, Aydin, Turkey*

Aims: Changes in spermatozoa production and decrease in amount of hormone secretion have been shown in testis tissues in long-term diabetes. The current study aims to investigate the molecular changes caused by diabetes in rat testis tissues and also the possible treatment role of high and low dose vitamin C administration in diabetes using Fourier Transform Infrared (FTIR) spectroscopy technique.

Methods: 11-week-Wistar male rats were divided into four different groups, namely; control (n=6), diabetic (n=6), and also low dose (15 mg/kg, n=6) and high dose ascorbic acid (100 mg/kg, n=6) that is administered to diabetic rats. Diabetes was induced with single dose (50 mg/kg) of streptozotocin (STZ) injection. After 6 weeks from streptozotocin injection (at the end of this time interval, rats were accepted as diabetic), vitamin C was given to diabetic rats daily, for 6 weeks. At the end of this period, the rat testis tissues were dried, grounded and mixed with KBr at a 1:100 ratio. The pellets obtained from the mixture were investigated by FTIR spectroscopy.

Results: A decrease in the area of nucleic acid and protein bands was observed in diabetic testis tissues. There were significant shifts in frequency values of the main protein bands, Amide I and Amide II. Moreover, an increase in bandwidth of Amide I band and the CH_2 stretching bands was detected. An increase in the area of olefinic band was observed. While the area values of the lipid bands in diabetic group decreased, the area values of the lipid bands in ascorbic acid treated group were closer to the results of control group. However, no positive effect of ascorbic acid was observed in spectral parameters in the bands originating from other macromolecules.

Discussion/conclusion: The results of the current study clearly demonstrated that diabetes causes changes in composition and structure of macromolecules. A decrease in RNA and protein synthesis, an increase in the membrane fluidity and an increase in the amount of end-products of lipid peroxidation were observed. There was no restorative effect of ascorbic acid treatment on proteins and nucleic acids. The findings of this study imply that ascorbic acid may exert its treatment effect on diabetes via the lipid metabolism. In addition, results of this study reveal that diabetes causes changes in the secondary structure of proteins.

Relation between the index of insulin resistance HOMA-R and the aldosterone/renin ratio in a young adult population

G. Dieuzeide[1], F. Dadamia[1], C. Pirola[2], C. Gonzalez[3]
[1] *Center of Integral Attention in DiabetesEndocrinology and Metabolism (CAIDEM), Buenos Aires, Chacabuco, Argentina*
[2] *Instituto Alfredo Lanari, Buenos Aires, Buenos Aires, Argentina*
[3] *Facultad de Medicina, Universidad de Buenos Aires, Buenos Aires, Argentina*

Introduction: The cardiovascular disease is the greatest cause of mortality in diabetes (DBT) type 2. At the same time, the resistance to insulin is a precocious indicator of DBT risk and it has been indicated as an independent predictor of cardiovascular disease. Therefore, it seems important to know the existing relation between the two great endocrine systems that regulate on the one hand the metabolism of carbohydrates (insulin), the insulin resistance syndrome, and on the other the main hormonal system involved in the control of the cardiovascular apparatus: the renin angiotensin-aldosterone system (RAA). From the work of De Fronzo it is known that the insulin has an antinatriuretic effect with retention of sodium and expansion of volume. The expected answer for this case is a relative inhibition of the RAA system. Nevertheless, recent publications have questionated this theory in essential hypertensive patients and adults with obesity
Objectives: The objective of our research was to determine the existing relation between a validated index of insulin resistance (HOMA-R) and the quotient aldosterone/renin in a young adult population, comparing its value between those with normal weight (BMI<25)and those with overweight or obesity (BMI>25).
Material and methods: 112 young adults of the polimodal cycle of our city were studied. Age X:17.06 years old (16-29 years old), 68 women and 44 men. All of them were in the Tanner V of development. A survey of filiatory´s illnesses and of education level was made. Also, we made a survey of eating habits and a standardized questionnaire about habits of physical activity. We made an anthropometric evaluation (weight, height, BMI and waist circumference) and determined arterial blood pressure (BP) according to protocol of the Task Force. The individuals received a free sodium diet. They were in standing position until 10´previous to the extraction of blood. Conventional analyses were obtained. The insulin was determined by immunoanalysis and the renin and aldosterone by RIE, both by duplicate. The HOMA-R was determined by the conventional formula (glycemia/18x insulin/22.5). Statistical method: test t of student and Mann Whitney, coefficient of correlation of Spearman and Pearson.
Results: The aldosterone/renin index has a positive correlation with systolic BP (r:-0.32,p<0.01), diastolic BP (r:-0.21p<0.04) and the waist circumference (r:-0.20 p<0.04). When the values of HOMA-R in subjects with BMI>25 or <25 were compared we observed a significant difference (HOMA-R X:BMI<25:0.98±0.6 BMI >25:1.67±2.4 p<0.02). When the values of aldosterone/renin ratio were also compared they showed a significant difference in those subjects with BMI<25:Aldo/renin X:41.5±55.2 ng/dl/ng/ml/h,and those with BMI>25:Aldo/renin X:29.6±43.1 ng/dl/ng/ml/h p< 0.02)
Conclusions: In young adult population an increase of the index HOMA-R is observed along with a diminution of the quotient aldosterone/renin when subjects with normal BMI vs those with overweight or obesity are compared.

Correlation between fasting plasma glucose and autonomic dysfunction in healthy subjects with normoglycemia: an early impairment in cardiovascular adaptation

R. Takacs[1], P. Legrady[1], T. Varkonyi[1], L. Rudas[2], G. Abraham[1], T. Wittmann[1], C. Lengyel[1]
[1] *University of Szeged, 1st Department of Medicine, Szeged, Hungary*
[2] *University of Szeged, Department of Anaesthesiology and Intensive Therapy, Szeged, Hungary*

Introduction: Autonomic neuropathy associated with the higher risk of cardiovascular mortality. It is known that the autonomic dysfunction appears in the early phases of the disturbances of the carbohydrate metabolism already. The aim of this study was to determine the correlations between autonomic dysfunction and the fasting plasma glucose in healthy subjects with a normal carbohydrate metabolism according to the WHO criteria, normal body weight and blood pressure.
Materials and methods: 14 healthy subjects (age: 45.6±6.86 yrs, fasting plasma glucose: 5.0±0.63 mmol/l [3.9-5.9 mmol/l], HbA1c: 5.3±0.45 %, BMI: 24.0±3.89 kg/m^2, blood pressure: 123/66±14.6/8.6 mm Hg, mean±SD) were included. Autonomic function was investigated by means of the five standard cardiovascular reflex tests, heart rate variability (HRV) and the spontaneous baroreflex sensitivity (BRS). The blood pressure was measured continuously with the Finapres 2300. The ECG signal was detected continuously by means of a Siemens Sirecust 730 ECG. The signals were fed through an analog-digital converter into a computer and analysed off-line. The oscillation amplitude of R-R intervals were analysed as well as the time and frequency domain indexes of HRV. The spontaneous BRS was calculated in the supine position and after standing up and based on the analysis of the spontaneous fluctuations of blood pressure and interbeat intervals. Statistical analysis was performed by SPSS program.
Results: There were statistical significant negative relationships between the fasting plasma glucose and the heart rate response to deep breathing (r=-0.58, p<0.05), the heart rate response to standing up (r=-0.56, p<0.05), standard deviation of all RR intervals (r=-0.59, p<0.05), root mean square of successive RR differences (r=-0.57, p<0.05), power of low frequency component of HRV (r=-0.56, p<0.05), power of high frequency component of HRV (r=-0.57, p<0.05) and the BRS after standing up (r=-0.56, p<0.05). There were no statistical differences between the fasting plasma glucose and the other cardiovascular reflex tests.
Conclusions: Our results suggest the existence of a close relationship between the increase of the normal range for fasting plasma glucose in healthy subjects and the autonomic dysfunction which may forecast the early cardiovascular adaptation damage.

Decreased plasma concentration of adiponectin in acute phase of myocardial infarction in type 2 diabetes patients with multivessel disease

P. Krasnodebski[1], M.I. Bak[1], B. Mrozikiewicz-Rakowska[1], G. Opolski[2], W. Karnafel[1]
[1] *Medical University of Warsaw, Department of Gastroenterology and Metabolic Dieseases, Warsaw, Poland*
[2] *Medical University of Warsaw, Department of Cardiology, Warsaw, Poland*

Background and aims: Adiponectin is a protein produced in adipose tissue, has potential antiatherogenic properties and takes part in pathogenesis of insulin resistance. It is also decreased in patients with cardiovascular disease and type 2 diabetes. The aim of the study was to assess the potential relationships between plasma adiponectin levels and progression of atherosclerotic changes in coronary arteries in patients with acute coronary syndrome.
Material and methods: Coronary angiography was performed in 43 patients with acute myocardial infarction. The study group comprised 25 patients with type 2 diabetes mellitus (14 men, 11 women, median age 64,6±11,6 years) and 18 non-diabetes subjects (13 men, 5 women, median age 58,8±11 years) - control group. One or two vessel disease was observed in 10 diabetes patients (group I), and three vessels disease was observed in 15 diabetes patients (group II). All patients underwent a medical examination with body mass index (BMI) and Waist/Hip Ratio (WHR). We estimated the level of adiponectin using RIA method.

Results: Three vessels disease was observed more frequently in patients with diabetes mellitus than in control group (60% vs. 16%; p=0,004). Plasma adiponectin level was significant lower in diabetic patients with three vessels disease as compared to the group II (8,3 ± 2,8 vs. 5,9 ± 2,0 µg/ml; p=0.024). There were no significant differences in plasma adiponectin concentration in non-diabetic patients with multivessel and one or two vessels disease (8,6 ± 3,2 vs. 5,3 ± 2,1 µg/ml; p=0,107). The patients with diabetes have lower adiponectin concentration than non-diabetic (6,9±2,6 vs. 8,1±3,3 µg/ml; p=0,2). Adiponectin levels correlated with BMI (r=-0.35; p<0.05) and WHR (r=-0.32; p<0.05).

Conclusions: Plasma adioponectin levels in diabetic patients with acute myocardial infarction correlated significantly with progression of atherosclerotic changes in coronary arteries. This may suggest that decreased plasma adiponectin concentration is associated with a higher risk of multivessel disease.

High osteoprotegerin levels in newly diagnosed type 2 diabetic males and correlations with glucose parameters

M. Boyadzhieva[1], K. Hristozov[1], S. Georgiev[2], T. Chervenkov[3], I. Balabanski[3], N. Usheva[4], R. Yordanov[2]

[1] Medical University, Endocrinology and metabolic diseases, Varna, Bulgaria

[2] Medical University, Clinic of Interventional Cardiology, Varna, Bulgaria

[3] Medical University, Immunology laboratory, Varna, Bulgaria

[4] Medical University, Dep. of medical statistics, Varna, Bulgaria

Osteoprotegerin (OPG) was initially discovered as an inhibitor of bone resorbtion, but recently increased OPG levels were found in diabetics and in patients with coronary artery disease (CAD) too. Up to date there are insufficient data on OPG concentrations in newly diagnosed type 2 diabetic patients. The aim of our study was to determine serum OPG in males with newly diagnosed T2DM associated or not with concomitant CAD as well as in males with known T2DM.

Serum OPG levels were measured in 36 type 2 diabetic males (mean age 56.9 ± 1.5 years), including 17 newly diagnosed subjects without history of CAD (group 1) and 17 diabetic patients who underwent percutaneous coronary interventions (PCI) for a clinical manifestation of CAD, the latter consisting of 9 newly diagnosed diabetics (group 2) and 8 patients with known T2DM, with mean duration of diabetes of 10.9 ±3 years (group 3). All newly diagnosed glucose abnormalities were detected during 2 screening programs among risk groups. Glucose tolerance was defined by performing a standard OGTT. The control age- and BMI-matched group (n=20) had normal glucose tolerance. OPG was measured by ELISA (BioMedica).

OPG was significantly higher in all type 2 diabetics (3.8±0.2 vs 2.7 ± 0.2 pmol/l, p=0.0002) and especially in all newly diagnosed diabetics (3.9±0.2 vs 2.7 ±0.2 pmol/l, p=0.0004). There was no significant difference between newly diagnosed diabetic males with performed PCI (group 2) or those without known CAD (group 1)- 3.4 ± 0.2 vs 4.1 ± 0.3 pmol/l, p=0.14 respectively. Males with known diabetes and performed PCI (group 3) were with higher OPG compared to controls (3.6 ± 0.2 vs 2.7 ± 0.2pmol/l, p=0.02), but there were not significant differences with other newly diagnosed diabetic patients (3.6 ± 0.2 vs 4.1 ± 0.3 pmol/l, p=0.2; 3.6 ± 0.2 vs 3.4 ± 0.2 pmol/l, p=0.7 for group 1 and 2 resp.). We found positive correlation of OPG concentrations with fasting plasma glucose (r=0.27, p=0.04), 120 min post-OGTT glucose (r=0.32, p=0.02) and HbA1c (r=0.31, p=0.03).From lipid parameters OPG correlated positively only with HDL-cholesterol (r=0.3393, p=0.02).

We found higher serum OPG levels in newly diagnosed type 2 diabetic males independently of presence of CAD, and no difference compared to males with long-lasting diabetes. The positive correlations of OPG with glucose parameters may explain the higher concentrations in diabetics and we speculate that OPG rises early in the evolution of diabetic disorders but further investigations are needed.

Low intensity physical activity improves left heart brachial aortic pulse wave velocity in elderly hemiplegics with type 2 diabetes mellitus: a randomized control trial

A. Kimura[1], S. Fujiko[2]

[1] Kinjyo University, Health Sciences, Ishikawa, Japan

[2] Kanazawa University, Health Sciences, Ishikawa, Japan

The aim of this study was to investigate the effect of low-intensity physical activities (LIPAs) on left heart-brachial aortic pulse wave velocity in elderly hemiplegics.

LhbPWV has high correlation with sudden death in T2DM people.

The method of study, the design of study was a randomized control trial.

The participants were 25 elderly hemiplegics (mean age ±SD=73 ± 8 years) with independent ADL, living in private residences and utilizing a nursing home. We got informed consent of them.

The length of time elapsed from the occurrence of the stroke was greater than 5 years, and they required a walking aid (e.g., a cane) outdoors. Twenty-two participants (88%) also used a walking aid indoors.

The subjects' main co-existing medical conditions included hypertension (92%) and diabetes mellitus (80%).

The intervention was to increase the energy consumption from baseline physical activity (PA) through LIPAs (approximately 40 kcal/day; 3.3% of daily calories). LIPAs involved all limbs and body movement such that the body's centre of gravity moved up and down while in a standing position (interventional group [IG]; n=13).

The movement gave a passive motion to the affected arm and leg.

In the control group (CG; n=12), only the baseline PA was measured.

Outcomes were evaluated by the left heart-brachial aortic pulse wave velocity (lhbPWV), body weight, body mass index, resting systolic blood pressure, calculated PA from daily activities, and the ankle-brachial pressure index.

The data analyzed of the independent t-test on the outcomes to compare the differences between the CG and the IG at baseline (1st week) and after 4 and 8 weeks of intervention.

In the results, the lhbPWV values in the affected arm were significantly difference in the IG compared with the CG (pre 1172cm/s vs.1162cm/s, post 1201cm/s vs. 1332cm/scm/s; P < 0.05) eight weeks after the initiation of the trial.

These activities resulted in significant improvement to deterioration in their aortic stiffness, as reflected by a change in the lhbPWV.

Cardiovascular risk factors in type 2 diabetic patients: a cross sectional study, Iran

R. Hosseini[1], M. Fahmi[2]

[1] Qom University of Medical Sciences, endocrinology & metabolism, Qom, Iran

[2] Qom Azad University of Medical Sciences, internal medicine, Qom, Iran

Aim: The aim of the study was to evaluate cardiovascular risk factors and assess coronary heart disease (CHD) risk at 10 years according to Framingham point scores. Moreover the possible relation of other CHD risk factors, which were not considered in Framingham equation, was evaluated.

Methods: We assess the CHD risks in type 2 diabetic patients referred to university hospital diabetes clinic from October 2007 to July 2008 in Qom, Iran. Based on probability of CHD events in 10 years, patients were classified in three groups :< 10%, 10-20% and >20% according to NCEP/ATPIII Framingham risk score. We also evaluate the relationship between other CHD risk factors not included in Framingham equation such as BMI, Waist circumference, LDL cholesterol, TG and Diastolic blood pressure (DBP). Lipid profiles and hypertension were defined according to ATP III and JNC VII criteria respectively.

Results: A total 360 patients (50% males) with mean age 53.9± 10 years were evaluated. 80.3% had BMI>25, 37.2% of females and 10% of males had waist circumference>88 and >102 cm respectively.

LDL-cholesterol>100 and TG>150mg/dl were seen in 78.8% and 73.6% respectively. According to JNC VII criteria, 40% had prehypertension state and 45.3% were hypertensive. Family history for CHD was positive in 34%. HbA1C>7%was seen in 91.3%.Total score according to Framingham equation was 14.9±4.4 in males and 11.4±3.7 in females.70.6% of males and 11.6% of females had probability of CHD in 10 years>10%. Correlation between DBP and LDL cholesterol with CHD risk in women and men was statistically significant. In men TG levels had linear correlation with CHD risk (P=0.02).

Conclusions: Most diabetic patients did not have adequate control of cardiovascular risk factors, and for assessing CHD risk in diabetic patients other risk factors, not included in Framingham score, such as LDL-C, DBP and TG, should be considered important.

Spontaneous platelet macro-aggregation (SPMA) and high clopidogrel maintenance dose in patients with diabetes mellitus and coronary artery disease

P. Sardar[1], P. Guha[1], S. Deb[2], P. Chakraborti[3], U. Chaudhuri[3], A. Dasgupta[2], S. Guha[4], P. Lahiri[3]

[1] *Medical College, General Medicine, Kolkata, India*

[2] *Calcutta University, Department of Biochemistry, Kolkata, India*

[3] *Medical College, Institute of Hematology & Transfusion Medicine, Kolkata, India*

[4] *Medical College, Department of Cardiology, Kolkata, India*

Aims: Platelets in diabetic patients show exaggerated aggregation, both spontaneous and in response to stimulating agents, even after treatment with aspirin and clopidogrel. Whether inhibition of platelet aggregation can be enhanced by increasing clopidogrel maintenance dosage in diabetes patients with Spontaneous platelet macroaggregation (SPMA) is unknown. The aim of this study was to assess the impact of a high maintenance dose in diabetes patients with SPMA.

Methods: Diabetic patients with acute coronary syndrome (ACS) who were on dual antiplatelet therapy with aspirin (150mg/day) and clopidogrel (75mg/day) for at least 7 days, were screened to identify the SPMA cases. Spontaneous platelet aggregation was studied in an aggregometer cuvette without agonist while the stirring rate was fixed at 1000 rpm/min. SPMA cases were randomized to 15-days treatment with a standard (75 mg; n=8) or high (150 mg; n=8) daily maintenance dose of clopidogrel. Platelet aggregation with agonist (collagen, ADP and epinephrine) was assessed before and after dose doubling.

Results: A total of 107 diabetic ACS patients were screened to identify 16 SPMA cases. Aggregation profiles of SPMA cases were unique and different from non-SPMA cases. All SPMA cases showed higher aggregation with agonists even after 7 days of therapy. After randomization, ADP induced (10 µM/L) platelet aggregation was significantly reduced in the 150-mg group compared with the 75-mg group. After 15 days therapy SPMA disappeared in 5 patients on 150 mg clopidogrel and only 2 patients in 75 mg clopidogrel. The response to even 150mg clopidogrel was suboptimal in 40% cases.

Conclusions: SPMA cases are related to high platelet reactivity. The antiplatelet effect of 150mg maintenance dose of clopidogrel is much better as compared to 75mg maintenance dose in diabetic ACS patients with SPMA. Large scale clinical trials are needed to further study the response.

P-1069

Association of cardiac autonomic neuropathy and right bundle branch block in type 2 diabetic patients

A. Sato[1], S. Ootake[1], K. Sakai[1], Y. Iwamoto[1]

[1] *Tokyo Women's Medical University, Diabetes Center, Tokyo, Japan*

Aim: Recent research indicates that cardiac conduction defects are associated with increased risk of mortality of cardiovascular diseases. Right bundle branch block (RBBB) is more common in older age, male, hypertension and diabetes. The cause of increased prevalence of RBBB in diabetic patients is not known. The aim of this study is to evaluate the relationship of RBBB and diabetic autonomic neuropathy.

Objects and methods: Among 1064 type 2 diabetic in-patients between January and December in 2004, 363 type 2 diabetic patients under 80 years old, without chronic renal failure, without ischemic heart disease, and not taking drugs related to autonomic nerve function, were examined by electrocardiogram. RBBB was determined according to the Minnesota code; rSR' or rR' in lead V1, and wide S wave in lead V5 and V6. Fifteen patients (men 11,age 65±9 years old) had RBBB in electrocardiogram (ECG) (RBBB group). Age and sex matched 30 patients (men 22,age 65±9 years old) with normal ECG were recruited as normal control (C group), then we performed case-control study. Cardiac autonomic neuropathy was assessed by the change in heart rate resulting from taking a deep breath (R-R). R-R was examined after 10 minutes rest, and R-R interval measured every 6 deep breath in 1 minute. Results were expressed as heart rate differences (max-min), and heart rate difference more than 15 beats were defined normal. Blood pressure, HbA1c, serum lipid, and presence of diabetic retinopathy were compared between RBBB group and C group.

Results: The average R-R was 7.4±3.3 beats/min in RBBB group. No one had normal R-R in RBBB group. In C group, 32% of patients had normal R-R, and the average of R-R was 11.5±7.3 beats/min. R-R was significantly decreased in RBBB group as compared with C group ($p<0.05$). While HbA1c (9.1±1.5% vs 8.6±1.5%, RBBB vs C group), duration of diabetes (20±9 vs 21±8 years), systolic blood pressure (131±19 vs 123±17 mmHg), diastolic blood pressure (72±6 vs 71±9 mmHg), LDL cholesterol (113±26 vs 112±27 mg/dl), HDL cholesterol (48±11 vs 49±14 mg/dl), triglyceride (154±130 vs 125±76 mg/dl), and presence of diabetic retinopathy (67 vs 67 %) were not significant differences between two groups. In multiple regression analysis, presence of RBBB was an independent risk factor for decreased R-R ($p<0.05$) adjusted by HbA1c, blood pressure, serum lipid, presence of diabetic retinopathy.

Conclusions: Our study shows that type 2 diabetic patients with RBBB decreases the change in heart rate resulting from taking a deep breath as compared to patients with normal ECG. It suggests diabetic autonomic neuropathy may play a role of cause for RBBB in type 2 diabetic patients.

P-1070

Cardiovascular disease risk factors in individuals with a family history of type 2 diabetes mellitus

S. Bahendeka[1]

[1] *Saint Francis Hospital, Medicine, Kampala, Uganda*

To determine the prevalence cardiovascular disease (CVD) risk factors in individuals with a family history of type 2 diabetes, 346 subjects residing in Bushenyi and Kasese districts of Uganda were enrolled into the study between April and December 2006. Of these, 114 (41 men; 73 women), mean age 49 years, mean BMI 23.9 kg/m^2, had a family history of type 2 diabetes (FHD group); 112 (45 men; 67 women), mean age 54 years, mean BMI 23.1 kg/m^2, were subjects with no family history of diabetes (Control group), and 120 (53 men; 67 women), mean age 55 years, mean BMI 24.7 kg/m^2, were patients with type 2 diabetes (Diabetics group).

Data was collected on history of smoking, consumption of alcohol, fruit and vegetables, and physical activity. Weight, height, waist circumference, blood pressure and fasting plasma glucose and lipids were measured after an overnight fast.

A one-way between groups analysis of variance was conducted to explore differences in high density cholesterol (HDL-C), low density cholesterol (LDL-C), total cholesterol (Total-C) and triglycerides (TG) in FHD group, Controls and Diabetics. No significant differences were observed. The mean ± SD mmol/l HDL-C was 0.8 ± 0.31; 0.9 ± 026 and 0.8 ± 0.31 for FHD, Controls and Diabetic groups: [$F(2, 325) = 2.4$, $p = 0.90$]. The mean ± SD mmol/l LDL-C was 2.2 ± 0.67; 2.1 ± 0.61 and 2.2 ± 0.59 for FHD, Controls and Diabetic groups: [$F(2, 236) = 1.0$, $p = 0.36$]. The mean ± SD Total-C was 3.5 ± 1.01; 3.5 ± 0.86 and 3.6 ± 0.86 for FHD, Controls and Diabetic groups: [$F(2, 326) = 0.84$, $p = 0.43$]. The mean ± SD mmol/l TG was 1.8 ± 1.21; 1.6 ± 0.87 and 1.9 ± 1.11 for FHD, Controls and Diabetic groups: [$F(2, 327) = 2.6$, $p = 0.07$].

The prevalence (95% CI) of undiagnosed diabetes in FHD group was 7% (2.7 – 13.3%) and 2.7% (-0.3 – 6.1%) in controls. The prevalence of undiagnosed hypertension was 31.2% (16.7 – 33.7%) in the FHD group and 34.5% (22.8 – 40.6%) in controls. The prevalence of hypertension was 43.1% (34.2 – 52.0%) in diabetics. The prevalence of 'taking fruit and vegetables rarely' was 41% (31.4 – 50.6); 44% (32.8 – 51.8%) and 39% (24.1 – 40.9%) in the FHD group, controls and diabetics respectively. The prevalence of physical inactivity (sedentary lifestyle) was 29% (20.1 – 37.9%); 47.1% (37.5 – 56.7%) and 43.3% (34.4 – 52.2%) in the FHD group, controls and diabetics respectively. The prevalence of severe forms of obesity was low, as was the prevalence of smoking.

The results indicate a prevalence of 7% of undiagnosed diabetes in subjects with a family history of diabetes compared to 2.7% in those without, and an associated high prevalence of undiagnosed hypertension of 31%.

P-1071

Agreement and correlation of cardiovascular risk measure in patients with diabetes type 2 through Framingham, UKPDS V 2.0 and WHO (AMRD) 2008 scales.

F. Barrera[1]

[1] *Ministerio Salud Pública del Ecuador, Dirección Provincial de Salud de Pichincha AREA No.4, Quito, Ecuador*

Cardiovascular risk assessment allows adequate management of diabetic type 2 patients (DM2). Agreement between risk scales has been controversial. We examined the agreement in risk definition and the correlation in the cardiovascular risk measure between Framingham, UKPDS V 2.0 and WHO (AMRD) 2008 chart.

All 148 DM2 patients from Otavalo, Ecuador were submitted to cardiovascular risk assessment applying Framingham, UKPDS v2 and the WHO chart. A multivariate analysis was done

Average age was 61.4 ± 10.4 years. Time of disease was 8.5 years (1-32 years). Risk probabilities were correlated between Framingham and UKPDS for non-fatal coronary (r=0.78), fatal coronary (r=0.72) and non fatal stroke risks (r=0.67). Comparing WHO with Framingham, contingency coefficient was of 0.675. Correlating Framingham with the UKPDS, contingency coefficient was of 0.595, 0.553 and 0.572 for non-fatal, fatal coronary and non fatal stroke risks respectively. Analysis by age (<65 years and >= 65 years) and time of disease (<10 years and >=10 years), showed lower correlation and contingency coefficients than those of the general sample except for people over 65 years old. The correlation coefficient between Framingham and UKPDS for non fatal and fatal coronary risks were higher than 0.7 in the multivariate analysis of age and time of the disease.

There is a good correlation between fatal and non fatal coronary risk assessment (UKPDS) compared to the Framingham, as well as a good agreement for the definition of low risk, especially in people older than 65 years and with more than 10 years of disease.

Association between hyperglycaemia and subclinical coronary atherosclerosis in patients with diabetes mellitus

E. Buchaca[1], *S. Bermudez*[1], *L. Rodriguez*[1], *L.L. Bencomo*[2], *F. Fernandez*[1], *D. Hierro*[2], *M. Valdes*[1]

[1] *Hospital Hermanos Ameijeiras, Internal Medicine, Ciudad de la Habana, Cuba*

[2] *Hospital Hermanos Ameijeiras, Radiology, Ciudad de la Habana, Cuba*

An observational and transversal study was carried out in 42 patients without symptoms of ischemic heart disease with the objective of identifying whether there was a relationship between hyperglycaemia and coronary atherosclerosis. The presence of atherosclerosis was determined by measuring the calcium score and studying the morphology of the coronary territory, by means of a multislice computerized axial tomography, related to the glycaemia control. Other coexistent risk factors were analyzed as well: hypertension, nicotinism, obesity and dyslipidaemia.

Patients with hyperglycaemia (fasting and post prandial) showed a significant association (p= 0.024) with coronary damage. This relationship was more evident with postprandial hyperglycaemia (p=0.016). The presence of hyperglycaemia represented a significant increase (5.9 times) with the relative risk of identifying coronary atherosclerosis (p = 0.045). However, it was not confirmed with other conventional risk factors.

We conclude that the lack of glycaemia control (glycaemia disorders) was positively related with the coronary damage detected by a multislice computerized axial tomography among the diabetic patients studied, who showed no clinic manifestation of ischemic cardiopathy

P-1073

Prevalence of coronary artery disease in type 2 diabetes among hospitalised patients

S. Devasahayam[1], *C. Muniasamy*[1], *C. Sathiakumar*[1], *V. Selvarajan*[1]

[1] *Sugam Hospital, Department of Internal Medicine, Chennai, India*

Aim: In India both Diabetes and Cardiovascular disease occur in epidemic proportions.The present prevalence of diabetes in India ranges from 9-14%.It is estimated that type 2 diabetics have a 2-4 fold higher risk for cardiovascular disease than non diabetics. We aim to assess the prevalence of Cardiovascular disease among hospitalised diabetic patients in Chennai, Southern India.

Materials and methods: We studied patients admitted between Jan 2007 and Jan 2008 in a community hospital in an industrial area of Chennai, a city in Southern India. A total of 4997 were included in the study. Among these patients the total number of diabetics (both known diabetics and newly detected diabetics using standard diagnostic criteria) were estimated. Among these diabetics, the incidence of coronary artery disease (acute coronary disease and ischaemic heart disease) were assessed using standard protocols.

Results of the study: Out of the 4997 hospitalised patients 634 (12%) had diabetes. Out of these 634 diabetics 172 (27%) had coronary artery disease of which 100 (58%) were male patients and 72 (42%) were female patients. Out of 172 patients who had cardiovascular disease 70 (40.69%) patients had Acute Coronary Syndrome and the remaining 63.3% had Ischaemic Heart Disease. Out of the 172 patients diagnosed to have Coronary Artery Disease 27 (15.69%) had no symptoms referable to Cardiovascular System.

Conclusion: Prevalence of Diabetes Mellitus in hospitalised patients is equal to the Indian average. But the incidence of Coronary Artery Disease (Ischaemic Heart Disease and Acute Coronary Syndrome) among these diabetic patients is alarmingly higher than the previous Indian Study Research. Among these patients with Coronary Artery Disease, 15.69% presented with features not referable to Cardiovascular System. This new observation from this study calls for thorough screening for Cardiovascular Disease among hospitalised Diabetic patients whether symptomatic or not, as Diabetes Mellitus is considered to be a Coronary equivalent.

Role of intracellular zinc on phosphorylation level of cardiac ryanodine receptors in normoglycemic and hyperglycemic rats

E.N. Zeydanli[1], *D. Akman*[1], *S.S. Yildirim*[1], *B. Turan*[1]

[1] *Faculty of Medicine, Biophysics, Ankara, Turkey*

Abnormal intracellular Ca^{2+} ($[Ca^{2+}]_i$) handling by the sarcoplasmic reticulum (SR) is a critical factor in the development of heart dysfunction. Excitation-contraction coupling is predominantly controlled by Ca^{2+} release from the SR via the ryanodine receptors (RyR2). Hyperphosphorylation of RyR2 induces Ca^{2+} leak during diastole, which can cause fatal arrhythmias and lead to heart dysfunction in diabetes. Several Ca^{2+} binding proteins in cardiomyocytes bind Zn^{2+} suggesting that Zn^{2+} can modulate the structure and function of many proteins such as SR, which play important role in excitation-contraction coupling. It was also demonstrated that Ca^{2+} dependence of RyR2 binding to the SR of cardiomyocytes is greatly affected by Zn^{2+}. Since free Zn^{2+} is altering function of numerous cellular proteins, its mobilization by ROS in diabetic heart can be likely to cause significant effects. It is highly likely that any mechanism that alters the concentration and distribution of intracellular free Zn^{2+} ($[Zn^{2+}]_i$) in cardiomyocytes will cause profound functional effects. Previously we clearly established that the defects in intracellular Ca^{2+} –related mechanisms could be attributed to anomalous RyR2 behavior such as reduced amount of RyR2 and FKBP12.6 levels and the PKA-dependent phosphorylation of RyR2. In this study, we aimed to examine role of intracellular zinc on the phosphorylation level of RyR2. We used pulverized hearts from normal and streptozotocin-induced diabetic rats and exposed them to different concentrations of either ZnCl2 or Zn-pryt. We measured total protein level of RyR2 and phosphorylated level of RyR2 (P-RyR2). Firstly, we observed that P-RyR2 level was significantly higher than that of the control. Second, the P-RyR2 level of both normal and diabetic hearts increased significantly with increasing zinc concentration, whereas the increase was more pronounced in normal heart compared to the diabetics. It is, therefore, concluded that a detailed understanding of the basic structure and function of RyR2 and relationship with intracellular zinc levels will provide us their involvement in heart diseases, and the development of drugs to prevent RyR2 malfunction and recent patents.

P-1075

Role of antioxidant treatment on diabetes-induced altered actors of MAPK pathway of the heart

S. Yildirim[1], E. Zeydanli[1], D. Akman[1], B. Turan[1]
[1] Health Science, Biophysics, Ankara, Turkey

Oxidative stress contributes to the development of a wide range of diseases including diabetes and results from an imbalance between the production of reactive oxygen and the system's ability to readily detoxify the reactive intermediates repair the resulting damage. Cells are normally able to defend themselves against the oxidative stress induced damage by regulating the cellular redox status through the antioxidant systems. The present study was performed to examine the effects of antioxidant treatment (sodium selenate; 15 µmol/kg/day for 4 weeks) on the actors of MAPK pathway such as ERK and NF-kappaB in diabetic rats. We measured total and phosphorylated ERK and NF-kappaB levels in the heart tissue by using Western Blot technique. Total and Phospho - ERK levels were increased about 40% compared to those of the controls. We also observed 30% decrease in the level of total NF-kappaB while 85% increase in the level of Phospho - NF-kappaB. Sodium selenate treatment of the diabetic rats preserved these altered levels of MAPK actors, significantly. For comparison, we also treated the diabetic rats with another antioxidant, omega - 3E for the same period and obtained the similar beneficial effects on these parameters. In conclusion, the results of the present study show that diabetes induced a significant increase in the levels of oxidative stress and/or caused a defect into antioxidant defence system. Furthermore, our data demonstrated that antioxidant supplementation might be beneficial for diabetes therapy due to an improvement of antioxidant defence system against diabetes induced altered cell defence state.

Beneficial effects with beta-adrenergic receptor blockers on diabetes-induced intracellular Ca2+ related mechanisms in the heart

E. Tuncay[1], A.A. Seymen[1], B. Turan[1]
[1] Health Science, Biophysics, Ankara, Turkey

Beta adrenergic receptor blockers play an important role in the management of the cardiovascular diseases. Chronic beta adrenergic receptor (ß-AR) blockade improves cardiac contractility and prolongs survival of the patients with heart failure. An important disease of the modern life, Diabetes Mellitus is associated with cardiovascular diseases. Defective mechanical activity of the heart in type 1 diabetic animals includes alteration of Ca^{2+} signaling via changes in critical processes that regulate intracellular Ca^{2+} concentration.

Methods: Since propranolol and timolol are nonselective agents with different ß1- potency, we previously examined the long-term beneficial effects of non-selective ß-AR blockers, propranolol (25 mg/kg/day) - or timolol (5 mg/kg/day) administrations (intragastrically, 3 months) on the depressed mechanical activity of the heart.

Aim: Therefore, in this study we aimed to examine the effects of these agents on L-type Ca^{2+} currents (I_{Ca}) and electrically stimulated intracellular Ca^{2+} transients of freshly isolated cardiomyocytes from diabetic rats.

Results: Diabetes induced a significant increase in cell size without any significant effects on the I_{Ca} density, a significant increase in basal free Ca^{2+} concentration, and marked decrease in amplitude of the Ca^{2+} transients. In addition, the caffeine induced Ca^{2+} transients was %30 smaller than that of the controls. Both beta-blockers preserved these altered parameters of intracellular Ca^{2+} related mechanisms in diabetic cardiomyocytes, significantly. These beneficial effects obtained with both beta-blockers were not in the same order; mostly their effects were differential except their effects on the cell size. In addition, we observed that these beneficial effects with these two beta-blockers were not only related with their direct effect on their receptors but also related with intracellular secondary signaling pathways such as adenyl cyclase.

Discussion/conclusion: As summary, although prevention of diabetes-induced altered cardiac function by beta-blockers might present a useful pharmacological strategy for the treatment of diabetic cardiomyopathy, it can be clearly concluded that there are differences in the effect of individual beta-adrenergic blocking agent.

P-1077

Prevalence of accompanying pathology in patients with type 2 diabetes mellitus by results of autopsies

A. Terekhova[1], A. Zilov[1]
[1] I.M. Sechenov Moscow Medical Academy, Endocrinology, Moscow, Russia

Aims: To evaluate prevalence of accompanying pathology, its contribution to causes of death in patients with type 2 diabetes mellitus (type2 DM) according to medical histories and pathologic diagnoses.

Methods: 1927 patients died in Moscow's City clinical hospital N50 during 2006-2007 years, 289 of them had hyperglycemia. Only 188 patients (65.05%) had established type 2 DM. In these subjects the main causes of death, prevalence of accompanying pathology, and equivalence of clinical and pathologic diagnoses were studied at the base of case reports and results of autopsies.

Results: Among the 188 patients with type 2 DM there were 136 women (72.34%) at the age of 76 [69; 80.25] years and 52 men (27.66%) at the age of 76 [71.75; 81] years. Cardiovascular diseases were reported in 177 subjects (94.14%): an acute/recurrent myocardial infarction (MI) in 40 patients (21.27%) and postinfarction/atherosclerotic cardiosclerosis in 143 patients (76.06%). Cerebrovascular disease (ischemic and hemorrhagic strokes/postinsult state) was detected in 86 cases (45.74%). 85 patients (45.2%) had a combination of cerebrovascular and cardiovascular pathology. Diseases of respiratory system (chronic obstructive/mucopurulent bronchitis, bronchial asthma) and malignant tumors were revealed in 56 (29.78%) and 31 patients (16.48%), respectively. Pyelonephritis and inflammatory diseases of urinary tract were detected in 20 cases (10.63%). The main causes of death of 188 subjects were ischemic/hemorrhagic strokes (27.65%), postinfarction cardiosclerosis (23.93%), acute/recurrent MI (21.27%), malignant tumors (13,83%). All the cases were mainly complicated by renal impairment - actually every second patient from 188 had renal failure (53.72%). Pyelonephritis was the immediate cause of death certified by autopsy only in 10 of 20 patients, however renal failure was detected in 18 subjects (90%). Combination of several nosological forms (2-5) in one patient was revealed in 166 cases (88.3%), 56 of 188 fatal outcomes (29.78%) were resulted from 2 competitive diseases. Divergences of clinical and pathologic diagnoses were registered in 52 of 188 (27.65%) cases and in 15 cases (28.95%) they were clinically significant.

Conclusions: Along with considerable prevalence of cardiovascular and cerebro-vascular diseases, high rate of infectious pathology of urinary tract was detected, its potential contribution in renal failure was confirmed. Substantial prevalence of pyelonephritis leading to death demands more active identification and correction. High frequency of combination of several diseases in one subject should determine more careful examination and treatment of patients according to the accompanying pathology. Ascertained rate of divergences of clinical and pathologic diagnoses underlines great value of autopsy for retrospective analysis of severe medical cases, for assessment of quality of treatment.

P-1078

Evaluation of adiponectin and leptin levels in acute myocardial infarction and period of convalescence in patients with type 2 diabetes mellitus

P. Krasnodebski[1], W. Karnafel[1], M.I. Bak[1], G. Opolski[2]
[1] *Medical University of Warsaw, Department of Gastroenterology and Metabolic Dieseases, Warsaw, Poland*
[2] *Medical University of Warsaw, Department of Cardiology, Warsaw, Poland*

Aims: The aim of the study was to evaluate adiponectin and leptin concentrations in acute myocardial infarction and period of convalescence in patients with type 2 diabetes mellitus.
Material and methods: Coronary angiography was performed in 58 patients with acute myocardial infarction (within 12 hours from symptoms onset). The study group comprised 35 patients with type 2 diabetes mellitus (25 men, 10 women, mean age 64,6±11,2 years) and 23 non-diabetic subjects (17 men, 6 women, mean age 59,6±10 years) - control group. All patients underwent medical examination and body mass index (BMI) and Waist/Hip Ratio (WHR) were calculated. Venous blood was collected after 24 hours of admission (second day), on day 5 and three weeks after admission.
Results: Patients with diabetes had lower adiponectin concentration than non-diabetics (in acute phase 6,33±2,55 µg/ml vs. 6,81±2,71 µg/ml p=0,4; in period of convalescence 6,31±2,68 vs. 7,97±3,56 µg/ml p=0,04). Adiponectin levels correlated negatively with waist circumference (r=-0,47; p=0,004). Plasma adiponectin levels in non-diabetic patients declined significantly on days 2 and 5 compared to the concentrations on day 21 (p<0,05). Adiponectin level was significantly associated with BMI, arterial blood pressure, glucose and insulin blood levels. These independent variables explained 32% of the plasma adiponectin variability.
Mean levels of leptin was significantly lower in non-diabetics compared to diabetic patients. Plasma leptin level in diabetic patients was significantly higher in acute myocardial infarction than in period of convalescence (18,3±14,33 µg/ml, 16,17±12,88 µg/ml, 14,84±11,22 µg/ml, X^2 ANOVA=7,1 p=0,02). Leptin level was significantly associated with BMI, waist circumference, proinsulin/C-peptide (marker of ß-cells dysfunction) and HOMA-IR index, and these independent variables explained 69% of the plasma leptin variability.
Conclusions: Plasma leptin levels in diabetic patients were significantly higher in acute myocardial infarction than in period of convalescence. Plasma adiponectin levels in non-diabetic patients with acute myocardial infarction declined significantly on days 2 and 5 compared to the concentrations on day 21.

Serum 25-hydoxyvitamin D levels are associated with arterial stiffness in type 2 diabetes

J.I. Lee[1], S.J. Oh[1], T.S. Sohn[1], H.S. Son[1], S.A. Chang[1], B.Y. Cha[1], J.H. Kim[1], J.M. Lee[1], S.S. Lee[1], S.J. Yoo[1]
[1] *The Catholic University of Korea, internal medicine, Seoul, Korea*

Aims: Many tissues including vascular smooth muscle, endothelium, and cardiomyocyte express the vitamin D receptor. 25-hydoxyvitamin D (25-OH D) has been found to play an important role in prevention of cancers, auto-immune disease, cardiovascular disease, diabetes, and infections. Viatmin D deficiency seems to predispose to cardiovascular disease. But clinical data to support these results are lacking.
Methods: We studied 60 type 2 diabetic patients over age 30 (mean age 58 years; 55% women) without prior cardiovascular disease. Vitamin D status was assessed by measuring 25-OH D levels. Pulse wave velocity measured by the Vascular Profiler 1000 (VP-1000) wave form analysis.
Results: Their mean duration of diabetes was 9 ± 3.8 years and mean A1c was 10.4 ± 2.1%.
46% of individuals had 25-OH D levels <20 ng/mL, and 10% had levels <10ng/mL. Mean pulse wave velocity was 1803.0 ± 412.6 cm/sec. Serum 25-OH D level was significantly reduced in increased PWV group.
Conclusion: Serum 25-hydroxyvitamin D levels are associated with arterial stiffness in type 2 diabetes.
Type 2 diabetic patients in vitamin D insufficiency or deficiency need to monitor cardiovascular disease and should consider vitamin D supplement.

Correlations between left ventricular wall thickness and short-term beat-to-beat QT variability in patients with type 1 diabetes mellitus

C. Lengyel[1], A. Nemes[2], R. Takács[1], A. Orosz[3], T.T. Várkonyi[1], H. Gavallér[2], I. Baczkó[3], T. Forster[2], T. Wittmann[1], J.G. Papp[4], A. Varró[3]
[1] *University of Szeged, First Department of Medicine, Szeged, Hungary*
[2] *University of Szeged, Second Department of Medicine and Cardiology Centre, Szeged, Hungary*
[3] *University of Szeged, Department of Pharmacology and Pharmacotherapy, Szeged, Hungary*
[4] *Hungarian Academy of Sciences and University of Szeged, Division for Cardiovascular Pharmacology, Szeged, Hungary*

Background and aim: Determination of short-term QT-interval variability (QTV) is an intensively investigated new and non-invasive method for assessment of proarrhythmic risk. Several studies have demonstrated that temporal QTV is a more sensitive predictor of ventricular arrhythmias than conventional QT-measurement parameters. Enhanced QTV has been observed in patients with diabetes mellitus (DM). Furthermore, elevated QTV has also been found in an experimental model of left ventricular hypertrophy in normoglycemic dogs. The aim of the present study was to evaluate the possible connections between the QTV, the left ventricular wall thickness and the autonomic function in patients with type 1 diabetes mellitus.
Subjects and methods: 38 DM patients (age: 31.9±1.7 years, male/female ratio: 19/19, duration of DM: 14.0±1.9 years, HbA1c: 8.2±0.2%, BMI: 24.5±0.6 kg/m^2, blood pressure: 127/76±2.6/2.0 mm Hg; mean±SEM) were enrolled into the study. ECGs were recorded continuously for 5 min and all leads acquired by an ECG signal processing system. After analogue-to-digital conversion, the data were stored on hard disk and analyzed off-line using SPEL Advanced Haemosys software (v3.0). The RR and QT intervals were measured as the average of 31 consecutive beats (RR: 812±24.5 ms, QT: 387±5.6 ms, QT_c: 432±4.2 ms). To characterize the temporal instability of beat-to-beat repolarization, Poincare' plots of the QT intervals were constructed, where each QT value was plotted against its former value. QTV was calculated using the following formula: QTV= ?$|QT_{n+1}-QT_n|$/ (30xv2). Left ventricular dimensions and function were measured by transthoracic echocardiography. Autonomic function was assessed by means of five standard cardiovascular reflex tests.
Results: In DM patients, the QTV (4.3±0.2 ms) exhibited positive correlation with the thickness of the posterior wall ($r = 0.47$, $p < 0.001$) and the interventricular septum ($r = 0.37$, $p < 0.001$) of the left ventricle. There were no significant correlations betweeen the QTV values and the parameters of the autonomic tests.
Conclusion: Our data suggest a close relationship between the left ventricular thickness and the short-term QTV in patients with DM. This relationship suggests a possible additive role of cardiac hypertrophy in the etiology of increased instability of cardiac repolarization in DM population.

P-1081

Plasma ascorbic acid levels and angiopathic complications in Portuguese type 2 diabetic patients

A. Valente[1], R. Duarte[2], R. Carvalho[2], H.S. Costa[1]
[1] *Instituto Nacional de Saúde Doutor Ricardo Jorge I.P. (INSA), Departamento de Alimentação e Nutrição (DAN), Lisboa, Portugal*
[2] *Associação Protectora dos Diabéticos de Portugal (APDP), Lisboa, Portugal*

Background: Diabetes is now one of the most common non-communicable diseases globally. Non-insulin-dependent diabetes mellitus (type 2) is the most prevalent form of the disease in Portugal. A recent prevalence study of diabetes in Portugal performed by the Portuguese Diabetes Association (APDP) indicated that approximately 1 million of Portuguese suffer from this disease. Type 2 diabetes has been associated with oxidative stress and it is considered an important risk factor for cardiovascular disease. Epidemiological studies have shown that an increased intake of free radicals and decline of antioxidant concentrations were related to low antioxidant function in type 2 diabetes. Ascorbic acid (vitamin C) is an important dietary derived antioxidant and usually its blood levels are evaluated in oxidative stress status. However, it is unclear whether plasma ascorbic acid levels are different in type 2 diabetic patients with and without the presence of macro- or microangiopathic complications.
Aim: To compare ascorbic acid levels in Portuguese type 2 diabetic patients with and without angiopathic complications.

Methods: Plasma ascorbic acid was measured in 120 type 2 diabetic patients (40-75 years) from APDP using a validated UPLC method. Group I: 60 patients (25 males and 35 females) with macro- or microangiopathy and group II: 60 patients (21 males and 39 females) without angiopathy. The inclusion criteria for group I were: presence of at least one of the following complications – personal history of angina pectoris, coronary artery disease, peripheral vascular disease or retinopathy and for group II: absence of any macroangiopathy and retinopathy. A statistical analysis was performed to test differences in plasma ascorbic acid levels between the studied groups.
Results: Ascorbic acid levels in Portuguese type 2 diabetics with cardiovascular complications or retinopathy were significantly ($p<0.05$) lower (20.92 ± 7.77 µmol/l) than diabetics without complications (24.16 ± 8.06 µmol/l).
Conclusion: The results showed statistically significant differences between the groups in plasma ascorbic acid levels. Cardiovascular complications and retinopathy in type 2 diabetes are inversely related to vitamin C plasma levels.

P-1082

Cross-sectional survey of aspirin use and dose in Albertans with diabetes

E. Law[1], S.H. Simpson[1]
[1] University of Alberta, Faculty of Pharmacy & Pharmaceutical Sciences, Edmonton, Canada

Aim: Antiplatelet therapy, primarily with 80 to 325 mg aspirin daily, is recommended for cardiovascular (CV) risk reduction in diabetes. Emerging evidence suggests, however, that people with diabetes may have resistance to aspirin and require doses in excess of 160 mg daily to effectively lower the risk of CV disease. Although several population-based surveys suggest that about 40% of people with diabetes use aspirin regularly, the daily dose used remains unknown. This study measured (1) the proportion of people in Alberta, Canada, with diabetes who currently use aspirin regularly for CV risk reduction; and (2) the most common aspirin dose used.
Methods: Pharmacy students in their 4th year of undergraduate training are required to complete 16 weeks of experiential learning in various practice settings. During their community pharmacy rotations, these students have an opportunity to collect information on aspirin use from Alberta residents living with diabetes. Students were responsible for obtaining informed consent from the participants, completing a short survey to identify CV risk factors and aspirin use, and faxing information to the data collection centre. Data were examined using descriptive statistics.
Results: This analysis is based on 117 surveys returned during the first term and half of the second term of this project. The mean age of participants was 62 (± 13) years, 62 (53%) were women, and 97 (83%) had type 2 diabetes. Aspirin was used regularly by 72 (61%) participants. Of these, 61 (85%) were using 81 mg daily, 8 (11%) were using 325 mg daily, and 3 (4%) did not report their daily dose. Of the 45 individuals not using aspirin regularly, 5 (11%) people reported a previous vascular event (3 were using other antiplatelet agents) and 35 (78%) had one or more risk factors for cardiovascular disease. The remaining 5 (11%) individuals not using aspirin regularly did not have any cardiovascular risk factors.
Discussion: It appears that aspirin use in Alberta residents with diabetes is higher than previous reports. The most common aspirin dosage used is 81 mg, which may not be optimal for effective CV risk reduction. In addition to the examination of aspirin use, this project introduced pharmacy students to practice-based research activities. It is our hope that these activities will encourage them to participate in future studies.

Risk factors for coronary artery disease in the population of the municipality of Maracaibo, Zulia State

E. Rojas[1], V. Bermudez[1], F. Finol[1], G. Ruiz Acosta[1], D. Sanchez[1], F. Moreno[1], J. Gonzalez[1], D. Rodriguez[1], A. Urdaneta[1], M. Bracho[1]
[1] Endocrine-Metabolic Research Center "Dr. Féliz Gómez", Faculty of Medicine University of Zulia, Maracaibo, Venezuela

Introduction: Cardiovascular diseases are the leading cause of morbidity and mortality in most westernized countries. The aim of this study was to identify major risk factors for coronary artery disease in Maracaibo Municipality, Zulia State.
Materials and methods: A cross-sectional study in 1400 subjects (women 54.7% and 45.3% men) who had a complete clinical history and measured blood glucose, lipid profile, insulin and lipoprotein (a). The normal behavior of the variables was determined using the Geary test and the results were expressed as mean ± SD. The group differences were studied by T-Student test or ANOVA one factor considered as significant when $p<0.05$.
Results: 0.7% (n = 10) of the population exhibited previous history of Myocardial Infarction (MI), presenting family history of hypertension (90%), MI (60%) and Type 2 Diabetes (DM2) (60%), and background Personal HBP (50%) plus an additional 10% with high BP who did not know their status (Systolic Blood Pressure = 138 ± 28.5 mmHg, Diastolic Blood Pressure = 84.5 ± 8.5 mmHg) with significant differences with the group without history of MI (Systolic Blood Pressure = 119.28 ± 17.14 mmHg, Diastolic Blood Pressure = 76.9 ± 11.5 mmHg, $p<0.05$) and DM2 (30%), coupled with this 70% had central obesity, low HDL 60% and hyperglycemia 50% without significant difference between groups. Moreover, the 1.43% of individuals had a history of angina pectoris, of whom 60% were hypertensive (Systolic Blood Pressure = 135.1 ± 18.74 mmHg, Diastolic Blood Pressure = 81.45 ± 10.1 mmHg) presenting differences with the group without a history of angina (Systolic Blood Pressure = 119.42 ± 17.14 mmHg, Diastolic Blood Pressure = 77.13 ± 11.51 mmHg, $p<0.05$). 65% of them had low HDL-c and 40% had hyperglycemia with no significant differences according to groups. Sedentariness was present in 70% of patients with heart attack and angina.
Conclusion: The 0.7% and 1.43% of patients had personal history of angina pectoris and MI, respectively. High Blood Pressure was the predominant personal and family history of triacylglicerides and the only significant difference between those with no or MI or angina.
Keywords: risk factors, myocardial infarction, angina pectoris, hypertension

Uric acid levels in patients with acute coronary events

E. Rojas[1], G. Ruiz[1], V. Bermúdez[1], A. Luis[1], D. Aparicio[1], Y. Luti[1]
[1] Centro de Investigaciones Endocrino-Metabólicas "Dr. Félix Gómez", Endocrine-Metabolic Diseases, Maracaibo, Venezuela

Introduction and objectives: There is growing evidence on the possible association between high concentration of uric acid (UA) and cardiovascular disease. The objective of this research was to assess the levels of UA in patients with myocardial infarction (MI) and unstable angina (UA).
Materials and methods: We studied 180 patients divided into three groups: Group A, patients with IM (n = 60, female = 30, male = 30), Group B, patients with UA (n = 60, female = 29, male = 31) and Group C, control patients (n = 60, female = 30, male = 30) who had a complete clinical history, lipid profile and determination of UA. Statistical analysis was performed using the SPSS program for Windows ver.15. The distribution of variables was corroborated by the evidence of Z-Kolmogorov-Smirnov expressing the results as median or mean ± SD as appropriate. Comparisons were made by means of one factor ANOVA test or Mann-Whitney U as appropriate considering as significant a p value <0.05.
Results: There was no significant difference in anthropometric and blood pressure. The levels of uric acid in group A, B and C were 8mg/dL, 4mg/dL and 4 mg/dL respectively, showing statistically significant differences between Group A and B ($p<0.01$), group A and C ($p<0.01$) but not between Group B and C. Lipid profile values are displayed:

Patients	CT* (mg/dL)	LDL-c* (mg/dL)	VLDL-c* (mg/dL)	HDL-c* (mg/dL)	TAG* (mg/dL)
Group A	245,5	158,2	64	40,00±12,92	320
Group B	170,5	105	27	32,53±12,46	135
Group C	202,5	124	28,8	40,11±10,53	144

** One factor ANOVA: p <0.01*

Conclusions: Our results suggest that a high concentration of uric acid is an independent risk factor for myocardial infarction, but not for unstable angina.

Cardiovascular risk in diabetic patients with hepatitis C

E. Rusu[1], F. Rusu[2], M. Jinga[2], I. Ancuta[3], A. Dragomir[4], G. Radulian[5], D.M. Cheta[6], V. Stoica[7]

[1] University of Medicine "Carol Davila" Insitute of Diabetes Nutrition and Metabolic Diseses "Prof. N. Paulescu, diabetes, Bucharest, Romania
[2] Emergency Hospital "Carol Davila", diabetes, Bucharest, Romania
[3] University of Medicine "Carol Davila", gastroenterology, Bucharest, Romania
[4] Healthy Nutrition Foundation, gastroenterology, Bucharest, Romania
[5] University of Medicine "Carol Davila"Insitute of Diabetes Nutrition and Metabolic Diseses "Prof. N. Paulescu, diabetes, Bucharest, Romania
[6] University of Medicine "Carol Davila"Insitute of Diabetes Nutrition and Metabolic Diseses "Prof. N. Paulescu", diabetes, Bucharest, Romania
[7] University of Medicine "Carol Davila"Insitute of Diabetes Nutrition and Metabolic Diseses "Prof. N. Paulescu", gastroenterology, Bucharest, Romania

Aim: The aim was to evaluate the association between chronic hepatitis C (CHC), insulin resistance (IR), and cardiovascular risk, in patients with CHC and type 2 diabetes.
Methods: We selected 80 patients with type 2 diabetes mellitus and chronic hepatitis C. We evaluated liver enzymes, lipids, insulin resistance (by Homeostasis model assessment - HOMA-IR) and CHD risk by the UKPDS prediction score. The liver fibrosis was non-invasively assessed using the Forns index, which depends on age, gamma-glutamyl transpeptidase, cholesterol and HDL-cholesterol; a value < 4.2 excludes liver fibrosis and a value > 6.9 is a predictor for significant fibrosis.
Results: The average age was 60.3±9.4 years. Obesity was present in 34.4% of patients. Forns index > 6.9 was associated with increased CHD risk (r = 0.68), low-density lipoprotein cholesterol (r = 0.54), alanine aminotransferase (r = 0.66), aspartate aminotransferase (r = 0.35), diastolic blood pressure (r = 0.39) and HOMA - IR (r = 0.43), high-density lipoprotein cholesterol (r = -0.50). The correlations hold also in multivariate analysis after adjusting for age and gender.
Conclusion: Increased CHD risk, and HOMA-IR are associated with high values of Forns index. Patients with hepatitis C and diabetes have a greater risk to develop cardiovascular diseases. The clinical impact of CHC on cardiovascular risk deserves particular attention because of the growing number of patients with CHC and diabetes.

Vitamin D deficiency is associated with cardiovascular risk factors among Saudi patients with type 2 diabetes mellitus

N. Al-Daghri[1], O. Al-Attas[1], M.S. Alokail[1], E. El-Kholie[1], Y. Al-Saleh[2], A. Bamakhramah[1]

[1] King Saud University, Biochemistry, Riyadh, Saudi Arabia
[2] King Abdulaziz Medical City, Endocrinology, Riyadh, Saudi Arabia

Aims: Very few studies have been done with regards to vitamin D and its impact in Saudi male and female patients with type 2 diabetes mellitus. This study aims to fill this gap.
Methods: Patients with type 2 diabetes (86 males and 71 females) were randomly recruited in this cross-sectional study. Anthropometric data were collected. Serum glucose and lipid profile were determined using routine laboratory methods. Serum insulin, adiponectin, resistin leptin, TNF-a, CRP, vitamin D and iPTH were measured using enzyme-linked immunosorbent assays.
Results: 57% of the female subjects had severe vitamin D deficiency while 43% were noted in males. Gender, BMI and LDL-cholesterol had modest but significant negative associations with vitamin D (p-values 0.012, 0.027, 0.005 respectively)
Conclusion: Severe vitamin D deficiency is highly prevalent among Saudi patients with type 2 diabetes. This study supports vitamin D supplementation as an adjuvant therapy for type 2 diabetes.

Prevalence of diabetic retinopathy and related risk factors in diabetic patients in Tirana district, Albania

V. Mema[1], F. Toti[2], M. Ismaili[2], G. Bejtja[3], A. Hafizi[4]

[1] University Hospital Centre "Mother Theresa", Ophthalmology, Tirana, Albania
[2] University Hospital Centre "Mother Theresa", Endocrinology & Metabolic diseases, Tirana, Albania
[3] Institute of Public Health, Statistics, Tirana, Albania
[4] Albania Office, Novo Nordisk, Tirana, Albania

Backgrounds: Diabetic Retinopathy (DR) is a serious and frequent complication of diabetes. Often it is present since the diagnosis of type 2 diabetes. It remains largely preventable with proper screening, followed when required by proper interventions' therapy.
Objectives:
1. To define the prevalence of diabetic retinopathy in Tirana district.
2. To analyze the clinical features associated with this complication in the examined group.

Material and methods: As part of ALBDIAB Project, we examined all the medical records of diabetics updated during the last year. In total, we included 7226 diabetics. Male 3530 (48.8 %). 740 (10.2%) type 1 Diabetes and 6480 (89.3%) type 2. Type 1 Diabetes duration 9.7±7.8 years and T2 Diabetes duration 4.6±4.9 years. In all patients clinical and metabolical profiles were determined. Trained ophthalmologists defined the stages of retinopathy by ophthalmoscope after pupillary dilatation.
Results: Diabetic retinopathy of different stages was present in 43% of T1DM and 22% of T2DM. The multivariate analyses revealed that significant predictors for diabetic retinopathy were: diabetes duration (p= 0.0001 OR= 4.36), poor metabolic control as HbA1c >8% (p= 0.0015 OR= 3.02), insulin treatment (OR=4.24) and HTA =150/95mm Hg (p= 0.002 OR= 2.45) and smoking status more than 10 years (p= 0.0023 OR= 1.34) although for smoking 6-10 years OR= 0.57. We found a good correlation between retinopathy and nephropathy. The other features such as BMI, coronary artery disease and diabetes or HTA treatment were univariate predictors of diabetic retinopathy, but they lost significance in multivariate analyses.
Conclusions: Our study showed that DR remains one of the most frequent complication of Diabetes. We were able to confirm that type 2 diabetes with poor metabolic control, longer diabetes duration, nephropathy, uncontrolled HTA, and on insulin treatment are more prone to develop DR. The smoking status remains a controversial feature.

The development of diabetes retinopathy in the senile-onset type 2 diabetes mellitus -- based on the Diabetes Case Management Program 2001, Taiwan

F. Martin[1], H. Su[2], H. Chang[3], C. Li[4], C. Chang[1], R. Chen[1], C. Chen[1], C. Lee[5], C. Lin[6]

[1] China Medical University Hospital, Medicine, Taichung Country, Taiwan
[2] Taipei Medical University Hospital, Dietetics, Taipei Country, Taiwan
[3] National Health Research Institute, Division of Health Policy Research, Hsinchu Country, Taiwan
[4] China Medical University Hospital, Medicine Research, Taichung Country, Taiwan
[5] China Medical University Hospital, Neurology, Taichung Country, Taiwan
[6] China Medical University Hospital, Family Medicine, Taichung Country, Taiwan

Background and aims: In order to evaluate retinopathy in the senile-onset type 2 diabetes mellitus and ensuing development of primary preventive interventions in the geriatric diabetes population, a nationally standardized, multi-professionally integrated, evidence-based and patient-centered healthcare program -- DCMP 2001 was implemented in a medical center, Mid-Taiwan.
Materials and methods: From Jan. 2003 to Dec. 2006, 8238 diabetes beneficiaries were randomly and cumulatively recruited in DCMP 2001 via outpatient clinic visit. Accordingly, the lifestyle measurements (lifestyle I: no smoking, no alcohol and regular exercise; lifestyle II: smoking and/or alcohol and/or no exercise), total daily caloric intakes, macronutrient consumptions and lifestyle and dietary recommendations were tri-monthly recorded following

adequate history taking in each diabetes patient after seeing physician. The annual eye examination was routinely performed in patients enrolled in DCMP 2001 within one month by using the digital retinal photography. All the baseline data in this cohort were used for study. The ages of onset of diabetes calculated by subtracting the duration of diabetes from age were further divided up into 3 groups, < 40 years (n=1305), >=40 to < 65 years (n=4718), and over 65 years (n=972) for analysis. Comparisons between groups were performed by using multiple comparisons among slopes and Chi-Square test. The significant level was set at $p<0.05$.

Results: The relationship between different age ranges of onset of diabetes in the prevalence of diabetes retinopathy was demonstrated in Fig. 1. It was clearly indicated that the development of diabetes retinopathy occurring in senile-onset T2DM was significantly slower than T2DM with onset at ages less than 40 ($p < 0.01$). The initial ~10 years after developing T2DM, however the prevalence of retinopathy was shown higher in T2DM with onset at ages over 65 as compared with ages less than 40. Neither lifestyle nor macronutrient consumption had significant impact on the prevalence of diabetes retinopathy in senile-onset T2DM.

Conclusions: The cross-sectional aforementioned results clearly indicated that the prevalence rates of diabetes retinal complication were also determined by the age of onset of diabetes, whereas diabetes retinopathy in the senile-onset T2DM was lower, even though the first ~10 years was higher as compared with onset of diabetes at ages less than 40. Therefore, for the primary prevention of the development of diabetes retinopathy in high risk geriatric population, further study would be required.

Survival free of retinopathy differs according to aldose reductase microsatellite alleles

A. Al-Agha[1]
[1] *King AbdulAziz University, Pediatric Department, Jeddah, Saudi Arabia*

The aim of the study is to examine whether the "survival free" period for retinopathy is linked to aldose reductase microsatellite alleles.

Two hundred and sixty Australian adolescents with type 1 diabetes attending for complication screening were genotyped. The aldose reductase microsatellite region was amplified by Polymerase chain reaction to produce fragments of 126-152 base pair (Z = 138). Kaplan-Meier survival analysis was used to determine duration free of retinopathy according to genotypes Z-2/Z-2, Z-2/non Z-2 and non Z-2/non Z-2. Stereoscopic fundal photography was performed blinded to the patients' genotype. The presence of background retinopathy was defined as any microaneurysm or hemorrhage.

The results of our study shows that, Median survival time free of retinopathy was significantly shorter in patients having the Z-2/Z-2 genotype (8.8 yr) or the Z-2/non Z-2 genotype (9.6 yr) compared to the non Z-2/non Z-2 genotype (11.8 yr) ($p=0.01$).

So we concluded that, the Survival free of retinopathy was significantly reduced in Australian patients with a Z-2 allele and not with other alleles. This may represent the functional mechanism of the reduced duration free of retinopathy in patients with a Z-2 allele.

Key words: aldose reductase, diabetes, microangiopathic complications, genetic polymorphism, dinucleotide repeat

P-1090

Diabetes and blindness in Mexico: The role of poor quality of care

J. Rodriguez-Saldana[1], *A.C. Rosales-Campos*[1], *C.B. Rangel-Leon*[1], *L.I. Vazquez-Rodriguez*[1], *F. Martinez-Castro*[2]
[1] *Resultados Medicos Desarrollo e Investigacion SC, General Direction, Pachuca de Soto, Mexico*
[2] *Diabetic Retinopathy Committee, Vision 2020 Program Latin America, Mexico City, Mexico*

Rationale: Even though clinical trials have shown that glycemic control reduces the incidence of chronic complications, diabetes is one of the leading causes of non traumatic blindness worldwide. In Mexico, lack of coverage or limited access to the public and private services, deficiencies in the quality of diabetes care, low rates of dilated eye examinations, scarcity and denial of diabetes educators, organizational deficiencies, scarce economic resources, and shared lack of interest are leading contributing factors.

Objective: Investigate the quality of previous diabetes care in patients treated for ophthalmologic complications in Mexico as a contributing factor in the pathogenesis of diabetes complications.

Patients and methods: Starting in 2006, agreements were made to provide structured diabetes education to patients seeking specialized treatment at the three largest Opthalmology hospitals in the country, and at a public tertiary level hospital, in Mexico city. Patients invited received a survey in which history of diabetes was investigated, including age and diagnostic methods, glycemic control, treatment, cardiovascular risk factors and chronic complications.

Results: 900 patients were analyzed for this report: 557 females and 343 males. Despite that these hospitals are devoted to treat persons without access to social security, 25.2% of them had this type of "coverage". Comparative percentages, odds ratios (OR) and statistical significance regarding methods of glycemic control, treatment modalities, cardiovascular risk factors and complications in patients with social security and without social security, in some of the variables investigated are shown in the table:

Variable	Patients with SC	Patients without SC	Odds ratio	P
Fasting blood glucose	57.2%	54.4%	1.12	0.91
Capillary blood glucose	48.0	49.1	0.95	0.95
A1c	6.1%	2.9%	2.13	0.29
Diet	32.0%	30.7%	1.06	0.90
Insulin therapy	20.6%	14.7%	1.49	0.24
No therapy	10.6%	15.3%	0.65	0.31
Hypertension	58.01%	53.25%	1.21	0.48
Retinopathy	52.67%	53.84%	1.03	0.93
Blindness	18.32%	19.52%	0.92	0.90
Diabetic foot	12.21%	8.87%	1.42	0.45
Current smokers	15.26%	3.55%	4.89	<0.001
Amputations	3.05%	3.55%	0.85	0.93

Conclusions: The results of this survey clearly demonstrate that poor quality of diabetes care is a leading contributing factor in the pathogenesis of diabetic eye disease and blindness in Mexico. Glycemic control is based on fasting and capillary casual measurements; A1c is rarely used, even at social security institutions. Overall, quality of diabetes care is worse in recipients of social security in Mexico than in patients without access to these services. One fourth of the patients treated at these public hospitals should be receiving this type of specialized care at the institution that charges to provide health services. Rates of diabetic foot are also higher in the insured.

Positive effects of angiotensin receptor blocker on the course of microvascular complications of diabetes mellitus

L. Tsutskiridze[1], *R. Kurashvili*[2], *G. Kurashvili*[2], *A. Tsibadze*[3], *E. Shelestova*[2], *M. Dundua*[2]
[1] *Diabeti da Jamrteloba/ Georgian Diabetes Center, Clinical care, Tbilisi, Georgia*
[2] *Georgian Diabetes Center, Clinical care, Tbilisi, Georgia*
[3] *Tbilisi State Medical University, Dept. of Biophysics, Tbilisi, Georgia*

Aim: Evaluate in dynamics the regulatory mechanisms of some clinical and hemodynamic indices in patients (pts) with type 1 and type 2 diabetes (DMT1 and T2) at an early stage of diabetic retinopathy (DR), and their correction with angiotensin II receptor blocker (AT_2).

Materials and methods: Totally, 250 DMT1 and T2 pts were studied, they were divided into 3 groups (Gr.): Gr.1 (n=115) – no DR; Gr. 2 (n=43) – DMT1 and DR; Gr.3 (n=92) - DMT2 and DR. Using physical examinations we assessed their clinical status, lipid profile, microalbuminuria, urine creatinine, and glycemia levels. Pts were treated with candesartan (16/ 32 mg). When necessary, other antihypertensive agents (except ACE-inhibitors) were added. Eye fundus monitoring was performed - evaluation of 7, 30^0 - standard zone stereoscopic retinal pictures according to ETDRS.

Results: Three years post treatment no pathologic changes on retina in normotensive and normoglycemic pts were observed; repeated examinations demonstrated that normotension/normoglycemia in mild DR at baseline were associated with regression of changes. When more serious changes of various severity were present, the examinations revealed either no changes (72/75, 96%), or DR deterioration (proliferative DR, neovascularisation stage), (4%).

Conclusion: Results obtained showed that use of candesartan in DM resulted in regression of pathologic changes on retina and decrease in urinary albumin

excretion rate. Thus, we recommend including candesartan in the standard treatment, due to its positive effect on the course of diabetes microvascular complications in males and females.

Study: regular annual eye screenings and early detection of diabetes eye related disease

L. Chionh[1], P.K.G. Praveen Kaur Gosal[1], L.P.H. Lee Peng Hoon[1], R.J. Rathi Jayabalan[1]

[1] Diabetic Society Of Singapore, South West Diabetes Education and Care Centre, Singapore, Singapore

Introduction: Diabetes eye related disease is very common in patients with diabetes. If not detected early can lead to blindness. People with diabetes are 25 times more likely to become blind than those without diabetes. The disease does not have any early warning symptoms such as pain, and vision may not change until the disease becomes severe. Annual eye screening for patients with diabetes plays a very important role in detecting diabetic eye disorders.
Objective: Regular annual eye screening for patients with diabetes help in early detection of diabetic related disease and reduce the rate of blindness.
Method: Diabetic Society of Singapore performed diabetic retinal photography screenings for patients with diabetes every year. In 2008, 956 patients were informed to attend their appointments to get their eye screenings done.
Results: 956 patients had their diabetic retinal photography screenings done, 248 patients were detected to have diabetic related diseases such as glaucoma, maculopathy, proliferative non-proliferative bleedings and aged related maculopathy, 678 patients retina photography results were normal. The 248 patients with diabetic related eye diseases were referred to eye specialists for treatments and will be closely monitored for follow-up visits.
Conclusion: Regular yearly diabetic eye screenings play an important part in early detection of diabetic eye related disease and helps in reducing the rate of blindness. This will not only help to save more eye sights but also reduce healthcare costs in the long run.

Heart rate variability in non-proliferative diabetic retinopathy

L. Tsutskiridze[1], R. Kurashvili[1], G. Kurashvili[1], E. Shelestova[1], M. Dundua[1], T. Gvaladze[1], A. Tsibadze[2], S. Khutsurauli[3]

[1] Georgian Diabetes Center, endocrinology dept., Tbilisi, Georgia

[2] Tbilisi State Medical University, dept. of Biophysics, Tbilisi, Georgia

[3] High Medical School "Aieti", Endocrinology dept., Tbilisi, Georgia

Background and aims: Diabetes Mellitus (DM) is a serious medical and social problem. Elevated blood glucose levels cause pathologic changes in all organs and systems of the human organism. DM is a common cause of autonomic neuropathy. Cardiac autonomic neuropathy (CAN) is asymptomatic in one fifth of patients and can be revealed while heart rate variability is assessed. The aim of our work was to study the heart rate variability and arterial blood pressure (ABP) changes in patients with diabetic retinopathy (DR).
Materials and methods: In total, 250 patients with DM were enrolled in the study. Based on clinical data they were allocated to following groups (Gr.): Gr. 1 (controls) – 115 patients with type 1 and type 2 DM, mean ABP – =130/85mmHg, fundus photography grading 10/10; and Gr. 2 (study) where 135 patients were subdivided into Gr. 2a, n=43 type 1 patients with mean ABP =130/85 mmHg and fundus photography grading from =20/10 to =47/47; and Gr. 2b, n=92, type 2 patients with mean ABP =160/90 mmHg and fundus photography grading from =20/10 to =47/47. Diabetes duration in the groups was 7±1,6, 6,6±1,9 and 8,3±2,4 yrs, respectively. According to fundus examination: Gr. 1 – no DR was registered; Gr. 2a – mild DR – 28 patients, moderate DR – 15 patients; Gr. 2b – mild DR – 61 patients, moderate DR-22 patients, severe DR – 9 patients. Heart rate variability (HRV) was assessed based on following parameters: SDNN, PNN50 (%).
Results: In hypertensive patients (Gr. 2b), comparing with normotensive ones (Gr. 1 and 2a) decrease in 24h HRV indices was observed. Besides, hypertension associated with disorders in normal circadian dynamics. While assessing mean 24h circadian HRV data, QT-interval and QT-corrected by Holter monitoring it became obvious that in hypertensive patients, compared to normotensives, QT interval prolongation in daytime was observed.
Conclusion: Thus, elevated ABP in patients with DM is associated with a number of negative electrophysiological shifts in left ventricle myocardium that result in its hypertrophy and dysfunction of the vegetative nervous system. Risk of CAN development depends on the diabetes duration and glycemia control and increases together with development and progression of other complications, such as retinopathy and nephropathy.

Diabetic foot osteomyelitis can be successfully treated with antibiotics

M. Soliman[1,3], S. Acharya[1], A. Egun[2], S.M. Rajbhandari[1]

[1] Lancashire Teaching Hospitals, Medicine, Chorley, United Kingdom

[2] Lancashire Teaching Hospitals, Vascular surgery, Preston, United Kingdom

[3] Zagazig University, Medicine, Zagazig, Egypt

Background: Osteomyelitis (OM), a common complication of diabetic foot ulcer, is associated with higher risk of amputation. In our centre we treat OM primarily with antibiotics and we wanted to study the outcome of patient who had diagnosis of OM.
Aims of study: The aim of this study was to analyse clinical outcome of subjects who had diagnosis of OM in the past 5 years.
Subjects and methods: In this retrospective study, cases were selected from the electronic record with the diagnosis of OM. Results were crosschecked with radiology database. Pathology and microbiology database were also used to collect data.
Results: 147 cases had clinical diagnosis of OM out of which 130 (mean age 66.2±14.4 years and mean duration of diabetes 13.2±10.9 years) had diagnosis reconfirmed on at least one of the established criteria (Probe to bone 102, X-Ray changes 69, Bone scan 27, leukoscan 4 and bone biopsy 5). Of these reconfirmed cases, majority (66.9%) were male and had type 2 diabetes (80%) with mean HbA1c of 8.1± 2.1% and cholesterol of 4.2±1.5 mmol/L. Peripheral vascular disease, defined by absence of palpable pulses, was present in 61 (46.9%) subjects. Blood count performed on 112 cases showed raised neutrophil count (>7.5) only in 26 (23.2%). 64 had staphylococcus isolated from wound swab of which 20 (31.3%) had MRSA. Flucloxacillin and fusidate combination was used in 81 cases whereas ciprofloxacin and clindamycin combination was used only in 17 cases. 87 (66.9%) healed with single (n=46) or multiple (n=41) courses of antibiotics. 18 (13.8%) had amputation of which 16 (12.3%) were minor (Toes or Ray amputation) and 2 (1.5%) were major (above or below knee). 12 (9.2%) had vascular intervention (8 angioplasty & 4 bypass) and 8 (6.2%) died within 12 months of diagnosis due to other causes. There were no differences in outcome between subjects with or without x-ray changes. When compared between those which healed (n=87) and those patients who died or needed amputation (n=26), there was no difference in age, sex, duration of diabetes, site of ulcer, presence of x-ray changes or peripheral vascular disease. OM due to MRSA was the only factor that predicted adverse outcome (21.1% vs 53.3%; p=0.04). Higher rate (p=0.01) of adverse outcome was noted in patients using combination of ciprofloxacin and clindamycin, which may be due to its use as a last resort in our clinic.
Discussion: Our data confirms that OM can be successfully treated with antibiotics. Flucloxacillin and fusidate can be used as first line treatment in majority of cases. Surgery should be reserved only for cases that fail to respond to medical treatment.

Spectrum of microbial flora and their susceptibility to antibiotics in diabetic foot infections in an African setting: case of Yaounde central hospital

L. Fonkoue[1], J. Bahebeck[2], A.P. Kengne[3], M. Dehayem[4], E. Sobngwi[4], J.C. Mbanya[5]

[1] *Bafia Central Hospital, Internal Medecine, Bafia, Cameroon*
[2] *Yaounde Central Hospital, Surgery, Yaounde, Cameroon*
[3] *University Of Sydney, George Institute For International Health, Sydney, Australia*
[4] *Yaounde Central Hospital, Centre National D'obesite D'hypertension Et De Diabete, Yaounde, Cameroon*
[5] *University Of Yaounde I, Internal Medicine, Yaounde, Cameroon*

Background: Diabetic foot infections are a common cause of morbidity and mortality in people with diabetes in Africa. But, there are few local studies about bacterial ecology and probabilistic antibiotherapy in diabetic foot infections, since many patients cannot afford bacterial culture. The aim of this study was to determine the common bacteriological flora of diabetic foot infections and their sensitivity to antibiotics in order to inform possible empirical treatment.
Methods: We consecutively collected deep wound swabs from 34 diabetic patients admitted for foot infections and/or gangrene at the diabetes unit of the Yaoundé central hospital from August 2006 to January 2008. Bacteriological isolation and antimicrobial sensitivity tests were carried out by standard microbiological methods.
Results: A total of 65 microorganisms (64 bacteria and 1 fungi) were isolated with an average of 1.94 ± 0.85 germs per case. Infections were polymicrobial in 70.6% of the patients. Gram negative germs constitute 75.4% of isolates and there was an association of both Gram positive and negative in 40.6% of patients. The most isolated germs were Morganella morganii, Staphylococcus aureus, Escherichia coli, and Pseudomonas aeruginosa in 35%, 26%, 23% and 21% of patients respectively. All bacteria showed a high sensitivity to imipenem, amikacin, ceftazidim for Gram-negative; erythromycin and lincocin for Gram-positive. Contrary to previous studies, there was a worrying resistance to penicillin, amoxicillin+clavulanic acid and second generation's quinolones which before were the first line probabilistic antibiotherapy recommended in our milieu for diabetic foot infections.
Conclusions: Infections of diabetic foot are usually polymicrobial with a high association of both gram positive and negative bacteria. Probabilistic antibiotherapy in our milieu should associate imipenem or amikacin or ceftazidime and erythromycin or lincocine. The highly used fluoroquinolones should be abandoned.

The multiple diagnostic approaches in diabetic patients with peripheral arterial disease

O. Bondarenco[1], K. Pryakhina[1], I. Sitkin[1], D. Egorova[1], G. Galstyan[1], I. Dedov[1]

[1] *Endocrinology Research Centre, diabetic foot, Moscow, Russia*

Objective: To evaluate the involvement of different arterial segments in diabetic patients with peripheral arterial disease (PAD).
Materials and methods: Between September 2008 and February 2009 42 diabetic subjects referred to Diabetic Foot Department with clinical signs of limb ischemia. In cases with reduced or absent foot pulses, reduced ankle systolic blood pressure and TcPO2, duplex scanning (DS) of leg/foot, carotid and renal arteries was performed. In case of stenosis more than 50% of vessel diameter, arteriography and peripheral transluminal angioplasty (PTA) was performed. In patients unsuitable for PTA, by-pass graft (BPG) was considered.
Results: 12% of patients had neither an ulcer nor a rest pain. In 42 patients at least one pedal pulse was reduced or absent, and ankle-pressure was able to evaluate only in 50% (n=21) cases due to medial calcifications and/or ulcer on the dorsal part of the foot. In all patients the TcPO2 was <50mmHg, and in 82% (n=34) cases it was < 30mmHg. DS demonstrated Sn >50% of vessel diameter of leg in all subjects. All these patients were referred for an angiographic study. Obstructions of >50% of vessel diameter were located in the iliac/femoral-popliteal axis in 5% (n=2), exclusively in the infrapopliteal axis in 38% cases (n=16), and in both femoral-popliteal and infrapopliteal axis in 57% (n=24). In 47% (n=20) cases was found out stenosis of carotid arteries >50%, and in 24% (n=10) >70%, in 2 cases was revealed the occlusion of carotid artery at one site. In 19% (n=8) cases was found out >50% stenosis of renal arteries and in 2 cases occlusion by one site documented. Revascularization of peripheral arteries was performed in 83% (n=35) patients. A concomitant PTA procedure was performed in 76% (n=32) patients, and there was 15 of stents placed in femoral arteries. A BPG was performed in 10% (n=4) patients. In 17% (n=7) patients neither a PTA nor a BPG was possible due to high surgical risk or lack of outflow, they were treated by a prostanoid therapy. The patients with stenosis >70% of carotid and renal arteries were operated (2 endarterectomy of carotid arteries and 2 PTA with stenting of renal arteries). Follow up outcome will be assessed in all cases.
Conclusion: The multiple diagnostic approaches in diabetic patients with occlusive peripheral disease are highly necessary. The inspection of carotid, renal arteries by using DS as well as peripheral arteries is needed. About 20% and more diabetic patients needed revascularization of carotid and renal arteries.

Determining ambulatory diabetic patients' health status in the primary public health system of Esteli, Nicaragua

B. Tapia[1], L. Villagra[2], A. Martinez[3], M. Narvaez[3], P. Guimet[4], E. Pasquier[4]

[1] *Handicap International, Technical Coordination, Managua, Nicaragua*
[2] *Hospital Lenín Fonseca, Internal Medicine, Managua, Nicaragua*
[3] *Handicap International, Diabetes Project, Estelí, Nicaragua*
[4] *Handicap International, Chronic diseases, Lyon, France*

Introduction: In Nicaragua, diabetes was the third cause of death according to the 2007 national statistic report of the Ministry of Health. Its prevalence was estimated to be 9 % in 2003. Handicap International in partnership with the Ministry of Health has implemented the project "prevention and diminution of the complications by diabetes in the department of Estelí, Nicaragua". In the framework of this project, one baseline epidemiological study was realised on the health status of diabetic outpatients.
Objectives: To determine the glycemic control, complications and cardiovascular risk factors of primary health care diabetic outpatients of the six municipalities of Esteli, Nicaragua
Methodology: This cross sectional study included 313 outpatients with diabetes who were randomly chosen in the list of registered patients in the primary health care units. Four consultations during the last year was the selection criterion.
Each patient answered a questionnaire and underwent medical examination and biological tests. Tests included ophthalmologic, neurological and foot examination; and hemoglobin A1c, lipid profile, fasting and postprandial glycaemia, serum creatinine and microalbuminuria determination.
Results: Of the 313 patients, 66% [61-71] were women and 90% [87-93] were more than 40 years of age. Regarding the disease, 91% [88-93] have type 2 diabetes and 73% [68-78] have been diagnosed for less than 10 years. 76% [71-81] of the patients had Hemoglobin A1c level above the threshold of 7%.
Considering cardiovascular risk factors, 60% [55-65] had hypertension, 7% [4-10] were smoker, 31.2% [26-36] had hypercholesterolemia, 48.4% [43-54] had hypertriglyceridemia and 53% [47-59] declared having a family history of diabetes. The mean BMI was 28 kg/m2 in people with type 2 diabetes and 24 kg/m2 in people with type 1 diabetes.
Lastly, regarding chronic complications, retinopathy was clinically found in 39.2% [34-45] of the cases, cataract in 29% [24-34], glaucoma in 20% [16-24], symptoms of angina in 4.8% [2-7], strokes in 1% [0-2], microalbuminuria in 38.9% [34-44], lower limb neuropathy symptoms in 58.6% [53-64], intermittent claudication in 39.2% [34-45], chronic foot ulcer in 12.4% [9-16] and amputation in 5.1% [3-8].
Conclusion: The prevalence of chronic complications found in this study was generally in the range of the complications prevalence found in other clinic-based studies (from 2006 IDF diabetes Atlas). Nevertheless, we noticed that the amputation prevalence was higher than the IDF data of 4.8%. The quality of diabetes care needs to be improved in these primary health care units. The ophthalmologic and diabetic foot follow-up and care must be given attention to decrease the visual impairment and amputations respectively.

Manitoba First Nations Patient Wait Time Guarantee pilot project

T. Scott[1], M. Horton[2]
[1] Saint Elizabeth Health Care, First Nations Program, Winnipeg, Canada
[2] Assembly of Manitoba Chiefs, Health, Winnipeg, Canada

The Canadian government's health care plan calls for a guarantee that ensures that all Canadians receive medical treatment within wait times that are clinically acceptable. Fundamental to a wait time guarantee is defined time frames for care and a set of alternative care options, should that time frame be exceeded (recourse). In January 2007, a unique Patient Wait Time Guarantee pilot project for the prevention, treatment and care of diabetic foot ulcers among Manitoba First Nations (MFNs) was announced. The project involved a partnership between an innovative home care nursing organization, Saint Elizabeth Health Care (SEHC), and a First Nations leadership advocacy organization, the Assembly of Manitoba Chiefs (AMC). Within a PWTG framework, the project partners sought to establish a clinical care pathway, benchmarks for care and recourse options for patients who do not receive treatment within this time frame. The difficulty in testing the clinical benchmarks is that the real challenge facing people living with diabetes in MFN communities was more a matter of access than wait times. Funding for community based foot care services is inconsistent and insufficient resulting in considerable disparity in foot care services. As a result persons living with diabetes rarely have their feet assessed.This lack of assessment, early intervention, and care means that all too often MFNs are presenting for care of their diabetic foot ulcer at a stage when amputation may be the only option. Basic primary foot care services are critical to addressing this issue. However, the project partners also understood that there were challenges far more fundamental then access to health care impacting this issue for MFNs. Action on the broader determinants of health (housing, water, food) impacting MFNs will be necessary to truly address the higher rates of diabetes and the shockingly disproportionate rates of amputations.The issues of care and access to care also cannot be viewed only through a western or biomedical model. This project was committed from the outset to consider all effective options, including traditional healing, and to build a solution that recognized and emphasized MFN cultural values and perspectives. This project demonstrates that the most effective model to change wait times, and understand the reasons underlying those waits, is not to rely on health care professionals alone, but instead, to adopt different ways of involving the people most affected. The project also documented important lessons learned for improving health care and wait times for FNs and for all Canadians. The approach, finding, and recommendations from this important project will be shared in this presentation.

The role of taking history in diabetic neuropathy diagnosis

W. Karnafel[1], M. Jasik[1], A.B. Niebisz[1], A. Cacko[1], M. Cenkier[1], M. Cacko[1], B. Mrozikiewicz-Rakowska[1], P. Krasnodebski[1]
[1] Medical University of Warsaw, Department of Gastroenterology and Metabolic Diseases, Warsaw, Poland

Introduction: Diabetic neuropathy (DN) is one of the most common complications of diabetes mellitus (DM). Its prevalence is about 25%. Early DN diagnosis results in improvement of patients quality of life and outcomes.
Aims: Estimation of usefulness of taking history in early DN diagnosis.
Methods: Into the study 80 patients (41 females, mean age 66,4 +/- 13,3 years) with DM were included. The prevalence of DN symptoms was estimated according to questionnaire prepared by ourselves containing symptoms of 4 types of DN: chronic peripheral polyneuropathy (CPP), autonomic neuropathy (AN), mononeuropathy (MN) and acute-onset neuropathy (AON). Time from DM onset and presence of other DM complications were also analized.
Results: One or more DN symptoms were diagnosed in 68 (85%) patients. The most common were CPP symptoms (57 patients, 71,3%) and AN symptoms (56 patients, 70%). AON symptoms were found in 28 patients (35%) and MN symptoms in 12 patients (15%). Among patients reporting DN symptoms, more often other DM complications were found (85,3% vs 50%), longer time from DM onset (13,05 +/- 9,76 years vs 8 +/- 9,77 years) and insulin used (63,2% vs 50%).
Conclusions: DN symptoms are observed in about 3/4 patients with DM, the most common were CPP and AN symptoms. This serious complication prevalence correlates with time from DM onset, presence of other chronic complications and insulin-use.

Ankle-Brachial Index abnormalities in Nigerian patients with diabetic foot ulceration

S. Iwuala[1], O.O. Fadahunsi[1], O.A. Fasanmade[2], A.E. Ohwovoriole[2]
[1] Lagos University Teaching Hospital, Medicine, Lagos, Nigeria
[2] College of Medicine University of Lagos, Medicine, Lagos, Nigeria

Background: Foot ulceration is a major cause of morbidity and mortality in diabetes mellitus patients worldwide. It often occurs in a background of neuropathy and peripheral arterial disease (PAD). Peripheral arterial disease can be assessed clinically or more accurately with the use of simple devices such as a mini-doppler which unfortunately is not readily available in resource poor settings.
Aim: To determine the prevalence of peripheral arterial disease in patients with diabetes mellitus foot syndrome in a tertiary health care centre in Nigeria using mini-doppler.
Methods: An analysis of the mini-doppler findings of patients with diabetes mellitus foot syndrome (DMFS) was done. The data retrieved from the mini-doppler report included the age, gender, presence of hypertension, smoking history and ankle-brachial pressure index (ABPI). Peripheral arterial disease was defined as the presence of ABPI of < 0.9.
Results: There were 64 patients, 28 (43.8%) females and 36 (56.3%) males. The mean age of the study participants was 63.9 (10.9) years. Hypertension was present in 56% of the patients and 15.7% had a significant smoking history. The mean ABPI was 0.9 (0.4) with no significant difference in APBI in the males and females ($p=0.12$). Decreased ABPI indicating PAD was present in 27 (42.2%) patients, 14 (51.9%) males and 13 (48.1%) females. There was no difference in the frequency of PAD in the males and females ($p=0.32$). PAD was not significantly associated with a significant smoking history or presence of hypertension ($p=0.19$ and $p=0.47$ respectively) or with age in the study population ($r=0.2$, $p=0.20$).
Conclusion: The contribution of PAD to the development of diabetes foot ulceration appears high in this population of Africans with diabetes. It can be reliably detected with the use of simple devices like the mini-doppler. Such devices should be made available at least in major hospitals in resource poor settings for better management of DMFS.

Comparative investigation of glucose fluctuation in subjects with type 2 diabetes, prediabetes and normoglycemic subjects measured by CGMS

C. Hoffmann[1], C. Koehler[1], S. Bilz[1], C. Schoner[1], M. Helbig[1], S. Sulk[1], J. Stelzer[1], M. Hanefeld[1]
[1] GWT-TUD GmbH, Center for Clinical Studies, Dresden, Germany

Introduction/background: Glycemic homeostasis has been shown to be associated with oxidative stress and endothelial dysfunction. So far little is known on glycemic variability in different stages of dysglycemia. We compared parameters of glucose fluctuation measured by continuous glucose monitoring system (CGMS) in subjects with Type 2 diabetes (T2D/3), prediabetes (PD/2) vs. normoglycemic subjects (NGT/1).
Material and methods: Overall 218 adults participated in the study: 47 NGT, 61 PD and 110 T2D. The method of CGM allows to measure tissue glucose values for every five minutes during 72 hours. We used CGMS by Minimed with Gold sensor (Medtronic Inc.). At the second day (D2) the subjects got a standardized test meal (TM). We compared parameters of glucose excursion: fasting tissue glucose before test meal (TM0), peak of TM (TMp), 2h tissue glucose after TM (TM120), AUC 2 hours after TM (TMAUC), ascent after TM (TMa), mean amplitude of glucose excursion during day 2 (MAGED2) and during the day 3 (MAGED3), average tissue glucose during day 2 (avD2) and day 3 (avD3), standard deviation of mean tissue glucose during day 2 (SDD2) and day 3 (SDD3) in NGT to those with PD or T2D.

Results:

Mean (SD)	NGT (1)	PD (2)	DM (3)	P
Age [yrs]	55.0 (17.7)	65.8 (5.6)	63.4 (8.4)	1 vs. all p<0.001
BMI [kg/m*]	26.6 (3.9)	29.5 (4.5)	30.9 (5.0)	1 vs. all P<0.05
avD2 [mmol/l]	5.6 (0.8)	6.1 (0.8)	7.5 (2.2)	3 vs. all p<0.001
avD3 [mmol/l]	5.9 (0.7)	6.3 (0.8)	7.4 (1.9)	3 vs. all p<0.001
TM0 [mmol/l]	5.3 (0.9)	6.1 (1.1)	7.0 (2.4)	3 vs. all p<0.05
TM 120 [mmol/l]	5.8 (1.1)	6.5 (1.3)	9.6 (3.7)	3 vs. all p<0.001
TMa [mmol/h]	0.7 (0.6)	1.1 (0.8)	2.5 (2.1)	3 vs. all p<0.001
SDD2 [mmol/l]	0.8 (0.3)	1.1 (0.5)	1.8 (0.8)	3 vs. all p<0.001
SDD3 [mmol/l]	0.8 (0.4)	1.0 (0.4)	1.5 (0.8)	3 vs. all p<0.001
MAGED2 [mmol/l]	1.6 (0.6)	2.1 (0.9)	3.5 (1.9)	3 vs. all p<0.001
MAGED3 [mmol/l]	1.7 (0.8)	2.1 (1.0)	3.3 (2.2)	3 vs. all p<0.001
TMp [mmol/l]	7.4 (1.4)	8.8 (1.9)	11.4 (3.5)	1 vs. all p<0.05 **2 vs. 3 p<0.001**
TMAUC [mmol/l*h]	12.9 (2.2)	15.1 (2.8)	19.3 (6.0)	3 vs. all p<0.001
HbA1c [%]	5.4 (0.4)	5.6 (0.3)	6.8 (1.5)	3 vs. all p<0.001

Conclusions: In our study as expected T2D patients have the highest levels of parameters of glucose homeostasis measured by CGM. Significant differences between prediabetic and normoglycemic subjects were found only in the glucose peak (CGM) after the testmeal. CGM may be an additional helpful method to estimate dimension of the dysglycemia.

The change in plasma calcium is associated with those in lipids and glucose tolerance in Japanese subjects with fatty liver

Y. Wada[1], Y. Hamamoto[1], K. Nomura[2], S. Honjo[1], J. Fujikawa[3], H. Ikeda[1], Y. Kawasaki[1], Y. Iwasaki[1], H. Koshiyama[1]

[1] The Tazuke Kofukai Foundation Medical Research Institute Kitano Hospital, Center for Diabetes and Endocrinology, Osaka, Japan

[2] Kobe university graduate school of medicine, Division of diabetes metabolism and endocrinology, Kobe, Japan

[3] The Tazuke Kofukai Foundation Medical Research Institute Kitano Hospital, Department of Clinical Laboratory, Osaka, Japan

Aims: Recently, an association has been reported between several abnormalities which characterize the metabolic syndrome and plasma calcium in a normal population. In the present study, we investigated the possibility of change in plasma calcium as a marker for aggravation of blood pressure, dyslipidemia and glucose tolerance in subjects who received the oral glucose tolerance test (OGTT) annually in clinical check-up in our Institute.

Methods: The study included a total of 314 subjects (age 30 to 80 years, male: n = 211, female: n = 103). They received OGTT, routine blood chemistry tests as well as physical examinations in the annual regular check-up of Department of Preventive Medicine of our Institute during 2005 to 2008. The same examinations were performed one year after the first examinations. Their age was 62.6 ± 0.6 SE years. The subjects were divided into two groups depending on the presence (n = 177, male: n = 138, female: n = 39) or absence (n = 137, male n = 73, female: n = 64) of fatty liver, which was based on the diagnosis by ultrasonography. The correlation between the changes in plasma calcium and those in other parameters during one year follow up were studied by linear regression analyses.

Results: First, we investigated the relationship between the changes in all parameters in the subjects as a whole. There was a significant correlation between the changes in plasma calcium and those in HbA1C (r = -0.28, P = <0.001), 2-hour post-challenge plasma glucose levels (PCPG) (r = 0.11, P = 0.03), low density lipoprotein cholesterol (LDL-C) (r = 0.19, P = <0.001), high density lipoprotein cholesterol (HDL-C) (r = 0.32, P = <0.001) and triglyceride (r = 0.12, P = 0.02).

Second, we investigated the relationship between various parameters in a subgroup of subjects with fatty liver. There was a significantly positive correlation between the changes in plasma calcium and those in HbA1C (r = -0.24, P = <0.001), 2-hour PCPG levels (r = 0.11, P = 0.03), LDL-C (r = 0.23, P = 0.001), HDL-C (r = 0.30, P = <0.001) and triglyceride (r = 0.16, P = 0.02). Finally, the relationships between the changes in parameters were examined in a subgroup of subjects without fatty liver. The changes in plasma calcium showed a significant correlation with those in HbA1C (r = -0.24, P = <0.001) and HDL-C (r = 0.32, P = <0.001), but there was no correlation with LDL-C and triglyceride.

There was no correlation between the change in plasma calcium and those in liver enzymes, blood pressure, waist circumference, body mass index and body weight among the subjects.

Conclusion: The change in serum calcium levels over one year can be a predictor of aggravation of dyslipidemia in Japanese subjects, especially in those with fatty liver. The change in 2-hour PCPG showed a positive association with those in plasma calcium whereas the change in HbA1C is negatively correlated with those in plasma calcium.

P-1103

Thyroid autoimmunity is not linked to low free T3 syndrome in type 2 diabetes subjects

H. Khan[1], S. Khan[2], Z. Afsana[2], U. Khondker[2], S. Ahmed[2], S.A. Khan[3]

[1] King's College London, Pharmacology and Therapeutics, London, United Kingdom

[2] North South University, Pharmacy, Dhaka, Bangladesh

[3] BIRDEM Hospital, Endocrinology, Dhaka, Bangladesh

Background: Like diabetes, diseases of the thyroid gland are amongst the most abundant endocrine disorders in the world. An overactive thyroid may increase insulin requirements, while an underactive thyroid can decrease insulin requirements. Thyroid hormone affects carbohydrate metabolism, mainly by modifying the effects of other hormones such as catecholamine and insulin.

Aims: The aim of the study was to observe the relation of thyroid dysfunctions in type 2 diabetic subjects (T2DM), to measure the glycemic status, levels of thyroid hormones, thyroid antibodies and lipid profile in a Bangladeshi population.

Materials and method: The study was conducted in the Research Division, BIRDEM in the period of 2007-08. A total of 50 healthy T2DM subjects were taken from the out patients department. Of them 16 were female. Again 50 healthy age sex matched control (without self and family history of Diabetes and Thyroid diseases) were taken to compare and among them 17 were female. Clinical and biochemical tests were done in the standard laboratory (WHO recognized).

Results: The mean± SD age of T2DM subjects were 41.86 ±6.43 and control was 41.54±7.88. Fasting blood glucose (FBG) was significantly higher in T2DM subjects than control (p<0.001) and mean HbA1c (%) was also significantly higher in T2DM subjects than control (p<0.001). Serum TSH level was significantly lower in T2DM subjects than that of control group (p<0.01). No significant difference was observed in serum free T4 (FT4) levels between two groups (15.42±2.90 vs 15.61±2.98). Serum free T3 (FT3) level was significantly lower between two groups (p<0.001). Thyroid auto-antibodies showed a significantly lower anti TG level in T2DM subjects than control (p<0.05). It has been found that FBG levels and HbA1c were abnormally high and serum FT3 were abnormally low in T2DM subjects. Levels of TSH, FT4, anti TG and anti TPO were all within the normal range in T2DM subjects. A significantly negative correlation was found in serum FT3 with FBG and HbA1c (r= - 0.789**, p= 0.0001 and r= -0.820**, p=0.0001 respectively) irrespective of the groups. Lipid profile analysis showed significantly higher total cholesterol (p<0.05), LDL cholesterol (p<0.001) and lower HDL cholesterol levels (p<0.001) in T2DM subjects than control group, with levels within the normal range.

Conclusions: The findings of the study suggest that Bangladeshi population indicates the possibility of low FT3 syndrome in T2DM subjects, in which thyroid autoimmunity is not related.

Type 2 diabetes mellitus, impaired fasting glucose, impaired glucose tolerance and cardiovascular risk factors in patients with autoimmune thyroiditis

C. Neves[1], M. Alves[1], L.M. Pereira[1], E. Carvalho[1], I. Pimentel[1], R. Ramalho[2], C. Guimarães[2], J.P. Ramos[2], D. Carvalho[3], L. Delgado[2], J.L. Medina[3]

[1] S. João Hospital University of Porto, Endocrinology, Rio Tinto, Portugal

[2] S. João Hospital University of Porto, Immunology, Porto, Portugal

[3] S. João Hospital University of Porto, Endocrinology, Porto, Portugal

Introduction: Thyroid hormones modulate enzyme activity, receptor expression, and lipid breakdown and clearance, thereby contributing to the expression of the lipid phenotype, especially in impaired fasting glucose (IFG), impaired glucose tolerance (IGT), and diabetes mellitus (DM).

Aims: To examine the hypothesis that thyroid function, in euthyroid subjects with autoimmune thyroiditis (AIT), is associated with IFG, IGT, DM, insulin resistance, serum lipid concentrations, homocysteine, and CRP (C-reactive protein).

Methods: We recorded thyroid function tests, BMI, insulin resistance markers comprising the HOMA-IR, QUICKI, IGI (Insulinogenic Index) and the levels of total cholesterol (TC), HDL, LDL-cholesterol, triglycerides, apolipoprotein B (ApoB), ApoA1, lipoprotein (a), homocysteine, CRP (C-reactive protein), folic acid and vitamin B12, in 255 patients with AIT with a mean age of 45,8±12,8 years and a mean BMI of 27,6±5,8 Kg/m2. Patients with AIT were treated with levothyroxine, in order to normalize FT3, FT4 and TSH levels. A 75-g OGTT was performed and blood samples were obtained every 30 min for 120 min to measure plasma glucose, insulin, and C-peptide.

Results: After dividing the sample in 3 groups (IFG-16,6%, IGT-24,2% and DM-9,6%) we found that patients with IFG had significantly higher levels than IGT patients in C-peptide (3,73±1,43ng/ml vs 2,69±0,73ng/ml; p=0,01), homocysteine (9,49±2,89µmol/l vs 7,42±1,34 µmol/l; p=0,002) and HOMA-IR (3,90±2,80 vs 2,16±1,09; p=0,01). In the whole sample we observed significant correlations between TSH and insulin (r=0,23; p=0,02), C-peptide (r=0,21; p=0,02), TC (r=0,40; p<0,001) and IGI (r=0,19; p=0,03). In the IFG group we found significant negative correlations between FT3 and TC (r=-0,54; p=0,01), LDL (r=- 0,59; p=0,006) and ApoB (r=-0,55; p=0,03). In the IGT group we detected significant correlations between insulin and CRP (r=0,59; p=0,002) and between homocysteine and anti-TPO antibodies (r=0,49; p=0,02).

Discussion/conclusion: Even in the euthyroid range, TSH was positively associated with insulin, C-peptide, and IGI, in this group of patients with IFG, IGT, DM, and AIT. In patients with IFG, FT3 was negatively associated with TC, LDL, and ApoB. In the IGT group, insulin was positively associated with CRP, and homocysteine was positively associated with anti-TPO antibodies. These findings suggest a pro-atherogenic pattern associated to the low grade of chronic inflammation in euthyroid patients with AIT. Thyroid function and lipid levels are associated with prediabetes and diabetes, even in subjects with AIT classified as being euthyroid, thereby extending the established relation between (sub)clinical hypothyroidism and dyslipidemia in the normal range, especially in subjects with IFG.

Adherence to protocol during the acute management of diabetic ketoacidosis

B. Devalia[1], *J.C. Shneerson*[1], *G. Thomson*[1]

[1] *Kingsmill Hospital, Diabetes and Endocrinology, Nottinghamshire, United Kingdom*

Background: Diabetic Ketoacidosis (DKA) is a hyperglycaemic emergency associated with major morbidity and mortality. Initial management is primarily with fluid resuscitation. It has been shown that treating patients admitted with DKA using an integrated care pathway, or protocol, reduces time taken to initiate management thus optimising care. A new protocol for managing DKA was devised based on current literature and introduced in Sherwood Forest Trust in July 2008.

Aims: To assess whether the trust DKA protocol is being followed at Kingsmill and Newark District General Hospitals during acute management (first 4 hours) of patients.

Methods: Retrospective case note review of all adult patients coded as DKA from July 2008 to February 2009. We reviewed the use of the protocol and extracted information from medical documentation and fluid balance charts.

Results: 57 cases were coded as DKA of which we analysed 46. This was made up of 36 individual patients some of whom had multiple admissions. 78% of patients were correctly diagnosed according to protocol and 68% had a copy of the protocol in their notes. 100% of patients had IV access and correct blood tests within 1 hour of admission. 80% were given appropriate fluid resuscitation within the first hour. 72% had the correct insulin prescribed and 73% were on the correct sliding scale. 78-91% of patients had the correct initial investigations ordered. 89% of patients were managed on the Acute Medical Unit or a specialist diabetes ward as higher level of care was not needed. However only 46% of patients requiring High Dependency Unit care were referred appropriately. 41% had severity documented and 38% had repeat electrolytes checked at 2 and 4 hours. Between hours 2 and 4 only 35-60% of patients had the correct fluid prescribed.

Conclusion: The findings indicated that there was awareness of the new DKA protocol. It was referred to and placed in clinical notes but not always followed. Management of patients with DKA within the first hour was compliant as initial investigations and fluid resuscitation were ordered as per protocol. However, subsequent fluid management and electrolyte monitoring was poor. This may reflect the clinical judgement of the admitting physician, thus emphasising the importance of evaluating each clinical case individually. Unfortunately this was unclear from documentation. Another factor may be inefficient handover when patients are transferred to different wards. There was also poor compliance to the HDU referral criteria. This may be partly due to inadequately defined parameters on the protocol. Therefore, the protocol does help to standardise initial management of patients but further education is needed and referral criteria need clarifying.

P-1106

The association of Type 2 diabetes and autoimmune hypothyroidism in an urban setting in Eastern India

S. Mukherjee[1]

[1] *Advanced Medicare Research Institue, AMRI Institute of Diabetes & Hormonal Disorders, Kolkata, India*

Background and aims: Thyroid disease is common in the general population, and the prevalence increases with age. Hypothyroidism is a recognized risk factor for atherosclerotic cardiovascular disease, hyperlipidemia, low grade inflammation and hypercoagulability.Type 2 diabetes is a major risk factor for atherosclerosis and cardiovascular disease.As diabetes and hypothyroidism are independent risk factors for the same disease process, namely cardiovascular disease, it is possible that patients suffering from both these disease entities may have a compounded risk. Our study is an effort to investigate the proposed association between these two disease entities and to identify the factors that increase the risk of this association.

Materials and methods: A crosssectional study from a tertiary care hospital in Kolkata city, Eastern India. 1485 patients (between 20-70 years of age) attending the Endocrinology & Diabetes clinic were studied between October 2008 till January 2009, for 4 months. 1059 patients had diabetes (624 males, 435 females), 426 (96 males, 330 females) had hypothyroidism only. TSH, FT4 were measured for both the groups using electrochemiluminescence immuno assay. Anti thyroidperoxidase (TPO) antibody was measured in all patients with raised TSH, using enzyme linked immunosorbent assay. 231 patients (93 males, 138 females) had diabetes and hypothyroidism (with positive anti TPO antibody). The baseline characteristics between the groups were compared with Student's t-test. Chi-square test was used to analyze the association between diabetes and hypothyroidism. Logistic regression analysis was applied to identify the association between hypothyroidism and the patient characteristics in the study group.

Results: Of the 1485 patients, 720 were males (48.48%), 765 were females (51.51%) with mean age 46 ± 9.4 years. Of the 1059 patients with diabetes, 435 were females (41.08%), 624 males (58.92%) with mean age 45 ± 11.2 years. Of the 426 patients with hypothyroid only, 96 males (22.53%), 330 females (77.46%), mean age 41± 12.4 years. In the entire group, 231 patients (93 males (40.25%), 138 females (59.74%) had diabetes and hypothyroidism coexisting together. This accounts for 15.56% of the total group having both hypothyroid and diabetes associated together. 2x2 Chi square test was used to look for association of of diabetes and hypothyroidism and the independence value of Chi square was rejected, thereby proving association of diabetes and hypothyroidism. Logistic regression analysis recognized the association between female gender (P = 0.031) and hypothyroidism (P = 0.011) more strongly when compared with males.

Conclusion: Hypothyroidism and type 2 diabetes may coexist together and it would be prudent to screen patients with diabetes for hypothyroidism in order to treat cardiovascular risks more effectively.

A simple work tool for assessing and following up type 2 diabetic patients

C. Sánchez Fernández de la Vega[1]
[1] *Sergas, Primary Care, Lugo, Spain*

Introduction: The clinical evaluation and follow-up of type 2 diabetic patients in primary care can be made more simple by using this methodology as a daily work tool in clinical practice. There are very good diabetes guidelines available, however, they are not usually followed by general practitioners. It can be due to lack of time to examine the patients affected by chronic diseases, and this is an important reason to explain why it may be tempting to ignore guidelines in primary care. We must have enough time to use them, and in primary care, each GP has too many patients and few minutes for each.
Aim: To facilitate the clinical assessment of type 2 diabetic patients in primary care, and to optimize the medical resources used in these patients. Using this methodology, we also obtain a cardiovascular risk profile according to which give an individualized treatment. A further aim is to improve the cooperation between general practitioners and a hospital's medical specialists.
Method: This methodology is based on a method that consists of:
1st.- Asking five questions about the clinical process that we are evaluating.
Is hyperglycaemia due to diabetes mellitus? / What type of diabetes is it? / What about systemic and organ damage? In which phase of the disease is the patient now? / What diagnostic tools can we use to evaluate the organ damage? / Which is the optimal treatment for each patient?
2nd.- Following five-steps for patient's clinical assessment. Each step is related to a question, so we have five questions and five steps that we must follow.
3rd.- The steps lead to obtaining five answers. If we have followed every one of these steps, we will have obtained five answers.
Results: These answers are used:
1. To confirm hyperglycaemia.
2. To classify hyperglycaemia.
3. To know the organ and systemic damage, when the patient comes to the doctor's for the first time.
4. To know the cardiovascular risk factors involved.
5. According to these answers the physicians give the patient a individualized treatment.

This methodology makes it possible to detect the correct stage of the disease by:
1st.- Selecting the type of prevention required (primary/secondary).
2nd.- Metabolic control degree.
3rd.- Regulating the therapies employed focussing on possible organ and systemic damage, usually frequent in type 2 diabetic patients.
Conclusions: This work tool makes easier the clinical assessment and follow-up of the type 2 diabetic patient by physicians and nurses in primary care. The usefulness of this methodology is based on:
1st.- Improving the quality of medical care, making GP and nurses work efficiently in daily clinical practice.
2nd.- Establishing a better relationship between general practitioners and hospital's medical staff.

Evaluation of clinical profiles in relation to the titer of anti-GAD antibodies in patients with diabetes

M. Itoh[1], *T. Hara*[1], *N. Hayakawa*[1], *Y. Yoshino*[1], *A. Yokoyama*[1], *K. Hirai*[1], *M. Kimura*[1], *S. Yamamoto*[1], *T. Itoi*[1], *H. Kakizawa*[1], *A. Suzuki*[1], *N. Oda*[1]
[1] *Fujita Health University School of Medicine, Division of Endocrinology & Metabolism, Toyoake, Japan*

Background and aims: Anti-GAD antibodies (GAD) have been widely used for the diagnosis of type 1 diabetes, although the relationship between titer of GAD and clinical phenotype still remains uncertain. The titer of GAD declines depending on the duration of diabetes, but some patients have sustained high titer of GAD. The present study was undertaken to retrospectively investigate the relationships between titer of GAD and clinical parameters.
Methods: Six hundred and fifty-two patients who were measured their GAD during 8 years were enrolled this study. Those patients presented ketosis, rapid deterioration of blood glucose, unstable blood glucose levels, or young onset of diabetes. The GAD was measured by RIA and titer above 1.5U/ml was defined as positive. One hundred and two patients (15.6%) showed positive results. The titer of GAD ranged from 1.5 to 57400 U/ml. Nine patients were excluded, because of age (below 12 years old), under hemodialysis, or pancreatic and renal transplantation. The GAD-positive patients were arbitrarily classified into four groups by titers as low (L:1.5-9.9U/ml), middle (M: 10-99U/ml), high (H: 100-999/ml), and extraordinary high (EH: >1000U/ml).
Results: The prevalence rates in each group among GAD-positive patients are 36.6% for L, 41.9% for M, 15.0% for M, and 6.5% for EH, respectively. There is no significant difference among age, HbA1c, dose of insulin at the time of measurement. The titer of GAD in EH declined but still remained high values. On the contrary, three cases increased the titer (L to M, M to H, and M to EH). There is no relation between the titer of GAD and the duration from the onset of diabetes to the introduction of insulin therapy. The basal values and increment of serum CPR after glucagon stimulation test are not statistically different among each groups. The prevalence of complication such as autoimmune thyroid disease is significantly high in EH ($p<0.05$). The prevalence rates of diabetic complications are not different among each group. Eighteen percent of L group are treated with oral agents without insulin, and other groups are all treated with insulin ($p<0.05$).
Conclusion: High titer of GAD are closely associated with other autoimmune disease such as thyroid disease, but not related to insulin requirement or diabetic complications, suggesting heterogeneity of GAD.

Hyperglycemia among patients coinfected with HIV and Hepatitis C Virus

R.E.T. Navarrete[1], *A.C. Santomauro Jr*[1], *A.R. Catharino*[1], *A.T.M.G. Santomauro*[1], *F.F. Fraige*[1]
[1] *Faculty of Medicine ABC, Department of Endocrinology, Santo Andre, Brazil*

Objectives: To ascertain the prevalence of hyperglycemia among patients coinfected with HIV and hepatitis C virus (HCV) who had been taking antiretroviral therapy (HAART).
Material and Methods: A cross-sectional descriptive study was conducted with 213 HIV patients attending Beneficencia Portuguesa Hospital, Sao Paulo, Brazil. Two groups of patients were considered: Eighty-seven HIV/HCV coinfected patients were compared with 126 HIV-monoinfected patients. Inclusion criteria were HCV-RNA positive and a sustained increase of aspartate aminotransferase (AST), alanine aminotransferase (ALT) and gamma-glutamyl transferase (GGT) of at least twice the normal value. Our data also included clinical variables as age, gender, body mass index (BMI) and percutaneous liver biopsy. Hyperglycemia was defined as a fasting plasma glucose (FPG) >110 mg/dL.
Results: The median age for HIV/HCV group was 44±12 vs 39±9 years in HIV group. Blood glucose level, GGT, ALT in the HIV/HCV group vs. HIV group were respectively 95±74 vs. 96±33mg/dl ($p= 0.17$), 99.24±132 vs. 52.18±76.44 UI/l ($p=0.0001$), 68±62 vs. 55±94 UI/l ($p=0.0001$). Although HOMA IR was not different (2.35 vs 2.41, $p =0.88$), the prevalence of hyperglycemia was higher in the HIV/HCV group (12 vs 5%, $p=0.004$). The median duration of combination antiretroviral therapy was 57±28 months. Eight-two percent taking HAART, 9.7% naive and 8.3% stop the antiretroviral treatment. The injury liver was found in 58 % patients HIV/HCV group vs 24% HIV group ($p< 0.005$). In the HIV/HCV group, older age (OR: 1.03, 95% CI 1.01 – 1.08), longer duration of HAART (OR: 1.02 95%CI 1 – 1.03) and liver injury (OR: 2.46 95%CI 1.16 – 3.56) are related with hyperglycemia. There was no difference between HIV/HCV and HIV groups in BMI, CD4+ cell, gender.
Conclusion: Our findings suggest that older age and liver injury are significant factors associated with the development of hyperglycemia in HIV/HCV patients receiving antiretroviral treatment for long time. Further studies on the cofactors such as family history of type 2 diabetes, HCV genotype and viral replication are needed to clarify the exact role of HCV infection in the induction of this metabolic disorder.

P-1110

A prospective observational intention to treat study on glycaemic management in patients receiving steroids

M. Ramprasad[1], *B.S. Narendra*[1], *S. Jain*[1], *A. Bhattacharyya*[1]
[1] *Manipal Hospital, Department of Diabetes & Endocrinology, Bangalore, India*

Introduction: Steroids are used for many different medical disorders. Abnormal glucose metabolism induced by steroids may cause both fasting and postprandial hyperglycaemia or worsening of preexisting diabetes. It is

important to monitor blood sugar levels in patients taking steroids. In this study, we try to find out which Insulin regimen is better in managing steroid induced/worsened diabetes.

Aim: We aim to assess the glycaemic control with different insulin regimens using both regular and analogue insulin.

Materials and methods: Patients male or female who received steroids more than three times the replacement dose, with a fasting sugar more than 126 or a random sugar more than 200 mg/dl were included in this study. Patients were allocated to any one of the four insulin regimens, namely: A - Modified basal bolus regimen, B - true basal bolus regimen, C- three premix regular insulin and D - three premix analogue insulin. In all patients glucose monitoring was done both premeal and 2hr postmeal. In addition to this sugars were monitored for hypoglycaemia. Target was to achieve a premeal between 80-140 and postmeal between 120-180 mg/dl.

Results: A total of 40 patients were included. Baseline characteristics were identical in all the four groups, with the mean age being 61 years, 3 in each group were new detection of high sugars; average HbA1c in those with preexistent Diabetes was 6.6%. Average steroid dose each patient received was the equivalent of 100mg prednisolone/day. In all the four groups (same order as mentioned earlier) average fasting sugar was 185, 147, 201 and 155 respectively; average premeal sugar was 206, 181, 270 and 165 while average postmeal was 268, 234, 380 and 222 respectively. Insulin requirement (short and long acting) in each of the four regimens were as follows: 29 and 28, 39 and 35, 33 and 46, 20 and 26 units. 44% of our patients on regimen B and 60% in regimen D achieved target pre and postmeal sugars in comparison to none in the other two regimens. One each in A and C regimen were upgraded to D regimen with persistent high sugars. 3 patients in A, B and D regimen developed hypoglycaemia, fortunately all were mild and managed easily.

Conclusion: Steroid Diabetes is a challenge to the treating physicians. Though our cohort was small, yet we find that analogue insulin seem better in controlling sugars. We need to try this in a bigger cohort to see the response.

Perioperative glycaemic control: sliding scale versus glucose potassium & insulin infusion

H. Butterworth[1], R.F.D. Powell[1], M. Sigaroudinia[1], D. Olojugba[1]
[1] Warrington and Halton Hospitals NHS Foundation Trust, Vascular Surgery, Warrington, United Kingdom

Surgery in the diabetic population is linked with an increased risk of surgical complications, especially wound infections, and can cause increased length of stay in hospital. It is estimated that 50% of patients with diabetes will undergo surgery at some point in their lives.

Aim: This audit looked into perioperative glycaemic control and aimed to determine whether the use of glucose, potassium and insulin (GKI) infusions or use of sliding scales (SS) resulted in better glycaemic control, and which was preferred by staff. National guideline adherence was to be determined, and we aimed to make recommendations for a new hospital policy. Staff preferences were discovered by use of questionnaire.

Method: In this prospective audit, 36 diabetic patients undergoing surgery were selected. The first three preoperative BMs, intraoperative BM and first three postoperative BMs were collected for each patient, with type of surgery, HbA1c, and whether they were on GKI, SS or neither perioperatively.

Results: The GKI regime caused a 24.4% increase in postoperative BMs, SS had a 4.7% decrease, and those on neither showed a 16.4% decrease in BMs. There were no national or local guidelines to recommend either regimen, hospital guidelines were found from another trust, and were used for this audit. Questionnaire showed that 60% of staff preferred SS, compared to 40% GKI, but this did not reflect prescribing, where SS was only prescribed in 20% of patients.

Conclusions: The sliding scale offered the greatest degree of BM control compared to the GKI. National guidelines are needed to better control perioperative glycaemic control to reduce postoperative complications and length of stay. Prescribers need to be educated on the indications for, and correct use of GKI and SS, and standardised treatment should be indicated.

Recommendations: Re-audit with increased number of patients, staff education, national/local guideline development to standardise practice.

The effect of improved periodontal health on metabolic control in type 2 diabetic patients attending national institute of diabetes in Cairo

F. Tadros[1], A. Ismail[2], I. Emara[3], M. Aziz[3], A. El Messry[1], S. Ibrahim[1]
[1] nationl institute of diabetes, dental, Cairo, Egypt
[2] nationl institute of diabetes, clinical and chemical pathology, Cairo, Egypt
[3] nationl institute of diabetes, biochemistry, Cairo, Egypt

Objective: The aim of the present study was to evaluate the effect of improved periodontal health on the metabolic control in type 2 DM patients.

Subjects and methods: One hundred patients with type 2 DM were selected and assigned into two groups treated group and control group or untreated group.

Data collection: Plaque index (PI), gingival index (GI), probing pocket depth (PPD) and bleeding on probing (BOP) were recorded at baseline and 3rd month. Fasting plasma glucose (FPG), 2-h post-prandial glucose (PPG), glycated haemoglobin (HbA1c), total cholesterol (TC), triglyceride (TG), HDL-Cholesterol and LDL-Cholesterol were analysed at baseline, 3 months after periodontal therapy.

The treatment group received full-mouth scaling and root planing whereas the control group received no periodontal treatment.

Results: A statistically significant effect could be demonstrated for PI, GI, PPD and BOP for the treatment group. HbA1c levels in the treatment group decreased significantly while the control group showed a slight but insignificant increase in this parameter.

Conclusion: The results of this study showed that periodontal treatment associated with improved glycemic control in type 2 patients.

Perception of clinical usefulness and relevance of a novel diabetes risk stratification tool by clinicians

S. Eslava[1], C. Pegus[1], D. Guattery[1], T. Schaible[1], J. Fischer[2], R.M. Bernstein[3]
[1] SymCare, Personalized Health Solutions, West Chester PA, USA
[2] DGD Clinic, San Antonio TX, USA
[3] Reg. Endocrin. Assoc., Santa Fe NM, USA

Background and aims: Blood Glucose (BG) Variability, a measure of a person's hypo and hyperglycemic excursions over time, was identified by the Diabetes Control and Complications Trial (DCCT) as a good predictor of Diabetes complications[1].

Out of the methods used to measure BG Variability, only a few are sensitive to both hypo and hyperglycemic events. One of them is ADRR (Average Daily Risk Range), an algorithm developed by Kovatchev et al from U. of Virginia that computes an index and risk group from Self Monitoring Blood Glucose (SMBG) data and is highly correlated with the incidence of Diabetes complications[2].

Our aim was to assess the clinical usefulness and relevance of the ADRR algorithm to estimate BG Variability in patients with Diabetes in a clinical setting, utilizing proprietary software.

Materials and methods: 28 participants with Diabetes and 3 Endocrinologists in 2 sites were included in the study.

We built a software application for the study, the ADRR Glycemic Variability Calculator (ADRR-GVC), which uses ADRR to compute the index and risk group from SMBG and presents them to physicians using bar charts to help them observe BG Variability trends.

Participants attended 3 visits (days 0, 30 and 60), during which physicians used ADRR-GVC as described, and then answered a survey containing 5 questions on the clinical usefulness and relevance of ADRR, plus one optional free-text comment.

The questions were scored ("Acceptable" if lower 90% confidence limit was at least 70%, "Not Acceptable" otherwise), and aggregated. The comments were qualitatively analyzed to extract meaningful trends.

Results: 24 out of the 28 participants completed all 3 visits.

All questions were graded as "Acceptable", indicating a high level of acceptability of the system by the physicians in terms of clinical usefulness and relevance.

Physicians perceived a much higher clinical value from ADRR during the second and third visit, specifically for the ability to use ADRR as a quantitative index to assess improvement or worsening of glycemic control between visits, and also found it useful to better understand the patient's BG trends over time and in educating patients on their diabetes management.

Conclusions: The ADRR algorithm is an important risk stratification tool that offers clinically meaningful information to physicians with patients who regularly perform SMBG.
The more time physicians use ADRR with patients the more value they get. It is an effective method to assess improvement or worsening of glycemic control, to understand patient's glycemic trends, and as an educational aid to explain trends to patients.
Given the small sample size it may be advisable to conduct further studies in a larger population to confirm results.

Are glucometers sensitive enough to detect hypoglycemia?

A. Sonmez[1], Z. Yilmaz[1], G. Uckaya[1], S. Tapan[2], A. Taslipinar[1], A. Aydogdu[1], M. Yazici[1], H. Turan[1], S.E. Bolu[1], O. Azal[1], A. Corakci[1], M. Kutlu[1]
[1] Gulhane School of Medicine, Endocrinology and Metabolism, Ankara, Turkey
[2] Gulhane School of Medicine, Biochemistry, Ankara, Turkey

Aim: Self monitoring of blood glucose is essential in the follow up and management of patients with diabetes mellitus. The results given by these devices are in accordance with those of the reference laboratories in normoglycemic conditions. However, we observed that some of the devices are not sensitive enough to establish hypoglycemia. Thus, we designed a controlled study to evaluate the sensitivities of different brands of glucometers in detecting hypoglycemia.
Methods: Twenty five healthy volunteers (22M/3F, mean+/-SD; age: 23+/-2.2 yrs, body mass index: 24+/-3.1 kg/m^2) were enrolled in the study. None of the subjects had any acute or chronic condition that may confound the study results. Five different devices, commonly used in daily practice (Optium Xceed, Contour TS, Accucheck Go, Smart, One Touch Select), were supplied by the manufacturers. Hypoglycemia was induced by bolus injection of 0.1 Unit/kg body weight of regular insulin from the antecubital venous catheters. The readings with the glucometers were performed in the venous and the fingertip capillary blood samples, simultaneously. To validate the results of the glucometers, the venous blood samples were collected in EDTAK2 /sodium fluoride vacuum tubes and analyzed in the reference laboratory. All subjects gave informed consent and the local ethical committee of Gulhane School of Medicine approved the study.
Results: A total of 23 readings were obtained in hypoglycemia and 29 readings in normoglycemia. The glucose determinations either venous or capillary were not statistically different in normoglycemia. The readings performed in hypoglycemia (36.5+/-9.9, 38.3+/-9.7, 39.9+/-9.1, 51.1+/-7.6, 47.0+/-10.3 mg/dL, respectively) were significantly different when compared to those of the reference laboratory (30.2+/-9.9 mg/dL, p<0.01, ANOVA).
Discussion/conclusion: The results of the present study show that the commercial glucose measuring devices may give inaccurate results in hypoglycemia. Therefore, health providers involved in patient care must pay more attention to the symptomatology of hypoglycemia than the values obtained by the glucometers.

Current practices and utilization of blood glucose test strips in Canada

D. Belanger[1], C. Cameron[1], A. Lal[1], B. McIntosh[1], S. Singh[1]
[1] Canadian Agency for Drugs and Technologies in Health, Canadian Optimal Medication Prescribing and Utilization Service, Ottawa, Canada

Aims: The objective of this work was two fold: 1) investigate the current utilization patterns of blood glucose test strips in Canada; and 2) evaluate the current practices and beliefs of Canadian healthcare professionals and patients with respect to self-monitoring of blood glucose (SMBG).
Methods: Current utilization patterns were assessed using a retrospective analysis of administrative claims data from publicly and privately funded drug plans in Canada. The current practices of physicians (n = 43), pharmacists (n = 19), diabetes educators (n = 18) and patients (n = 40) were evaluated in a series of 20 focus groups conducted in Ottawa, Vancouver, and Edmonton. The responses of health care professionals and patients were collected and a thematic analysis was performed.
Results: Our current utilization analysis has demonstrated that the usage of blood glucose test strips varies by therapeutic regimen. For both publicly and privately funded drug plans, insulin users had the highest mean frequency (± SD) (2.76 ± 3.71 strips/day for public; 3.18 ± 2.70 strips/day for private) and patients using no antidiabetes pharmacotherapy had the lowest (0.99 ± 1.46 strips/day for public; 0.69 ±1.95 for private). Patients using oral antidiabetes agents (without insulin) are the largest users of blood glucose test strips (52% of claims) for the publicly funded Ontario Drug Benefit Program; whereas, patients using insulin (without oral antidiabetes agents) account for the largest proportion in the privately funded drug plans (40% of claims).
Our current practice analysis demonstrated that the vast majority of physicians recommend SMBG to their patients and that most patients are compliant with the recommendation. The focus groups also revealed an important divergence in the views of heath care professionals and patients with respect to reviewing glucometer results. Health care professionals indicated that they reviewed SMBG results with their patients, but most patients reported that their physician based treatment decisions on glycosylated hemoglobin test results and typically ignored SMBG results.
Discussion/conclusion: Despite testing at a lower daily frequency than insulin users, patients not using insulin currently account for the largest users of blood glucose test strips. The increasing prevalence of type 2 diabetes may further increase usage of blood glucose test strips. Physicians recommending SMBG should clearly establish the role that SMBG results will play in the therapeutic decision making process with their patients.

Application of ADRR combination with HbA1c for evaluation of SMBG performance in diabetes

D.H. Tsai[1], S.L. Su[1], P.Y. Liao[1], K.D. Chen[2], S.D. Lin[1], S.Y. Wang[1], S.R. Hsu[1], Y.N. Chang[3], S.L. Lin[4], S.M. Lin[4], C.W. Wu[4], H.L. Wu[5]
[1] Changhua Christian Hospital, Division of Endocrinology and Metabolism, Changhua, Taiwan
[2] Chang Gung Memorial Hospital-Kaohsiung Medical Center and Chang Gung University College of Medicine, Center for Translational Research in Biomedical Sciences, Kaohsiung, Taiwan
[3] TaiDoc Technology Corp., TeleHealth Business Group, Taipei, Taiwan
[4] Changhua Christian Hospital, Diabetes Education Center, Changhua, Taiwan
[5] Chang Jong Christian University, Department of Nursing, Tainan, Taiwan

Aims: Recent studies showed that the ability of patients to tightly control their glycemic variation may become a paramount task of diabetes management. Glucose variability, considered in combination with A1c, may be a more reliable indicator of blood glucose control and the risk for long-term complications than A1c alone, and a good prediction performance of the measure for diabetes called the average daily risk range (ADRR) has been demonstrated. It is therefore important to evaluate the application of ADRR in health education performance from routine self-monitoring blood glucose (SMBG) task.
Methods: 28 patients (14 men, 14 women, 16 Type 1 DM, 12 Type 2 DM) were enrolled consecutively into the trial. The age of patients ranged from 24 to 98 years, and had an average duration of diabetes of 12.4 years (ranging from 1 to 27 years). Metabolic control values of diabetes were considered good or poor according to whether HbA1c levels were <7.0 or >8.0%, respectively. When HbA1c was between 7.0 and 8.0%, the patients were considered as fair metabolic control. The ADRR is computed from the continuous 5-month SMBG data for each patient.
Results: 11 of 28 patients were selected as good metabolic control based on initial HbA1c values less than 7.0. The mean A1c values at initial, 3rd month and 6th month were 6.0, 6.1 and 5.9%, respectively (P = 0.843). The mean ADRR by month of the 11 patients were changed from 14.33 to 17.09 during the continuous 5 months SMBG educational trial. Furthermore, 4 of 28 patients were selected as fair control group with mean A1c values at initial, 3rd month and 6th month were 7.5, 8.1 and 8.6%, respectively (P = 0.367). The mean ADRR by month were changed from 37.66 to 33.44. However, significant improvement (9.9 to 7.4%) of A1c values in 13 patients of poor control group were observed (P = 0.007), and the mean ADRR by month were steadily kept moderate from 24.35 to 24.88 during the 5 months SMBG program.
Conclusion: Our study introduces that ADRR values were used to evaluate the variability of daily blood glucose and the performance in SMBG health education. Patients with different metabolic control status in HbA1c levels before trial would represent improved consequences after the SMBG trial durations if the ADRR values indicated as low risk. In this study, we found that not all patients represent improved consequences after the SMBG trial

durations. Significant reduction in A1c levels was exhibited in patients with poor metabolic control status. These patients showed steady maintenance of ADRR values during the trial implies the importance in control of habitual medication and diet, and would represent by routine measured ADRR values for glycemic variability evaluation in SMBG program. The regular feedback of ADRR to patients and their clinicians would result in improvements in glycemic control.

Dyslipidemic peculiarities in patients with diabetes mellitus

M. Rusalenko[1], T. Mokhort[2], A. Rozhko[3]
[1] *The Republican Center For Radiation Medicine and Human Ecology, Endocrinology, Gomel, Belarus*
[2] *Belarusian State Medical University, Endocrinology, Minsk, Belarus*
[3] *The Republican Research Center for Radiation Medicine and Human Ecology, Endocrinology, Gomel, Belarus*

Objective: Study of carbohydrate metabolism compensation level and lipidoses in patients with T1DM.
Materials and methods: Total 726 patients with T1DM (348m, 378f), mean age (M±s) 34,71±0,58 yrs (1-78), age of T1D manifestation 12,41±0,36 yrs and special form including questions about T1DM. Levels of triglycerides (TRIG), total cholesterol (CHOL), high density lipoprotein (UHDL), low density lipoprotein (LDL), very low density lipoprotein (VLDL), $HbA1_c$(%) were measured by biochemical analyzer 'ARCHITECT c8000' (Abbott, USA).
Results: The data on indicators of age-sex composition, body mass index (BMI), systolic blood pressure (sBP), diastolic blood pressure (dBP) are presented in Table 1.

Age groups	Age, years	N (number)	Female/ Male	BMI, kg/ m^2	sBP	dBP
					mm Hg	
I	1–9	25	16/9	16,19	99	62
II	10–13	48	20/28	17,87	104	66
III	14–17	57	28/29	20,16	103	70
IV	18–39	309	167/142	23,79	121	79
V	40–59	257	127/130	27,59	135	85
VI	over 60	30	20/10	30,06	151	83
Total	total	726	378/348	24,46	124	79

It was noticed that patients above 40 years have overweight and obesity, and systemic hypertension.

Indicator	Patients	Control	p
	M±m		
$HbA1_c$ %	8,95±0,08	5,13±0,02	0,0001
CHOL, mmol/l	4,85±0,04	4,78±0,08	0,386
TRIG, mmol/l	1,39±0,05	1,08±0,06	0,0001
VLDL, mmol/l	0,63±0,02	0,48±0,03	0,0001
UHDL, mmol/l	1,49±0,02	1,41±0,02	0,071
LDL, mmol/l	3,28±0,57	3,01±0,06	0,0001

The difference of TRIG (p<0,001), VLDL (p<0,001) and LDL (p<0,001) indicators in patients with T1DM is obvious in comparison with healthy people. At division of the groups by sex, the levels of CHOL (4,21±0,14) and TRIG (1,49±0,08) are higher in sick men than in men without T1DM with CHOL (3,59±0,15; p<0,05) and TRIG (1,14±0,1; p<0,05); the levels of TRIG (1,29±0,05) and LDL (3,89±1,1) are higher in sick women than in the comparison group with TRIG (1,04±0,08; p<0,001) and LDL (3,1±0,08; p<0,001). The general growth of CHOL, TRIG and LDL indicators was noted in both groups with the age, and the growth of indicators in women is more obvious. The patients of all age groups have unsatisfactory compensation of T1DM by the level of $HbA1_c$: MAX in III (10,25±0,3%), and MIN in VI (8,52±0,33; p=0,0001), and $HbA1_c$ is higher in men of younger age group (I - 8,91±0,64%; II - 10,16±0,45; III - 10,54±0,44%) than in women (I - 8,76±0,65%; II - 8,87±0,4; III - 9,94±0,4%; p<0,05) with decrease to MIN in men of senior age group (VI - 7,4±0,4%, V - 8,33±0,18%) in comparison to women (VI - 9,08±0,4%, V - 8,79±0,16%; p<0,05). We got the direct dependence of $HbA1_c$ level on the level of CHOL (r=0,133 is received; p=0,001), TRIG (r=0,188; p=0,001) and LDL (r=0,166; p=0,001) under the correlation analysis.
Conclusion: Cholesterol exchange indicators of the patient group with T1DM differ from the ones of the comparison group in the form of atherogenic fractions increase of CHOL (p=0,386), TRIG (p=0,001), VLDL (p=0,001) and LDL (p=0,001). $HbA1_c$ figures show unsatisfactory compensation of T1DM in all age groups; however, in men the indicator improves with the age and statistically significantly correlates with atherogenic lipid indicators.

P-1118

The effect of partial meal replacement therapy on weight loss and glycemic control in obese individuals with type 2 diabetes

R. Otto[1], Y. Mullan[1], H.C. Gerstein[1]
[1] *McMaster University Medical Centre Hamilton Health Sciences, Diabetes Care and Research Program, Hamilton, Canada*

Background and aims: Approximately 80 to 90% of people with type 2 diabetes are overweight or obese. Weight loss of 5 to 10% of body weight, has been shown to improve glycemic control. According to the Canadian Clinical Practice Guidelines on the Management and Prevention of Obesity in Adults, meal replacement therapy may be considered as a component of an energy-reduced diet. The aim of this study was to examine weight and treatment changes in obese individuals with type 2 diabetes using meal replacement as part of a calorie reduced diet.
Methods: We retrospectively studied a cohort of obese individuals with type 2 diabetes who commenced a calorie reduced diet which included liquid meal replacements, and who followed this program for at least 3 months between March 2006 and March 2008. Individuals were instructed by a registered dietitian to include 2 cans of Glucernaä per day (each can provided 230 kcal, 30 g carbohydrate, 11 g protein, 8 g fat) as part of a 1200 to 1400 calorie diet.
Results: 47 obese individuals with type 2 diabetes (20 males, 27 females; mean age: 60 ± 8.8 yrs; mean weight: 115.4 ± 22.4 kg; mean BMI: 40 ± 6.4kg/m^2; mean $A1_{C:}$ 7.6±1.5%) were assessed before and at 3 monthly intervals after starting partial meal replacement. Diabetes therapy included: diet only (43%); oral agents only (29.8%); insulin only (25.5%); and insulin + oral agents (40.4%). In 66% on insulin, the mean baseline daily dose was 156 ± 95 units. Individuals followed the program for a mean of 11.4 ± 4.1 months. 34% of people withdrew after a mean of 9.7 ± 3.7 months. Compared to baseline, mean weight change at 3 months was – 3.4 ± 3.3 kg (p<0.001) and at 6 months was – 6.1 ± 14.4 kg (p<0.005); mean $A1_c$ change at 3 months was – 1.0 ± 1.8 % (p< 0.01) and at 6 months was – 1.2 ± 2.1 % (p< 0.05); and mean insulin dose change at 3 months was –24.1 ± 38.3 units (p< 0.005) and at 6 months was – 27.7 ± 44.1 units (p< 0.005).
Conclusion: Partial meal replacement therapy can achieve significant weight loss and improvement in glycemic control at 3 and 6 months. The high attrition and non-adherence rates suggest that it may be a viable short term option to stimulate weight loss while transitioning to a lifestyle program which incorporates healthy eating, physical activity and behaviour change to attain a healthy weight.

Weight status, nutrient intakes and food choices in type 1 diabetic children with carbohydrate counting meal plans

V. Blouin[1], I. Bouchard[2], I. Galibois[1]
[1] *Université Laval, Food Science and Nutrition, Québec, Canada*

Aims:
1. To assess prevalence of overweight and obesity in a sample of type 1 diabetic children with carbohydrate counting meal plans, and
2. to compare nutrient and dietary intakes according to insulin regimen and to level of carbohydrate counting (basic level = consistency in day-to-day carbohydrate intake and in meal insulin doses; advanced level = variable carbohydrate intake with adjustment in meal insulin doses using carbohydrate to insulin ratios).

Methods: 70 type 1 diabetic children aged between 6 and 12 years took part in this study; 42 were on multiple daily injections (MDI) and 28 were on insulin pump. Body weight and height were recorded in all subjects and two 24-h dietary recalls were completed in 67 of them. Prevalence of overweight and obesity was assessed based on international body mass index (weight/height^2) cut-off points. Food recalls were analysed for nutrient intake and for number of food exchanges ingested on a daily basis.
Results: Prevalence or overweight and obesity was very similar to that observed in the general Quebec youth population, as 78.6% of diabetic subjects were not

overweight (versus 77.4% in the general population), 15.7 % were overweight (versus 15.5%) and 5.7% were obese (versus 7.1%). Nutritional analysis of food recalls showed that mean daily energy intakes and % kcal for protein were significantly lower in children on insulin pump than in those on MDI. With the latter, when comparing numbers of food exchanges according to the level of application of carbohydrate counting, it was found that diabetic children at the basic level consumed more milk and substitutes (3.8 ± 1.7 exchanges/day, mean ± SD) than children at the advanced level (2.7 ± 1.1, $p < 0.05$). The opposite was noted for meat and meat substitutes (4.2 ± 1.9 exchanges/day for basic level, 5.7 ± 2.3 for advanced level, $p<0.05$). Numbers of exchanges were similar for basic and advanced level of carbohydrate counting for foods of the starch group (6.6 ± 1.8 and 7.1 ± 1.7), fruit group (2.4 ± 1.9 and 3.2 ± 1.6), vegetable group (1.6 ± 1.3 and 1.5 ± 1.2), fat group (6.4 ± 3.3 and 7.8 ± 2.9) and foods with added sugar (3.0 ± 2.2 and 3.3 ± 1.7).

Conclusion: According to these results, a flexible meal plan focusing on carbohydrate counting does not seem to lead to overweight or obesity in type 1 diabetic children. Although advanced level of carbohydrate counting could theoretically allow for larger intakes of food or poorer food choices, this was not observed in the present study.

Pilot study demonstrates promise for dietary counseling-cooking lesson intervention in type 2 diabetes

K. Dasgupta[1], L. Joseph[2], D. Da Costa[1], L. Pilote[1], S. Christopoulos[3], R. Gougeon[4]

[1] *McGill University, Department of Medicine, Montreal, Canada*
[2] *McGill University, Department of Epidemiology Biostatistics and Occupational Health, Montreal, Canada*
[3] *Jewish General Hospital, Department of Medicine, Montreal, Canada*
[4] *McGill University, School of Dietetics and Human Nutrition, Montreal, Canada*

Aims: Among adults with type 2 diabetes in Montreal, we sought to assess the feasibility and potential effectiveness of dietary counseling combined with cooking lessons to achieve weight loss and cardiovascular risk factor control in type 2 diabetes.

Methods: Pilot single-arm interventional study wherein 35 adults with type 2 diabetes participated in a group cooking class approximately once every two weeks over 16 weeks. Lessons were led by a chef who led participants through recipes selected by the research team from a recipe book endorsed by the Canadian Diabetes Association. The intervention was conducted at the kitchen workshop of a local grocery store (Loblaw's) that is normally used for birthday parties. Lessons were hands-on and ended with participants eating together and discussing dietary principles with a registered dietitian. All participants underwent evaluation prior to and following the intervention. Outcomes assessed included weight, BMI, glycemic control, blood pressure, and dietary intake. Participants were recruited through McGill University-affiliated clinics and local advertisement at the McGill University Health Centre.

Results: Approximately 60% were women, 60% Canada-born, and 75% were White. Mean age was 59.6 years (SD 9.8), mean baseline BMI was 32 kg/m2 (SD 6.0), mean A1C 7.2% (SD 1.4), blood pressure 131 (SD 13.6)/82 (SD 8.7) mm Hg, and waist to hip ratio 0.9 (SD 0.09). Among the 35 participants enrolled, 33 completed the intervention and outcome assessments at approximately 20 weeks from the first visit. There were significant changes post intervention in BMI (-0.63 kg/m2, 95% CI -1.0 to -0.3), and weight (-1.7 kg, 95% CI -2.5 to -0.90). No significant changes in blood pressure, A1C, or waist to hip ratio were detected at 20 weeks. Among the 33 participants who remained in the study, all attended at least 75% of the sessions.

Discussion: We have demonstrated that an eight lesson program of group cooking lessons combined with dietary counseling is a feasible strategy that is well-received by participants. The intervention was associated with significant reduction in BMI. We are presently testing the impact of longer programs (15 lessons; 18 lessons) combined with a pedometer-based walking intervention to see if we are able to achieve higher levels of weight loss and greater impact on glycemia and blood pressure.

[5] *Public Health Foundation of India, Biostatistics, New Delhi, India*
[6] *Insitute of Home Economics, Nutrition, New Delhi, India*
[7] *Public Health Foundation of India, Public Health, New Delhi, India*

Aims: Observational studies suggest greater risk of coronary heart disease in those with higher fasting blood glucose (FBG). Whereas many studies have examined the impact of dietary supplements on lipid profile, few have described the effect of plant sterols and/or omega-3s (w-3s) supplementation on FBG. We compared the independent and combined effects of a yoghurt drink providing 2 g/d plant sterols and fish-oil capsules providing 2 g/d w-3s on FBG in Indian industrial workers.

Methods: Following a 2-week run-in period, 200 mildly hypercholesterolemic (Total Cholesterol 5.0-8.0 mmol/L) adults aged 35-55 years, were randomized into one of four groups of a 2 x 2 factorial, double-blind, placebo-controlled trial. 178 subjects provided blood samples before and after the 4-week intervention. FBG levels were analyzed (quasi Intention-to-treat; n=178) using analysis of covariance (ANCOVA) models with relevant baseline measurements as covariates; adjusted means were compared across groups.

Results: There were no significant differences in the baseline FBG concentrations of the four treatment groups (Range: 106.7 to 115.4 mg/dL). The adjusted means for FBG were 111.4 (Confidence Interval: 107.7 – 115.0), 108.8 (104.9 – 112.7), 105.8 (102.2 – 109.5) and 110.3 (106.6 – 114.0) mg/dL for the control, w-3 alone, plant sterols alone and combination group respectively, indicating a 5 percent non-significant decrease in FBG concentrations of the subjects receiving plant sterols alone compared with the placebo group.

Conclusions: The trial results suggest that there are no significant short-term negative effects of supplementing either plant sterols and/or fish oil w-3s on the FBG concentrations of dyslipidemic Indian industrial workers. More studies in this area are warranted.

Changes of plasma free amino acids in type 2 diabetic patients

H. Tian[1], T. Chen[1], X. Zhang[2], Y. Long[2], Y. Gao[2], X. Chen[2], J.Y. Shi[1]

[1] *West China Hospital of Sichuan University, Department of Endocrinology and Metabolism, Chengdu, China*
[2] *West China Hospital of Sichuan University, Laboratory of Endocrinology and Metabolism, Chengdu, China*

Background and aims: The aim of this study is to investigate the alterations of plasma free amino acids (AAs) in T2DM patients so as to provide some valuable information for further clinical high protein diet researches.

Subjects and methods: A total of 132 Type 2 diabetic patient and 137 age, sex, cigarette and alcohol use matched healthy controls are included in this study. All of them have no history of severe disease such as pulmonary, heart, liver and kidney diseases. Dichotomous data were described as percent (%). Continual data with normal distribution or near normal distribution was described as mean ±S.D., others were described as median and quartiles and were transformed as "Ln" for statistical analysis. Categorical variables were compared by chi square tests. Continuous variables were evaluated by Student's t tests. Correlations between analyzed by Pearson test. All reported P values are two tailed, and those $\alpha<0.05$ were considered statistically significant.

Result: Levels of total plasma free AAs, essential AAs and branched chain AAs in T2DM patients are higher than those in controls (P=0.000 for all). Non-essential AAs' level is also high in T2DM patients but with marginal significant difference (P=0.044). Statistic results of individual AAs show that plasma alanine, valine, leucine, isoleucine, phenylalanine, tyrosine, methionine, glutamic acid and lysine are higher in T2DM than in control (P<0.01 for all),

while plasma glycine, glutamine are lower in T2DM than in control (P=0.003 and P=0.034 respectively). Further analysis show that total plasma free AAs, especially essential AAs and branched chain AAs, are strongly associated with BMI, Waist, GGT, UA, Ferritin, ALT, TC and TG. Alanine, valine, leucine, isoleucine, phenylalanine, tyrosine, methionine, glutamic acid and lysine are positively correlated with BMI, Waist, GGT, UA, Ferritin, ALT, while, glycine and glutamine negatively associated with BMI, Waist, GGT, Ferritin, ALT.

Conclusion: There are significant differences in plasma AAs quality and quantity between T2DM patients and controls. Some AAs, especially essential amino acids and branched chain amino acids are correlated with identified T2DM risk factors. Whether or not there exists a causative relationship between plasma AAs changes, T2DM risk factors and T2DM is very necessary to be further investigated.

Optimizing diabetic control with a low glycemic index diet

B.N. Mohd Yusof[1], A.T. Ruzita[2], A.K. Norimah[2], K. Nor Azmi[3]

[1] *University Putra of Malaysia, Nutrition & Dietetetics, Serdang, Malaysia*

[2] *University Kebangsaan Malaysia, Nutrition & Dietetetics, Kuala Lumpur, Malaysia*

[3] *University Kebangsaan Malaysia, Medicine, Kuala Lumpur, Malaysia*

Aims: Cross-sectional studies suggest that postprandial hyperglycemia had a greater contribution than fasting hyperglycemia in attaining HbA1c goals, especially for those patients with an A1c below 10%. We hypothesized that subjects who started with low level of HbA1c and treated with low GI diet would have larger improvement in glycemic control than their counterparts treated with conventional diet. This is important in the present context because low GI diet is meant to reduce postprandial hyperglycemia. Therefore, we examined whether based on their HbA1c level at entry into our dietary intervention study would result in any differences in HbA1c levels at the end of the 12 week period.

Methodology: We undertook a prospective, parallel, randomized intervention study to assess the effectiveness of low GI diet (GI) vs. conventional carbohydrate exchange (CCE) dietary advice on glycemic control in patients with type 2 diabetes over a 12-week period. A total of 100 subjects (age=56.4±9.9 years; 37% male; years of diagnosis= 6.3±4.9 years), treated with diet or on a stable dose of medication were enrolled in the dietary intervention program. In this secondary analysis, subjects from the GI (n=51) and CCE (n=49) groups were sub-divided according to their starting levels of HbA1c of either less or more than 8%, a criterion used by major clinical diabetes study.

Results: At week 12, HbA1c level declined to a lesser degree on a low GI diet (-0.51%) than on a conventional carbohydrate exchange (-0.29%) dietary advice. The intervention failed to detect any absolute differences between the two groups but the mean changes from baseline for subjects who started with lower HbA1c level (<8%) were significantly greater in the GI than in the CCE group (-0.4% ± 0.1 vs. +0.1 ± 0.1%; p< 0.05).

Conclusions: In type 2 diabetes patients whose HbA1c is close to target (HbA1c between 7-8%), the introduction of a low GI diet is able to further reduce the HbA1c. The result is interesting and seems to fit a priori hypothesis that low GI diets are meant to reduce postprandial hyperglycemia.

Effect of Ramadan fasting on anthropometric parameters and on food consumption in 276 type 2 diabetic obese women

M. Khaled[1]

[1] *Djillali Liabes University, Department of Biology, Sidi-Bel-Abbes, Algeria*

Aims: To assess the effect of Ramadan fasting on body weight and food consumption in type 2 diabetic obese women.

Methodology: Two hundred and seventy six (276) outpatient women receiving oral antidiabetic drugs (OADs) (BMI=34.63±3.29 kg/m2), aged 49 (±6 years), were selected. The study was carried out over 3 periods - before (T1: pre-fasting), during (T2: fasting), and after (T3: post-fasting) Ramadan - in 3 towns located in the Northwestern region of Algeria. During the course of 3 days, we first recorded the daily food intake, and then we measured as anthropometric parameters weight, height, waist and hip circumferences, body mass index (BMI) and waist-hip ratio (WHR). A one-way ANOVA test was used to compare the groups.

Results: The main effect of fasting during Ramadan was a significant weight loss ($P < 0.01$), a decrease in meal frequency (2.2±0.3 vs. 4.3±0.4) as well as in energy intake (-209 Kcal/d), and an important increase in dietary fat consumption (35.84% of total calories), especially the saturated one (43.33% of total fat), dietary cholesterol (392±121 mg/d), and polyunsaturated fatty acids (PUFA). Except for three cases, there were no frequent hypoglycaemia episodes observed among the participants.

Conclusions: Fasting during the month of Ramadan causes weight loss and decrease in calorie intake which is correlated with a decrease in meal frequency. However, more foods rich in fat and dietary cholesterol were consumed during this period. The latter could constitute a high risk for diabetics who are fasting, in particular when medication advice and/or health care control are insufficient or ignored.

P-1125

Trace mineral status and glycaemic control in Nigerians with type 2 DM

K.I. Akhuemokhan[1], A. Eregie[2], O.A. Fasanmade.[3]

[1] *Irrua Specialist Teaching Hospital, Department of Medicine, Irrua Edo State, Nigeria*

[2] *University of Benin Teaching Hospital, Department of Medicine, Benin City Edo State, Nigeria*

[3] *Lagos University Teaching Hospital, Department of Medicine, Idi-araba Lagos State, Nigeria*

Background: Trace minerals have been implicated in the metabolism of glucose and glycaemic control but there is no documented study of a Nigerian population.

Aims: The objective is to evaluate serum chromium and zinc status in patients with type 2 DM and correlate this with glycaemic control.

Patients: Persons with type 2 DM attending the DM clinic of the University of Benin Teaching Hospital, who met the inclusion criteria, were recruited with informed consent. Proteinuria, hypoproteinaemia and pregnancy were exclusion criteria.

Methods: The study was cross sectional in design. Questionnaires were administered to subjects to obtain socio-demographic information. Subjects had a detailed physical examination, and blood was collected for FBG, serum lipid profile, serum chromium and zinc, HbA1c, serum urea and creatinine after an overnight fast of 8-10 hours. The SPSS statistical software was used for analysis. Differences were significant when p-value was = 0.05. Person's moment correlation was used to correlate the different variables with zinc and chromium.

Results: 120 persons, age and sex matched were studied. The mean (±SD) age was 54.0 (±7.4) years, males 54.4 (±7.8) years and females 53.7 (±7.1) years. The mean (±SD) duration of diabetes was 4.3 (±4.0) years, range = 1-23 years, males 3.7 (±3.7) years, range 1-17 years and females 4.9 (±4.3) years, range 1-23 years. The mean (±SD) BMI was 29.8 (±5.1) kg/m^2, males 30.1 (±4.6) kg/m^2 and females 29.5 (±5.6) kg/m^2.

The prevalence of hypertension was found to be 61.7%, while the prevalence of chromium deficiency was 66.7% and that of zinc was 60%. The mean (±SD) serum level of chromium was 0.4 ±0.2mcg/L. The mean (±SD) FBG was 159 (±79) mg/dl. The mean (±SD) HbA1c was 8.8 (±2.7) %. A total of 40.7% of subjects had FBG <126mg/dl and 59.3% ≥126mg/dl. 157 (37.4%) had HbA1c <7%, and 62.6% had HbA1c ≥7%. Serum chromium level correlated inversely with FBG and HbA1c, unlike the serum concentration of zinc which had no significant correlation with FBG and HbA1c.

Discussion: Chromium is a cofactor in the action of insulin and it potentiates the action of insulin. This may account for the inverse relationship between serum chromium and glycaemic control. Zinc is useful in synthesis, storage and secretion of insulin. However, no correlation was found between zinc and glycaemic control in this study.

Conclusion: Serum chromium significantly correlated inversely with glycaemic control. Persons with DM should be encouraged to eat local specific food rich in chromium. A study of locally available food is essential so that patients can be better informed.

P-1126

Diabetes control achieved without increase in hypoglycemic medication in DM2 patients on medical nutrition therapy

P. Moreira-Cali[1], H. Xin[2]
[1] Diabetes & Nutrition Education Center, Diabetes, Gainesville - Florida, USA
[2] University of Florida, Health Education & Statistics, Gainesville - Florida, USA

Aims: Due to the progressive nature of diabetes type 2, it's generally expected that patients will need to initiate pharmacotherapy or add more hypoglycemic agents to keep their diabetes under good control. Most published studies measure changes in A1c over time, without addressing the change in hypoglycemic medication which could happen concurrently. The objective of this retrospective study is to assess the impact of individualized Medical Nutrition Therapy (MNT) on the diabetes control of type 2 diabetics, controlling for the possible effect of diabetes medication.
Materials and methods: Of the 1136 DM2 adult patients referred by physicians to a clinical dietitian/diabetes educator for diabetes management education, 615 patients kept follow-up appointments, had A1c and medication information available, meeting the inclusion criteria for this study. 56% were females and 44% males, average age was 62 years and the mean number of years since diagnosis of DM was 6 years. 35% of the patients were not on any hypoglycemic medication and 65% were on DM medication at the time of initial education. The initial 1* hour appointment included an assessment, instruction on diabetes management, and development of a personalized meal plan with 30 to 60 grams of carbohydrate per meal and 15 to 30 grams per snacks. A reduction of 500 kcal/day was applied to the meal plans of overweight patients and increase in physical activity was encouraged. Education also included carbohydrate counting, label reading, food portioning and glucose monitoring. Thirty-minute follow-ups were scheduled at least 3 month intervals, glucose diaries were reviewed and recommendations reinforced. Statistic analysis was performed using a multiple regression model controlling for change in hypoglycemic medication use, A1c and weight at 3, 6 and 12 month follow-ups, compared to initial measurements.
Results: Individualized MNT generated statistically significant improvement in glycemic control (A1c), independently of medication effect. The mean A1c was 6.8, 6.5 and 6.5 mg/dl at 3, 6 and 12 months. BMI decrease was also statistically significant, with patients losing an average of 7.0 kg/year. Weight loss was associated with decrease in A1c and independent of medication effect. Change in DM medication at 12 months reflected more patients off or on less medication, and only a statistically insignificant number of patients on more medication.
Conclusion: This 12-month retrospective study demonstrates that individualized MNT can lead to diabetes control without the need for increase in DM medication. This positive effect is probably related to the weight loss, improved lifestyle and carbohydrate intake of educated patients. Further research should investigate the impact over a longer period of time.

P-1127

Effects of green tea consumption on metabolic and anthropometric indices in type 2 diabetic patients

A. Mousavi[1], M. Vafa[1], T. Nyestani[2], M. Khamseh[1], F. Hosseini[1]
[1] Iran Medical University, Nutrition, Tehran, Iran
[2] Shahid beheshti university, Nutrition, Tehran, Iran

Aims: Diabetes is a worldwide high prevalence disease and the rate of diabetic patients is growing rapidly. Cardiovascular disease (CVD), the most important cause of mortality among these patients, is believed to be triggered, at least in part, by two key processes; glycation and oxidative stress. It is therefore likely that antioxidants may help to manage prevention of diabetic long term complications. Green tea, a popular Chinese beverage, is a good source of antioxidant polyphenolic compounds including Epigalocatechin gallate. This study was undertaken to evaluate the possible effects of different daily doses of green tea intake on certain metabolic and anthropometric biomarkers in type 2 diabetic patients.
Methods: A total of 63 patients of known cases of diabetes mellitus type 2 (28 male and 36 female) were introduced to a randomized clinical trial and randomly assigned to three groups for a two months interventional study. First group drank four cups of Green Tea per day (n=24, mean age=56.2), second group drank two cups of Green Tea per day (n=25, mean age=54.6) and third group was control group and didn't drink green tea (n=14, mean age=52.0). Patients in Green Tea groups prepared Green Tea with a 2.5g tea bag in a standard method. At the beginning and in the end of intervention, fasting venous blood samples (10 cc) were taken from all patients (test and control) and dietary assessment was done using 24hr recall diet questionnaire. Anthropometric (height & weight) and blood pressure measurements were also carried out in the beginning and at the end of the intervention.
Results: Daily intake of 2 or 4 cups of green tea per day did not have any significant effect on fasting blood glucose, total cholesterol, LDL cholesterol, triglyceride, blood urea nitrogen, creatinine, apolipoprotein A1 and B100, total antioxidant capacity and malondialdehyde. BMI (27.45 to 26.94, $p<0.0001$) and systolic blood pressure (126.25 to 118.64, $p<0.01$) in patients in the 4 cups of Green Tea group significantly decreased, and also the waist circumference of both Green Tea groups decreased (95.82 to 91.56 in 4 cups Green Tea and 93.63 to 90.65 in 2 cups Green Tea group, $p<0.001$).
Conclusion: Daily intake of green tea may help to prevent hypertension, and may help weight control in diabetic patients.

P-1128

Dietary intervention in patients with metabolic syndrome: short and long-term effects on abdominal obesity

O.N. Korneeva[1], O.M. Drapkina[1], V.T. Ivashkin[1]
[1] I.M. Sechenov Moscow Medical Academy, Cardiology, Moscow, Russia

Background: Caloric restriction is a key element of a weight loss program in Metabolic Syndrome (MS) management. In some studies obese men and women had different short- and long-term outcomes in dietary intervention. Our aim was to assess prospectively the short- and long-term effects of a calorie-reduced diet on obesity anthropometric measures like body-mass index (BMI), waist circumference (WC), waist-to-hip ratio (WHR) and compliance to the diet in men and women with MS.
Methods: 60 MS patients were enrolled according to IDF criteria (36 men) with average age 48±13 years. BMI at baseline = 33.4 ± 4.9 kg/m2 both sexes; WC=115.3 ± 11.3 cm men, = 108.8 ± 9.6 cm women; WHR = 1.02 ± 0.06 men, = 1.00 ± 0.07 women. We compared obesity anthropometric changes in two diet programs: short-term hypo-caloric diet of 1800 kcal per day during 3 weeks supervised by hospital physicians; after that diet was home-based and completed by the participants on their own during 6 months
Results: At 3 weeks, in supervised group there were significant reductions in all obesity anthropometric measures in both sexes ($p < 0.0003$); however, men have achieved larger reduction in WC and WHR than women (baseline-3weeks difference WC men = 4.6 ± 1.7 cm vs difference WC women = 3.7 ± 2.1 cm; difference WHR men = 0.03 ± 0.01 vs difference WHR women= 0.027 ± 0.01). At 6 month unsupervised patients had less WC and WHR reductions compared with 3 weeks data (WC men 112.1 ± 10.7 cm vs 110.6 ± 10.4 cm; WC women 103.0 ± 6.9 cm vs 104.7 ± 9.3 cm; WHR men = 1.0 ± 0.05 vs 0.99 ± 0.05; WHR women = 0.96 ± 0.05 vs 0.98 ± 0.06). Compliance to the home-based diet was related to sex (women better than men) and was associated with greater reduction in WC and WHR in women. At 6 months home-based diet men had a significant increase in abdominal obesity compared with 3 weeks diet (difference 3weeks-6months WC = - 1.44 ± 2.9 cm men, p=0.02; difference WHR = - 0.014 ± 0.02, p=0.003)
Conclusion: In this prospective study supervised short-term hypo-caloric program is more effective than home-based 6 months diet. We demonstrated the predictive value of gender in outcomes: men had greater reductions in WC and WHR in short-term supervised program, but due to the less men compliance to the long-term home-based diet, women had greater reduction in WC and WHR after 6 months

No conflict of interest

P-1129

Effect of dietary carbohydrate to protein ratio on body weight, body composition and glycemic control in Type 2 diabetes

N. Deshpande[1], N. Patankar[2], N. Kapoor[3], A. Syed[3], R. Pilankar[3], P. Deshmukh[3], N. Pawar[3], A. Dorugade[3], R. Dhareshwar[4]

[1] *Belgaum Diabetes Centre and JN Medical College, Diabetes & Obesity, Belgaum, India*

[2] *Jupiter Hospital, Diabetes & Obesity, Mumbai, India*

[3] *Belgaum Diabetes Centre, Diabetes & Obesity, Belgaum, India*

[4] *Belgaum Diabetes Centre, Biostatistics, Belgaum, India*

Background & aim: We tested the hypothesis that by making up the deficient proteins in a meal, up to standard recommended levels, in the usual low protein Indian diabetic diet, we would achieve a better glycemic control. Protein extracts, which did not alter the taste or the usual cultural food practices, such as consumption of rice and chapatti, were provided as a Carbohydrate:Protein (CP) Balanced diet.

Methodology: 18 Type 2 diabetics, 8 cases (Consuming CP Diet) and 10 controls (Consuming usual diet), of either sex, aged 18-60 yrs, with an HbA1c 7.5 – 10 (both inclusive) were enrolled. Only those patients who were on stable treatment of diabetes with a stable weight (+/- 3 kg variation in previous 3 months) were included. Patients with diabetic nephropathy, secondary causes of obesity, neuropsychiatric disorders or on weight altering drugs were excluded. Written Informed Consent was taken, the protocol which was approved by the Independent Ethics Committee was explained to the subject. Electronically measured, balanced protein meal was provided to achieve an ideal (CP) ratio, through a structured diet chart containing calories as determined by their BMR. Oral meal tolerance test was performed at 30 min, 60 min, 90 min and 120 min after the ideal CP meal to assess glycemic control.

Results: Clinical characteristics were comparable among the cases and controls with respect to age (48.13 & 50.38), sex, anthropometry (BMI 34.1 & 32.87, W/H 0.91 & 0.94), renal profile (GFR 149 ml/min & 106 ml/min), duration of diabetes (7.25 & 5.25yrs) and diabetic treatment.

The Oral meal tolerance test results were as follows:

	CASE	CONTROL	%Age Rise Case	%Age Rise Control	P Value
FBS	168.8	138.7	-	-	-
30 MIN	207.2	197.2	20.1±17.7	41.2±23.1	0.07
60 MIN	207.5	228.2	21.7±18.2	64.7±16.8	0.0001
90 MIN	217.2	224.5	28.1±21.2	61.6±16.6	0.003
120 MIN	197.3	208.5	17.3±20.5	49±21.8	0.01

Discussion/conclusion: Patients who consume a CP balanced diet have a better postprandial glycemic control than those who consume a normal diet. In this study we observe that the diabetic subjects on CP Diet have lower peak of glucose and a lesser (around 29 mg/dl) postprandial rise in blood sugar when compared to the diabetic controls on normal diet. The controls had a total rise of around 70 mg/dl.

This suggests that a simple increase of the dietary proteins to the recommended value in usually low protein Indian diet would improve the glycemic control to a significant extent. Long term studies would be needed to confirm this hypothesis.

Can a low glycaemic index-based dietary intervention produce a sustained improvement in glycaemic control?

B.N. Mohd Yusof[1], A.T. Ruzita[2], A.K. Norimah[2], K. Nor Azmi[3]

[1] *University Putra of Malaysia, Nutrition & Dietetetics, Serdang, Malaysia*

[2] *University Kebangsaan Malaysia, Nutrition & Dietetetics, Kuala Lumpur, Malaysia*

[3] *University Kebangsaan Malaysia, Medicine, Kuala Lumpur, Malaysia*

Background: Previous studies have reported that intensive diabetes management can significantly reduce the complications of diabetes. However, in many patients, the diabetes control deteriorated after the end of the intensive therapy. Recently, we have shown that low glycemic index (GI) -based dietary intervention resulted in significant improvement in serum fructosamine (at 4 week), fasting and postprandial plasma glucose among Asian patients with type 2 diabetes over a 12-week period compared to those following a conventional carbohydrate exchange (CCE) diet. Whether this improvement goes beyond the 12 week period is of interest in the current analysis.

Aims: In the 12-week post intervention follow-up visit, we examined the changes in the glycemic control after the discontinuation of the active phase of the dietary intervention.

Methods: Patients (n=104) with established type 2 diabetes were randomly assigned to low GI (n=52) or CCE (n=52) intervention groups. After 12 weeks of active intervention, patients who had still met the initial study criteria were followed at week 24. Per protocol analysis was performed to compare the changes in glycemic control, anthropometric measurement and dietary intake between the two groups.

Results: At week 24, the GI group had a larger reduction in HbA1c (Δ= -0.6±0.1%) than the CCE group (Δ= -0.3+0.1%). There was a trend for more subjects from the GI group (41%) achieving the HbA1c target of <6.5% compared to the CCE group (23%) (p=0.07). Similarly, subjects in the GI group were able to maintain a higher fibre intake and lower dietary GI than those following the conventional dietary advice.

Conclusion: The beneficial effect of low GI-based dietary intervention on glycemic control and nutritional intake persisted 12 weeks after the end of the active phase of the intervention.

P-1131

A short-term, self-financed meal replacement program improved metabolic control of overweight or obese Chinese patients with type 2 diabetes

C.S. Chan[1], Y. Lee[1], S.C. Siu[1], K.W. Wong[1], T.P. Ip[1]

[1] *Tung Wah Eastern Hospital, Medicine & Rehabilitation, Hong Kong, China*

Aim: To evaluate the effects of a short-term self-financed meal replacement program in overweight or obese Chinese patients with type 2 diabetes.

Method: This is a retrospective analysis of a set of prospectively collected data (from February 2008 to January 2009). Patients with body mass index (BMI) >23kg/m^2 and type 2 diabetes in the absence of severe diabetic complications from the Diabetes Centre were invited to join the self-financed meal replacement program. They were started on meal replacement formulae (Resource® Diabetic / Glucerna SR™ / Nutren® Diabetes) to replace 2 usual meals for 12 weeks. Body weight (BW), fasting blood glucose (FBG), HbA1c, lipid levels and blood pressure (BP) were measured before and after the intervention.

Results: Forty patients (M: F=27:13) with mean age 49.1±8.3 years and duration of diabetes 9.3±5.8 years joined the program. Baseline BW was 86.5±16.9kg. BMI was 31.7±4.7kg/m^2 and HbA1c was 9.0±1.4%. All patients were on oral anti-diabetic drugs (OADs) and 18 (45%) were also on insulin. Only 23 (58%) completed the 12-week program (completers). The main reasons for withdrawal were intense hunger (53%) and monotony (17%). No participant withdrew because of financial difficulty. Detail analysis showed that improvements in metabolic control were only achieved in completers.

Table 1 Improvements of metabolic control in the completers:

	Baseline	Week 12	Change	P
BW (kg)	87.2±18.7	83.7±18.3	-3.5±2.4	<0.01
BMI (kg/m^2)	31.9±5.1	30.6±4.9	-1.3±0.85	<0.01
FBG (mmol/L) (n=21)	10.0±3.5	7.7±1.9	-2.3±3.5	<0.01
HbA1c (%)	8.9±1.5	7.1±0.8	-1.8±1.1	<0.01
Systolic BP (mmHg)	139.1±16.1	131.9±19.8	-7.2±13.1	0.026
TG (mmol/L) (n=15)	2.38±1.4	1.83±1.0	-0.55±0.75	<0.01

Nine completers required a reduction of OADs or insulin dosage whereas three had an increase at the end of the intervention. The proportion of completers achieving a HbA1c level of <7% (the American Diabetes Association's recommendation for glycemic control) increased from 13% to 52% (P<0.01). Hypoglycemia and constipation were reported in 48% and 39% of completers respectively.

Discussion/conclusion: The results showed that short-term meal replacement improved metabolic parameters of overweight or obese Chinese type 2 diabetic patients. Over-consumption of the third meal and mild hypoglycemia with compensatory food intake might explain the small amount of weight loss (-4%) achieved. This study also demonstrated the feasibility of self-financing of meal replacement formulae in clinical practice. The small sample size, short duration and the non-randomized, non-controlled retrospective design, however, limited the strength of the results. We concluded that self-financed meal replacement may potentially be an effective strategy to improve the metabolic control in overweight or obese Chinese patients with type 2 diabetes.

Nutritional intervention and body weight change in outpatients with type 2 diabetes mellitus, Sao Paulo, Brazil

L. Asakura[1], D. Tarasautchi[1], N.C. Santos[1], M.Q. Freire[1], M.C. Ferreira[1], S.K. Oku[1], L.C. Coelho[1], A. Sachs[1]
[1] UNIFESP/EPM, Preventive Medicine, São Paulo, Brazil

The prevalence of Diabetes Mellitus is around 7,6% in Brazil and it is one of the most important risk factor for cardiovascular disease, which is the first leading cause of death.
Aim: to evaluate nutritional intervention among patients with metabolic syndrome and type 2 diabetes (DM2) according to weight change.
Methods: it is a follow-up study of nutritional intervention including all the patients from the Metabolic Syndrome and Nutrition Health Care from Federal University of Sao Paulo, Brazil who undertook 3 nutrition counsellings followed by 8 months during 2008. Metabolic syndrome was defined on the basis of the National Cholesterol Education Program Adult Treatment Panel III criteria (2006). Weight was measured at 3 different times (pre intervention, mean of 2 months and after a mean period of 4 months). All the patients received an individualized meal plan (hypocaloric and adequate in macro and micronutrients). A 24hour food recall was applied at each counselling when doubts on the diet plan were solved, tips about eating out were given and patients were encouraged to follow the diet and to self monitor eating behaviour.
Results: there were 42 patients (14 men; 28 women); mean age was 56 (± 9) years; there was a significant decrease in the mean weight (86,9 ± 19,7 vs 85,8 ± 19,9 kg) and in the body mass index (33,2 ± 6,2 vs 32,8 ± 6,3 kg/m^2) after the nutritional intervention among all the participants, specifically among women (84,6 ± 18,7 vs 83,1 ± 18,9 kg; 34,0 ± 6,4 vs 33,4 ± 6,5 kg/m^2) but not among men. Almost 11% of the women achieved normal weight by height. It was not shown any association between weight reduction and gender, neither age, school aging and marital status.
Conclusion: Nutritional counselling and a personal meal plan showed good results among women, who had a significant decrease in the mean weight and in the body mass index as compared to men although, there was no association between weight reduction and gender. The follow-up period can be considered a limitation for more significant results.

Management of a case of neonatal diabetes secondary to pancreatic agenesis

E. Pytka[1], V. Morinville[2], N. Dumouchel[1], J. Mitchell[1]
[1] Montreal Children's Hospital, Endocrinology and metabolism, Montreal, Canada
[2] Montreal Children's Hospital, Gastroenterology, Montreal, Canada

Case report: A symmetrical IUGR male infant born G1P1 mother at 37weeks was found to have hyperglycemia (19 mmol/L) in the first day of life, and insulin therapy was commenced. Further examination revealed a non-dysmorphic child with an atrial-septal defect, pulmonary valvular stenosis (PVS) and a left congenital diaphragmatic hernia (CDH). Surgical repair of the PVS and CDH allowed abdominal exploration, which failed to reveal a pancreas or gallbladder. Nutritional management of this patient was complicated by failure to thrive secondary to pancreatic exocrine insufficiency. Despite initiation of pancreatic enzymes, the baby continued to have problems with weight gain (wt and wt-for length <3 percentile on CDC growth curves) and eventually required admission at age 8 months for continuous IV insulin infusion and nutritional repletion. The infant was fed orally using a hypercaloric infant formula (partially-hydrolyzed protein) with added glucose polymers (polycose) and medium chain triglycerides concentrated to 1 kcal/ml. Nutritional intakes were maintained via naso-gastric tube supplementation, and solids were introduced to preserve and enhance normal developmental oral-motor skills. Blood glucose was extremely variable with significant episodes of hyper and hypoglycemia. Two weeks post admission, the baby was switched to a regime consisting primarily of insulin glargine (0.6 u/kg/d) q am with sliding scale lispro (1:10 dilution) 5 times/day and subsequently insulin carbohydrate ratios to avoid hypo and hyperglycemia when food refusal behaviors began. Insulin pump therapy was not possible at this time due to a lack of subcutaneous tissue. Although this regime helped greatly with weight gain, nocturnal hypoglycemia secondary to pancreatic endocrine insufficiency remained a problem despite the addition of raw cornstarch to nocturnal feeds. At age 18 months nocturnal hypoglycemia were diminished greatly when a subcutaneous insulin pump was initiated. The patient, at two years of age, is now thriving (wt and wt/length 10-25 percentile) with good metabolic control and normal feeding behaviors.
Conclusion: We describe the difficulties in management of a child with neonatal diabetes secondary to pancreatic agenesis. Insulin pump therapy allowed the flexibility needed to address both exocrine and endocrine pancreatic deficiencies and should be considered early on in management of these rare cases.

Impact of sweet preference and sweet taste sensitivity on specific eating pattern or life-style related disease

E. Mizuta[1], T. Hamada[1], T. Ohkura[1], S. Taniguchi[1], O. Igawa[1], C. Shigemasa[1], Y. Hirota[2], M. Mishima[2], I. Hisatome[2]
[1] Tottori University Faculty of Medicine, Division of Molecular Medicine and Therapeutics, Yonago, Japan
[2] Tottori University Graduate School of Medical Science, Division of Regenerative Medicine and Therapeutics, Yonago, Japan

Aims: Although sweet preference or sweet taste sensitivity is considered to influence specific eating pattern or life-style related disease, few reports have shown an association between them. Recently we reported that genetic polymorphisms affect obesity along with individual sweet preference in humans. Thus we examined the associations of sweet preference and sweet taste sensitivity with specific eating pattern or life-style related disease to obtain further insight into their relationships.
Methods: We recruited 48 Japanese patients with life-style related disease (21 males and 27 females). Blood samples were drawn after overnight fasting. A questionnaire of sweet tooth was asked to each subject, as followed: "Do you like a sweet taste?" and the answer was chosen from one of the following choices; 1. No, I hate it; 2. No, I don't like it very much; 3. Neither yes or no; 4. Yes, I like it; and 5. Yes, I like it very much. The written answers were confirmed during an interview. We defined the subjects who selected number 5 as having a sweet preference and those that selected answer number 1, 2, or 3 as the controls. We also examined individual sweet taste sensitivity using the paper disk methods. Further nutritionist examined specific eating pattern in a unified way. All examinations were done on the same day, and we evaluated the association among these parameters using variance analysis or logistic regression analysis with consideration of potential confounding factors (age, sex).
Results: When clinical characteristics were compared between the subjects with sweet preference and the controls, the results indicated that LDL and total cholesterol values were significantly higher in the subjects with sweet preference (p values: LDL, 0.022; total cholesterol, 0.036). There were no significant associations between sweet taste sensitivity and clinical parameters. In addition, the subjects with sweet preference significantly ate more fatty meal than the controls (p=0.047), especially they tended to eat diet in higher saturated fatty acid (p = 0.083).
Discussion and conclusion: This was because something sweet tends to contain saturated fatty acid in abundance like cake or ice cream, we considered that the subjects with sweet preference significantly ate more fatty meal than the controls. In conclusion, we considered that our findings may contribute to better management of obesity or lifestyle-related diseases.

Camel milk, adjunct to insulin therapy, improves glycemic control and lowers insulin requirement without risk of hypoglycemia in patients with type 1 diabetes: 2 years randomized controlled trial

N. Mohta[1], R.P. Agrawal[1], S. Jain[1], S. Goyal[1], R. Dogra[1]
[1] Diabetes Care & Research Centre, Medicine, Bikaner, India

Aim: To assess the efficacy, safety and acceptability of camel milk as an adjunct to insulin therapy in type-1 diabetics.
Methods: In this two year randomized clinical parallel design study, 24 type-1 diabetics were enrolled and divided in two groups. Group-I (n=12) received usual care i.e. diet, exercise and insulin and group-II (n=12) received 500ml camel milk in addition to usual care. Insulin requirement was titrated weekly by blood glucose estimation. Results were analysed using ANOVA.
Results: In camel milk group, there was significant decrease in mean blood glucose (118.58±19 to 93.16±17.06 mg/dl, $p<0.001$), HbA_1c levels (7.81±1.39 to 5.44±0.81%, $p<0.05$) and insulin doses (32.50±9.99 to 17.50±12.09u/day, $p<0.05$). Out of 12 subjects receiving camel milk, insulin requirement in 3 subjects was reduced to zero. There was no significant change in C-peptide, plasma insulin and anti insulin antibodies in both the groups.
Conclusions: Camel milk is safe and efficacious in improving long-term glycemic control with a significant reduction in the doses of insulin in type-1 diabetic patients.

Assessment of glycaemic index of dietary and herbal based mucilages on the selected type 2 diabetic subjects

N. Peerkhan[1]
[1] Periyar University, Lecturer Department of Food Science, Salem, India

Aim: To assess the Glycemic Index and Glycemic load of the prepared okra mucilage powder.
Methods: Diabetes mellitus is a physiological problem affecting the lives of millions of people and one of the leading causes of death. It has the world's largest diabetic population in terms of numbers with over 3.5 million people affected with Diabetes mellitus. Okra (Ladies Finger) is valued for its edible, delicious and nutritious green fruits as vegetables throughout the world. The fruit contains mucilaginous material that has several medicinal uses. Hibiscus Rosa-sinensis is commonly found throughout the tropics and a house plant throughout the world. Flowers are used to treat diabetes. For the present study, matured okra fruits and hibiscus flowers are selected and the mucilage was extracted using physical and solvent method and it was finally made into powder. About 125 Type 2 diabetic subjects belonged to the age group of 30-55 years were surveyed. Among them 50 were selected for the Glycemic Index assessment and they are divided into five groups with 10 diabetic subjects in each group. Group I was kept as control group, Group II and Group III was supplemented with 3 grams of okra and hibiscus mucilage powder incorporated in Rice based idlis respectively and Group IV and Group V was supplemented with 3 grams of okra and hibiscus mucilage powder incorporated in Finger millet based idlis respectively. The study was approved by the Institution ethical committee. The developed food products are organoleptically evaluated and analyzed for the available carbohydrates. The data were analyzed using ANOVA and Duncan's multiple range tests to find the significance difference.
Results: It revealed that all the developed recipes are highly acceptable with the available carbohydrate of 49.19g, 53.59g for rice based okra and hibiscus mucilage powder incorporated idlis and 51.57g, 54.7g for finger millet okra and hibiscus mucilage powder incorporated based idlis. The mean glycemic index and glycemic load was found to be 81.01 and 44.70 respectively for Group I, 76.17 and 37.4 for Group II, 83.69 and 43.32 for Group III, 67.68 and 43.48 for the Group IV, 79.80 and 53.25 for Group V subjects. Duncan's test revealed that there was a significant difference ($P< 0.05$) in the Glycemic Index and Glycemic load between okra and hibiscus mucilage powder incorporated idlis with the control group.
Conclusion: Thus the study concludes that the addition of okra and hibiscus mucilage has produced beneficial effects on controlling the diabetes by reducing the Glycemic Index among the selected diabetic subjects.

Effects of Ramadan fasting on some risk factors of type 2 diabetes in Indian origin adult Muslims living in the North-West province of South Africa

M. Islam[1]
[1] University of KwaZulu-Natal (Westville Campus), Department of Biochemistry, Durban, South Africa

Aims: The present study investigated the effects of Ramadan fasting on some risk factors of type 2 diabetes in Indian origin adult Muslims living in the North-West province of South Africa.
Methods: Initially, a total of 52 subjects (31 male, mean age 49.87 years and 21 female, mean age 41.20 years) participated in the study, however the final data were possible to collect only from 44 subjects (26 male and 18 female). The initial and final data for height, body weight, waist circumference, hip circumference, body fat percent, and systolic and diastolic blood pressure were taken on the 0th and 28th day of Ramadan month, respectively. The body mass index (BMI) and waist-hip ratio were calculated from the collected data.
Results: It was found that the body weight, waist circumference and BMI were significantly ($p < 0.05$) decreased at the end of the Ramadan month. The systolic and diastolic blood pressures were also significantly ($p < 0.05$) decreased in subjects with high blood pressure while increased up to an optimal level (systolic: 75-80 mmHg and diastolic: 115-120 mmHg) in subjects with a history of low blood pressure. The waist-hip ratio was markedly ($p = 0.087$) decreased at the end of the Ramadan fasting. However, the hip circumference and body fat concentration were not influenced by the Ramadan fasting.
Conclusion: The data of this study suggest that Ramadan fasting has some beneficial effects on the reduction of several risk factors of type 2 diabetes and metabolic syndrome.

P-1138

Voglibose inclusion liberalizes diet (VILD): a simplified approach to diet therapy treated early type 2 diabetes patients

L.K. Shankhdhar[1], K. Shankhdhar[2], U. Shankhdhar[3], S. Shankhdhar[4]
[1] L.K.Diabetes Centre, Endocrinology, Lucknow, India
[2] L.K.Diabetes Centre, Diabetology & Podiatry, Lucknow, India
[3] L.K.Diabetes Centre, Nutrition, Lucknow, India
[4] L.K.Diabetes Centre, Diabetes Education, Lucknow, India

Background and aims: Conventional diet (CD), based on Exchange Table, is frequently adopted by the physicians in developing countries with scarcity of Nutritionists. In "VILD" approach, "Voglibose" is added before major meals to delay carbohydrate absorption. Although common sugar is allowed sparingly, sugar dense items are denied totally and Fat dense edibles allowed in limited quantity, during festivals only.
Present study aimed to evaluate results of VILD versus CD.
Research and Design: 30 drug naïve early cases (duration of T2D =1 year), A1c 7 to 8% on CD were randomized into 2 groups - one continuing with CD and the other offered VILD approach. Follow up period was 12 months with bimonthly OPD visits. Both groups had matchable baseline characteristics:-

Characteristics	CD	VILD
Age (yrs)	51.26±6.32	52.40±6.96
DOD (months)	7.13±2.85	6.60±2.74
Wt (Kg)	68.21±7.25	68.32±7.18
BMI (Kg/M^2)	26.53±2.88	25.83±1.89
FBG (mg%)	112±7.52	120±9.18
PPBG (mg%)	167.06±7.01	179.53±11.51
ABG (mg%)	140.93±7.01	149.76±7.74
A1c (%)	7.71±0.09	7.56±0.22

Results: VILD group revealed better outcomes, as shown in the table:-

Characteristic		CD	VILD
FBG (mg%)		-4.65±7.45	-12.10±8.29
PPBG (mg%)		-9.00±10.76	-32.98±13.12
ABG (mg%)		-8.10±5.19	-22.56±9.66
A1c (%)		-0.003±0.97	-0.43±0.28
Wt (Kg)		0.91±0.74	0.08±0.53
BMI (Kg/M^2)		0.32±0.24	0.02±0.21
Lipid Profile	Total	-16.06±22.52	-18.26±27.87
	TG	-18±33.99	-16.60±19.87
	LDL	-13.26±22.38	-19.20±27.02
	HDL	1.13±2.47	4.26±1.94

While no pt in CD attained target A1c (<7%), 33.33% pts in VILD group did achieve. GI upsets were marginally more in VILD group (9%) compared to CD (5%)

Conclusion: VILD Approach can be a good solution to the problem of non availability of Nutritionists in developing countries, since it alleviates the need for special diet cards; in addition, it yields better clinical outcomes too.

A comparative study of dietary habits and anthropometric changes in diabetic and non-diabetic groups in the same socio-cultural backgrounds

R. Chandni[1], V. Udayabhaskaran[1], K.P. Ramamoorthy[1]
[1] Calicut Medical College, Medicine, Kozhikode, India

Aims of the study:

1. To compare the dietary pattern and habits among diabetic and non diabetic people in the same ethnic and socio cultural backgrounds.
2. To compare the anthropometric measurements in diabetic and non diabetic people in the same socio cultural backgrounds.

Materials and methods: This was a case control study.153 subjects having diabetes of varying duration on treatment were compared with 153 non diabetics matched for age, gender, cultural and religious backgrounds. Those having familial hyperlipidemias, hypothyroidism and those on glitazones, lipid lowering drugs were not included. Detailed history, social habits, and anthropometry done in both the groups and were compared.

Observations: The age group ranged between 26 and 85 years with mean age of 53.93 ±10.66. There were 86 (56.2%) males and 67 (43.8%) females among both the groups. The groups were comparable in religious background, smoking and alcoholism. Among the diabetic subjects mean caloric intake was 1285.96±222.35 and among the controls it was 1166.66±266.3 (p = 0.00). Mean carbohydrate consumed among subjects was 259.00±54.84 and controls was 250.92±57.32 (p = 0.21). Mean Protein consumption among diabetics was 46.41±17.15 and among controls was 42.10±11.61 (p = 0.01). Mean Fat consumption among diabetics was 23.36 ± 6.35 and among controls was 20.412± 6.94 (p = 0.00). Among the diabetics mean BMI was 25.18±3.89 and 24.12 ±3.20 among the controls (p = 0.009). Among Diabetics, mean BMI of males was 24.46±3.24 and of females was 26.11±4.45 (p = 0.009).In females mean BMI was 24.34±3.62 for controls and 26.11±4.45 for diabetics (p=0.013).Among the diabetics mean waist circumference was 92.07±8.997. Among the controls it was 87.73 ± 8.76 (p = 0.00). Among diabetics mean waist circumference of males was 89.71±7.88 and of females was 95.1±9.48 (p = 0.000) and among controls mean waist circumference of males was 87.41±7.87 and of females was 88.14±9.84 (p = 0.61). Among females mean waist circumference was 88.15±9.84 for controls and 95.11±9.48 for diabetics (p=0.000).

Conclusions: Mean calorie, carbohydrate, protein and fat intakes were higher in the diabetic group compared to the controls. Mean BMI was higher in the diabetic group. Mean BMI and waist circumference was higher in females in the diabetic group compared to males. Moreover females in the diabetic group had higher BMI and waist circumference compared to the females in the non diabetic group.

Effect of oyster mushroom (Pleurotus spp.) on glycemic control, lipid profile and diabetic quality of life in type 2 diabetic patients - double blind placebo controlled study

A. Chopra[1], R.P. Agrawal[1], M.M. Padhi[2], B. Sihag[1], S. Goyal[1], N. Sharma[1], S. Jain[1]
[1] Diabetes Care & Research Centre, Medicine, Bikaner, India
[2] Central Council For Research in Ayurveda & Sidhha, Medicine, New Delhi, India

Aims and objectives: The aim of the study was to evaluate the efficacy of oyster mushroom (pleurotus spp.) on glycemic control, lipid profile and diabetic quality of life in type-2 diabetic patients.

Material and method: Study design: A randomized double blind placebo controlled study.

Total 150 type-2 newly onset diabetic patients were recruited. After 1 month stabilization period 120 patients were randomly selected. These patients were divided into three groups Group-1 given type A biscuit, group 2 given type B and group 3 given type C biscuits by dietician without any awareness about nature of the biscuits. All the three groups were also given conventional treatment i.e. diet, exercise for 3 months. Anthropometric parameters, FBS and BP were recorded weekly and HbA_1c, lipid profile, diabetic quality of life questionnaire were performed initially as well as after 3 months. After 3 months decoding was done and concluded that type A biscuits were Ajwain biscuits, type B were Ajwain + Mushroom biscuits and type C were Mushroom biscuits.

Results: After 3 months period blood sugar was found reduced in ajwain+mushroom group (225.41±3.35 to 113.83±4.03; p<0.005) as also in mushroom group (212.9±4.29 to 112±1.37; p<0.005), Systolic blood pressure reduced in both groups ajwain + mushroom (130.75±2.10 to 121.50±1.16; p<0.05) and in mushroom group (126.8±1.73 to 121.65±1.3; p<0.05), Diastolic blood pressure reduced in [ajwain + mushroom group (85.00±1.31 to 79.70±0.70; p<0.05) and in mushroom group (82.00±0.96 to 79.95±0.79; p<0.05)]. There was also significant effect on glycemic control (HbA_1c) in both groups [ajwain + mushroom group (8.47±0.17 to 7.27±0.14; p<0.02) mushroom group (8.00±0.13 to 6.99±0.12; p<0.05)], there was significant reduction in lipid profile i.e. total cholesterol ajwain + mushroom group (190.69±4.39 to 166.83±2.47; p<0.001) and mushroom group (186.77±3.43 to 157.39±2.32; p<0.05), HDL in ajwain + mushroom group (40.42±0.92 to 45.40±0.91; p<0.005) and in mushroom group (45.81±2.03 to 49.30±1.47; p<0.05), LDL in ajwain + mushroom group (110.05±2.55 to 98.21±1.38; p<0.05) and mushroom group (103.04±3.41 to 96.99±3.30; p<0.05), VLDL in ajwain + mushroom group (42.62±2.03 to 28.62±1.26; p<0.05) and in mushroom group (42.42±2.35 to 31.40±1.81; p<0.05), serum triglyceride in ajwain + mushroom group (213.93±14.24 to 144.73±7.01; p<0.05) and in mushroom group (210.71±12.49 to 157.41±7.79; p<0.02), Diabetes quality of life also improved significantly but there was no significant change in BMI & waist hip ratio.

Conclusion: Oyster mushroom (pleurotus spp.) consumption appears to be effective in controlling glycemic control, lipid profile and diabetic quality of life.

Statistical method: Using ANOVA, confidential limit and correlation.

P-1141

Effect of varying the source or amount of dietary carbohydrate on glycemic and insulinemic response in subjects with type 2 diabetes

B. Edalat[1], S.H. Egtesadi[1], F. Tahbaz[2]
[1] Iran University Of Medical Science School Of Hygiene, Nutrition, Tehran, Iran
[2] Shahid Beheshti University Of Medical Science Faculty Of Nutrition And Food Science, Nutrition, Tehran, Iran

Background and aim: Diets of low glycemic load (GL) may dampen postprandial glycemic response which is beneficial for managing insulin resistance. The GL can be reduced by decreasing either carbohydrate intake or glycemic Index (GI). The present study was carried out to investigate whether these 2 dietary maneuvers have the same effects on glycemic and insulinemic response in subjects with type 2 diabetes.

Methods: This study was conducted in 15 newly-diagnosed type 2 diabetic patients (age: 52.8±9.26 y; BMI: 25.17±2.69 kg/m^2; disease duration: 2.7±1.8 y; fasting blood glucose level: 128.00 ± 25.58 mg/dl). Subjects received the experimental dinners on 3 days with one week intervals. The three dinners were: 1- A medium-GL, medium-GI diet (62% CHO, 23% PRO., 15% fat;

GL=50), 2- A low-GL, low-GI diet (62% CHO, 23% PRO., 15% fat; GL=38), 3- A low-GL, low-CHO diet (52% CHO, 25% PRO., 23% fat; GL=38). Venous blood samples were collected before (after 12 hours fasting), 60 and 120 minutes after consumption of the standard breakfast (63% CHO, 17% PRO., 20% fat; GL=20). Serum glucose concentrations were determined by "glucose oxidase" method. Serum insulin assays were performed by "IRMA test". The data were analyzed with the use of a repeated-measure analysis of variance.
Results: Only varying carbohydrate amount (and not the GI) had an effect on 60-minute postprandial glucose response and also incremental area under the curve (AUC) for glucose (p=0.04). Varying neither the GI nor the carbohydrate amount had a significant effect on insulin response.
Conclusion: Reducing the amount of carbohydrate intake had a significant effect on glycemic response and GI couldn't predict postprandial glucose level in diabetic patients as accurately as GL, which is the combination of both the quality and quantity of carbohydrate. The two dietary maneuvers did not have any significant effect on blood insulin levels.

Effectiveness of professional dietary guidance on dietary practices of diabetic subjects in Karachi, Pakistan

R. Hakeem[1], A. Fawwad[1], A. Siddiqui[2], M.Y. Ahmedani[3], A. Basit[3]
[1] *Baqai Institute of Diabetology & Endocrinology, Department of Research, Karachi, Pakistan*
[2] *Baqai Institute of Diabetology & Endocrinology, Department of Diet & Education, Karachi, Pakistan*
[3] *Baqai Institute of Diabetology & Endocrinology, Department of Medicine, Karachi, Pakistan*

Aims: Impact of dietary guidance given to diabetic subjects has not been assessed much in low resource communities. This study was planned to assess the effectiveness of professional and individualized dietary guidance on dietary practices of diabetic subjects.
Methods: Dietary guidance is given by dietician and clinical and dietary profile of Subjects is routinely recorded at patients first visit at BIDE. For this study 200 consecutive subjects were recruited to assess impact of dietary guidance and were invited to make a repeat visit after three months. On the basis of data recorded at first and repeat visit number of modifications needed in a patient's diet at each stage were calculated. Relative frequency of number of modification needed by the subjects was used to identify the individual having relatively better dietary practices. Reduction in total number modifications needed indicated improvement in diet.
Results: Out of 200 subjects, 50.7% were females. Mean age of subjects was 50.3 ±10.7 years. Significant improvement was seen at second visit in terms of intake of most of the food items (p value <0.005).
Conclusions: This first of its kind study from Pakistan, has documented the efficacy of dietary guidance and highlighted the need for utilizing professional services to persuade life style modifications in diabetic subjects.

Analysis of food standard in educational activities for people with diabetes

A.C. Martins[1], F.O. Magalhães[1], R.G.C. Bomfim[1], S.P. Nunes[1], E.E. Leite[1], D.R.M.C. Oliveira[1], F.A. Avelar[1], A.L. Cançado[1], N.M. Ferreira[1], S. Messias[1], A.P. Silva[1], L.K. Oliveira[1]
[1] *Universidade de Uberaba, medicina, Uberaba, Brazil*

The prevalence of Diabetes Mellitus is increasing exponentially, bringing epidemic characteristics, especially in developing countries. The modification of feeding behavior appropriate and weight loss, associated with the practice of regular physical activity, are considered therapies coadjuvants to assist in the glycemic control these patients.
To assess the impact of food in the life of diabetic, we conducted a search with a population, during physical activity-recreational and educational performed on the World day of Diabetes. Investigation was carried out food frequency, measured fasting and post-prandial capillary glycemia. Data were analyzed by SPSS 14.0 program and through the chi-square with a significance level of 5%
It was possible to observe this examines what in the total of 126 individual interviewees, 28.6% had diabetes mellitus. The greater prevalence in daily diet was fruit with 64.3 %, followed by coffee less than 63.5 %, and juices 54.8 %. In relation to consumption of sweets found: 67.1% wore saps with sugar 3 times/week; 48.2% interfered soft drinks 1 time/week and 23.2% 3 times/week; 65.2% consumed desserts once/week and; 66.7% interfered chocolate once/week and 52.4% bullets. The intake of fruits and vegetables was: 34.1% consumed 3 times/week and 46.3% once/day. Fried food was consumed in 49.3% once/week and 40.3% once/day. There was no significant relationship with the presence of diabetes and: ingestion of saps (X2=3.259, p=0.196), soft drinks (X2=2.149, p=0.542), chocolate (X2=1.434, p=0.231), fried food (X2=6.371, p=0.383) and bullets (X2=2.436, p=0.656). There was no relationship between the consumption of foods and glycemic level.
We conclude that the dietary patterns of individuals analyzed were inadequate, with low consumption of fruit and vegetables and frequent ingestion of sweets. There was no difference between the pattern of food in non-diabetic and diabetic. We need greater awareness this population in relation to food.

Nutrition education with emphasis on carbohydrates and glycemic index

C.E.G. Reis[1], G.F. Mendes[2], F.D. Moreira[2], A.O.P. Protzek[3], A.S.M. Silva[2], J. Dullius[4]
[1] *Federal University of Viçosa, Department of Nutrition and Health, Viçosa, Brazil*
[2] *Federal University of Brasília, Sweet DESAFIO, Brasília, Brazil*
[3] *Federal University of Brasília, School of Medicine, Brasília, Brazil*
[4] *Federal University of Brasília, College of physical education, Brasília, Brazil*

Aims: To assess the understanding of diabetes on benefits of a healthy diet, counting carbohydrates and application of the glycemic index (GI).
Methods: 19 type 2 diabetic participants of an education program in diabetes (age 30-75 years), attended a nutrition education project focusing on CHO and GI, consisting of 7 lectures on healthy eating for diabetics, one of a specific count of CHO and other of GI and cooking workshop. They received a table of GI and CHO counting specially prepared. In the final, subjects answered a questionnaire. All subjects gave written informed consent. This investigation was approved by the institutional review boards of the University of Brasília, Brazil.
Results: 31.57% (n = 6) hit the question "What is GI?" 89.47% (n = 17) said that low GI (LGI) is related to full and rich in fiber, 68, 42% (n = 13) marked the high GI (HGI) are rich in CHO, usually processed and industrialized, only 21% (n = 4) related to GI cooking and the presence of fiber; and 100% (n = 19) mentioned fruits, vegetables, legumes and whole foods as LGI. Asked about the benefits of LGI diet, 100% marked: "Help to control weight" and "improves the glycemic control." 84.21% (n = 16), 73.68% (n = 14) and 10.53% (n = 2) answered "Control cholesterol," "Slow the absorption of CHO" and "Increases satiety" respectively. The answer: "It is bad to health", "are not indicated to diabetics", "fattening", "Leads to Diabetes" and "greatly increase the blood glucose" were not marked. In a list of 38 foods were asked to mark the LGI and HGI. 7 of these foods had index of accuracy of 100%, 8, 81-99% of hits, 8 of 61-80%, 10, of 41-60%, at 2, 21-40% and in 3 food <20% of hits. The concept of GI diet was confused with the increase of blood glucose. Others, associated HGI foods with high quantities of protein and fat and foods as not healthy.
Discussion/conclusion: In general, they showed the general knowledge of LGI and HGI food, its implications on health, examples and food of choice. The study may show the difficulties of a work of health education with adults and elderly, and require a wide work for results to be more expressive

Low and high glycemic index diets: application with type 2 diabetes and its variations on glycemia

C.E.G. Reis[1], G.F. Mendes[2], F.D. Moreira[2], A.O.P. Protzek[3], A.S.M. Silva[2], J. Dullius[4]

[1] Federal University of Viçosa, Department of Nutrition and Health, Viçosa, Brazil

[2] Federal University of Brasília, Sweet DESAFIO, Brasília, Brazil

[3] Federal University of Brasília, School of Medicine, Brasília, Brazil

[4] Federal University of Brasília, College of physical education, Brasília, Brazil

Aims: To assess the impact of HGI and LGI diets on blood glucose and correlate with the amount of CHO consumed.

Methods: Transversal study applied cross-over. 12 type 2 diabetic participants of education program in diabetes were divided into 2 groups random and instructed to follow HGI and LGI diets for 2 consecutive days in 2 consecutive weeks. Group A in the 1st week followed a HGI diet and LGI diet on the 2nd week, group B took the opposite. All were oriented about the research and the need to maintain a regular use of medication and lifestyle, and follow the recommendations of the professionals on days of data collection. Measurements were made of capillary glycemia through own glucometers (Accu-check and OneTouchUltra) in 2 days (fasting, pre-lunch, post-prandial lunch and pre-dinner) and a fast glycemia in the 3 days. The food record was also made during the days in which it was possible to count CHO meals. To compare the variables were applied the Wilcoxon test and to correlate the data of glycemia with the amount of carbohydrate ingested before, the Pearson Correlation Coefficient test. Was used a significance level of 0.05. All subjects gave written informed consent. This investigation was approved by the institutional review boards of the University of Brasília, Brazil.

Results: The variation of mean glucose of the diabetics in the 1st week showed major in the HGI diet. Already in the 2nd week, the glycemia average fasting begins at the same glycemic value in both groups (132 mg/dl) and the LGI diet shows higher glycemia, but without statistical significance (p = 0,344). By the graph of dispersion made between the amount of CHO ingested and the glycemic responses, we could not see a correlation between variables (p = -0128).

Discussion/conclusion: There were distortions in the interpretation of food choices by patients, complications such as insomnia and stress which may have influenced the results. LGI diet shows is beneficial in the treatment of diabetes and glycemic control. It was possible to observe in practice the difficulties encountered by patients in their day to-day work with these diets, besides seeing that psychosocial factors influence its decisions on the very food choices. But the group has adopted food choices most appropriate when the glucose values were changed.

Challenges of nutritional management of diabetes in Tanzania

H. Semu[1]

[1] Tanzania Food and Nutrition Centre, Community Health and Nutrition, Dar es Salaam, Tanzania

Background: Diabetes mellitus is an emerging serious medical problem globally. Among the contributing factors are unhealthy lifestyles such as poor nutrition and sedentary lifestyle. In Tanzania, the incidence of diabetes is rising much faster with little advancement in service delivery. As a result, diabetics are at increased risk of complications that occur early, resulting in substantial morbidity, mortality, and economic costs.

For better management of diabetes, a comprehensive care is required which include nutrition education. This is the corner stone for diabetes management if properly delivered, however in Tanzania that is not the case. Diabetes clinics are run without nutritionists or dieticians and in most cases, nutrition education is given by doctors or nurses who have not been given any formal training. As a result, myths and misconception regarding nutrition management of diabetes predominate due to inadequate, inappropriate, inaccurate, misleading and confusing nutrition information. Furthermore, there are no guidelines for nutritional management of diabetes, and limited locally developed and culturally sensitive nutrition education materials.

Current status of diabetes care and nutritional management of diabetes.

Tanzania has made a tremendous progress in improving diabetes care by establishing clinics at referral and regional hospitals with an extensive service to district hospitals and Primary Health Care. The clinics are equipped with resources, however human resource includes only doctors, nurses and lab technicians. Diabetes education particularly dietary and lifestyle education is lagging behind. Hospitals do not employ dietetic experts, and the structures of health facilities and that of the diabetes clinics do not include a nutritionist/ dietetic cadres

Proposed intervention: Nutrition education is the crucial component in diabetes care that plays an important role which consequently contributes to delay or even prevention of diabetes complication hence, a model of care which will advocate for a dietetic/nutrition cadre as part of comprehensive diabetes care is proposed as a long term solution. The use of trained nurses for provision of dietary education is proposed as a short term solution. The model should take consideration of shortage and workload of available staff, low literacy level of care providers and of patients, locally developed, cultural sensitive and user friendly materials

The model should contain a guidance tool to include nutrition management guidance booklet and its training manual; patient education materials to include information on dietary management of diabetes and lifestyle modification; Community reader materials to address risk factors, signs and symptoms and lifestyle modification for prevention of diabetes.

[3] Universidad Autonoma del Estado de Hidalgo, Area Academica de Odontologia, Pachuca, Mexico

[4] Resultados Medicos Desarrollo e Investigacion, Research Director, Pachuca, Mexico

Some researches have shown that the morbidity due to type 2 diabetes, in Mexico the number of hospitalizations for diabetic complications metabolic (acute and chronic) have increased. In the last years the number of cases of type 2 diabetes has increased five times more than other pathologies; brought consequently it worsens conditions. The high levels of final advanced glycoxidation end products, in pleople with type 2 diabetes cause other conditions, as the neuropathy, retinopathy, nephropathy. The diet for people with type 2 diabetes based only on the restrictions of simple and complex carbohydrates, with the main aim is controled high levels of glucose; they do not bear in mind the risks associated with the high temperatures used in the different food cooking techniques as: roasting, frying and baking. These techniques induce the production of glicotoxines.

Aims: Determining the association of the food cooking techniques and the metabolic control in patients with type 2 diabetes from Instituto de Seguridad y Servicios Sociales de los Trabajadores del Estado, Hospital in Ixmiquilpan, Hidalgo.

Methods: It is a descriptive, analytical and transversal study which included 65 type 2 diabetes patients. We evaluated the survey includes those patients willing to answer questions about food cooking techniques, medical history, 24 hours reminders, patients who had complete exams as: triglycerides, serum glucose, preprandial and postprandial capillary glucose as well as those patients who had glycated hemoglobin.

Results: In 27 food with the high glycotoxines contained, that were included in the review of food cooking techniques, 10 of them was associated with poor control of glycemia and lipids on type 2 diabetes patients of the Hospital Instituto de Seguridad y Servicios Sociales de los Trabajadores del Estado in Ixmiquilpan.

Discussion/conclusion: The outcome of this study proves that the patients that utilize food cooking techniques, like frying, baking and grilling suffer decontrol glucose and lipids.

[4] *Universidad Autonoma del Estado de Hidalgo, Area Academica de Psicologia, Pachuca, Mexico*

The diabetes is a group of metabolic diseases characterized by hyperglycemia cost by defects in the insulin secretion, in the insulin's action or both, the majority nutritional treatment recommended 15-20% protein, 50-60% carbohydrates in patients with normal renal function.

Aims: Effect of a feeding plan with high content of proteins and low carbohydrates on glycemic control in patients with type 2 diabetes for the Programa Estatal de Diabetes Hidalgo in it clinics: Actopan and Tizayuca.

Methods: in this study were included 34 patient with type 2 diabetes which 17 were assigned of feeding plan with American Diabetes Association recomendations (15:55:30) and 17 a feeding plan modified in proteins (30:20:50) by a period of 12 weeks. It was included person both sex and between 18-60 years old. We applied a survey which include clinical interview, 24 hours follow-up, physical examination [weight, height, Body Mass Index (BMI), blood pressure], and blood tests [cholesterol HDL, LDL, triglycerides, glycated haemoglobin (A1c) and fasting glucose].

Results: The blood glucose diminished significant ($p<0.001$) from 125.9±32.1mg/dL to 114.1±24.4 mg/dL and 146.4 ± 63.6mg/dL to 121.7 ± 30.9 mg/dL in the 2 feedings plan respective; the A1c diminished significant from 8.5 ± 2.2% to 7.0 ± 1.0% ($p<0.05$). Additional there was a diminution in LDL, triglycerides ($p<0.05$) in weight and waist circumference ($p<0.001$) and BMI ($p<0.05$) in the feeding plan modified in proteins.

Discussion/conclusion: In this study was verified in proteins contribute and is an option recommendable a short time to the glycemic control.

Evaluation of knowledge of the diabetics about nutritional label about light and diet references

L.J. Noronha[1], J. Dullius[2], F,D. Moreira[2], I.M.A. Soares[3]

[1] *University of Brasília, Doce Desafio Program Dietitian School, Brasilia, Brazil*

[2] *University of Brasília, Doce Desafio Program, Brasilia, Brazil*

[3] *Catholic University of Brasília, Dietitian School, Brasilia, Brazil*

Introduction: The nutritional label is a means through which consumers get to learn about the products they buy. Most of the target consumers of many companies are the diabetics. Diabetes Mellitus is a disease characterized basically by an absolute or relative deficiency of insulin. In spite of the technological advance of food industry and the popularity of Light and Diet products, there is a certain difficulty for interpreting the nutritional values from the nutritional facts label. As the healthy feeding is a fundamental factor for a good control of DM, the knowledge about the nutritional label is quite necessary.

Objective: Evaluating the knowledge of diabetics about the nutritional label of diet and light products.

Methodology: A transversal study made with people with diabetes from Doce Desafio Program (Program of Health Education and Supervised Physical Activities for Diabetics/ University of Brasília).

Results: The data is composed by information from 40 individuals, from 20 to 78 years of age (Average = 59; DP = 13), with an average period of 9 years of diagnosis (DP = 8); 82,8% have coursed the High School; 57,5% (n=23) knew what a light product is, however 32,45% (n=13) thought that a light product is the one with a low level of fat or any fat if compared to the conventional product. Concerning the dietetic products, 15,3% (n=6) answered it is a product insent of a nutrient on its composition, and 64,4% (n=6) thought it was a special product for diabetics, believing it contains no sugar. 69,9% says the Diet and Light food nutritional label is hard to understand and when asked if there was any reduction of weight caused by the consumption of Diet and Light products, 52,25% (n=21) answered "sometimes"; 25,3% (n=10) answered "no" and 22,45% (n=9) answered "yes". In spite of the high schooling level, the participants of the program did not know the real function of these products.

Conclusion: It is necessary for every health professional to instruct diabetic people about the labels of these types of products, once their consumption is common in modernity and prescribed for this public.

Clinical and preclinical profiles of DSP-7238: a potent enzyme/substrate-selective DPP IV inhibitor

T. Nakagawa[1], M. Horiguchi[1], E. Sugaru[1], Y. Masui[1], M. Sakai[1], T. Kawamura[1], M. Ono[1], Y. Furuta[1], J. Shimakura[1], H. Nakahira[1], C. Brearley[2], M. Taiji[1]

[1] *Dainippon Sumitomo Pharma Co. Ltd., Drug Research Division, Osaka, Japan*

[2] *Dainippon Sumitomo Pharma Europe Ltd., Research and Development, London, United Kingdom*

Aims: The aims of studies were to investigate preclinical profiles such as enzyme / substrate selectivity of DSP-7238. In addition, pharmacokinetics (PK), pharmacodynamics (PD) and tolerability of DSP-7238 after administration of single ascending doses to healthy subjects were assessed.

Methods: The inhibitory property was evaluated using plasma and recombinant enzyme with fluorogenic substrates. Substrate selectivity of each inhibitor was evaluated by mass spectrometer with the changes in molecular weight of peptide substrates by the release of the N-terminal dipeptides. In rats and monkeys, radioactivity was measured in urine and feces after oral dosing of

[^{14}C] DSP-7238 to asses the excretion profile. Phase I studies that characterized the PK, PD profiles and initial safety of DSP-7238 were conducted in healthy subjects.

Results: DSP-7238 competitively inhibited recombinant human DPP IV with Ki of 0.60 nM, but did not inhibit DPP IV-related enzymes including DPP8, DPP9, DPP II and fibroblast activation protein a, whereas vildagliptin (Vilda) and saxagliptin (Saxa) showed inhibitory potential on DPP8 and DPP9. Inhibition of GLP-1 degradation by DSP-7238 was more potent than that of IP-10 or SDF-1a degradation. In contrast, Vilda and Saxa showed comparable inhibition for all substrates tested. In rats and monkeys, following an oral administration of [^{14}C] DSP-7238, the cumulative urinary excretion of unchanged DSP-7238 up to 48 hr postdose was approximately 5%. As a primary elimination pathway is not associated with renal excretion, it is possible that a dose adjustment for the renal insufficiency is not required for DSP-7238, as cautioned for sitagliptin. In the clinical study, DSP-7238 was readily absorbed after a single oral dose. The geometric mean $t_{1/2}$ ranged from 17 to 32 hours. An E_{max} model was fitted to the data of DSP-7238 plasma concentration versus DPP IV inhibitory activity, estimating EC_{50}s for Caucasian and Japanese subjects to be 5.4 and 4.4 ng/mL, respectively. An 80% inhibition of DPP IV at 24 hours post-dose was observed after a single dose of DSP-7238 at 40 mg and above. Single doses of DSP-7238 were well tolerated and no severe or serious adverse events were reported at any dose.

Conclusion: These data suggest that DSP-7238 is a selective DPP IV inhibitor without potential concerns on adverse reactions caused by inhibitions of DPP8/9 or chemokine degradation. A once-daily dosing regimen for DSP-7238 is strongly supported by the PK/PD data with a long half-life and sustained inhibition of DPP IV activity.

P-1152

Patient characteristics are associated with prescription of sitagliptin vs. other oral antihyperglycemic agents based on an electronic medical record database from US

Q. Zhang[1], S. Rajagopalan[2], P. Mavros[1], S. Engel[3], D. Yin[1], L. Radican[1]

[1] *Merck & Co. Inc., Global Outcomes Research and Reimbursement, Whitehouse Station New Jersey, USA*

[2] *MedData Analytics Inc., MedData Analystics, Williamsville New York, USA*

[3] *Merck & Co. Inc, Clinical & Quantitative Science, Whitehouse Station New Jersey, USA*

Aims: This study examined differences in patient characteristics between patients with type 2 diabetes (T2DM) treated with sitagliptin (SITA) vs other oral antihyperglycemic agents (OAHA) in real-world practice in the US.

Methods: The General Electric Centricity electronic medical record database, covering 9 million US patients of all ages from 49 states, was used to select patients with T2DM, aged >=30 years, who received their first SITA, metformin, sulfonylureas, or thiazolidinediones prescriptions (Rx) as index Rx between Oct 2006 and June 2008. Included patients were new to OAHA mono, dual or triple therapy. Patient's demographics, diagnoses, Rxs, and lab results were extracted for the 1 year period (baseline) prior to index Rx. Baseline characteristics were stratified by mono, dual, or triple therapy and were compared between regimens with and without SITA. Adjusted logistic regression analyses were used to estimate odds ratio (OR) associated with SITA use in relation to patient characteristics.

Results: Among 45418 patients new to OAHA monotherapy, 1091 (2.4%) received SITA. Compared to patients initiating other OAHA, patients on SITA were older (64 vs 61 years), had higher HbA_{1c} (7.4% vs 7.1%) with fewer patients at HbA_{1c} <7% (46% vs 58%), had higher serum creatinine (106 vs 88 mmol/L), and had higher prevalence of macro- (18.1% vs 12.7%) and microvascular (15.1% vs 6.8%) conditions (all p<0.0001). Adjusted logistic regression shows that significant predictors of prescribing SITA were older age (OR 1.01, 95% CI 1.00, 1.02), higher HbA_{1c} level (OR 1.13, 95% CI 1.08, 1.18), and presence of retinopathy (OR 2.29, 95% CI 1.38, 3.80) or renal insufficiency (OR 2.65, 95% CI 2.20, 3.19). Of 24806 patients new to dual therapy, 2261 (9.1%) were on SITA regimens. Relative to patients on other dual regimens, patients prescribed SITA dual regimens were older, had higher serum creatinine, had higher prevalence of macro- and micro-vascular conditions, and greater use of lipid lowering and antihypertensive drugs (all p<0.0001). Among 10774 patients new to triple therapy, 3194 (29.6%) were on triple SITA regimens. Relative to patients on other triple regimens, patients on SITA triple regimens were older, had higher serum creatinine and greater use of antihypertensive or lipid-lowering drugs (all p<0.0001). Lipid lowering Rx was associated with higher adjusted likelihood of prescribing SITA dual and triple therapy.

Conclusion: This study found patients with T2DM who were prescribed SITA were older and likely to have more preexisting diabetic complications and comorbidities compared to patients receiving other common OAHA in real-world practice. This has important implications for future observational studies in that estimated outcome measures may be biased.

[7] *Merck & Co. Inc., Diabetes & Obesity Admin., Rahway, USA*

Aims: To assess the efficacy and safety of initial combination therapy with sitagliptin (SITA) + pioglitazone (PIO) compared with PIO monotherapy in drug-naïve patients (A1C 8–12%) with type 2 diabetes treated up to one year.

Methods: Following a 2-week, single-blind, placebo run-in, 520 patients (mean baseline A1C=9.5%) were randomized (1:1) to SITA 100 mg q.d.+ PIO 30 mg q.d. or PIO 30 mg q.d. + placebo for 24 weeks. Patients were eligible to enter a 30-week extension study if they had ≥75% study medication compliance during the base study, completed the base study on or after the initiation of the extension study, and consented to the extension study. The PIO dose in each treatment group was increased to 45 mg q.d. in the extension. Patients not meeting specific glycemic goals in the base study were discontinued. Patients not meeting specific glycemic goals in the extension were rescued with metformin therapy. Efficacy and safety results for the extension excluded data after initiation of rescue therapy.

Results: Of the 520 patients randomized, 446 completed the base study. In the base study, initial treatment with SITA+PIO compared with PIO monotherapy led to a mean reduction from baseline in A1C of -2.4% vs. -1.5%, respectively, at Week 24 (between-group difference = -0.9%, p<0.001). Significantly more patients in the SITA+PIO group vs. the PIO monotherapy group had an A1C <6.5% at Week 24 (38% vs. 14%, respectively; p<0.001). Mean reduction in fasting plasma glucose (FPG) was -63.0 mg/dL vs. -40.2 mg/dL, respectively (between-group difference = -22.8 mg/dL, p<0.001). Of the 446 patients who completed the base study, 317 entered the extension. In this cohort, the mean reductions from baseline in A1C and FPG at the end of the base study (Week 24) were -2.5% and -62.1 mg/dL with SITA+PIO vs. -1.9% and -48.7 mg/dL with PIO monotherapy, respectively. At the end of the extension (Week 54), the mean reduction in A1C was -2.4% with SITA+PIO vs. -1.9% with PIO monotherapy (between-group difference [95% CI] = -0.5% [-0.8, -0.3]) and the mean reduction in FPG was -61.3 mg/dL with SITA+PIO vs. -52.8 mg/dL with PIO monotherapy (between-group difference [95% CI] = -8.5 mg/dL [-16.3, -0.7]). Compared with PIO monotherapy, initial treatment with the combination of SITA+PIO was similarly well tolerated. As expected, mean increases in body weight from baseline were observed in both treatment groups at Week 54: 4.8 kg and 4.1 kg in the SITA+PIO and PIO monotherapy groups, respectively (between-group difference [95% CI] = 0.7 kg [-0.7, 2.1]).

Conclusion: One-year treatment with initial combination therapy with sitagliptin and pioglitazone compared with initial treatment with pioglitazone monotherapy led to a substantial and durable incremental improvement in glycemic control. Compared with pioglitazone monotherapy, initial combination therapy with sitaglipin and pioglitazone was similarly well tolerated.

Assessment of usage of oral antidiabetic drugs in patients with type 2 diabetes mellitus in the Asia Pacific region: results from REASON-AP study

A. Vichayanrat[1], B.J. Matawaran[2], A. Wibudi[3], H.S. Ferdous[4], A.H. Aamir[5], S.K. Aggarwal[6]
[1] *Siriraj Hospital Mahidol University, Endocrinology and Metabolism, Bangkok, Thailand*
[2] *University of Santo Tomas Hospital, Endocrinology and Metabolism, Manila, The Philippines*
[3] *Gatot Subroto Army Hospital, Internal Medicine, Jakarta, Indonesia*
[4] *BIRDEM, Internal Medicine, Dhaka, Bangladesh*
[5] *Hayatabad Medical Centre, Diabetes Endocrinology and Metabolic Diseases, Peshawer, Pakistan*
[6] *Sanofi-Aventis, Medical, Singapore, Singapore*

Background: The prevalence of type 2 diabetes mellitus (T2DM) is increasing across the world with the greatest increase expected in developing countries especially of the Asia-Pacific region. This presents a great health care challenge.
Aim: The REASON-AP study assessed the management of T2DM patients (pts) with widely available oral antidiabetic (OAD) agents.
Methods: This multinational observational study comprised 2 parts: 1) cross-sectional study assessing demographics and baseline characteristics and 2) longitudinal study evaluating 6 months follow-up of sulfonylurea (SU) treated pts. Inclusion criteria: Pts with T2DM newly diagnosed (OAD naive) or currently treated with a single OAD for <6 months but inadequately controlled, age >21yrs.
Results: Pts were enrolled at 76 centres in Bangladesh, Indonesia, Philippines, Pakistan and Thailand. Data for 1487 pts were analyzed for the cross sectional study. Newly diagnosed: 75.9%; Males: 46.7%; Mean age: 52.0±11.6 years (males 50.7, females 53.2); Mean BMI: 25.47±4.03 for males, 26.09±4.59 kg/m^2 for females; Central obesity: 59.1% males, 84.7% females; Mean ABP: 131/81 mmHg; Hypertension: 43.8% (87.6% treated, 57.9% with ACEi/ARB); ABP <130/80: 24.1%; Dyslipidaemia: 60.5%; Mean diabetes duration: 1.1yrs; Previously received OAD: 21.8% (58.3% received SU and 47.2% received biguanide); Mean HbA_{1c}: 9.84±2.40%; Mean FBG: 203.2±76.5mg/dL. 1066 pts entered the longitudinal phase of the study at T_0, and 830 attended the 6 month visit at T_6. At T_0, 99.8%, 42.7%, 2.7% and 0.5% pts received SU, biguanide, TZD and alpha glucosidase inhibitors; at T6, the rates were 97.1%, 56.6%, 5.1% and 1.5%. SUs used at T_0: glimepiride 40.2%, glipizide 24.1%, glibenclamide 21.4%, gliclazide 11.2%, others 3.1%. Treatments were generally altered and doses titrated similarly during the first 3 months of follow up and in the latter 3. Mean SU doses increased between 21% (glimepiride) and 46% (glipizide). Compliance was generally high throughout. Mean HbA_{1c} decreased significantly from 10.24% at baseline to 7.28% at T_6, with a decrease of over 2.5% by T_3 and a further decrease at T_6.

HbA1c (%)				
	N	Mean	Change	p
T_0 to T_3	829	10.18 to 7.65	-2.53	<0.0001
T_3 to T_6	755	7.62 to 7.26	-0.35	<0.0001
T_0 to T_6	742	10.24 to 7.28	-2.96	<0.0001

The percentage of pts with HbA_{1c}<7% increased over time: 4.5%, 32.9% and 46.8% at T_0, T_3 and T_6. A similar pattern of changes was noted with FBG with a decrease from T_0 to T_6 of 76.0 mg/dL (p<0.0001). The major reasons for not achieving target HbA_{1c} were poor diabetes education 51%, non-compliance 21% and fear of hypoglycemia 20% although the incidence of hypoglycemia was very low 1.1%
Conclusion: The REASON-AP study showed that marked reductions in HbA_{1c} and FBG are achievable for T2DM pts using widely available OADs. However, patient education and compliance to anti-diabetic therapy are essential for effective management.

P-1155

Metformin regulates immune activity of natural killer (nk) cells of type 2 diabetic patients by influencing the cellular glucose transport (CGT)

P. Piatkiewicz[1], A. Czech[1], M. Nowaczyk[2]
[1] *Warsaw Medical University, Chair and Department of Internal Medicine and Diabetology, Warsaw, Poland*
[2] *Warsaw Medical University, Department of Clinical Immunology, Warsaw, Poland*

Background and aims: Impairment of CGT is involved in the pathogenesis of diabetic hyperglycaemia and may suppress the function of peripheral blood NK cells. Significant differences in glucose transport and immune activity of NK cells of prediabetic patients in comparison to healthy subjects have been shown. The aim of this study was to evaluate the number and activity of NK cells obtained from type 2 diabetic patients (T2DP) before and after the administration of metformin, and to determine the CGT in these cells.
Materials and methods: The study group included 12 newly-diagnosed T2DP, naive to any hypoglycaemic drugs and 13 matched control subjects; in the diabetic patients, the cytotoxicity tests and glucose uptake experiments were repeated after 6 months of therapy with metformin accordingly to clinical indications. Peripheral blood mononuclear cells (PBMC) were isolated by Ficoll gradient centrifugation. Immunofluorescent phenotyping of NK (CD16+/CD56+) cells in PBMC was performed using specific murine anti-human CD16 PE-conjugated monoclonal antibodies. The K562 human erythroleukemia cell line was used as the standard target for human NK cytotoxicity assay. After 4 hours of incubation, data were collected for analysis on the Becton-Dickinson FACScalibur flow cytometer. The data was analyzed using Cell Quest software. Glucose transport was monitored with deoxy-D-glucose (2-[^{3}H (G)]). At previously assigned time points (15, 30, 60 minutes of incubation) deoxy-D-glucose uptake was stopped and its concentration in the cells was measured by scintillation counting.
Results: The significant differences were revealed between deoxy-D-glucose transport in NK cells obtained from T2DP and the control group (P<0.01). The mean values of 4564 ccpm at 15 min. 9423 ccpm at 30 min. and 12860 ccpm at 60 min. were obtained in NK cells of healthy subjects. The glucose uptake was, respectively, 2063 ccpm, 4328 ccpm and 7790 ccpm in NK cells of T2DP before metformin therapy. The T2DP at baseline in comparison to healthy subjects had an increased number (13,35±6,0% vs 9,63±4,7%) but decreased activity (3,1±2,2% vs 9,2±3,7%) of NK cells (P<0.01). Treatment with metformin resulted in a statistically significant reduction in fasting plasma glucose of 1.65 mmol/L (P<0.001) and in HbA_{1C} of 0.82% (P<0.001). After 6 months of metformin therapy the significant increase in glucose uptake (mean values of 4296 ccpm at 15 min. 8721 ccpm at 30 min. and 11755 ccpm at 60 min.) by NK cells of T2DP was found (p<0.01). The T2DP after metformin administration demonstrated substantially decreased number and increased activity of NK cells when compared to the baseline conditions (10,83±4,6% and 5,7±2,8% respectively vs 13,35±6,0% and 3,1±2,2%).
Conclusion: Diabetic hyperglycaemia may be the cause of increased number and decreased activity of NK cells of T2DP. Metformin therapy improves NK cell cytotoxicity in Type 2 diabetes by regulating the CGT. The CGT seems to be one of the mechanisms influencing the NK cell killing function and therefore may be regarded as a target for the action of antidiabetic therapy.

Metabolic and insulin resistance-related indices during pioglitazone and vildagliptin association versus glimepiride and vildagliptin association in type 2 diabetic patients

G. Derosa[1], A.F.G. Cicero[1], P.D. Ragonesi[1], S.A.T. Salvadeo[1], I. Ferrari[1], F. Querci[1], I.G. Franzetti[1], G. Gadaleta[1], L. Ciccarelli[1], M.N. Piccinni[1], A. D'Angelo[1], R. Fogari[1]
[1] *University of Pavia, Department of Internal Medicine and Therapeutics, Pavia, Italy*

Aims: The aim of our study was to verify the effects of pioglitazone (P) and vildagliptin (S) association vs glimepiride (G) and vildagliptin (V) association on metabolic and insulin resistance related-indices in type 2 diabetic patients.
Methods: Ninety-one type 2 diabetic patients with uncontrolled type 2 diabetes mellitus (HbA1c > 7.5 %) were randomised to P 30 mg o.d. and V 50 mg b.i.d. or to G 2 mg t.i.d. and V 50 mg b.i.d. All type 2 diabetic patients were resulted not well controlled with diet and physical activity and P at dosage of

30 mg/day and G at dosage of 6 mg/day. The treatment period had a 9 months duration. We evaluated BMI, HbA1c, FPG, PPG, FPI, Homa index and collected plasma samples of adiponectin (ADN), resistin (R), tumor necrosis factor-alpha (TNF-a), and high-sensitivity C reactive protein (Hs-CRP) at baseline, and after 9 months. Eighty-four patients completed the study (42 in PV and 42 in GV group).

Results: Eighty-six patients completed the study (44 in PV and 42 in GV group). BMI does not change in both groups. HbA1c was decreased by 1.3±0.08 % (p< 0.01), and by 1.3±0.08 % (p< 0.01); FPG was reduced by 20±4 mg/dl (p< 0.01), and by 23±5 mg/dl (p< 0.01); PPG was decreased by 36±8 mg/dl (p< 0.01), and by 44±9 mg/dl (p< 0.01), in PV and GV group, respectively. FPI was decreased by 2.3±0.1 mU/ml (p< 0.05, p< 0.05 vs GV), and by 0.4±0.03 mU/ml (p< 0.05), and Homa index by 1.7±0.6 (p< 0.01 vs baseline, p< 0.05 vs GV), and by 1.1±0.4 (p< 0.05) in PV and GV group, respectively. ADN was increased by 0.9±0.01 mg/ml (p< 0.05 vs baseline, p< 0.05 vs GV), and by 0.2±0.002 mg/ml (ns vs baseline), in PV and GV group, respectively. Resistin was reduced by 1.1±0.1 ng/ml (p< 0.05 vs baseline, p< 0.05 vs GV), and by 0.1±0.001 ng/ml (ns vs baseline), TNF-a by 0.9±0.2 ng/ml (p< 0.05 vs baseline, p< 0.05 vs GV), and by 0.1±0.001 ng/ml (ns vs baseline), and Hs-CRP by 0.8±0.007 mg/l (p< 0.05), and by 0.7±0.005 mg/l (p< 0.05), in PV and GV group, respectively. There was a significant correlation between Homa index decrease and ADN increase (r= -0.49, p< 0.01), R decrease (r= 0.52, p< 0.01), and TNF-a decrease (r= 0.54, p< 0.01).

Conclusion: Both combinations ameliorated diabetes control, but only PV improved insulin resistance related-parameters. The ADN increase, R and TNF-a decrease seem to be related to Homa index improvement.

Pioglitazone improves 2-hour glucose level after OGTT in patients with type 2 diabetes

J. Liu[1], M. Raanan[2], R. Spanheimer[1], A. Perez[2]

[1] *Takeda Pharmaceuticals North America, Medical and Scientific Affairs, Deerfield, USA*

[2] *Takeda Global Research & Development Center Inc., Clinical Sciences, Lake Forest, USA*

Aims: Increased postprandial glucose (PPG) contributes to hyperglycemia in patients with type 2 diabetes, and may be associated with an increased risk of cardiovascular disease. Effective control of PPG is especially important in early-stage disease when PPG contributes significantly to the elevation of HbA1c (A1C). Pioglitazone is an oral antidiabetic agent that lowers plasma glucose by improving insulin sensitivity. Several studies have shown that pioglitazone reduces the total incremental glucose exposure during the oral glucose tolerance test (OGTT), suggesting it may also improve PPG. We pooled the OGTT data from four studies and examined the effect of pioglitazone on the 2-hour OGTT glucose level, a commonly used indicator for peak PPG.

Methods: Data were pooled from 4 similar studies (Quartet, total n=3713 patients): 2 pioglitazone monotherapy studies comparing with metformin or gliclazide, respectively; 1 study of add-on therapy to metformin comparing pioglitazone with gliclazide, and 1 study of add-on therapy to gliclazide comparing pioglitazone with metformin. The data were deemed poolable due to similarity of the studies in duration (52 weeks), drug dosages, patient population, and endpoints. Only patients who had baseline and 52-week OGTT data were included. Statistical analysis used two-way ANOVA with study, treatment, and study-by-treatment interaction as factors.

Results: Baseline characteristics were similar between the pioglitazone (titrated up to 45 mg/d) treatment group and the comparator group (metformin titrated up to 2550 mg/d or gliclazide titrated up to 320 mg/d), and there was no difference in 2-hour OGTT, A1C, or fasting plasma glucose (FPG) between the two groups at baseline. At 52 weeks, all glucose parameters were significantly reduced from baseline in the pioglitazone and comparator groups (Table). The reduction of 2-hour OGTT with pioglitazone was significantly greater (by 1.6 mmol/L, P<0.0001) than with comparator treatment, and this was consistent with the results of each individual study. The differences in A1C reduction and FPG reduction between pioglitazone and the comparators, however, were not significant (P>0.05).

	Pioglitazone	Metformin or Gliclazide
2h OGTT (mmol/L)	n=694	n=682
Baseline	19.2	19.3
Change at 52 weeks	-4.1* †	-2.5*
A1C (%)	n=652	n=646
Baseline	8.7	8.6
Change at 52 weeks	-1.4*	-1.4*
FPG (mmol/L)	n=652	n=646
Baseline	11.3	11.3
Change at 52 weeks	-2.2*	-2.1*

*Data are LS means. *P<0.05 vs baseline; †P<0.0001 between treatment groups.*

Conclusion: Pioglitazone significantly reduces PPG, as shown by the 2-hour OGTT measurement, in 52 weeks. While achieving similar A1C and FPG reduction, pioglitazone demonstrated greater reductions in PPG than metformin and gliclazide.

Improvement of glycemic control via reducing insulin resistance with pioglitazone and metformin fixed-dose combination therapy

R. Spanheimer[1], Z. Zhao[2], A. Perez[2]

[1] *Takeda Pharmaceuticals North America, Medical and Scientific Affairs, Deerfield, USA*

[2] *Takeda Global Research & Development Center Inc., Clinical Sciences, Lake Forest, USA*

Insulin resistance is a core defect in the development of type 2 diabetes mellitus (T2DM). Pioglitazone, a thiazolidinedione, improves glycemic control primarily by reducing insulin resistance (IR), which can be quantified by homeostatic model assessment (HOMA), whereas metformin, a biguanide, exerts its effect primarily by decreasing hepatic glucose output. A fixed-dose combination (FDC) of pioglitazone and metformin would have complementary mechanisms to improve glycemic control in T2DM. This randomized, double-blind, parallel-group study evaluated the effects of initial therapy with FDC pioglitazone/metformin compared with the effects of each drug alone on efficacy and safety in T2DM patients. These patients were receiving no antidiabetes medications for 12 weeks and had a stable hemoglobin A1c (A1c) >/=7.5% but
A1c showed a significant decrease from Baseline in all 3 study groups at Week 24 (P<0.0001 compared with Baseline of respective group). A1c reduction was –1.83% for FDC from Baseline 8.89% vs –0.96% and –0.99% for pioglitazone monotherapy from Baseline 8.69%, and metformin from Baseline 8.65%, respectively, demonstrating nearly additive reduction effects of the FDC relative to pioglitazone and metformin monotherapies (P<0.0001 compared with FDC). There were no significant differences in hypoglycemic event rate (1.0%, 0.5%, and 1.4% for FDC, pioglitazone, and metformin, respectively).
Mean decreases from baseline in HOMA-IR (Baseline mean = 6.3, 7.0, and 6.4 for FDC, pioglitazone, and metformin, respectively) were observed across all 3 treatment groups. A significant decrease in HOMA-IR was observed Week 16 through 20 for the pioglitazone/metformin FDC, which was comparable to pioglitazone monotherapy, with a smaller decrease observed in the metformin group. At Final Visit (Week 24), the greatest decrease from Baseline in HOMA-IR was observed in pioglitazone/metformin FDC treatment (–2.7) and pioglitazone (–2.1) monotherapy, compared with metformin (–1.1) monotherapy. Treatment-emergent adverse event incidences were similar across all 3 study groups, with 50.7% for pioglitazone/metformin FDC, and 52.1% and 53.1% for pioglitazone and metformin monotherapy, respectively. In summary, the improvements in A1c and HOMA-IR were greatest in pioglitazone/metformin FDC and pioglitazone monotherapy, with the major contributing factor of the FDC effect due to pioglitazone.

P-1159

Vanadium addition into diet of patients with diabetes mellitus

F. Mukhamedova[1], S.I. Ismailov[2], Z. Shamansurova[1], A. Tashmanova[1], A. Alieva[1]
[1] Endocrinology, Diabetology, Tashkent, Uzbekistan
[2] Endocrinology, Endocrinology, Tashkent, Uzbekistan

Aims: Vanadium compounds show an insulin mimetic effect and used in treatment of insulin resistance in patients with type 2 Diabetes Mellitus (2DM). The aim of investigation was study the glycemia and HOMA indexes and biochemical markers after vanadium supplementation in diet of patients with DM2.
Methods: In 12 patients with DM2, blood glucose fasting (FG) and 2 hour after breakfast (2HG), HbA1c, CRP, plasma insulin (PI), erythrocytes sialidase activity (ESA), serum nitrites and nitrates level (NN), blood lipids as total cholesterol (TC), triglycerides (TG), LDLP, HDLP level were measured and insulin resistance index HOMA was calculated as (FG x PI): 22.5 before and after drink mineral water contained 500 mkg vanadium every day during 2 months. Other 8 DM2 patients and 11 healthy subjects (HS) observed in same times and present control groups.
Result: In DM2 patients, blood FG, 2HG, HbA1c level, TC, TG, LDLP, HDLP, CRP, ESA was significantly increased in compare with HS and suggested poor glycemic control and sufficient biochemical abnormalities. After 2 months not any significant differences were detected between DM2 groups with and without vanadium supplementation for FG, 2HG, HbA1c level, but blood CPR, LDLP level, ESA and HOMA index substantially decreased and NN, HDLP level increased in DM2 patients after vanadium supplementation compared with control DM2 group. The data shown that glycemia indexes not differ in this period but biochemical markers which reflected tissue damage and insulin resistance significantly improved in DM2 after vanadium supplementation and may be useful for preventing of complication.
Conclusion: Addition vanadium into diet of patients with type 2 DM during 2 months improved insulin resistance and tissue damage markers.

Metformin inhibits the expression of antioxidant enzymes in non-diabetic male wistar rats

O. Adaramoye[1], M.A. Akinsanya[1]
[1] University of Ibadan, Biochemistry, Ibadan, Nigeria

Metformin (MET) hydrochloride is widely used to lower glucose levels by decreasing hepatic glucose production in type 2 diabetes. The present study was designed to examine the effect of therapeutic dose of MET on the hepatic antioxidant enzymes in normal male Wistar albino rats. Twenty-four non-diabetic rats were divided into 4 groups; group I (control) received distilled water, group II received MET alone, group III received both MET and vitamin C (VC) and group IV received VC alone. MET was given at a therapeutic dose of 21.4 mg/kg body weight (bd wt) and VC at 100 mg/kg bd wt. MET and VC were given for seven consecutive days by oral gavage. Experimentally, therapeutic dose of MET enhanced oxidative stress as evidenced by elevated levels of hepatic malondialdehyde (MDA) in the treated animals. Precisely, MET caused 73% elevation of MDA in test animals when compared to controls. Furthermore, administration of MET caused significant decrease ($p< 0.05$) in hepatic reduced glutathione (GSH), glutathione-s-transferase (GST) and superoxide dismutase (SOD) levels by 48%, 58% and 42%, respectively when compared to controls. However, there were no significant differences ($p> 0.05$) in the levels of serum aminotransferases, alkaline phosphatase and catalase of MET-treated rats when compared to controls. In addition, co-administration of VC during MET therapy significantly ameliorated MDA, GSH and SOD levels in the treated animals. These findings suggest that MET could enhance oxidative stress and may adversely affect the expression of antioxidant enzymes in animals. Antioxidant supplementation may be advisable during MET treatment.

Thiazolidinedione precipitated thyroid associated ophthalmopathy

M. Sehgal[1], R. Menaka[1], M. Lakshmi[1], A. Bhattachharyya[1]
[1] Manipal Hospital, Endocrinology, Bangalore, India

Background: Thyroid associated ophthalmopathy (TAO), a cardinal clinical pointer to diagnose Graves' disease (GD), is seen less frequently in our country than in the West, but can have sight threatening consequences. Smoking, diabetes, male gender, increasing age and radioactive iodine treatment for thyrotoxicosis are known precipitating factors for TAO. A recent addition to the list is thiazolidenediones (TZD). We report four cases of TZD precipitated TAO. Cases:

	Age/ Sex	Duration of T2DM	Thyroid diagnosis	Thyroid status at presentation & current treatment	TMA TGA	Diagnosis of TAO after TZD
Case 1	55/ M	5 years	Graves'	Euthyroid with Antithyroid drugs	+ve/ +ve	6 months
Case 2	46/ M	6 months	Graves' 5yrs back	Euthyroid, no treatment	+ve/ +ve	3 months
Case 3	63/ M	5 years	Graves' 5yrs back	Euthyroid, no treatment	+ve/ +ve	6 months
Case 4	60 /M	8 years	Hashimoto's Thyroiditis	Euthyroid, on Thyroxine	+ve/ +ve	3 months

Discussion: Expression of TSH-receptor and adipogenesis in orbit is well documented in Graves' disease. TZD is known to enhance adipogenesis. PPAR-gamma activation by TZD has been shown to stimulate functional TSH-receptor expression and to induce recruitment and differentiation of orbital fibroblasts into mature lipid-laden adipocytes. Thus, TZD can exacerbate TAO; we clinicians need to keep this in mind in treating patients with T_2DM. Further research is required to establish and prove the role of TZDs in TAO. Meanwhile, we suggest TZDs better be avoided for patients with T_2DM with active Graves' disease and in people with autoimmune thyroid disease.

Effect of sibutramine in combination with L-carnitine in comparison with sibutramine as monotherapy on adiposity and insulin sensitivity in obese women

S. Hernandez-Gonzalez[1], M. Gonzalez-Ortiz[1], E. Martinez-Abundis[1], V. Ramirez-Ramirez[1], X. Dominguez-Vazquez[1], O. Jacques-Camarena[1]
[1] Mexican Institute of Social Security and University of Guadalajara, Medical Research Unit in Clinical Epidemiology and Cardiovascular Research Unit, Guadalajara, Mexico

Aim: To evaluate the effect of sibutramine in combination with L-carnitine in comparison with sibutramine as monotherapy, on adiposity and insulin sensitivity in obese women.
Methods: A randomized, double-blind, clinical trial was carried out in 13 adult (20-50 years old), obese [body mass index (BMI) 30-40 kg/m^2] women. Volunteers received sibutramine (15 mg) with L-carnitine (600 mg) in a single pharmacological presentation or sibutramine 15 mg once a day during 3 months. Before and after the pharmacological intervention, weight, BMI, waist circumference (WC), % adiposity, blood pressure, uric acid, lipid profile and insulin sensitivity (IS) were measured. % adiposity was evaluated with bioimpedance analysis and IS was assessed by the insulin tolerance test (ITT). Statistical analyses were performed with Mann-Whitney U and Wilcoxon tests.
Results: Both, sibutramine and sibutramine with L-carnitine decreased weight [85.9 (64.3-111.6) vs. 78.9 (61.8-99.2) kg, $p = 0.02$ and 94.0 (79.4-98.2) vs. 86.2 (71.5-91.4) kg, $p = 0.01$; respectively], BMI [33.3 (31.0-38.6) vs. 31.7 (26.1-35.9) kg/m^2, $p = 0.02$ and 34.7 (31.7-36.1) vs. 31.7 (29.5-34.0) kg/m^2, $p = 0.01$; respectively] and WC [98 (91-115) vs. 92 (87-102) cm, $p = 0.02$ and 105 (91-110) vs. 93 (84-100) cm, $p = 0.01$; respectively]. Furthermore, sibutramine reduced adiposity [43.0 (34.5-51.9) vs. 39.4 (32.7-45.8)%, $p = 0.02$] diastolic blood pressure and uric acid concentration. Pharmacological interventions did not modify the lipid profile and IS.
Conclusions: Sibutramine and sibutramine with L-carnitine reduced weight, BMI and WC. Sibutramine as monotherapy reduced adiposity, diastolic blood pressure and uric acid concentration. There was no modification in IS with the interventions.

Sustained release metformin improves glycemic control in type 2 diabetes mellitus patients with poor adherence to immediate release metformin

S.H. Hsiao[1], H.Y. Ou[2], C.H. Chou[1], Y.L. Liang[2], W.L. Lin[1], H.C. Hung[2], P.Y. Chen[2], T.J. Wu[2]

[1] *National Cheng Kung University Hospital, Department of Pharmacy, Tainan, Taiwan*

[2] *National Cheng Kung University Hospital, Department of Internal Medicine, Tainan, Taiwan*

Background: To evaluate the difference in adherence to immediate release metformin (metformin IR) and sustained release formulation (metformin SR) and the role of metformin SR in metformin therapy in general practice.
Study design: Retrospective observational cohort study from a prospectively structured diabetes mellitus care recorded database.
Methods: General surveys before and after changing metformin formulation from the IR form to metformin SR were performed. The glycemic control at 2 and 4 months after changing to metformin SR were compared with the baseline data when metformin IR was used. The relationship between metabolic changes and adherence to metformin was analyzed.
Results: Thirty-seven (13.3%) patients had poor adherence to metformin IR therapy. Patients with poor adherence to metformin IR had higher HbA1c (8.65 ± 1.43 vs. 8.08 ± 1.20, p<0.01). After replacing metformin IR with SR, the difference of the changes in HbA1c between the groups (+0.18% ± 0.64% for the good adherence group vs. -0.15% ± 0.61% for the poor adherence group, p<0.01) is statistically significant.
Conclusion: The percentage of poor adherence to metformin therapy is high in general practice. Improving adherence to metformin therapy may associate with better HbA1c. By improving adherence, metformin SR can improve glycemic control in those patients with poor adherence to metformin IR therapy.

Pioglitazone, but not ramipril reduces cardiovascular risk in non-diabetic patients with hypertension

A. Pfützner[1], M. Hanefeld[2], L. Afzal-Dekordi[1], J. Müller[3], I. Kleine[4], W. Fuchs[4], T. Forst[1]

[1] *IKFE GmbH, Medical, Mainz, Germany*

[3] *Acromion GmbH, Biometrics, Frechen, Germany*

[4] *Takeda Pharma, Medical, Aachen, Germany*

Background: The acute-phase protein CRP, when measured with a highly sensitive assay (hsCRP), has been identified as a predictive marker for cardiovascular (CV) risk. The generally accepted stratification identifies patients with values from 0-1 mg/L to have a low risk, from 1-3 mg/L to have a moderate risk, and from 3-10 mg/L to have a high risk. Values > 10 mg/L may indicate unspecific inflammatory conditions and should not be used for cardiovascular risk assessment. It has been shown that non-diabetic patients with hypertension or dyslipidemia may suffer from vascular insulin resistance contributing strongly to their CV risk. The aim of this analysis was to investigate the effects of pioglitazone (PIO), ramipril (RAM) or their combination (PIRA) on the CV risk stratification in hypertensive non-diabetic patients.
Methods: This placebo-controlled, double-blind, multicentre, randomized, parallel study was performed with 149 non-diabetic patients (72 male, 77 female, age: 60±9 yrs., BMI: 30.4±4.7 kg/m^2, duration of hypertension: 9±8 yrs.). Patients were treated with 15/30 mg PIO (dose titration), 2.5/5 mg RAM or a combination thereof for 12 weeks. A CV risk stratification using the hsCRP concentration was performed at baseline and after 3 months.
Results: A pronounced and general improvement of the mean (±SD) hsCRP-value was seen with PIO (baseline: 3.54±2.54 mg/L vs. endpoint: 2.65±2.02 mg/L, p<0.01) and PIRA (2.98±2.15 mg/L vs. 2.50±1.98 mg/L, p<0.05), but not with RAM (2.90±2.26 mg/L vs. 3.47±2.62 mg/L, n.s.). This resulted from 69 % (PIO) and 66 % (PIRA) patients with lower hsCRP values at endpoint (RAM: 46 %). Consequently, 29 % (PIO) and 45 % (PIRA) shifted to a better risk group (worsening in 6 % and 13 %, respectively). While 11 % showed an improved risk profile with RAM, 23 % shifted to a higher risk group.
Discussion and conclusion: Activation of PPARg by pioglitazone but not ACE-inhibition by ramipril leads to an improved cardiovascular risk profile in non-diabetic hypertensive patients. These results point to an important role of insulin resistance in cardiovascular risk development in non-diabetic patients with hypertension. Further research efforts are encouraged by our findings to confirm a positive effect of pioglitazone on cardiovascular outcome in non-diabetic patients with vascular insulin resistance.

P-1165

Pharmacological remission in newly-diagnosed type 2 diabetes patients using metformin and pioglitazone

V. Panikar[1], P. Mahale[1], S.S. Hoskote[2], N. Gill[1], S.R. Joshi[2]

[1] *KJ Somaiya Medical College, Medicine, Mumbai, India*

[2] *Joshi Clinic, Endocrinology, Mumbai, India*

Aim: When a combination of pioglitazone (PG) and metformin are used in newly-diagnosed type 2 diabetes mellitus (DM) patients, they could help preserve beta-cell function and also simultaneously reduce insulin resistance. Theoretically, this combination could possibly reverse the diabetic state to a normoglycemic state and help to maintain long term pharmacological remission. Our study aimed to validate this hypothesis.
Methods: We prospectively studied 50 newly-diagnosed (<2 years) type 2 DM patients (33 males, 17 females) from our clinics over 1 year. Patients were not selected if they had any cardiac, renal or liver dysfunction; or if they consumed >60 ml/day of alcohol or had any allergy to the drugs used. The patients received a combination of MF (500mg, td) and PG (15mg, od) and gliclazide (GC) (80mg, titrated individually). All were also advised by a dietitian and regular exercise of brisk walking (40 minutes/day or 200 minutes/week) was prescribed. Patients were followed-up at monthly intervals with fasting blood sugar (FBS) and post-prandial blood sugar (PPBS). Patients were asked to report hypoglycemia on telephone, and GC dose was reduced accordingly. The dose of gliclazide was titrated based on the glycemic values every month. MF was continued at the full dose except in those who could not tolerate the full dose, in whom dose was reduced. Values are presented as mean±SD where applicable. Before-after comparisons were made using the paired t-test.
Results: (Table 1) There were no serious adverse events reported and no dropouts during the course of the study. At enrollment, the mean age was 48.07±10.6 years. In 43 patients (86%), glycemic control was maintained >2 months after stoppage of gliclazide (remission group); and gliclazide could not be stopped in the remaining 7 patients (non-remission group; 6 males, 1 female). The mean time required to achieve this remission was 3.0±1.81 months.

Table: Parameters under study

	Baseline	At 1 year	P value
FBG*	196.6± 70.7	105.9±22.7	<0.01
PPBG*	295.44± 103.4	139±39.0	<0.01
HbA1c (%)	9.41± 2.9	5.66±0.7	<0.01
Weight (kg)	72.7± 15.0	74.4± 15.9	>0.05
BMI (kg/m^2)	27.91± 5.7	28.76± 7.0	>0.05

FBG, fasting blood glucose; PPBG, post-prandial blood glucose; HbA1c, glycated hemoglobin; BMI, body-mass index
** Units: mg/dl*

Discussion: The study validates the concept that, once glutotoxicity abates, a combination of insulin sensitizers can sustain and maintain euglycemia in type 2 DM. We have termed this as "pharmacological remission" based on the lack of need to augment insulin production or supplement exogenous insulin. Our study provides evidence to support use of combination of MF, PG and GC in newly-diagnosed type 2 DM patients for improving glycemic control.

P-1166

Relationship between pioglitazone dose, weight gain and glycemic control in recently-diagnosed type 2 diabetes patients

V. Panikar[1], N. Kale[2], S.S. Hoskote[3], S.R. Joshi[3]
[1] KJ Somaiya Medical College, Medicine, Mumbai, India
[2] NMIMS University, Pharmacy, Mumbai, India
[3] Joshi Clinic, Endocrinology, Mumbai, India

Aim: Pioglitazone (PG) is an extremely useful agent in the treatment of type 2 diabetes mellitus (DM) through its actions on insulin resistance. However, fluid retention and its association with heart failure remain important adverse effects of this drug. We studied the relationship between PG dose, the resulting weight gain and glycemic control in recently-diagnosed type 2 DM patients.
Methods: A total of 300 patients were prospectively selected over 6 months from our clinics. According to the selection criteria, the patients had recent-onset type 2 DM (<2 years), were 30-80 years old, of either sex, were not receiving insulin therapy and had no concurrent hepatic, cardiac or renal dysfunction. Patients were randomly assigned to 3 groups of 100 patients each:
Group 1: Low-dose PG (7.5 mg/day)
Group 2: Standard-dose PG (15 mg/day)
Group 3: High-dose PG (30 mg/day)
Fasting blood sugar (FBS), post-prandial blood sugar (PPBS) and glycated hemoglobin (HbA1c) were measured at baseline and were followed-up every 2 months for 6 months. The paired t-test was used to compare results before and after the study and Student's t-test was used for inter-group comparisons.
Results: From the 3 groups, 78, 71 and 89 patients completed the study from the low, standard and high dose groups, respectively. The remaining patients were lost to follow-up. In all three groups, glycemic parameters (FBS, PPBS and HbA1c) showed significant reductions at 6 months ($P<0.05$ for each) (Table 1). A significant weight gain was observed in all groups at the end of 6 months. However, the magnitude of weight gain was maximum in group 3, intermediate in group 2 and least in group 1. Group 3 had a higher HbA1c at 6 months ($p<0.05$). Baseline HbA1c in group 3 was higher than groups 1 ($P<0.05$) and 2 ($P=0.2$).

Table: Findings from the study

		Group 1	Group 2	Group 3
Number		78	71	89
Age		57.65±11.72	55.93±10.72	54.12±8.14
Male/female		40/38	37/34	50/39
FBS (mg/dl)	Baseline	139.84±47.43	132.84±32.09	143.98±40.87
	At 6 months	120.08±31.83	113±21.62	122.73±29.99
PPBS (mg/dl)	Baseline	198.19±50	213.14±43.74	198.3±43.58
	At 6 months	164±51.85	171.47±48.31	163.13±36.82
HbA1c (%)	Baseline	7.4±0.56	7.6±0.46	7.7±0.66
	At 6 months	6.2±0.39	6.3±0.46	6.5±0.38
Weight (kg)	Baseline	73.72±15.13	69.65±12.38	68.9±13.37
	At 6 months	74.98±15.94	71.47±12.55	71.56±13.53

Figures written as mean ± SD
Discussion: Higher doses of PG caused a greater weight gain compared to lower doses. Group 3 had greater HbA1c at 6 months despite a higher PG dose. However, the baseline HbA1c in this group was also higher than the other two groups. Also, all groups satisfactorily reached the glycemic goal of HbA1c<7%. The fluid retention associated with PG may be dose-dependent, while the glycemic target is reached at all doses. In recently-diagnosed patients, it may be more prudent to start with a lower dose of PG to avoid adverse effects such as fluid retention and weight gain.

The impact of thiazolidinedione controversy on the prescription patterns in India

P.G. Talwalkar[1], P. Talwalkar[1]
[1] Talwalkar Diabetes Clinic, Diabetes, Mumbai, India

Aim: The publication of meta-analysis in New England Journal of Medicine in June 2007 implicating association of rosiglitazone with 43% increase in the risk of acute myocardial infarction and 64% increase in the risk of cardiac death in type 2 diabetic patients led to a major controversy regarding rosiglitazone in particular and thiazolidinediones in general, resulting in reduced use globally. In India more than 90% of diabetic patients are treated by the general practitioners whose exposure to the latest medical literature and conferences and seminars in the field of diabetology is limited. Thus we decided to study the impact of the controversy on the prescription trends.
Methods: We studied the Rupee value sales of rosiglitazone, pioglitazone and their combinations in the data generated by ORG for the period from June 2006 to May 2007 and compared with those in next twelve month period from June 2007 to May 2008. We interviewed 42 doctors.
Results: Sales of pioglitazone grew by 11%, those of rosiglitazone declined by 9%. As regards thiazolidinedione combinations with metformin, the sales of pioglitazone - metformin combination grew by 12% while sales of rosiglitazone - metformin combination declined by 3%. The pharmaceutical industry grew by 13% while anti diabetics grew by 25%. The growth rate of pioglitazone and its combination with metformin was significantly lower than that of total anti diabetics while rosiglitazone and its combination with metformin had negative growth. 11% doctors were unaware of the safety concerns on rosiglitazone while 30% were under the impression that thiazolidinediones were banned in western countries following the safety concerns. 40% doctors stated that they still use these medications but after carrying out thorough scrutiny.
Discussion: Even though an average Indian practitioner has far less exposure to the latest trends in medical literature, the concerns regarding safety of thiazolidinediones in general and rosiglitazone in particular were picked up quickly by them resulting in decline in their prescriptions. The relatively lesser decline of thiazolidinedione-metformin combinations as compared to the individual agents was intriguing. Multiplicity of branded anti diabetic combinations [205 brands were listed in Advanced Drug review December 2006- March 2007 issue] leading to confusion in prescriber's mind regarding the exact formula of the prescribed brand could be one of the reasons.

P-1168

Clinical effects of additional use of pioglitazone in diabetic patients receiving treatment at our outpatient clinic

T. Seguchi[1], K. Nakamaru[1], M. Koutoku[1], M. Oribe[1]
[1] Oita Prefectural Hospital, Department of Internal Medicine, Oita, Japan

Objective: To investigate the effects of combined therapy with pioglitazone on the basis of prescription records of patients receiving treatment at our outpatient clinic.
Methods: In order to examine the changes in the levels of HbA1c, LDL, HDL, and TG and in body weight at 0, 12, and 24 weeks, pioglitazone (7.5-30mg) was given additionally to 256 diabetic outpatients (the diet therapy group [D group: n=41], the insulin therapy group [I group: n=41] and the oral administration group [O group: n=174]) who did not respond to drug therapy using antidiabetics and lipid metabolism-improving agents.
Results: The levels of HbA1c, HDL, and TG improved significantly ($p<0.001$), although there was an increase in weight. No improvement was observed in the level of LDL. According to the type of the treatment for diabetes, an improvement was achieved at 12 weeks in the I group and the O group, while it was observed at 24 weeks in the D group. According to the degree of obesity, a decrease was observed in TG in the obese group. For the type of lipid metabolism-improving agents (the group without treatment [N group, n=155], the statin group [S group, N=74], and the fibrate group [F group, n=27]), an increase in weight and an improvement in A1c were observed in all the groups. With respect to the difference between sex, the level of A1c decreased by 0~12 weeks in females (n=135) and by 0~12~24 weeks in males (n=121).
Conclusions: The additional administration of pioglitazone contributed to a significant decrease of HbA1c, an increase in HDL and a decrease in TG at 0~24 weeks, respectively, although it was accompanied by an increase in weight. It was shown to be effective both in improving blood sugar control and in inhibiting the progress of arteriosclerosis.

Monosubstituted vanadium compounds: new molecules for improve GLUT4 mRNA expression?

P.M. Seraphim[1], G.L.V. Araujo[1], M.A.N. Oliveira[2], U.F. Machado[2], M.F.S. Teixeira[3]
[1] UNESP - Presidente Prudente, Physioterapy, Presidente Prudente, Brazil
[2] USP - Sao Paulo, Physiology and Biophysics, Sao Paulo, Brazil
[3] UNESP - Presidente Prudente, Physics Chemistry and Biology, Presidente Prudente, Brazil

Vanadium compounds have been believed to be ideal drugs for diabetes biological therapy. The aim of this study was to verify the effect of substituted group in the ligand on vanadyl (IV) compounds on the mRNA expression of glucose transporter insulin-sensitive isoform (GLUT4) in cardiac and skeletal muscles, relating the redox properties of the complexes and biological effects. Diabetic animals by alloxan injection (37.5 mg/Kg BW) were divided in 5 groups: Vehicle (CX – diabetic control group), [VO (salen)] (NS – non substituted), [VO (5NO2-salen)] (NO2), [VO (5OH-salen)] (OH) and [VO (5OCH3-salen) (OCH3) compounds using ip injections (12.5 nmol / kg BW) for 21 days. Skeletal muscle Gastrocnemius (GAST) and Heart were removed and total RNA was extracted using Trizol reagent. GLUT4 mRNA was quantified by RT-PCR. A group of non-diabetic animals was used as reference group (R). There was no alteration in body weight among all groups. All alloxan-injected rats with glycemia above 300 mg/dL were considered diabetic animals. After treatment, only NS group presented a 50%-reduction in glycemia (before:454.0±18.3; after 230.0±42.0*, *P<0.05 vs before). In GAST, there was an increase in GLUT4 mRNA content in NS, OH and OCH3 compared to R and CX (R=100.2±8.5 n=6, NS=152.5±19.2* n=6, NO2=112.5±8.2 n=7; OH=188.5±55.2* n=4; OCH3=252.4±19.0* n=3, CX=69.5±13.1 n=5 / *P<0.05 vs. R and CX, results expressed as Arbitrary Units, AU). On the other hand, in Heart, there were a reduction in GLUT4 mRNA expression in NS compared to R, an increase in OH and OCH3 compared to R, NS and CX, and an increase in NO2 compared to CX (R=99.9±5.0 n=5, NS=47.5±17.9* n=5, NO2=119.9±17.1# n=8, OH=158.3±17.3** n=4, OCH3=169.9±20.7** n=4, CX=56.4±10.8 n=4 / *P<0.05 vs. R, ** P<0.05 vs. R, NS and CX, # P<0.05 vs. CX, results expressed as AU). These results showed that: a) the non substituted compound [VO (salen)] has a muscle-specific action; b) the more efficient compounds are [VO (OH-salen)] and [VO (OCH3-salen)] having positive effect on GLUT4 transcription in both muscles; c) the [VO (5NO2-salen)] has a more discrete effect in GLUT4 mRNA expression in both muscles. It is important remind that the more efficient compounds are intermediary in terms of chemical behavior among further used molecules, presenting higher level of hydrophilicity, which can be responsible for positive effect on GLUT4 expression in both muscles. Financial Support: FAPESP 2004/10130-0.

A study of serum vitamin B12 levels in type 2 diabetic patients on long term metformin monotherapy

H. Kashetty[1], S. Reddy[2], G. Niveditha[1], M.C. Shivamurthy[1], K.M. Prasanna Kumar[2]
[1] M S Ramaiah Medical college, Pharmacology, Bangalore, India
[2] M S Ramaiah Medical college, Endocrinology, Bangalore, India

Introduction: Metformin induced impaired vitamin B12 absorption leading to fall in serum cobalamin levels has been described in literature as early as 1971. Approximately 10 % of patients and in some studies 30% of patients on metformin therapy developed metformin related cobalamin deficiency. The risk of cobalamin deficiency is comparatively more among patients with vegetarian diet than in non-vegetarians

Objectives:

Primary: To study the serum vitamin B12 levels in type 2 diabetic patients on long term metformin monotherapy

Secondary: To study the relationship of serum B12 levels to dietary habits.

Materials and methods: By using available database of patients with type 2 diabetes mellitus, lists of all patients with type 2 diabetes mellitus on metformin monotherapy or insulin and metformin were made. These patients will be asked to visit the hospital by contacting them through telephone. A total of 45 patients were chosen. By using a pilot-tested proforma, details were collected on demographic data, dietary habits. Duration of treatment with metformin and dose of metformin was also noted. All patients will undergo routine investigations which include RBS, PPBS, and HbA1C. After taking their informed consent, 5 ml of blood will be collected and sent to the central laboratory for serum vitamin B12 estimation. Vitamin B12 estimation was done using a recently developed method called active vitamin B12 assay. 35 age sex matched non-diabetic controls were also chosen, who also underwent serum B12 estimation.

Results: Our results showed that mean B12 of patients in study group and control group was 50.62 pml (picomoles)/dl and 40.66pml/dl respectively (p value 0.301). The sub group analysis showed that mean B12 levels was significantly lower among vegetarian cases (37.25 pml/dl) and controls (18.08 pml/dl) compared to non vegetarians.

Conclusion: Our study shows that patient's serum B12 deficiency is significantly higher in patients on vegetarian diet and is not related to long term metformin therapy.

P-1171

Drug usage by diabetics attending an outpatient clinic

S. N Kumar[1]
[1] Diabetes Care Centre, Diabetology, Trivandrum, India

Aim: To analyse the monthly usage of various drugs by Diabetic patients attending a Diabetes treatment facility in South India.

Methods: The drugs dispensed from our Diabetes centre, situated in a city in South India, was analysed to see the usage of drugs in various categories and to understand the prescription pattern. The drugs dispensed every month was categorized and tabulated for three consecutive months. Number of patients who used the facility was determined. The average monthly usage of each category of drug was noted.

Results: The following were the results obtained. Monthly average number of patients: 600. Monthly usage of various drugs are given below as number of strips (10 tablets).Oral hypoglycemic agents: Sulfonylurea: 85.3 (alone),1365 (combination), 1450.3 (total) Glibenclamide 27.3 (alone), 855 (combination), 882.3 (total),Glipizide200, Gliclazide 32,Glimepiride 58 (alone), 278 (combination), 336 (total). Thiazolidinediones (tzd) 197 (alone), 7.3 (combination), 204.3 (total), Sitagliptin 10.6 (alone), 32 (combination), 42.6 (total), Metformin161.7 (alone),+ sulfonylurea 1365, + sitagliptin 32, + tzd 7.3, 1566 (total), Voglibose 11.3, Antihypertensives: Calcium channel blockers 63 (amlodipine 52, nifedipine 11), Beta blockers 47, Angiotensin receptor blockers (ARB) 275, Aspirin 53, Atorvastatin 98, Insulin:number of vials: human 7, analogue 0, pen refills: human 87, analogue 36, total: Human 94, Analogues 36, Total Insulin (vials+penfills) 130

Discussion: The important groups of drugs used in Diabetic patients include hypoglycemic agents, antihypertensives, statins and aspirin. Amongst the hypoglycemic agents used metformin and sulfonylureas still continue to be the most widely used drugs because of lower cost, greater efficacy and availability. Our observation shows that metformin is the most widely prescribed drug followed by sulfonylureas. Glibenclamide was most widely used sulfonylurea in our practice while as a single agent it was glimepiride which had the highest usage. Use of conventional human insulin (94 vials) is more than analogues (36 vials). Insulin pen refills are more widely used (123 refills) than vials (7). ARBs are the most widely recommended group of antihypertensives in Diabetics. Our practice also shows ARB as the most preferred antihypertensive.

Conclusion: Analysis of monthly drug dispensing from our Diabetes centre in South India shows that the most widely prescribed OHAs were metformin and sulfonylurea and antihypertensive was ARB. Insulin pen refill usage was seen to be more than that of insulin vials. This shows that conventional drugs are more widely used than the newer ones. However insulin pen usage is more in our practice than vials and syringes.

Markers of endothelial dysfunction in type 2 diabetes mellitus: clinical prospective

K. Tripathi[1]
[1] Institute Of Medical Sciences, Medicine, Varanasi, India

Background: Cardiovascular complications due to diabetes mellitus are most common cause of mortality and tight glycemic control can reduce these complications.

Methods: Ninety poorly glycemic controlled type 2 diabetes mellitus patients with cardiovascular complications were included in this study. Based on antidiabetic drug received patients were divided in three groups and evaluated with respect to glycemic control, lipid profile, serum insulin level, CRP, TNF-α, NOx, VEGF and angiogenin after 16 weeks of antidiabetic drug treatment.
Results: Reduction in serum fasting glucose, post prandial glucose and glycosylated hemoglobin were significant in all groups. PPAR-γ agonists (pioglitazone, rosiglitazone) reduced FBS, PPBS and HbA1C% more than glipizide. HDL cholesterol was increased by PPAR-γ agonist while decreased by glipizide. Increase in serum insulin level and decrease in CRP were significant in all groups. Reduction in TNF-α, NOx and augmentation in VEGF angiogenin levels were significant in all three groups. Decrease in NOx, TNF-α and increase in VEGF were highest in pioglitazone group while angiogenin level was highest in rosiglitazone group.
Conclusion: This study demonstrate that the pioglitazone is more beneficial on the above parameters as it reduces endothelial dysfunction markers while maintaining the glycemic control almost equivalent to rosiglitazone.

Cerebral perfusion is affected during incremental aerobic exercise in patients with type 2 diabetes: is it a matter of cardiac output ?

P. Brassard[1], Y.S. Kim[2], T. Seifert[1], H.B. Nielsen[1], N.H. Secher[1], J.J. Van Lieshout[2]
[1] *Departement of Anaesthesia, The Copenhagen Muscle Research Center Rigshospitalet University of Copenhagen, Copenhagen, Denmark*
[2] *Department of Internal Medicine and Laboratory for Clinical Cardiovascular Physiology, AMC Center for Heart Failure Research Academic Medical Center University of Amsterdam, Amsterdam, The Netherlands*

In healthy subjects, cerebral blood flow increases in response to brain activation associated with dynamic exercise. Cardiac output is an important determinant of cerebral blood flow regulation during exercise. Type 2 diabetes is associated with systemic and hemodynamic abnormalities but it is unknown whether the cerebral blood flow response to dynamic exercise is affected.
Aims: We questioned whether the brain perfusion to aerobic exercise is affected in patients with type 2 diabetes in relation to systemic hemodynamics.
Methods: Eight patients with type 2 diabetes and 7 age-matched male control subjects performed incremental cycling exercise of 30 watts (W) stage^{-1}, and beginning at 60 W, until exhaustion. We measured systemic hemodynamics (arterial pressure, cardiac output), transcranial Doppler-determined mean middle cerebral artery flow velocity (MCA V_{mean}) and arterial pressure for carbon dioxide (P_aCO_2).
Results: With incremental cycling exercise, the arterial pressure response was comparable for both groups (Type 2 diabetes group: from 103±12 to 118±18 vs. Control group: from 104±10 to 112±12 mmHg, from rest to 150 W) but the increase in cardiac output was lower in patients with type 2 diabetes (Type 2 diabetes group: from 6.1±2.3 to 12.9±4.5 vs. Control group: from 5.7±0.9 to 15.3±1.9 L min^{-1}; p<0.05). MCA V_{mean} increased in the control group (Rest: 41±7; 60 W: 45±6; 90 W: 44±6; 120 W: 44±6; 150 W: 43±6 cm sec^{-1}; p<0.01 for 60 W and 90 W vs. rest and p<0.05 for 120 W vs. rest) but decreased in patients with type 2 diabetes (Rest: 41±7; 60 W: 41±8; 90 W: 39±8; 120 W: 38±8; 150 W: 36±8 cm sec^{-1}; p<0.01 for 150 W vs. rest). P_aCO_2 decreased from 90 W to exhaustion in patients with type 2 diabetes (from 5.1±0.4 to 4.2±0.7 kPa; p<0.01) but remained constant in the control group (from 5.1±0.4 to 4.7±0.4 kPa; p=ns).
Discussion/conclusion: As compared to control subjects, patients with type 2 diabetes lack the ability to elevate MCA V_{mean} during dynamic exercise with an attenuated increase in cardiac output. These findings identify a previously unrecognized impaired cerebral hemodynamic response to cycling exercise in patients with type 2 diabetes. We suggest that the attenuated increase in cardiac output in these patients limits the elevation in cerebral perfusion in response to incremental dynamic exercise.

Change of high molecular weight adiponectin and insulin resistance

S. Matono[1], E. Yoshimura[2], H. Kumahara[3], T. Tobina[1], T. Koshimizu[3], A. Kiyonaga[3], K. Anzai[4], H. Tanaka[5]
[1] *Fukuoka University, Graduate School of Sports and Health Science, Fukuoka, Japan*
[2] *Fukuoka University, Graduate School of Sports and Health Science, Fukuoka, Japan*
[3] *Fukuoka University, Faculty of Sports and Health Science, Fukuoka, Japan*
[4] *Fukuoka University Hospital, Department of Internal Medicine (Diabetes Unit), Fukuoka, Japan*
[5] *Fukuoka Univeristy, Faculty of Sports and Health Science, Fukuoka, Japan*

Aims: The reduction of visceral fat (VF) by exercise and diet is an important factor for improving insulin sensitivity, and it can also affect adiponectin secretion. Adiponectin is categorized into 3 types. Recent studies have demonstrated high molecular weight (HMW) adiponectin to more strongly influence insulin resistance (IR) than other types of adiponectin. Although, the HMW adiponectin level could decrease depending on the VF, the magnitude of the changes obtained by exercise intervention or calorie restriction remain unclear. Therefore, the aim of this study is to compare the changes in the HMW adiponectin levels and IR on exercise intervention and calorie restriction.
Methods: Thirty five subjects (men: 17 and women: 18, age: 57±9 years, weight: 76.15±13.36 kg) who all had at least one of the metabolic syndrome risk factors were recruited for this study. The subjects were randomly assigned to the exercise (Ex; n=11), diet (D; n=11), and the Combination of exercise and diet (C; n=13) groups. They participated in each program for 12 weeks. The exercise group participated in aerobic exercise training at the lactate threshold intensity (LT). The exercise volume was assigned to be 300 min/week. The subjects in the exercise group were ordered to not to change their normal life style except for exercise. The diet group controlled their food intake according to the advice of a dietician every week. The target calorie was 25 kcal/kg of ideal body weight (BMI=22). The subjects were ordered not to change their normal amount of physical activity. Blood samples were collected after 12 hours of fasting. The HMW adiponectin, glucose, and insulin levels were all determined by blood samples. IR was evaluated by HOMA-IR. The VF was measured by computed tomography.
Result: VF (Ex: -27.58±22.53 cm^2, p<0.01; D: -55.81±25.29 cm^2, p<0.01; C: -47.71±47.34 cm^2, p<0.01) and body weight (Ex: -3.43±2.09 kg, p<0.01; D: -7.85±4.26 kg, p<0.01; C: -6.50±3.50 kg, p<0.01)significantly decreased in all groups. The HMW adiponectin level increased in the D group (0.56±0.69 μg/ml, p<0.05), while in the Ex group it significantly decreased (-0.09±0.94 μg/ml, p<0.05). On the other hand, the C group showed no significant difference with baseline. HOMA-IR significantly decreased in D (-1.01±1.62, p<0.05) and C (-1.09±1.58, p<0.05) groups, but not in Ex.
Discussion and conclusion: Calorie restriction was observed to decrease IR, which may be induced by an increase in the HMW adiponectin levels. Although LT exercise training was seen to decrease the HMW adiponectin levels, IR was not affected. This study demonstrated that the exercise and diet may each induce different factors which can improve IR.

Changes in clinical and metabolic parameters in patients with Type 2 diabetes mellitus after exercise therapy

Y. Terry Pena[1], L. Gordon[2], E. Morrison[2], D. McGrowder[3], D. Garwood[4]
[1] *University of the West Indies, Medicine, Kingston 7, Jamaica*
[2] *Diabetes Association of Jamaica, Biochemistry, Kingston 5, Jamaica*
[3] *University of the West Indies, Pathology, Kingston 7, Jamaica*
[4] *University of the West Indies, Basic Sciences, Kingston 7, Jamaica*

Objective: The study investigate the effect of Hatha yoga and conventional physical training (PT) exercise intervention on clinical and biochemical parameters in patients with Type 2 diabetes mellitus.
Method: The patient population consisted of 77 Type 2 diabetic patients in the Hatha yoga group that was matched with the same number of patients in the conventional PT and control groups. The clinical parameters were weekly diastolic and systolic blood pressure, along with body mass index (BMI). Biochemical parameters include weekly blood glucose, serum creatinine, microalbuminuria and glycated hemoglobin (HbA1c) measured at baseline and two consecutive three-monthly intervals.

Results: There were significant differences in the blood glucose concentration "before exercise" and "after exercise" for the Hatha yoga and conventional PT exercise groups at differents weekly intervals ($p<0.05$). The frequency of signs and symptoms of hypo- and hyper-glycemia over the weeks during exercise was greater in the conventional PT exercise group than in the Hatha yoga exercise group ($p=0.004$). The HbA1c concentration decreased after six months in the Hatha yoga and conventional PT groups and was significantly different from that of the control group ($p<0.05$). There were significant reductions in systolic and diastolic blood pressure readingss observed before and after exercise for the Hatha yoga and conventional PT exercise groups ($p=0.0001$).
Conclusion: These observations suggest that short lifestyle modification using Hatha yoga exercise leads to favourable clinical and biochemical outcomes in patients with Type 2 diabetes mellitus.

Waist to hip mediates inverse association of walking with A1C but not of walking with blood pressure among women with type 2 diabetes

P. Manjoo[1], L. Joseph[2], L. Pilote[1], K. Dasgupta[1]
[1] *McGill University, Department of Medicine, Montreal, Canada*
[2] *McGill University, Department of Epidemiology Biostatistics and Occupational Health, Montreal, Canada*

Aims: Among men and women with type 2 diabetes, to assess the associations between walking and the cardiovascular risk indicators, A1C, blood pressure, and dyslipidemia; and to determine whether these associations persist after accounting for anthropometrics.
Methods: 200 adults with type 2 diabetes were recruited from outpatient clinics. Variables measured included daily steps (Yamax SW-200 pedometers), anthropometrics (body mass index; waist circumference; waist-to-hip ratio), A1C (Biorad II HPLC) and blood pressure. The use of any dyslipidemia therapy was the proxy for dyslipidemia. Age and race adjusted estimates were computed (linear/logistic regression) for the associations of (i) daily steps with A1C, blood pressure and the odds of dyslipidemia (with and without adjustment for anthropometrics); and (ii) daily steps with anthropometrics.
Results: Daily steps were inversely associated with A1C and the odds of dyslipidemia among women (Table 1). Adjustment for anthropometrics resulted in a loss of statistical significance among women, but had little or no effect on these associations among men. Daily steps were inversely associated with both systolic and diastolic blood pressure among women and with diastolic blood pressure among men (Table 1). Adjustment for anthropometrics decreased the magnitude of the association among women but it remained statistically significant. Adjusting for anthropometrics had no impact on the association between steps and diastolic blood pressure in men.
Conclusion: We detected significant inverse associations in women of daily steps with A1C, dyslipidemia, and blood pressure. It is possible that the inverse associations with A1C and dyslipidemia are mediated by abdominal obesity given the loss of statistical significance with the introduction of WHR in our models. In men, we detected a significant inverse association between daily steps and diastolic blood pressure.

Table 1: Age and race adjusted change in cardiovascular risk indicators per 1000 daily step increment

	Women	Men
A1C, %	-0.13 (-0.25, -0.01)	-0.10 (-0.22, 0.02)
Dyslipidemia* (odds ratio)	0.80 (0.63, 1.00)	1.08 (0.87, 1.33)
Systolic BP	-2.86 (-4.32, -1.40)	-0.82 (-2.22, 0.59)
Diastolic BP	-1.66 (-2.49, -0.82)	-0.77 (-1.55, 0.00)

P-1177

Effects of exercise training at anaerobic threshold intensity on glycemic control in type 2 diabetic women

T. Belli[1], M.A. Ackermann[1], L.F.P. Ribeiro[2], V. Baldissera[3], C.A. Gobatto[1], R. Galdino da Silva[4]
[1] *UNESP, Laboratório de Fisiologia Aplicada ao Exercício (LAFAE) - Departamento de Educação Física, Rio Claro, Brazil*
[2] *Universidade Estadual de Santa Cruz, Departamento de Ciências da Saúde, Ilhéus, Brazil*
[3] *UFSCar, Departamento de Ciências Fisiológicas, São Carlos, Brazil*
[4] *Universidade Estadual de Roraima, Pró-Reitoria de Pesquisa, Boa Vista, Brazil*

Exercise associated to diet and medication composed the type 2 Diabetes Mellitus (DM2) treatment. Although the anaerobic threshold (AT) is more sensitive for exercise intensity prescription, in general, maximum heart rate and oxygen consumption (HR_{max} and VO_{2max}) are used for this purpose. Therefore, the aim of this study was to assess the effects of exercise training at AT intensity on glycemic control in DM2 women.
Methods: Twenty four sedentary DM2 started in this study and nineteen (79%) were able to conclude it. These nineteen DM2 were separated in two groups: control group (C) (n=10; C: 55.9±2.2 years; 72±4kg; 37.3±1.9% fat; 155±2 cm of height; 3.7±0.9 years of diagnosis) which to keep sedentary during the study, and trained group (T) (n=9; 53.4±2.3 years; 75±6 kg; 39.5±2.4% fat; 152±2cm of height; 4.4 ±1.1 years of diagnosis) which to participate in exercise training: twelve weeks of walking at AT intensity (4.7±0.3km/h; 85±4% VO_{2max}; 82±3%HR_{max}), three times/week, 20-60 min of exercise session duration. Exercise tests were conducted on a previously calibrated treadmill (Moviment—LX-160), with initial velocity of 1 km/h and increments of 1 km/h every 2 min, without any inclination, and until voluntary exhaustion. AT were assessed by two independent investigators through the visual inspection of ventilatory parameters curves (VO2000 Gas Analyzer, Med Graphics). VE/VO_2 increases without a concomitant rises in VE/VCO_2 was used as the main criteria to identify AT. Glycemic control was evaluated by glycated haemoglobin (HbA1c) (HPLC-BioRad DiaSTAT Analyzer) and fasting blood glucose (FBG) (colorimetric enzymatic methods - Laborlab ® kits) before and after training period. Furthermore, each two weeks was measured blood glucose (Optimum-Medisense Product, Abbott Lab ®) pre and post exercise bouts. All data were expressed by mean ± SEM and ANOVA two way was used for comparisons (statistical significance $p<0.05$).
Results: Group T was 86-100% of attendance in exercise sessions. There was significant decrease in HbA1c values in group T after exercise training period and it was not observed in group C (6,8±0,4 vs 5,9±0,2%; 7,2±0,5 vs 7,2±0,7%, respectively). FBG did not change in either group T or group C after exercise training period (120±9 vs 110±8 mg/dL; 132±16 vs 142.8±20.3 mg/dL respectively). However, in every measured week, blood glucose was significantly different pre vs post exercise bouts (162.2±8,5 vs 118.5±7.1 mg/dL).
Discussion/conclusion: Exercise training at AT intensity promoted decrease in blood glucose post exercise bouts as HbA1c. It represents acute and chronic improvement in glycemic control, which it is very important to decrease DM2 complications due the hyperglycemia. Therefore, we point out the relevance of AT use for the exercise intensity prescription in DM 2 population.

Physical activity, a key part of diabetes education

P. de Luca[1], M.B. El Khoury[1], M.T.U. Barone[2], D.R. Franco[3], F.C. Branco[4], L.M. Aihara[1], R. Rezende[3]
[1] *Associação de Diabetes Juvenil, Physical Education, São Paulo, Brazil*
[2] *Associação de Diabetes Juvenil, and University of Sao Paulo, São Paulo, Brazil*
[3] *Associação de Diabetes Juvenil, Education, São Paulo, Brazil*
[4] *Associação de Diabetes Juvenil, Education and Nutrition, São Paulo, Brazil*

The purpose of the present study was to demonstrate the contribution of physical activity to glycemic control in diabetes mellitus patients enrolled in a workshop with multidisciplinary health care professionals.
Methods: We have analyzed, from August to December of 2006, 137 people enrolled in a physical activity workshop, which is part of a Diabetes Education Program. Patients who arrive at the "Associação de Diabetes Juvenil - ADJ" at

7:45am, are fasting since midnight. After measuring their blood glucose for the first time (gluc0), using a regular glucometer, they receive insulin and/or medication, as prescribed. During the day, patients' blood glucose is assessed two times every 2 hours: before a snack (gluc1) and before lunch (gluc2); and three hours after lunch: before (gluc3) and after (gluc4) physical activity. Physical activity consists of 5' of warm up, 20' of walking, and 5' of cool down for adults; and 5'of warm up, 10' of playing games, 10' of very light and fun activity, and 5' of cool down for children. The day ends at 5:00pm. Patients were divided into 3 groups as their own treatment: oral agent (OA), insulin (Ins), and OA plus Ins. Analysis of variance was used to asses the significant difference among groups. The significance level adopted was p<0.05.

	Treatment					
	oral agent n=59		oral agent plus insulin n=26		insulin n=52	
	mean	SD	mean	SD	mean	SD
age y	60	9	61	11	42	21
diagnostic y	6,6	5,4	12,4	5,4	10,3	9,2
gluc0 mg/dL	157,3	61,3	174,0	55,6	170,8	65,1
gluc1 mg/dL	#195,1	67,2	215,3	53,6	#221,5	57,6
gluc2 mg/dL	#148,8	66,5	159,5	53,6	#171,4	52,9
gluc3 mg/dL	187,7	71,8	197,8	57,1	200,3	64,7
gluc4 mg/dL	150,7	68,2	143,3	61,9	144,3	63,4

#Differences between groups OA and Ins (p<0,05).

There were differences in all paired test in all groups for (gluc0 to gluc1; gluc1 to gluc2; gluc2 to gluc3; gluc3 to gluc4; p<0,05). Post physical activity glycemic level of all groups was lower than the pre activity levels. The Insulin group had a greater glucose decrease than OA group (56±5,6mg/dL; 37± 4,4mg/dL; p<0,05; mean±SE).

Discussion: Glucose level was high in all groups. After physical activity the decrease of patients' glycemia from all groups was so noticeable that the levels returned to fasting state level in OA group, and below fasting state values in Insulin and OA plus Insulin groups.

Conclusion: Even though the target glucose level was not achieved, physical activity promoted a prominent reduction in glucose levels. This work reinforces the importance of: physical activity as one of the effective ways to control glucose levels in diabetes mellitus; and an interdisciplinary approach of health care professionals, including physical educators.

"Welhabit" Diabetes self-monitoring program using information technology

M. Kato[1], N. Kato[1]
[1] Kato clinic, Internal Medicine, Tokyo, Japan

Background: Healthcare assistance for persons with diabetes includes self-monitoring blood glucose, weight scales, sphygmomanometer, and pedometers. Having such patients monitor their health by self-administered urine glucose monitors has proven effective in controlling the disease. Self-monitoring also benefits health-care professionals receiving patient data via the Internet.

Objectives: The "Welhabit" diabetes self-monitoring program we developed collaboratively with a company consists of a hand-held equipment with a pedometer function. We studied its feasibility in conjunction with 12 outpatients.

Methods: Our clinic is specialized clinic in diabetes located in Tokyo. We treat approximately 900 outpatients per month, of whom 79% are diabetes, and 48% have hypertension. Subjects were 12 persons with diabetes. Subjects attached the hand-held equipment to a belt or other convenient site to automatically record daily exercise and other data, and then input data on meals, medications, blood glucose levels, and urine glucose levels measured by other urine glucose meters. They sent data each night to the hospital via the Internet and automatically received medical analysis results and advice from the host computer. Advice included comments on subjects' amount of exercise and energy, salt, and alcohol intake. All data was graphed and sent regularly to health-care professionals for reference.

Results: Self-administered questionnaires showed that subjects' exercise habits significantly improved by 92% and diet by 83%. Blood tests showed that their glycoalbumin decreased from 22.3 ±2.2% at baseline (mean ±S.E) to 19.0 ±2.9% three months after starting self-monitoring using our program. Total cholesterol decreased from an average of 222 ±8.9 mg/dl to 207 ±4.4 mg/dl. An unexpected result, however, was that 25% of subjects felt "overly supervised".

Conclusions: Despite the 25% of subjects feel "over-supervision," the transmission of diabetic lifestyle information to health-care professions each day and the quick advice that subjects received proved mutually beneficial and an overall lifestyle improvement for diabetic patients.

The effects of home-based brisk walking exercise on blood glucose, blood pressure and microalbuminuria in type 2 diabetic patients with microalbuminuria

L. Zhao[1], P.R. Chiu[2], S.H. Lo[3], Y.C. Fang[4]
[1] Hsin Sheng College of Medical Care and Management, Nursing, Jongli City Taoyuan County, Taiwan
[2] College of Medicine Fu Jen Catholic University, Nursing, Hsinchuang Taipei County, Taiwan
[3] TaoYuan General Hospital, Division of Metabolism Department of Internal Medicine, Tao-Yuan City, Taiwan
[4] Chung Hwa University of Medical Technology, Nursing, Tai-Nan City, Taiwan

The purpose of this study was to examine the effects of home-based brisk walking exercise on blood glucose, blood pressure and microalbuminuria in type 2 diabetic patients with microalbuminuria. A two-group pre-post test quasi-experimental research design was used. Sixty-one diabetics with microalbuminuria were selected from an outpatient department at regional hospital in Northern Taiwan. These patients, by their own choice were assigned to the experimental group (n=30) and the control group (n=31). Patients in experimental group received a 12-week home-based brisk walking program and routine health education, while patients in the control group received routine health education only. Research instruments were pedometer and electronic sphygmomanometer. The independent variable was the home-based brisk walking and the dependent variable were blood glucose, blood pressure and microalbuminuria. All data were analyzed by SPSS/Windows 15.0 statistical package software, included percentage, mean, standard deviation, minimum, maximun, chi-square, independent t-test, paired-t test, pearson correlation. Results of the data in the experimental group showed a markable decrease in fasting glucose (t = 2.164, p = .039), systolic blood pressure (t = 2.957, p = .006) and microalbuminuria (t = 2.324, p = .027), while data in the control group indicated no significant change in the above three variables. In the treatment group, decrease of microalbuminuria in the higher heart rate walking subgroup was greater significantly than those of the low heart rate walking subgroup (t = 2.128, p = .046). Walking steps correlated significantly with the lowering value of fasting glucose (r= .204, p = .012). While clinical nursing staff can use information generated from the study as one of educational resources for diabetes patients with micralbuminuria.

Reduction of blood glucose and excitability levels of physical exercise for people with Type 2 diabetes

J. Dullius[1], A.C.B. Prada[1], F.S. Santana[1], R.C. Alves[1], F.N. Ramos[1], V.D. Araújo[1], F.J.A. Prada[1]
[1] Doce Desafio Institute, Physical Education College, Brasilia, Brazil

Introduction: Diabetes Mellitus (DM) is a metabolic chronic-degenerative disorder that is associated with failure and/or inefficient action of insulin, characterized by elevated glucose in the blood. Currently, physical activity is an important factor for the treatment of diabetes mellitus type 2 to improve control of blood glucose and provide a better quality of life for people with diabetes. It is known that more vigorous physical activity can induce significant fluctuations in blood glucose, according to excitability levels (EL) involved in physical activity induced.

Objective: the aim of this study is analyze the glycemic reductions of a physical exercise program due to different levels of excitability.

Methods: This study was composed by twelve subjects with type 2 diabetes, aged between 40 and 60 years, both sexes, participants of Doce Desafio Institute / Proafidi. The program of physical exercise consisted of 16 weeks of training with sessions of resistance and cardiovascular exercises. The magnitude of glucose reduction was analyzed by the difference between capillary glycemia

(CG) CG = pre-exercise - CG post-exercise. EL were classified according to intensity, ie, EL1 = low; EL2 = medium, EL3 = high. The descriptive analysis was performed using the mean ± standard deviation, and inferential analysis performed by the Student t test, with significance level set at p = 0.05, that (*) when compared with EL 3 and (+) when compared with EL2.

Results:

Excitability Levels	CG Reductions
1	24,89 ± 13,24 *
2	17,06 ± 9,33 *
3	5,67 ± 3,06 +

Conclusion: It seems that the higher levels of excitability of the sessions of physical exercise, lower acute glycemic reductions. It should be noted that these requirements are not contra-indicated or ineffective, since the analysis was acute and it can not be said that the responses to chronic glycemia are bad.

Physical activity, as an effective remedy for achievement of psychosocial rehabilitation and normoglycemia in children and adolescents

K. Amirkhanashvili[1], R. Kurashvili[2], G. Amirkhanashvili[1], T. Lafanashvili[1], N. Bikashvili[1], N. Shengelia[1], M. Khutsishvili[1], G. Kurashvili[2]
[1] Diabetic Children's Protection Association, Endocrinology, Tbilisi, Georgia
[2] Georgian Diabetes Center, Endocrinology, Tbilisi, Georgia

Background and aims: Rehabilitation centre set up in 2008 on the base of Georgian Diabetic Children's Protection Association, serves diabetic children and adolescents 0-18 and 18-25 years of age. Rehabilitation centre is equipped with modern fitness and sport halls, where skillful professionals are employed.
Materials and methods: Diabetic children and adolescents started physical activity after theoretical training in the summer of 2008. The following control groups have been studied: Group 1: girls 13-18; Group 2: girls 18-25; Group 3: boys 13-18. HbA1c levels measured prior to rehabilitation exercise were: Gr. 1 - 9.13%, Gr.2 – 8.58% and Gr. 3 - 7.9%.
Results: Nine months of observation demonstrated, that HbA1c level decreased in 40% of patients in Gr.1 who regularly measured glycemia before and after exercise in average to 7.8%, and in patients who measured not regularly this parameter increased in average to 9.49%. The same was shown in girls 18-25 years of age, namely in 40% decreased from 8.48% to 7.6%, and among the rest of children this index increased to 9.2% and 8.0% respectively. Among the patients who improved HbA1c level, body weight was reduced by 3-5 kg, and insulin daily dose – by 12-18%.
Conclusion: Daily physical activity produces positive result only when combined with blood glucose regular control. Recommendation to the parents of diabetic patients: when blood glucose is >10-11 mmol/l, physical activity should be avoided.

P-1183

Effect of antidiabetic medication on acute post-exercise glucose response among subjects with type 2 diabetes

G. B. A. Rodrigues[1], J. Dullius[1]
[1] Instituto Doce Desafio - UnB, Faculty of Physical Education, Brasília - DF, Brazil

Introduction: Physical activity is part of the treatment of Type 2 Diabetes Mellitus (DM2) and the use of oral antidiabetic medication is very common among these individuals. Thus, a comprehensive knowledge of the action of these drugs on the glucose variation during physical exercise is necessary for a proper control of the subjects.
Aim: The aim of this study is to evaluate the acute post-exercise glucose response and its relation with the regular use of metformin, sulphonylureas or both among DM2 individuals. This might add to the precautions taken by physical education instructors and DM2 subjects when adjusting pre-exercise glucose values.
Methods: Sample of 29 sedentary subjects, aged 47 to 75 years, with DM2 who were not insulin-treated and took part in a diabetes and exercise education program. When they entered the study, 13 (47%) were using metformin (MET), 8 (27%) sulphonylureas (SUL) and 8 (27%) both (M+S). Glucose values were collected before (GB) and after (GA) the exercise sessions, using a glucometer, in 3 nonconsecutive days, not more than five days apart. The exercise sessions of 50 minutes included a warm-up, aerobic and resistance exercise and stretching. Analysis of variance (ANOVA) and Wilcoxon tests were used for statistical analysis.
Results: Regardless of the type of medication, the initial glucose mean value decreased significantly after the exercise sessions (GB=164, SD=52 and GA=115, SD=35), p=0,05. MET subjects (mean age=63) had GB=160 + SD= 50 and GA=108 + SD=36mg/dl. SUL individuals (mean age=57), had GB=161 + SD= 51 and GA=104 + SD= 33mg/dl. M+S subjects (mean age=57), GB=175 + SD 53 and GA=134 + SD=26mg/dl. M+S subjects had higher mean value of GB and GA but a smaller blood glucose decrease. This might be due to the fact that subjects using combined antidiabetic medications are normally having more difficulty in controlling glucose levels and might also use lower drug doses.
Conclusion: There was no statistical difference in the glucose behavior between the three groups. M+S group showed a trend to higher values of blood glucose before exercise and lower reduction after the sessions. SUL group showed a trend to a higher decrease of glucose values. In this sample, there was no glucose variation difference among individuals under different drug therapies.

P-1184

A comparative study of physical activity and anthropometric changes in diabetic and non diabetic groups in the same socio-cultural backgrounds

R. Chandni[1], V. Udayabhaskaran[1], K.P. Ramamoorthy[1], B.K. Ajitha[1]
[1] Calicut Medical College, Medicine, Kozhikode, India

Aims of the study:

1. To compare the physical activity and habits among diabetic and non diabetic people in the same ethnic and socio cultural backgrounds.
2. To compare the anthropometric measurements in diabetic and non diabetic people in the same socio cultural backgrounds.

Materials and methods: This was a case control study.153 subjects having diabetes of varying duration on treatment were compared with 153 non diabetics matched for age, gender, cultural and religious backgrounds. Those having familial hyperlipidemias, hypothyroidism and those on glitazones, lipid lowering drugs were not included. Detailed history, social habits, and anthropometry were done in both the groups.
Observations: The age group ranged between 26 to 85 years with mean age of 53.93 ±10.66. There were 86 (56.2%) males and 67 (43.8%) females among both the groups. The groups were comparable in religious background, smoking and alcoholism. Hours of physical activity and Television viewing were compared in both the groups. Among the controls, 76 (49.67%) were physically inactive and 77 (50.33%) active and from subjects, 121 (79.08%) were inactive and 32 (20.92%) active (p = 0.00). Among the controls 47 (30.72%) did not watch TV at all and 106 (69.28%) used to watch TV for some hours of the day. Among diabetics 21 (13.73%) did not watch TV at all and 132 (86.27%) used to watch TV for some hours of the day (p = 0.00).Mean BMI was 25.18±3.89 in the diabetics and 24.12 ±3.20 in the controls (p = 0.009). Among Diabetics, mean BMI of males was 24.46±3.24 and of females was 26.11±4.45 (p = 0.009).In females, mean BMI was 24.34±3.62 for controls and 26.11±4.45 for diabetics (p=0.013). Among diabetic patients mean waist circumference of males was 89.71±7.88 and of females was 95.1±9.48 (p = 0.000) and among controls mean waist circumference of males was 87.41±7.87 and of females was 88.14±9.84 (p = 0.61). Among females mean waist circumference was 88.15±9.84 for controls and 95.11±9.48 for diabetics (p=0.000).
Conclusions: Physical inactivity and hours of Television viewing were higher in the diabetic group compared to non diabetic group. Mean BMI was higher in the diabetic group. Mean BMI and waist circumference was higher in females in the diabetic group compared to males. Moreover females in the diabetic group had higher BMI and waist circumference compared to the females in the non diabetic group.

P-1185

Acute post-exercise glycemic variation in people with type 2 diabetes and its relation with initial value

A. Moritsugu Silva[1], J. Dullius[1], A. Protzek[1]
[1] Instituto Doce Desafio - UnB, Faculdade de Educação Física, Brasília - DF, Brazil

Aims: The aim of this study is to evaluate glycemic variation after physical exercise in noninsulin-dependent people with type 2 diabetes under different levels of blood glucose measured before exercise.
Methods: Sample size:28 noninsulin-dependent type 2 diabetic people, participating in a physical exercise program for people with diabetes, 15 men and 13 women, ages: 57±9 years, duration of diabetes: 6±7 years. Data was collected using questionnaire, glycemic levels measures by glucose monitors before and after exercise bouts. Selected 5 first exercise sessions of each subject, excluding those with glycemia <100mg/dL or >250mg/dL. Exercises prescribed: resistance training, flexibility training, walk, games. Categorized data according to initial glycemias: Level A - 100 to 139mg/dL; Level B - 140 to 199mg/dL; Level C - 200 to 250mg/dL. Variables analyzed: Initial glycemias and glycemic variations. Statistical analysis calculated by Pearson's Correlation Coefficient, p.
Results: Glycemic variation under different levels presented the following reductions: Level A = 12±20mg/dL (9%), Level B = 38±36mg/dL (22%) and Level C = 88±43 mg/dL (40%). It is observed a fall in Pearson's Correlation Coefficient related to the increasing of intial glycemia, being p=0,464 in Level A, p=0,3 in Level B, and p=0,085 in Level C. There was a moderate correlation between both variables, p=0,69.
Discussion: The glucose absorption depends on a lot of factors. Three of them are more relevant: intracellular metabolic process, glucose transporters (GLUT) translocation mechanism to the cell membrane and availability of glucose for the muscle cells. During exercise, the muscle tissue presents higher energetic demand, requiring higher expenditure of energetic substrate, usually, glucose. We can also observe a rise in concentration of glucose transporter in the cell membrane, facilitating the glucose absorption. The last factor was observed in this study. The hypoglycemic effect of exercise is more intense as higher is the availability of glucose for the muscle cells or the glycemic level at the beginning of the exercise.
Conclusion: We concluded that, based on this sample, the post-exercise glycemic variation is higher in cases where you observe higher glycemic level before exercise. We can also note that the glycemic responses to the exercise are less homogeneous the higher are the initial glycemic levels. We can not precisely predict the hypoglycemic effect of exercise, as shown how variable these effect is. What we can expect is a higher variation of glycemia as higher are its initial levels.

Glycemic variation post-exercise: comparison between people with type 2 diabetes insulindependent and noninsulindependent

A. Moritsugu Silva[1], J. Dullius[1], L. Valença[1]
[1] Instituto Doce Desafio - UnB, Faculdade de Educação Física, Brasília - DF, Brazil

Aims: The aim of this study is to compare the glycemic variation post-exercise between people with type 2 diabetes who are treated with or without insulin.
Methods: Sample size of 12 type2 diabetic subjects participating in a group of oriented physical exercise (8 men, 4 women, age 56±8 years; 9±8years of diagnosis). 6 of them were treated with insulin (3 men, age 58±8 years, 15±8 years of diagnosis) and 6 of them were treated with other different therapies (5 men, age 54±7years; 4±3years of diagnosis). Data was collected through questionnaires and glycemias were measured with portable blood glucose meter. In 5 different days, all the 12 subjects participated in the same activities. The exercise protocol consisted in 5 min of warm up, 6 resistive exercises for the major muscle groups with 2 set of 15 reps each.
Results: Before the beginning of the exercise bout, the mean glycemia was in the insulintreated group 228mg/dL and 120mg/dL in the group not on insulin. After the exercise, the two groups had different lowering effects on the glycemia. In the insulintreated group, there was a reduction of 31% (mean) of the level, reaching 158mg/dL. In the group not on insulin, the lowering effect was less expressive, 17%, but in absolute values, it was lower than the otrher group, 99mg/dL.
Conclusion: In this study, the insulintreated group presented higher glycemic levels before and after exercise and also a higher glycemic variation comparing to the group that was not treated with insulin.

Relationship between physical activity and fasting glycemia

D.R.M.C. Oliveira[1], F.o. Magalhães[1], A.c. Martins[1], R.g.c. Bomfim[1], S.p.d. Nunes[1], E.e. Leite[1], F.a. Avelar[1], A.l. Cançado[1], N.m. Ferreira[1], S.m. Freitas[1], A.p. Silva[1], L.k. Oliveira[1]
[1] Universidade De Uberaba, Medicina, Uberaba, Brazil

Diabetes mellitus has a high prevalence in proportion to Brazilian population in the world population, making necessary greater attention and education on the matter. On the world day of diabetes, in the city of Uberaba, is performed, there are 8 years activity physical-recreational and educational with the participation of diabetics and family. The objective was to evaluate the benefits of physical exercises in these individuals activity.
Methods: This was questionnaire, measured in capillary fasting glycemia and post-prandial, during the implementation of the activity. Data were analyzed by SPSS 14.0 program and through the chi-square with a significance level of 5%
Results: Among the 126 participants from gymkhana, 10 did not reply to the questionnaire, totaling then 116 individuals analyzed. 34.74% of these had taken of 3 or more years of activity. There was 28.6% prevalence of diabetes among these individuals. The majority 78.4% (91/116) performed physical activity regularly and 21.6% did not achieve. Among 91 individuals, 28.6% performed 3 times/week, 17.6% 2 times/week, 13.2% once/week and the remaining 4 or more times a week. The majority (85%) performed 30 to 60 minutes of exercise. There was no relationship between diabetes mellitus and physical activity, since 77.14% of diabetics and 80% of the non diabetics the performed (X^2=0.120, p=0.729). Was no relationship between fasting glycemia and physical activity, where 51.4% were atividdae remained physical fasting glycemia < 100 mg/dl, versus 23.1% of those not performed (X^2=9.837, p=0.007). There was no relationship between glycemia post-prandial and physical activity (X^2=2.741, p=0.98).
Discussion/conclusion: There was a high prevalence of the implementation of regular physical activity among individuals analyzed. Although there is no relationship between the glycemia post-prandial and physical activity, the relationship with fasting glycemia shows the importance of implementation of this type of activity. We must raise awareness and encourage even more the population through guidelines clinical and/or campaigns on the matter.

Sustained monitoring and support critical to improving exercise behaviour in type 2 diabetes

D. Casey[1], M. De Civita[2], K. Dasgupta[1]
[1] McGill University, Department of Medicine, Montreal, Canada
[2] Knowledge Translation Consultant, Montreal, Canada

Aims: We sought to assess exercise-related barriers and facilitators among overweight adults with type 2 diabetes (T2D) who had previously participated in a supervised exercise program.
Methods: Individuals invited to participate in the present study had previously participated in a program of supervised exercise through our previous trial. The supervised exercise program had been delivered through an established cardiac rehabilitation centre and was supervised by experienced exercise physiologists. The program had been 24 weeks in duration with three group sessions per week for eight weeks, then two sessions per week for the next eight weeks, and finally one session per week for the final eight weeks. Exercises included treadmill, cycling, and cross trainers, and participants wore a heart monitor. In the present study, focus groups were conducted approximately one and a half years following the exercise program. Focus group discussions addressed factors that could facilitate attendance, current engagement in exercise, reasons for continuing or discontinuing regular exercise, and ways to integrate exercise into daily life. Sessions were led by a trained moderator; audiotapes were transcribed verbatim; transcripts were coded and themes were identified. Themes that recurred across all three focus groups were considered to have achieved saturation.
Results: Fifty-six percent (18/32) of those invited participated in a focus group. Reasons for not participating included physical ailments (three), lack of time

(four), lack of interest (one), or was not specified (six). Barriers to exercise included lack of motivation, physical ailments (e.g. arthritic pain, respiratory tract infection), and travel time to an exercise centre. The support and supervision of the staff facilitated attendance during the program and absence of such supervision was a barrier to exercise following the program. Visible health outcomes such as reduced need for medications motivated exercise behaviour. Following the gym-based program, walking appeared to be the major form of exercise adopted by participants because of ease of integration into daily activities.
Discussion: Adults with T2D require long term monitoring and support for physical activity and exercise. Compared to gym-based exercise, walking may be more feasibly integrated into daily living.

P-1189

Correlations between flexibility indexes and previous level of glycemic control and exercise lifestyle in diabetic people with long-term diagnosed diabetes

C. Nader[1], J. Dullius[1], G.L. Fernandes[1]
[1] Instituto Doce Desafio - UnB, Doce Desafio Program, Brasília - DF, Brazil

Introduction: Lifestyle interventions have broad benefits on diabetes management and can help individuals to control glycemic levels which are an indicator of life quality. A direct relation between flexibility and quality of life in diabetics may be considered. The aim of this study was to verify if this relation exists, also considering the past exercise lifestyle and time of diabetes of the participants.
Methods: Sample: 8 diabetic people who attend Sweet Challenge program (Diabetes Education through an Oriented Program of Physical Activities to Diabetic People), both types 1 and 2, ages 25-64 (43±13) years old, diagnosed for at least 20 (29±7) years, from both sexes. An interview collected the data about past lifestyle. Flexibility measures were taken by goniometry (flexion and abduction of shoulders; flexion and extension of wrist, hip and plantar flexion, dorsiflexion and prayer maneuver). The diabetics were then classified into categories related to each test.
Results: It was found a positive correlation on flexion and abduction of non-dominant shoulder when comparing the level of past physical activity and flexibility. An inverse correlation was found on dominant wrist flexion. A positive correlation was found for dominant dorsiflexion and non-dominant wrist flexion comparing the diagnosis time and flexibility values. An inverse correlation was found on dominant and non-dominant plantar flexion, and also non-dominant hip flexion.
Conclusion: From the data analysis, we conclude that the time of diagnosis can influence joint flexibility, mostly on body extremities. Nevertheless, there is a need to understand better the correlations between these variables. We can also infer that the past active lifestyle can interfere on a frame of weak flexibility.

Evaluating the effect of continuous medical education: an application of the SDM workshop program in Korea

D.M. Kim[1], J.G. Kang[1], D.S. Choi[2], B.Y. Cha[3], K.Y. Min[4], H.W. Nam[5], H.J. Yoo[1], S.A. Kim[6]
[1] Hallym university, endocrine, Seoul, Korea
[2] Korea university, endocrine, Seoul, Korea
[3] the Catholic university of Korea, endocrine, Seoul, Korea
[4] Eulji university, endocrine, Seoul, Korea
[5] National medical center, endocrine, Seoul, Korea
[6] Handok Pharmaceuticals Co. LTD, marketing, Seoul, Korea

Background: To increase the diagnosis of unveiled diabetes patients and provide adequate management, Korean Diabetes Association (KDA) has been running the SDM (Staged Diabetes Management) workshop, mainly focused on the primary healthcare professionals, since 2000.
Objective: Analyzing the demographic features and satisfaction about the SDM workshop is the main objective of this study.
Method: The number of the attendances of the SDM, continuity in attendance, and satisfaction about education are applied to figure out the effect of the SDM in Korea.
Result: As a result of analyzing the diagnostic rate of diabetes, primary clinics account for 49.1% [1] of all healthcare institutes. 4,031 healthcare professionals of 2,880 healthcare institutes attended the SDM [2]. Primary clinics took up 2,408 (83.6%) institutes and hospitals (13.9%) and public healthcare centers (2.5%) were relatively occupied small portion[2]. In the aspect of specialty of medical doctors, internists and family physicians took up most as 54.2% and 14.9% among 2,315 doctors[2]. A number of attendance who participated twice or more during 8 years were 387 (9.6%) of all participants[2]. Satisfaction measurement about the programs by participants increased by 12.5% after attending the SDM workshop compared against expectation before workshop[3]. For contents of lecture and clinical usefulness, 65.8% of responders preferred the practice session about the stepwise use of insulin and oral anti-diabetic agents, and self test of blood glucose and injection[3].
Conclusion: For the past 10 years, the SDM workshop has contributed significantly to the diagnosis and management of diabetes in Korea. Not only the increased awareness of diabetes among healthcare professionals and patients, but also the increased number of various healthcare professionals like general physicians, nurses, and nutritionists who have capabilities to care for diabetic patients in primary care is an important achievement of the SDM workshop. Although the SDM has proven to be very effective in increasing the awareness of diabetes and promoting the application of updated knowledge of diabetes in healthcare professionals, there are some limitations. Therefore, we are planning more sophisticated study including the comparison between the patients cared by the healthcare professionals who attended the SDM workshop and who did not in the aspect of the quality of care using HbA_{1c}, the occurrence rate of complications, and cost of management.

P-1191

Effects of an intensive foot self-care education in the prevention of foot problems in adult patients with diabetes

L. Fan[1], Z. Li[2], J. Lu[3], Y. Zheng[3]
[1] University of Toronto, Faculty of Nursing, Toronto, Canada
[2] Peking Union Medical College, School of Nursing, Beijing, China
[3] Chinese PLA General Hospital, Department of Endocrinology, Beijing, China

Aims: Patients with diabetes are at risk for developing foot problems, which can contribute to significant physical, emotional, and financial losses. Instructing patients about foot-care is necessary to prevent foot complications. The study aimed to evaluate the effects of an intensive foot self-care education intervention in preventing foot problems in adult Chinese patients with diabetes.
Methods: A randomized controlled trial was used in the study. A total of 220 eligible patients with diabetes were randomly assigned to the intensive foot self-care educational group (experimental group: enrollment 110, drop out 24, completion 86) and to usual educational group (comparison group: enrollment 110, drop out 18, completion 92). The sample consisted of 178 adult patients with diabetes, average age was 61.6±11.9 years old, average duration of diabetes was 7.9±6.2 years. The patients in the usual educational group received the routine diabetic treatment and general diabetes education (4-5 hrs). The patients in experimental group received individual intensive education on foot self-care (6-7.5 hrs), given by the diabetes nurse educator in outpatient department on repeated occasions, in addition to usual diabetes education (4-5 hrs). In terms of participants' baseline data on demographic characteristics (i.e., age, sex, education, employment) and diabetes characteristics (i.e., type of diabetes, duration of diabetes, presence of complications, the type of treatment), there were no significant differences between the experimental group and the comparison group (all $P > 0.05$). The effects were evaluated before education and nine months after education.
Results: The results indicated improvement in patients' recognition of signs of foot problems, increased knowledge and skills of daily foot self-care strategies, selecting suitable shoes and socks, and cutting toenails were significantly improved in the experimental group after education ($P<0.05$). Foot problems

such as dry and cracked skin, callus, fungal infection, and foot lesions were reduced significantly nine months after education in the experimental group (P<0.05-P<0.001). FBG, 2h PBG, HbA1c, BMI and blood pressure were controlled much better in experimental group, compared with the comparison group, the differences were significantly found in the study (P<0.05).

Conclusions: The intensive foot self-care educational intervention was effective in enhancing patients' foot self-care skills and in preventing foot problems. This intervention should be incorporated as an additional component in intensive and comprehensive educational program to assist patients' diabetes self-management.

Breaking down the barriers to diabetes education: audience-specific multiplatform diabetes education

P. Pereira[1], D. Persad[1], A. Alexander[2]
[1] *Metrix Group, Medical Learning Solutions, Toronto, Canada*
[2] *Metrix Group, Global Performance Solutions, Toronto, Canada*

With type 2 diabetes accounting for approximately 85% to 90% of all diagnosed diabetes cases, it is essential that effective strategies to decrease the incidence of type 2 diabetes be developed. By 2025, worldwide incidence of diabetes is projected to affect over 300 million individuals with a prevalence of over 6% of the world population.

Diabetes education has been identified as an integral part of diabetes care by providing a cost-effective means through which prevention, treatment and quality of diabetes care can be communicated. Disseminating these strategies represents a potential barrier to their implementation, and thus the effectiveness of these strategies.

Metrix Group has demonstrated success in disease education through the creation of a community of learning framework. This structure provides the foundation for generating materials for specific audiences that include perspectives from patients (both adult and children) and physicians. Metrix Group is well-versed in diabetes and metabolic syndrome and has produced multiple educational materials and curricula in these therapeutic areas.

We have enhanced our approach to disease education through the development of paper-based training materials, classroom-based learning, eLearning delivery methods and a combination of the above. In doing so, we have created tools that appeal to various learning styles, which can be disseminated to different target audiences ranging from healthcare professionals to patients and caregivers.

Based on Metrix Group's track record and extensive experience in developing diabetes-related education materials, we have the infrastructure, experience and capability to develop multiplatform, audience-specific educational packages focusing on the prevention and management of diabetes.

In this presentation, you will learn how the Metrix Group approach to the delivery of disease education can break down the barriers of information access. Our approach allows for the delivery of educational materials in a focused, clear and efficient manner. These education materials, and the mode of their delivery, can be customized specifically towards key target audiences for diabetes education, such as children, adults, community-based organizations and healthcare providers.

The InSight programme - an audit of structured education delivery for people with type 1 diabetes in the UK

P.A. Dyson[1], J. Sumner[2], A. Hargreaves[2], S. Porsch[2]
[1] *University of Oxford, Oxford Centre for Diabetes Endocrinology & Metabolism, Oxford, United Kingdom*
[2] *OCDEM, Oxford Centre for Diabetes Endocrinology & Metabolism, Oxford, United Kingdom*

Background: Evidence from research studies has shown that education programmes addressing carbohydrate counting and insulin adjustment for people with Type 1 diabetes show benefits in terms of both quality of life and glycaemic control. Structured education for people with diabetes is recommended by both Diabetes UK and the Department of Health in the UK, but there is little evidence for its effectiveness when applied in routine clinical care.

Aims: To design and implement an interactive structured education programme for people with Type 1 diabetes and to evaluate clinical outcomes and well-being at two years follow-up.

Methods: The InSight education programme was developed to utilise reflective techniques based upon concrete personal experience of diabetes self-management and encourages peer support. InSight is based upon theories of adult education including experiential learning and runs over 4 weeks with weekly sessions providing 15 hours total contact time. It is designed to facilitate skills for carbohydrate counting and insulin adjustment and supports self-management of hypoglycaemia, hyperglycaemia, illness and exercise. Data were collected at baseline, 6, 12 and 24 months after completion and included biomedical indices, the Problem Areas in Diabetes Scale (PAID) and subject evaluation forms.

Results: The baseline characteristics of 88 subjects (28% male) in Oxford, UK were mean (SD): age 44.6 (12.4) years, diabetes duration 23.6 (12.6) years, A1c 8.5 (1.4) %, body weight 71.8 (15.1) kg, BMI 25.6 (4.1) kg/m2, total cholesterol 4.8 (0.7) mmol/l, HDL cholesterol 1.7 (0.5) mmol/l, LDL cholesterol 2.56 (0.62) mmol/l and triglycerides 1.1 (0.9) mmol/l.

Analysis of 72 (82%) of subjects at 2 years showed a significant reduction in A1c of -0.2% (p=0.004), and a reduction in lipid levels including total cholesterol (-0.3mmol/l, p=0.003), LDL cholesterol (-0.28mmol/l, p=0.003) and triglycerides (-0.19mmol/l, p=0.04). There were no significant changes in body weight, BMI or HDL cholesterol.

PAID questionnaires were completed by 56% of subjects at baseline and after 1 year of the study and the results showed a significant decrease in diabetes-related distress. The mean scores at baseline were 32% and these improved to 19% (p=<0.001) one year after completing the InSight course.

Subjective evaluation showed high satisfaction levels with both the content and the process of the education programme.

Conclusion: Audit of the InSight education programme for people with type 1 diabetes has shown that there are significant improvements in biomedical outcomes and in diabetes-related distress and that these positive outcomes are maintained at two years follow-up.

P-1194

Enhancing self-care practices of adults with diabetes using self-efficacy education approach

M.Y. Tan[1], J. Magarey[2]
[1] *Damai Medical & Heart Clinic, Diabetes Center, Melaka, Malaysia*
[2] *The University of Adelaide, Discipline of Nursing, Adelaide, Australia*

Background and aim: Previous studies from Malaysia have shown high prevalence of diabetes and diabetes complications among the local subjects. Diabetes self-management education has been shown to improve self-care practices and clinical outcomes. This study aims to assess the effectiveness of a self-efficacy diabetes education program.

Research design and methods: Using a longitudinal quasi-experimental design, 164 adults with diabetes were randomised to control and experimental groups from two settings. All subjects' glycated haemoglobin, diabetes knowledge and self-care practices, which included dietary and medication intakes, physical activity levels and self-monitoring of blood glucose (SMBG) practices, were assessed at baseline and 12th week. The intervention group received three monthly individual self-efficacy education sessions (2 face-to-face sessions and 1 telephone follow-up). Self-care practices and diabetes knowledge were assessed using a pre- and post-questionnaire (Cronbach's alpha = 0.86) administered using one-to-one interviewing approach. Analysis was done with descriptive statistics, 2-tailed t-test, Mann-Whitney U, Chi-square and multiple regressions.

Result: At 12th weeks follow-up, the intervention group had shown significant improvements in diabetes knowledge (p=0.001), HbA1c levels (p=0.01), SMBG practices (p=<0.001) and a small increment in physical activity levels (p=0.002) when compared with the control group. There was no significant improvement in dietary and medication self-care in either of the two groups. Within the intervention group, at follow-up there were statistically significant improvements in diabetes knowledge (p=<0.001), HbA1c level (p=0.001), SMBG practices (p=<0.001) and medication self-care (p=0.03) but not physical activity levels and dietary intake. Whereas the control group had slight improvements in diabetes knowledge (p=<0.001) and no change in HbA1c and all self-care practices. Seventy-seven percent of intervention subjects received all three education sessions There were significant relationships between total education time and SMBG practices (r=+0.38 p=0.001), medication adherence (r= +0.22, p=0.04) and diabetes knowledge (r= +0.34, p=0.02). Factors related to reduced education included transportation (rho= -0.31, p=0.006) and telephone access (rho= -0.28, p=0.01) problems. Medication adherence

(B=-0.23, p=0.009) and SMBG practices (B=-0.21, p=0.007) predicted the HbA1c levels at 12 weeks.

Conclusion: The self-efficacy diabetes education program was effective in improving knowledge, glycaemic control and self-care practices like SMBG, medication intake, but not dietary intake or physical activity. Social factors like telephone access and transportation problems appeared to reduce educational opportunities.

The impact of a diabetes education programme on some non-glycaemic endpoints in Nigerians with type 2 diabetes mellitus

B. Kolawole[1], C. Adegbenro[2], S. Adegoke[2], O.G. Adeola[2], T.B. Akintan[2], I.O. Ojoawo[2]

[1] *Obafemi Awolo University Teaching Hospital, Medicine, Ile-Ife, Nigeria*

[2] *Obafemi Awolo University Teaching Hospital, Community Health, Ile-Ife, Nigeria*

Background and objectives: This study evaluated the effectiveness of a structured group education programme on non-glycaemic endpoints of diabetes knowledge, compliance with treatment and medical advice, use of monitoring devices and treatment satisfaction.

Methods: A cross-sectional comparative design was employed. Study participants were members of the local Diabetes Association (DAN) who had participated in a structured group education programme, and control subjects were outpatients with type 2 diabetes mellitus who had not registered as members of DAN and do not attend DAN activities. Self and interviewer administered structured questionnaires were used to determine study endpoints. The responses of study participants were analysed and then compared.

Results: Seventy-five patients were studied in each group comprising 78 males and 72 females. DAN members had good knowledge of their disease, complied satisfactorily with their medications and physician's advice, knew and used at least one monitoring device and had better knowledge of hypoglycaemia than control subjects. Treatment satisfaction scores were also higher among DAN members.

Conclusions: Diabetes associations and clubs provide a practical and acceptable means of disseminating diabetes related information and should be strengthened

Evaluation of new educational program for type 2 diabetes patients on insulin therapy in Russia

A. Mayorov[1], E. Surkova[1], O. Melnikova[1], G. Galstyan[1], A. Tokmakova[1], I. Dedov[2]

[1] *Endocrinology Research Centre, Psychosocial rehabilitation and education of patients, Moscow, Russia*

[2] *National Centre for Endocrinology, Moscow, Russia*

Background and aims: Number of type 2 diabetes patients on insulin therapy in Russia is considerably increasing. The purpose of the study was to estimate the efficacy of new-developed program for insulin-treated patients with type 2 diabetes.

Materials and methods: Structured educational program consists of knowledge questionnaire, curriculum, teaching cards, photos of food plates, posters and handouts. 216 type 2 diabetes patients on insulin therapy were divided into two groups: 90 patients were educated in clusters (group 1) and 126 individually (group 2). Patients were comparable with age (60.1±6.4 vs 58.3±7.2 yrs, p=1.0), diabetes duration (10.1±4.8 vs 9.2±6.7 yrs, p=0.8), insulin therapy duration (2.7±1.1 vs 3.1±2.0 yrs, p=0.7), number of patients on different regimes of insulin therapy, HbA1c level (9.1±2.7 vs 9.7±2.3%, p=0.7). There were more employees among patients educated individually (58.7% vs 35.6%, p=0.01). Clinical and diabetes-related parameters were estimated before, 6 and 12 months after education.

Results: Number of patients on basis-bolus therapy was increased: from 38,9 to 77,8% in group 1 and from 33,3 to 62,7% in group 2 (p=0.05). Significant changes in patients' diabetes-related behavior were revealed in both groups. Decrease in HbA1c level was obtained in six months after education in both groups: to 7.4±1.6% and 8.1±1.1% respectively. In 12 months after education, lowering of patients' activity in self-monitoring blood glucose, completion of logbook, self-adjustment of insulin dose were revealed; 46.7% patients from group 1 and 27.8% from group 2 inadequately reduced daily dose of insulin. HbA1c level was 8.1±1.7% a year after education in groups and 8.4±2.0% after individual education (p<0,05).

Table

Clinical and diabetes-related parameters	Group education			Individual education		
	Before	After 6 months	After 12 months	Before	After 6 months	After 12 months
Regular self-monitoring blood glucose, % of patients	28.9	82.2	68.3	32.5	80.9	70.3
Using logbook, % of patients	20.0	78.9	64.7	46.1	95.2	88.3
Self-adjustment of insulin dose, % of patients	6.7	75.6	65.6	30.2	84.9	77.0
HbA1c, %	9.1±2.7	7.4±1.6	8.1±1.7	9.7±2.3	8.1±1.1	8.4±2.0

p<0.05 (intragroup comparison)

Conclusion: Results of the study demonstrate the efficacy of structured program for type 2 diabetes insulin-treated patients. The program should be recommended for both group and individual education. Lowering of patients' self-activity and inadequate reduction of insulin dose seemed to be the barriers to optimal glycemic control. Further studies are needed to investigate factors associated with behavioral changes.

[2] *Laboratory of Clinical Pedagogy Department of Internal Medicine, University of Turin, Turin, Italy*

[3] *Servizio di Diabetologia, Azienda Ospedaliera, Scandiano Reggio Emilia, Italy*

[4] *UONA Malattie Metaboliche e Diabetologia, ASL, Biella, Italy*

[5] *Dipartimento di Economia, Università di Torino, Turin, Italy*

[6] *Dipartimento di Sanità Pubblica e Microbiologia, Università di Torino, Turin, Italy*

To reduce the preventable burden of diabetes we need to translate diabetes research into daily practice, with the aim of improving new knowledge, health conduct, health outcomes and improve access to quality health care. The Group Care (GC) approach, in which traditional individual visits are substituted by group education sessions, permits to obtain better organization of outpatient clinics while improving the clinical management of type 2 diabetes (T2DM) (Trento, 2001, 2002, 2004). The multicentre clinical trial ROMEO (Rethink Organization to iMprove Education) was planned to evaluate the applicability and reproducibility of GC in different outpatient facilities and to verify if its encouraging results can be reproduced elsewhere, while assessing its clinical impact on a larger patient population (Porta e Trento, 2004; Gentile, 2004). ROMEO was closed in 2007, and is now under statistical evaluation. This paper reports on the results of a purpose-built questionnaire administered to assess the process of implementation of GC in the centres participating in ROMEO and to verify the 'input-workout-output' method in an experimental framework. We identified areas to better understand the impact of GC on daily clinical practice and to ascertain if the GC approach helps achieving patient empowerment in building strategies to cope with T2DM as well as other types of diabetes and chronic conditions. Using the ROMEO language, both in GC and individual visits, a symbolic reference was identified to be shared within the team. The systematic use of metaphors expresses the value and the meaning of the changing process. The ROMEO centres identified further areas of implementation of GC: metabolic settings (Type 1 diabetes, metabolic syndrome, obesity, gestational diabetes, new diabetes diagnosis, dyslipidaemia, self-monitoring and continuous subcutaneous insulin infusion, nutritional self-management education, exercise and diabetes, psychosocial assessment and care) and, interestingly, in rehabilitative and oncological settings. All centres involved in ROMEO have completed an analysis of their internal organization and started re-thinking their organization to continuously improve their team performance and support changing clinical processes, defining and sharing ongoing objectives beyond the mere enforcement of the clinical trial.

Diabetes self-management learning and adaptation process: weekly education program versus intensive program, the results

J. Gagné[1], J. Joly[1], C. Michaud[2]
[1] *Université de Sherbrooke, Faculty of Education, Sherbrooke, Canada*
[2] *Université de Sherbrooke, Faculté médecine et sciences santé, Sherbrooke, Canada*

Objective: This research compares the adaptation process to the disease of patients taking part in one intensive Diabetes Self-Management Education Program (DSMEP) (three-day session) or one weekly DSMEP (eleven-week two-hour session).
Method: A pretest posttest, non-equivalent control group, quasi-experimental design was used to compare the two DSMEP. Thirty-eight type 2 diabetic individuals correspond to the criteria of inclusion. In addition, qualitative semi-structured interviews, aimed at describing the evolution of the adaptation to diabetes, were completed with six type 2 diabetic individuals from both groups. All the data was collected from March 2005 until January 2006 in the Eastern Townships region of Quebec, Canada. Data analysis was made using SPSS and NVivo. The Adaptation Model to Diabetes Stress (Gosselin and Bergeron, 1991) was used as the framework for the research.
Results: No significant differences were found at pretest between groups except on gender (X^2=4,68, p=0,043*), urine tested by a health care professional for protein (X^2 =6,525, p=0,038) and referred or not to the program (X^2=8,782, p=0,032*). Participants also reported higher psychological distress than the general population. There was a significant program effect on the receptivity and adaptation to treatment (F=4,581, p=0,040*). Two significant program x time interactions were found on self-devaluation (F=4,052, p=0,052*) and the level of physical activity at work or as the principal activity (F=5,306, p=0,027*). Knowledge improved at the end of both programs and remained eleven weeks after (F=10,775, p=0,002**). The diabetic individuals interviewed report emotions that described the adaptation stages and psychological distress through time. The most important challenge in diabetes self-management was nutrition. Empowerment seems to reduce the psychological distress.
Discussion: Consistent with International Diabetes Federation (2006), our research points out the need to evaluate distress and adaptation process while participating in a DSMEP. In our sample, non-insulin-treated diabetic individuals present less psychological distress and more positive diabetes attitude. Therefore, they are in a positive stage of adaptation and have better social support. They also have a better perception of nutrition. Due to this, the weekly program presents positive results regarding the Body Mass Index and the level of physical activity through time
Conclusion: There is a gap between the needs of the type 2 diabetic individuals and the needs health professionals think they have. Further researches on how diabetes education programs should integrate literacy, psychological distress and adaptation process.

P-1199

The attitudes of nurses and physicians toward diabetes and its management

S. Bosseri[1], N. Busra[1]
[1] *Suri Seri Begawan Hospital, Dept of Medicine, Kuala Belait, Brunei*

Background: Diabetes is a major health care problem in Brunei and almost every health care provider (HCP) has to deal with person with diabetes. The non specialists are seeing increasingly more diabetes. Their attitudes towards diabetes are thought to be more important in improving outcomes than their diabetes-specific knowledge
The aim of this study is to explore the attitude towards diabetes amongst different HCPs who are not specialized in diabetes
Methods: The test tool was DAS-3 (Diabetes Attitude Scale-3) by Michigan Diabetes Research Training Center. DAS-3 contains 5 subscales; to capture the perceptions of health care providers on the need for special training, the seriousness of type 2 diabetes, the value of tight control, the psychosocial impact of diabetes, and the need for patient autonomy.
Random sample of nurses and physicians, who are practicing at hospitals and peripheral clinics in Brunei Darussalam were asked to complete DAS-3, Diabetologists, diabetes educators and dietitians were not included.
Mean scores for each of the five subscales of the DAS-3 were calculated. Scores on each subscales of the DAS-3 were compared by age, sex, and job categories Statistical testing was done with SPSS Statistics software, Version 17.
Results: 255 respondents, 62% were females, 58% were nurses and 70% were less than 45 years old.
The score mean 1.63±0.43 (Need for special training), 2.55±0.68 (Seriousness of type 2 diabetes), 2.73±0.55, (Value of tight control), 2.35±0.525 (Psychological impact of diabetes), 2.44±0.48 (Patient autonomy)
The attitude was negative for all DAS-3 subscales, the worst was for the need for special training, and it was also negative across all the age, sex and job categories. However males had higher score for seriousness of type 2 diabetes, older people scored better for seriousness of type2 diabetes and for psychological impact of diabetes, and physicians appreciate more the seriousness of type 2 diabetes, value of tight control and patient autonomy. (See the table)

		Need for special training	Seriousness of type 2 diabetes	Value of tight control	Psychological impact of diabetes	Patient autonomy
Age	< 45	1.70±0.44	2.44±0.63	2.71±0.50	2.20±0.47	2.36±40
	≥ 45	1.56±0.40	2.6±0.70	2.74±0.56	2.49±0.57	2.40±0.58
	P value	0.81*	0.05*	0.50*	0.019*	0.76*
Sex	Female	1.67±0.43	2.47±0.65	1.63±0.43	2.30±0.49	2.44±0.47
	Male	1.58±0.42	2.68±0.70	2.77±0.59	2.41±0.58	2.43±0.50
	P value	0.103*	0.016*	0.115*	0.17*	0.97*
Job	Nurse	1.65±0.44	2.34±0.60	2.60±0.43	2.30±0.54	2.36±0.48
	Physician	1.60±0.44	2.92±0.72	3.00±0.65	2.46±0.50	2.56±0.49
	P value	0.428*	<0.0001**	<0.0001*	0.34*	0.001

**Mann-Whitney Test, ** One Way Anova*

Conclusion: The nurses and doctors appear to have a negative attitude towards diabetes, especially for the need for special training. Such negative attitudes may affect organization of effective diabetes care. Therefore we are faced with a challenging problem of influencing the attitudes of healthcare providers towards diabetes.

Use of Western education programmes in Non-Western population is not recommended: Need exists to develop locally relevant education programmes in local languages when English is not the first language

R. Garg[1], A.K. Agarwal[2], D. Goyal[3], J. Sturt[4], C. Beck[4]
[1] *Queen Mary's Hospital, Diabetes Unit, London, United Kingdom*
[2] *Manor Hospital Walsall, Department of Medicine, Walsall, United Kingdom*
[3] *SMS Medical College and Hospital, Department of Medicine, Jaipur, India*
[4] *Warwick UNiversity, Diabetes, Warwick, United Kingdom*

Introduction: India with largest number of people with diabetes has very limited and unstructured diabetes education. Western programmes may lose their impact by being over-complicated as people in developing countries have had no previous diabetes education. Diabetes education programmes are not available in India.Use of Western education programme in Non-Western population has not been studied before.
Aim: Impact of group education, using The Alphabet Education Programme, used in South Warwickshire in United Kingdom, was studied in our pilot study in India. We assessed the existing level of knowledge, self-efficacy and attitude of the people, biomedical outcomes [HbA1C, lipids, blood pressure (BP), weight and fasting blood glucose (FBG)] in people with type 2 diabetes mellitus. This was a pre and post intervention (3-months after).
Method: 8-hours of structured diabetes education, delivered in four, 2 hours long weekly sessions using the Alphabet Education Strategy was delivered in people with diabetes in Jaipur,India. Modified Michigan questionnaire were used to assess the impact of the education programmes before and 3-months after the end of the education programme. Blood results were collected (before and 3-months after last contact with educator).
Results: 15 participants (9 male,6 female) completed the study. Results are shown as mean±standard deviation. Their mean age was 61.4±7.24, duration of diabetes was 7.5 years. Changes in different parameter at baseline vs 3-months: HbA1C 7.6±1.1vs7.9±1.7, systolicBP 144±13vs142±13, diastolicBP was 89±7vs85.2±7.7, total cholesterol 187±46.4vs177±39.5, triglyceride152±77vs153±58,FBG 156.0±48.3vs160±48.6 (all units mg%). Participants' levels of knowledge and self-efficacy score improved immediately after the intervention but returned to baseline at 3-months.Attitude towards diabetes improved significantly (correct response rate 3.49 vs 3.77,p=0.01) and continued to improve.

Summary: The education programme was well attended and liked by the participants. Our pilot study show that an important component of diabetes care is missing in India. This is reflected in participants' baseline knowledge and self efficacy score which improved immediately after education but returned to base line at 3 months period. Attitude towards diabetes continued to improve after end of education. This shows the need of continued input. Improved attitude show the benefits of diabetes education. Use of non-familiar phrases in the Western programme and in assessment tool, to education naïve cohort, may have caused ambiguity in participants' responses and distorted the results.
Conclusion: Diabetes education programmes and assessment tools should be in local languages and use culturally sensitive phrases, understood by participants. These should be assessed and validated in terms of various outcomes. Use of Western education programmes in Non- Western population is not recommended.

No conflict of interest

P-1201

An educational programme for Diabetes Care: Climbing all the way up the Kirkpatrick hierarchy of evaluation of teaching

V. Patel[1], J. Morrissey[2], L. Varadhan[2], A. Gopinath[2], J.D. Lee[2], S. Shaikh[2], P. James[2], J. Wilson[2], R. Nair[2], P. Saravanan[2], P. Sear[2], M. Afsal[2]
[1] *NHS Westmidlands / Warwick Medical School, Clinical and Social care Leads, Birmingham, United Kingdom*
[2] *George Eliot Hospital NHS Trust, Diabetes Centre, Warwickshire, United Kingdom*

Background: Kirkpatrick's hierarchy of evaluation of teaching can be summarised into 4 levels: Reaction, Learning, Behaviour change and Outcomes. Usually educational programmes only evaluate at the first level. In clinical practice it is outcomes that we are trying to achieve.
Aim: To evaluate an innovative locally created clinical education strategy for diabetes care using Kirkpatrick's hierarchy.
Method: Alphabet Strategy is a patient-centred, evidence-based strategy based on the most important aspects of diabetes care: Advice, BP, Cholesterol, Diabetes Control, Eyecare, Footcare, Guardian Drugs.
Main results:
Level 1: Reaction
Healthcare professional Education programme
Delivered on over 20 occasions as part of a clinical education programme. Evaluations have been consistently positive.
GAIA Survey (Global Alphabet Strategy Implementation Audit)
Survey in 35 diabetes centres in 25 countries revealed that 57.5% of 146 healthcare professionals felt they were likely to adopt the strategy. 84.5% felt it was evidence-based and 88.0% practical.
Level 2: Knowledge Skills Attitudes acquired
Patient Education Programme
Knowledge of diabetes care was evaluated in 100 patients, which showed a significant improvement from 61.5 % to 80.0% ($p<0.01$).
i-DREAM Programme (interactive Diabetes Research Evidence Application in Management)
In 100 multi-professional healthcare workers, improvement in clinical management plans, application of evidence-based research and correct prescribing scores (69% before, 98% afterwards ($p<0.001$)) in 100 clinicians on case studies.
Level 3: Changes in Professional Practice
ASIAD Study (Alphabet Strategy- Indian Application for Diabetes)
Implementation in an economically deprived clinical setting in India. Within 4 months there was improvement in the 100 patients studied ($p<0.01$). Main changes were: improvement in cholesterol profile (60% to 90%), statin use (5% to 38%), aspirin use (6% to 71%), proteinuria assessment (48% to 93%).
Diabetes In-patient Care Evaluation
Data was collected on quality of care before and after implementing this strategy (100 patients). There was significant improvement in 9 of the 10 main parameters of care ($p<0.05$).
Level 4: Patient Outcomes
POEM Clinical Audit (Practice Of Evidence-based Medicine)
Over 5 years BP, Lipid profile, diabetes control, eye and feet screening improved. CVD risk score improved from 31.2% to 23.7% ($p < 0.05$).
Our strategy has been shown to produce outcomes comparable to the intensively- treated cohorts of the UKPDS and Steno-2 studies.
Conclusion: This free, public domain strategy has helped deliver high quality patient education and reduction in CVD risk, catering for all 4 levels of Kirkpatrick's Hierarchy for evaluating an education programme. Such a programme has considerable potential to improve diabetes care.

Community-based diabetes prevention and management education program in Nepal.

R. Bhandari[1], S. Bhattarai[1]
[1] *NMC Teaching Hospital, Community Medicine, Ktm, Nepal*

Aim: In this study we evaluated a 7-month community-based nonpharmacological lifestyle intervention to prevent/reduce the risk of developing diabetes and its complications in a resource-poor village in Nepal.
Methods: A total of 203 village inhabitants, comprising adults and youth aged 10-92 years, were provided educational intervention using "trained trainers." Culturally and linguistically appropriate health education messages addressed diet, physical activity, and knowledge improvement. The prevalence of diabetes and the effectiveness of the intervention were assessed using select parameters.
Results: The crude prevalences of diabetes and pre-diabetes among adults were 5.1 and 13.5%, respectively, while the prevalence of pre-diabetes in youth aged 10-17 years was 5.1%. Intervention reduced fasting blood glucose levels of pre-diabetic adults by 11%, pre-diabetic youth by 17%, and type 2 diabetic adults by 25%. Improvements in obesity parameters and dietary intake also occurred. A stepwise worsening of parameters progressing from the normoglycemic state to the impaired levels of pre-diabetes and diabetes was observed.
Conclusions: This study has charted the increasing prevalence of diabetes and pre-diabetes in Nepal. Educational intervention was successful in reducing some of the obesity parameters and improving dietary patterns of individuals with pre-diabetes and diabetes.

The role of the community pharmacist in Japan: knowledge, attitude, and confidence in diabetes education

H. Okada[1], M. Domichi[1], M. Nishi[1], K. Okazaki[1], N. Sakane[1]
[1] *Kyoto Medical Center, Preventive Medicine, Kyoto, Japan*

In Japan, the number of people with diabetes or a condition of impaired glucose tolerance increased by five million from 1997 to 2006. As the number of cases of diabetes and the cost of medical care rise, there is increasing pressure on the health care system to provide more intensive care to more patients with diabetes. Community pharmacists are well positioned to take an active role in diabetes education because they can interact readily with other members of the disease management team such as general practitioners. Community pharmacists are ideally placed to assist in the education of diabetes patients, because they are accessible, available, and in frequent contact. So, we conducted a survey involving community pharmacists diabetes care in Japan.
Aims: To describe Japanese pharmacists' involvement in diabetes care, to investigate pharmacists' attitude, and to clarify pharmacists' confidence regarding diabetes care education on advising diabetics in community pharmacy.
Methods: In total, ninety-six pharmacists based in Japan received a questionnaire. The questionnaire covered areas ranging from confidence in diabetes education skills, to the pharmacists' views on which services the pharmacy should offer to promote diabetes care.
Results: All ninety-six questionnaires were completed. Ninety-two percent of the pharmacists had experience of being asked for advice other than on medications. A large proportion questions were about the assessment of laboratory examinations, healthy diets, supplements, diabetes-related complications, physical exercise, and weight loss. Sixty-four percent of the pharmacists state their desire to support diabetics in community pharmacy. The scores of educational confidence regarding the diet and physical activity were lower than those for medication and communication skills. The scores to assess knowledge regarding the diet and physical activity were relatively lower than those for medication and clinical evidence. Sixty-seven percent of the pharmacists said questions on the assessment of blood test results were the most often asked.
Conclusion: The results suggest that most community pharmacists counsel diabetics on lifestyle issues, even though their educational skills concerning diet and exercise were lacking. To improve pharmacists' knowledge, attitude, and

confidence regarding diabetes education, may be effective a workshop training program for pharmacists.

The Abhilasha training programme for diabetes educators

B. Kalra[1], S. Kalra[2], S. Saluja[3], A. Sharma[4], M. Thakral[4]
[1] Bharti Hospital, Diabetology, Karnal, India
[2] Bharti Hospital, Endocrinology, Karnal, India
[3] Bharti Hospital, Dietetics, Karnal, India
[4] Bharti Hospital, Clinical research, Karnal, India

This paper reports on the results of a novel training programme, Abhilasha, designed for nurses and diabetes counsellors, by DRFHE (Dr Reddy's Foundation for Health Education), the CSR arm of Dr Reddy's Laboratories Ltd. The word abhilasha means aspiration in Hindi. The programme focuses on both the science of diabetes care and on motivational training, and is a two day long workshop spread over 12 working hours, utilizing lectures, group discussions, film shows, role-plays and presentations by participants.
22 participants completed the pilot training programme at Karnal, India. They included 7 men and 15 women, of whom 10 were nurses, 3 had postgraduate qualification, while 9 had other degrees and diplomas. All participants were aged, 30 years, and experience in diabetes care ranged from 3 months to 3 years. Average number of patients counselled per day varied from 20 to 60 per day.
Participants were given structured, pretested, Likert scale-based questionnaires prior to, and after the programme, to assess their felt needs, and their opinions about the workshop. Questions were asked about the type of pedagogic methods they preferred, and about the relative importance of the modules taught in Abhilasha.
Nurses rated diet (4.4±1.26), insulin motivation (3.8±1.23) and stress management (3.9±1.37) as important topics in a pre-workshop assessment. Non-nurses felt that insulin motivation (3.9±1.24), handling difficult patients (3.8±1.27) and knowledge of antidiabetic drugs (3.1±1.64) were important areas. Least importance was given by both nurses and non-nurses to reproductive/sexual care (1.5± 1.08, 2.0± 0.90) and eye care (1.70.95, 2.3±1.23).
Non-nurse participants rated role-play (3.0±1.21) as the best method of learning, while nurses felt that films (3.8±1.48) would be the most effective method of training.
On completion of the workshop, maximum rating was given to modules on Team work/building, and Motivation, by nurses (5.0±0.0 each). Non-nurses gave a similar rating to the module Understanding self and others.Least rating was given to Importance of work by nurses (4.2±1.26) and to rapport building and stress management by non-nurses (4.2±0.75). Each feedback mentioned that oral antidiabetic drugs and other drugs used in diabetes were not covered adequately.
The paper highlights the positive impact of the Abhilasha training programme. It shows the feasibility of conducting joint training programmes for nursing and non-nursing staff, covering both the science and art of diabetes education, using an eclectic mix of pedagogic methods. It points out the preferred teaching methods, and the relative importance that should be given to various topics while planning such programmes.
This training programme should be adopted in other parts of the world.

Education for diabetes self-management improves quality of life and reduces HbA1c levels in people with diabetes

F. Toti[1], D. Pema[1], N. Thanasko[1], E. Kulluri[2]
[1] University Hospital Centre "Mother Theresa", Endocrinology & Metabolic Diseases, Tirana, Albania
[2] Faculty of Psychology, Psychology, Tirana, Albania

Backgrounds and aims: Knowing about patient's quality of life (QoL) is becoming increasingly important in delivering diabetes care and education. The purpose of our study was to estimate if the diabetes education improves patient QoL and reduces HbA1c levels.
Material and methods: The study sample included diabetic patients who attended a 5-day educational sessions at the Service of Endocrinology in Tirana/Albania. Patients were evaluated regarding their QoL at baseline and 6 or 12 months after their hospitalization. The HbA1c was measured at baseline, 6 and 12 months later. The DQoL (Diabetes Quality of Life) measure was used to assess the subjective QoL. DQoL is a validated 46 items survey covering four areas of interest: satisfaction and impact of treatment, worry about the future effects of diabetes and worry about social issues, as well a single question about the general health. A satisfactory level is accepted as a transformed score >60.
Results: The group consisted of 395 patients, 139 males (35%) and 256 females, 97 (24.5%) type 1 diabetes, mean age 44.2±4.7 years, diabetes duration 11.4±5.4 years, treated with insulin in 45% of cases, with baseline HbA1c 9.1±1.67%, having decreased respectively to 8.5±1.1% at 6 months ($p<0.05$) and 8.02±1.23% at 12 months after hospitalization ($p<0.001$). DQoL at baseline was 56±4.5, 68.2±5.7 six months later and 75.1±3.5 at 12 months interval ($p<0.05$). The satisfaction with treatment and worry about the future were the most improved scores at six and 12 months after.
Conclusions: The education for diabetes self-management improves patients' Quality of Life as well as their metabolic control.

No conflict of interest

P-1206

Weight loss and improved glycemic control: results from an interdisciplinary group-based weight management program

Y. Mullan[1], A. Brozic[1], B. Murch[1]
[1] Hamilton Health Sciences Centre, Diabetes Care and Research Program, Hamilton, Canada

Background and aims: Weight management is an important element in diabetes care. However, losing weight is a real challenge for most people and balancing diabetes and weight issues can be overwhelming. Strategies such as caloric restriction, increased energy expenditure and behaviour modification have been demonstrated to be effective in terms of weight loss and glycemic control among individuals with type 2 diabetes. Group-based weight management programs provide many opportunities for individuals to learn strategies and to identify with others. This study examined weight and A1c changes in individuals participating in a group-based weight management program.
Materials and methods: We studied a cohort of overweight or obese individuals with type 2 diabetes who participated in a group-based weight management program in 2008. Objectives of the program included: 1) weight loss; 2) increased physical activity, 3) improved food choices; and 4) awareness of healthy eating behaviours. The program consisted of 13 weekly group sessions led by a dietitian, kinesiologist or social worker. Data was collected at the beginning and end of the program.
Results: 37 overweight or obese program participants (14 males, 23 females) of mean age 59.8 ± 8.5 yrs treated with diet alone (5.4%), oral agents alone (40.5%), insulin alone (29.7%) and insulin +oral agents (24.3%) were studied. Their mean weight, BMI, waist circumference and A1C were 108.6 ± 18.4 kg, 37.7 ± 6.6 kg/m^2, 121.6 ± 13.0 cm and 7.4 ± 0.8 respectively. 15 individuals (41% of cohort) were assessed before and following participation in the group-based weight management program. Compared to baseline, the mean change in weight, BMI, waist and A1C were – 3.6 ± 4.4 kg ($p<0.01$), -1.4 ± 1.5 kg/m^2 ($p<0.005$), -2.6 ± 4.7 cm ($p=0.051$) and – 0.5 ± 0.2 % ($p<0.005$) respectively. All participants reported feeling more confident in their ability to make changes in physical activity levels, dietary choices, and to cope with emotional triggers to eating. Identified areas of improvement with respect to the program included: 1) regular monitoring and feedback of food diaries; 2) more physical activity; 3) more behaviour modification strategies.
Conclusion: Participation in an interdisciplinary group-based weight management program which incorporated healthy eating, physical activity and behaviour modification along with diabetes management resulted in significant weight loss and improvement in glycemic control after 13 weeks. Based on program evaluation, the program has added: 1) individual consultations with a dietitian; 2) mandatory 30 minute physical activity with each session; and 3) involvement of a health psychologist.

Evaluation of a diabetes education program using group and individual strategies, Brazil

H.C. Torres[1], L.R. Alexandre[1], T. Oliveira[1]
[1] Universidade Federal de Minas Gerais, Enfermagem Aplicada, Belo Horizonte, Brazil

Objective: Compare two strategies in a Diabetes Education Program: individual and group education.
Method: Patients with type 2 diabetes at an outpatient department and enrolled in an education program of the teaching hospital of Belo Horizonte, state of Minas Gerais, were selected randomly and placed randomly into two groups: group education (54 patients) and individual education (50 patients). The group education was done in three meetings a month, which involved play and interactive dynamics. Simultaneously, another group was monitored individually. this was done for six months and the following elements were evaluated: Knowledge of Diabetes (DKN-A), Psychological Attitudes (ATT-19), Change in Behavior (ESM), Quality of Life (SF-36) and clinical evaluation (HbA1c and Body Mass Index – BMI) at the beginning (T0), after three months (T3) and 6 months (T6) of intervention.
Discussion: The change in eating habits and physical activity in patients with type 2 DM, as a result of the program evaluation in education in group and individual diabetes, subject to the improvement of knowledge and change of attitudes about the disease. The whole process aims to control blood glucose and improve the physical and mental conditions of individuals. The quest to achieve change in behavior to self care, developed in the program of education in groups, through education, health promotion and access to information from health professionals. Education and knowledge transfer is a difficult process, especially for diabetes, a disease that affects individuals of all ages, with different educational levels and with different social and environmental databases.
Results: The sample was made up of 104 patients with type 2 diabetes, with an average age of 60.6 years. The results of group and individual education were similar in the tests of attitude, change of behavior and quality of life. A reduction in the levels of HbA1c was observed in both groups, but only in the group education a statistically significant difference ($p = 0.012$) was found.
Conclusion: Both diabetes education programs were effective, however, group education was superior to individual education in obtaining better glycemic control.

P-1208

Evaluation of knowledge gained through diabetes education sessions in a rural area (Cameroon)

C. Nono[1]
[1] District Hospital of Bafang, Medical Private Wards, Bafang, Cameroon

Background and aims: Education is an essential tool in diabetes management. In Bafang rural area where there are no specialists, the local branch of Cameroon Diabetes Association developed a strategy to educate diabetes patients using vernacular when needed in its monthly meetings from November 2007 to October 2008. Using donation of posters mostly in English to a population whose first official language is French, and considering ignorance of members on diabetes management, there was a need to evaluate the knowledge gained by local association members that attended educative sessions. To develop tools that will increase participation in diabetes educational sessions in the rural area.
Methods: Use of a questionnaire (during a normal session) formulated at the National Center of Obesity and Endocrinology of Yaoundé Central Hospital, Cameroon, designed to evaluate therapeutic education.
Results: Present at the meeting were 25 persons, of whom 15 participated. 9 of these were registered members of the local association, 5 had diabetes but were new comers and 1 was not a diabetes patient. Of all registered members, 66% attended meetings only once, 16% attended 2 times, 13% attended 3 or 4 meetings, and only 5% attended > 5 meetings.
Most participants (73%) defined diabetes as an excess of sugar in the blood and identified a glycemia test as the test that permit to measure the quantity of sugar in the blood. Only 20% of participants related elevation of sugar to an impaired function of insulin and defined glycated hemoglobin as the test that helps to appreciate the variation of glycemia during the past three months; 2/3 of them were regular meeting attendants. 53% noted the target range goal for a fasting blood glucose test as 0.70-1.20 g/l; of whom 75% attended education sessions. Few (27%) identified the post prandial glycemia test target: of whom 75% were regular meeting attendants. The majority (80%) noted 140/70mmhg as the goal for adult blood pressure measuring and could enumerate some complications of diabetes. 47% perform glycemia tests only when need arise, 40% do it once per month and only 13% do it regularly, at least each week. All participants agreed on the benefit of physical activity to the lowering of blood glucose.
Conclusion: Knowledge about diabetes care was gained by those who attended education sessions as evidenced by specific knowledge about the disease and the appreciation of goals to achieve for its management. Significant knowledge deficits remain however, and delivery of more education is required. The provision of tools including glycemia testing at a lower cost, education materials associated with the rural context, and in particular translation in the local vernacular, are likely to assist in disease self-management.

P-1209

Knowledge, attitudes and practices regarding diabetes among diabetic patients in Multan

M.N.A. Jadoon[1], R. Yaqoob[1], M.A. Shehzad[1]
[1] Nishtar Medical College, Medicine Unit 3, Multan, Pakistan

Aim: The aim of this study was to assess the knowledge, attitudes and practices regarding diabetes among diabetic patients visiting a tertiary care hospital in Multan, Pakistan.
Methods: This cross-sectional study was carried out on 250 diabetic patients attending diabetes clinic at Nishtar hospital, Multan. The patients were interviewed using standardized questions. There were a total of 15 questions related to knowledge about diabetes covering description, symptoms, complication and prevention of diabetes. There were five questions each for attitude and practices of patients regarding diabetes. Consent was taken before interviewing the participants.
Results: The mean age of patients was 46.03 ± 11.37 years. Majority of the patients were female (55%), literate (59%), married (91%), non-smoker (88%) and from urban locality (73%). Body Mass Index of patients was 26.40 ± 4.6 and fasting blood glucose level was 176.21 ± 61.55 mg/dl. Analysis revealed that 65%, 73% and 54% of the respondents correctly answered 50% or more questions on knowledge, attitude and practices regarding diabetes. Knowledge and attitude were found to be positively correlated ($p<0.05$) while no correlation existed between attitude and practice. Sources of information of patients were physician (78%), T.V (32%), Newspaper (17%), and Radio (12%). 55% patients said they were careful about education regarding disease and 15% patients were of the view that they were being stigmatized.
Conclusion: The results show that an increase in knowledge will result in better attitude regarding disease, however, the same does not hold true for relationship between attitude and practice. The study suggests the need for structured diabetes educational programs to improve the knowledge, attitude and practices of the diabetes patients. This will lead to attainment of desired blood glucose levels in majority of patients, preventing complications.

[3] UNIFESP/EPM, Medicine, São Paulo, Brazil

Nutritional status of type 2 diabetic patients reflects how the intervention of the health professionals should be conducted in order to achive ideal glycemic control. The Diabetes Education and Control Group (DECG) from the Kidney and Hypertension Hospital - Federal University of São Paulo, Brazil proposes a new treatment strategy for type 2 diabetes mellitus using the concept of Weekly Mean Glycemia (WMG). It intends to direct the treatment based on a mean value of the blood glucose related to capillary glycemia tests performed on 3 consecutive days, 6 times a day. Data of WMG and Body Mass Index (BMI) of 85 patients followed by the DECG during 2007/08 were analysed.

Results: 15 registries had been excluded for lack of information resulting in a sample size of 60. Pre-intervention data: total sample BMI was 30,41kg/m2, being 28,38kg/m2 for men and 31,78 for the women; 15% of the total group had normal weight, 32% were overweight, and obesity grades I, II and III were respectively 32%, 17% and 5% considering World Health Organization classification criteria (1998). Among men, 52% were overweight and among women 38% showed obesity grade I and 22% obesity grade II. In relation to WMG, 65% started the treatment with a glycemia ≥ 150 mg/dl (bad control) being 27% men and 38% women. The mean WMG for the group before intervention was 188,57 mg/dl, being 184,01 mg/dl for men and 191,41 mg/dl for women. Post-intervention data: the mean counseling sections was 8,6±4,6 for patient. The mean BMI was 31,07 kg/m^2; men did not show mean alteration; the 3% increase (mean BMI of 32,74 kg/m$^{2)}$ was for the female group. In this group 8% migrated from obesity grade I to obesity grade II. In relation to WMG, 67% presented good control (< 150 mg/dl), showing an improvement of 32% in relation to the beginning of the treatment. Women showed a 24% reduction in WMG even starting the treatment with higher values than men (20%). Of the 33% maintaining bad control, 20% were women. In conclusion it can be said that there was a significant improvement in glycemic control; women showed bigger BMI values before and after treatment and for this period they also composed the bigger percentage in bad control. This indicates that for the female population, health care diabetes care professionals should change their approach in order to improve glycemic and weight control.

Impact of World Diabetes Day commemoration

V. Sreejith[1], S. N Kumar[1]
[1] Diabetes Care Centre, Diabetology, Trivandrum, India

Aim: To assess the impact of World Diabetes Day commemoration on diabetes care in our society.
Method: Data of the patients who registered for the diabetes day programme was compiled. Observations were made on the methods of diabetes awareness executed and its impact on the participants.
Results: World Diabetes Day was commemorated on 14th November at a community hall in Thiruvananthapuram. A prominent vernacular daily assisted in the programme by announcing the event and encouraging its readers to register. 400 patients registered for the programme. An awareness lecture was held with the help of audio visual presentation to enlighten the participants on comprehensive management of diabetes, which called for evaluation of status of diabetes, complications and associated diseases. 178 patients voluntarily opted and underwent the comprehensive evaluation. A magazine on diabetes care in the local language was also released during the occasion. All the patients were given a free copy of the magazine. 120 patients also bought a book on diabetes. Patients showed keen interest in the proceedings and were present throughout the entire duration of the programme which lasted four hours.
Discussion: Diabetes education plays an important part in management of diabetes. Patients need to be made aware about control of blood glucose and associated diseases. They also need to be motivated to undergo comprehensive management of diabetes, whereby the prevalence or risk for complications and associated diseases too need to be managed along with diabetes. The impact of World Diabetes Day commemoration in imparting such awareness is found to be huge. Huge crowd of four hundred patients participated in the programme. All of them showed keen interest in various education modalities like lectures, magazine and book on diabetes. 44% of the participants further underwent comprehensive evaluation of diabetes which helped to control their disease better.
Conclusions: World Diabetes Day commemoration has a huge impact on propagating diabetes awareness in the society. Participants are a group of motivated patients willing to undergo education and comprehensive management of diabetes.

Impact of physical activity: recreational and educational, on life quality of diabetics

A. Lopes Cançado[1], F. Oliveira Magalhães[1], T. Martins Severino[1], R. Gimenes Cardozo[1], D. Ribeiro m.c. oliveira[1], A.C. Martins[1], S. Pereira Duarte Nunes[1], E. Espinola Leite[1], F. Andrade Velar[1], N. Mesavilla Ferreira[1], S. Messias Freitas[1], A. Paula Silva[1]
[1] Universidade de Uberaba, Medicina, Uberaba, Brazil

Diabetes mellitus (DM) is considered one of the main chronic diseases nowadays due to its high prevalence and high rates of morbidity and mortality. Currently, it represents one of the main problems of public health in Brazil and in the world, highlighted by the increase in proportions epidemiological relating to the increase in rates of obesity and overweight in all age groups. In the city of Uberaba, there are 8 years, is realized activity physical-recreational and educational on World Day of diabetic.
Methods: In the population who participated in the event was performed questionnaire, on the knowledge about the disease, changes in habit, acceptance of the disease, glycemic control and weight, physical activity, number of medical consultations, personal hygiene, self-esteem and quality of life of these people. Data were analyzed by SPSS 14.0 program and through the chi-square with a significance level of 5%.
Results: Of the 126 participants from gymkhana, 55 (43.7%) did not reply to the questionnaire on changes in their lives offered by gymkhana. Among 71 individuals, were identified the following changes after participation of activity: 9 (12.7%) gained acceptance of the disease; 12 (16.9%) improved glycemic control; 4 (5.6%) monitored the weight; 2 (2.8%) refer change in the quality of life; 10 (14.1%) refer improved self-esteem; 8 (11.3%) relate two changes; 5 (7%) referred three changes; 7 (9.9%) refer four changes; 13 (18.3%) refer five changes or more; and 1 (1.4%) does not change. In this group, only 28.6% were diabetics. With respect to psychological aspects, 44 (34.9%) did not answer this question. Those who replied (82-65.1%), 16 (19.5%) reported low self-esteem; and 51 (62.2%) high self-esteem. In this group, only 32.1% were diabetics. There was no relationship between the change in quality of life and diabetes (X^2=7.570, p=0.477), nor esteem and diabetes (X^2=6.003, p=0.199).
Conclusions: Due to the small proportion of participants who had diabetes GIDIUBE (28.6%), was not possible to affirm the GIDIUBE significant relation with the improvement of quality of life only in the group of diabetic patients. However, there is a marked change in the quality of life of people in general participants of the project, improving their standard of living and mainly, to self-esteem. Therefore, the activities promoted in gymkhana diabetics of Uberaba are so important as regards the prevention and promotion of health of this municipality.

The current access to diabetes journals in the Middle East, hard copy versus online versions

M. Ibrahim[1], H.Y.A.M. Tantawi[1], A.M.R. Mohamed[1]
[1] Egyptian Diabetes Centre, Diabetes, Cairo, Egypt

Background: The Egyptian Diabetes Center is currently publishing the Clinical Diabetes Journal as an official Journal of the American Diabetes Association in the Middle East & North Africa in addition to an online journal (onlinediabetes Journal) on its official web site.
New technologies are advocated as a means to overcome current barriers to get enough diabetes knowledge for Diabetes Health Care providers. Little is known, however, about the current usage or attitudes towards such technologies among Diabetes Health Care Providers.
Methods: A 2-page questionnaire was mailed to 1076 Health Care Providers seen in a diverse group of 79 diabetes care clinics in Eastern Mediterranean Region affiliated with a single academic health center. Current technology use, attitudes towards new wireless technologies, self-reported adherence, and efficacy were assessed compared to hard copy journals.
Results: Respondents reported frequent use of the internet (72.1%), and email (54.5%), versus hard copy publications (27.9%). Barriers to technology adoption included privacy concerns (52.5%) and lack of confidence in technology (34.8%).
As for the advantages of the online journals: Speed 66.8%, Ease of searching 88.4%, Interactive 34.5%, Accessible 52.1%, Links 33.4%, Added Value 54.3%, Inexpensive 92.7%, Flexibility 55.4%.

Disadvantages of online journals: Difficulty in reading computer screens 34.3%, indexing 23.3%, archiving 22.3%, perishable Citation 24.6%, Authenticity 34.3%, search engines ignore PDF files 62.4%

Conclusions: Our results suggest that most Diabetes Health Care Providers would be willing to use innovative wireless technology to get their knowledge about diabetes & its related disorders. However, barriers to adoption among technologically marginalized Health Care Providers must also be addressed.

Therapeutic adherence as a result of effective health educational programs on diabetes

F. Moreira[1], C. Reis[1], M. Karnikowski[2], J. Dullius[3]
[1] Instituto Doce Desafio - UnB, Dietitian, Brasília - DF, Brazil
[2] Instituto Doce Desafio - UnB, Pharmacologist, Brasília - DF, Brazil
[3] Instituto Doce Desafio - UnB, Doce Desafio Program, Brasília - DF, Brazil

Introduction: Educational processes, once implemented might improve one's behavior in such way he or she might adopt a different life style in order to prevent complications from diabetes. An obstacle for a successful prognostic of diabetes is the low adherence of patients to conducted precognitive therapies.
Objective: to maintain the importance of a health education for diabetics as a tool for adherence and adequation in and to several available therapies. Methodology: review of the literature in the following database: LILACS, BVS/MS, ENSP, FSP, PAHO, e MEDLINE. Articles published from 2005 to 2009 were consulted.
Results and Discussion: Reviewed studies have proved the importance of an appropriate intervention through an individual approach, once the daily care with the disease depends on the diabetic. Thus, actions such as health promotion, identification of determining factors on the health-disease process and the treatment of diabetes being performed through activities of "self-assistance" shall undertake welfares for diabetics; this self-care has been pointed as the main objective of Health Educational Programs. In this context, the individual must be seen through a holistic approach, this takes into account his/her experiences, besides biological, psychological, social, cultural and economic aspects, as well as his/her capacity of self care.
Conclusion: The benefits of health education can be visible for patients, their families and society as long as people verify that a better perception of the diabetic about his/her own condition contributes significantly for a favorable prognostic of the disease.

Diabetes mellitus: a nutrition education case study

A. Sachs[1], F.S. Carvalho[2], C.B.B. Uezima[2], P.T. Fan[2], B.S. Pires[2], A. Pimazoni[2]
[1] UNIFESP/EPM, Preventive Medicine, São Paulo, Brazil
[2] UNIFESP/EPM, Diabetes Education Group, São Paulo, Brazil

Despite recent technological advances in diabetes diagnosis and treatment there is a percentage of patients with no treatment compliance. Patients usually complain about few professional contact time in the public health care system. The key to this problem is education which consists of a continuous and interactive process to promote health style changes aiming at better life quality. The following case study reports a life style change through improving food habits and glycemic control. Patient GSR, male, 52 years old and history of type 2 diabetes of 13 years, treatment with metformin 850mg 2x/day and glibenclamide. Patient was sent to the Education and diabetes Control Group (EDCG) - the Kidney and Hypertension Hospital from Federal University of São Paulo, Brazil. The group is consisted of a multidisciplinary team (physicians, nutritionists/dietitians, nurses, physical educators, psychologists and diabetes educators). The patient was followed for 7 months (weekly at the first 2 visits and monthly later on). At the begining a nutritional assessment was performed including data about anthropometry, social and demographic aspects, food habit, a 3 day food record diary and 3 day glycemic profile (glycemia before and after main meals).
Results: patient was overweight (body mass index of 28,9kg/m2), waist circunference of 102cm. The diet was high in carbohydrate and lipid and low in fiber. The mean glycemia was 161mg/dl with a glycemic variability of 48. On the basis of these information a food plan was established considering the patient´s food habit, financial situation aiming at an improvement of his nutritional status, glycemia and comorbidities´control. At each meeting a new nutritional assessment was performed as well a 24h-food record in order to observe compliance and doubts on following the prescriptions and glycemic profile. The guidelines were reinforced at each visit. After the EDCG intervention it was observed compliance in relation to the nutrition and physical activity plans. The anthropometric parameters were improved observing a loss of 5.6% on the initial weight and 2.2% on waist circumference. A significant change on glycemic indexes was also observed: mean glycemia of 99mg/dl and glycemic variability of 20, showing a reduction of 38% on the mean glycemia. It can be concluded that the compliance to a diabetes control plan is founded in education tools improved by a multidisciplinary team and that changing nutrition aspects can result in a better diabetes control.

Educational activities to improve compliance to treatment among elderly diabetic people: complicators and facilitators of the process

F. Moreira[1], J.A.N.E. Dullius[2], C.A.I.O. Reis[1], M. Karnikowski[3], M. Novaes[4]
[1] Instituto Doce Desafio - UnB, Dietitian, Brasília - DF, Brazil
[2] Instituto Doce Desafio - UnB, Physical Education, Brasília - DF, Brazil
[3] Universidade Catolica de Brasilia, Pharmacologist, Brasília - DF, Brazil
[4] University of Brasilia, Pharmacologist, Brasília - Distrito Federal, Brazil

Introduction: Effective actions for health education of the elderly diabetic increase the adherence to therapies used and, consequently, to clinical evolution. Objective: Evaluate educational actions which favorably improve adherence and clinical evolution of elderly diabetic patients.
Methodology: Review of literature on databases: LILACS, AdSaúde, HISA, PAHO, WHOLIS, MEDLINE and PubMed. Two groups of indices were used as follows: complicators and facilitators. Articles published from 2000 to 2008 were consulted.
Results: Complicators: educators without didactic-pedagogical skills; programs aiming at glycemic control only; patients: fear of the disease, complications and death; difficult access to medicines and materials; monitoring: professional-patient of mutual requirements relationship; programs not tailored according to patients profile. Facilitators: psycho-educational programs, taking into consideration social, emotional and communication components as well as motivational techniques as part of the operational proposal are associated with increase in quality of life; individual aspects considered (acceptance of the condition, self care, experience, ability to learn, motivation, self-confidence) propitious environment with resources available, qualified professionals and family participation; exchanging experiences increases self-esteem; multi-disciplinary and multi-professional approach; flexible educators and tolerance to frustrations about the results; achievable targets and evaluation of results.
Conclusion: Programs developed whose purpose is the health education for elderly diabetic patients, should be carried out with a multi-professional staff, and this one must be trained technically and pedagogically to perform their job efficiently, which is to help patients, keep health and face adversities triggered by the disease.

Planting seeds for grassroots: Diabetes among Utah Pacific Islanders

F. Pasi[1], I. Nash[2], B. Ralls[3], W. Stinner[4], R. Bullough[3]
[1] National Tongan American Society, Executive Director, Salt Lake City, USA
[2] National Tongan American Society, Program Manager, Salt Lake City, USA
[3] Utah Department of Health, Utah Diabetes Prevention and Control Program, Salt Lake City, USA
[4] Utah State University, Professor Emeritus, Salt Lake City, USA

Type 2 diabetes prevalence is especially high among Pacific Islanders. The International Obesity Taskforce has called Pacific Islanders "the fattest people in the world." The state of Utah has the highest percentage of Pacific Islanders in the mainland U.S., but Pacific Islanders still comprise less than one percent of the state population. Unfortunately, most public health interventions address the majority population, and not enough attention is given to the excessive rates of type 2 diabetes and its risk factors in the Pacific Islander community. Because this population comprises such a small minority, their voice is not well heard in the public health forum. Furthermore, many complications suffered by

Pacific Islanders might be prevented if more culturally appropriate interventions were available.
The National Tongan American Society (NTAS), a community-based organization headquartered in Salt Lake City, Utah, collects data to study the root causes of diabetes in this population. Data include quantitative data from the 2008 Healthy Living in the Utah Tongan Community (HLUTC), as well as qualitative data from focus groups and key informant interviews.
Self-reported data from the HLUTC (n=390) showed the cultural significance of offering and sharing food as signs of nurturance and respect. Over half (55%) of Pacific Islander adults were obese (body mass index of 30 and over), yet most (86%) perceived themselves to be only moderately overweight or not overweight at all. The survey also examined dietary habits. Statistically significant associations with frequency of sugared drink consumption ($p < .05$) and "fast food" consumption ($p < .05$) with obesity were found. Qualitative data from three focus groups showed the generally fatalistic belief that diabetes could not be prevented but pointed to the need to hear about prevention efforts from a trusted community member. Family history of type 2 diabetes is pervasive. Ongoing key informant interviews draw attention to the recurrent amputations, vision loss, and premature death related to diabetes.
NTAS works to reduce diabetes, its risk factors, and its complications. NTAS trains lay people to conduct no-charge health education classes at community centers, churches, and senior centers, where messages are well received. NTAS has had considerable success with its "Walk for Life" program, a weekly low-impact walking program. Despite limited resources, this type of grass roots effort is making a substantial difference in diabetes awareness and bringing about behavioral changes. NTAS is well integrated into the community and is, therefore, able to understand and incorporate cultural values into designing interventions that are more effective for Pacific Islanders than broadscale, more costly, interventions.

Successful and effective lay educators in diabetes - can a formal recruitment and selection process help you find them?

M.E. Carey[1], P. Mandalia[1], H. Daly[1], S. Cradock[2], Y. Doherty[3], R. Hale[4], S. Heller[5], K. Khunti[6], J. Phillips[7], T.C. Skinner[8], M. Stone[6], M.J. Davies[9]
[1] *University Hospitals of Leicester NHS Trust, Dept of Diabetes Research, Leicester, United Kingdom*
[2] *Portsmouth Hospitals NHS Trust/ Portsmouth City PCT, Dept of Diabetes, Portsmouth, United Kingdom*
[3] *North Tyneside General Hospital, Northumbria Diabetes Service, Tyne and Wear, United Kingdom*
[4] *Diabetes UK, Fareham Group, Hampshire, United Kingdom*
[5] *University of Sheffield, Dept of Medicine, Sheffield, United Kingdom*
[6] *University of Leicester, Dept of Health Sciences, Leicester, United Kingdom*
[7] *Expert Patients Programme, CIC, Bath, United Kingdom*
[8] *Combined Universities Centre for Rural Health, Geraldton, Western Australia, Australia*
[9] *University of Leicester, Dept of Cardiovascular Sciences, Leicester, United Kingdom*

Aims/objectives: To describe a formal recruitment and selection strategy for prospective lay educators (LEs) delivering structured diabetes education.
Methods: An action research study reporting in 2006, concluded that ad hoc recruitment was not effective for identifying individuals likely to make successful lay educators in diabetes. Building on its recommendations, a task group of the DESMOND Lay Educator Study developed a formal strategy for recruiting and selecting lay educators, based on procedures currently existing in the UK National Health Service. Advertising, recruitment, short listing, selection and appointment of lay educators took place over 12 weeks in the 6 Primary Care Trusts (PCTs) taking part in the study. In 2 PCTs with a significant ethnic minority population (Gujerati speaking in Leicester City, and Mirpuri Punjabi speaking in Peterborough), the recruitment process involved community workers and non-health agencies in order to contact hard to reach groups. Recruitment advertising used a variety of methods: nationally, awareness raising was conducted through the national patient organisation, Diabetes UK; locally, advertisements ran in pharmacies, GP practices, diabetes clinics, community centres, libraries, and local media.
Results: In total, 179 people expressed an interest in the lay educator role, of whom 108 were ineligible (e.g. incomplete contact data provided, living outside required geographical area). Out of 71 people receiving application packs, 29 returned these completed. Reasons for not making an application were generally linked to appreciation of the level of commitment required, and how this was prioritised against existing commitments. Of those completing an application: 72% were female; 41% were in the 45-59 age group; 38% had higher education qualifications; 66% described themselves as working, and 79% either had diabetes themselves, or had a family member with diabetes.
Conclusion: A formal recruitment strategy is a useful process in identifying high calibre candidates to be lay educators, and a positive tool for helping prospective applicants decide if the role is suited to them.

Diabetes education in China - a systematic review of the literature

Z. Lu[1]
[1] *Sir Run Run Shaw Hospital ZheJiang medical school, endocrinology, HangZhou, China*

Purpose: The purpose of this systematic review is to assess and summarize evidence and gaps in the literature regarding diabetes education in China.
Methods: Data sources:Chinese-language articles were searched for the terms Diabetes and Education, from Chongqing Weipu and Qinghua Tongfang database. English-language literatures were searched for terms Education, and China or Chinese from National Science and Technology Library (NSTL). The search was assisted by information professionals.
Articles selected were included in the review if the participants lived in mainland China and were diagnosed with diabetes; original articles; control trials; results from a diabetes education intervention to promote self management; HbA1c or behavior changes should be measured in the evaluation; and the articles had been published between 1989 and July 22nd 2008. Data extracted from the 33 studies found to be eligible. Relevant data on participants' demographics, interventions, outcomes and methodological quality were tabulated. Outcomes were classified as learning, behavior change, clinical improvement and increased health status and others. Studies were compared in terms of sample types and sizes, duration, and content and results of intervention.
Results: Among 3031articles (3031articles, 3018 in Chinese and 13 in English), 33 studies meet inclusion criteria. The participants were almost all from inpatient and outpatient department. The educators were physician, nurse, dietitian and psychologist, but only 13 studies conducted by a multidisciplinary team. The methods of diabetes education were very similar---Didactic teaching (class teaching or one to one teaching). Most studies selected knowledge and glycemic control as the outcome measurement, less than half studies reported behavior change. Positive effects of diabetes education on knowledge, and glycemic control were demonstrated in studies with short follow-up (3~6 months). Effects of interventions on behavior change, BMI, blood pressure, lipids, and medical cost were not clearly addressed; long-term outcomes and adherence to diabetes education was unknown because all the studies were of short duration.
Conclusions: Diabetes education had a great impact on glycemic control in China. Future studies on diabetes education should use more creative ways of diabetes education other than class teaching and one to one teaching; duration of follow up should last more than 1 year, and Long-term impact of diabetes education should be evaluated. More importantly, we have to evolve diabetes education from didactic teaching to more theoretically based empowerment models.

Medical student perceptions and acceptance of a multidisciplinary diabetes elective

A. Rizvi[1]
[1] *University of South Carolina School of Medicine, Department of Medicine, Columbia, USA*

Aims: To describe the development and student acceptance of a one-month rotation for fourth-year medical students that emphasizes diabetes as its major component.
Methods: The Diabetes and Endocrinology Senior Medicine rotation for fourth-year medical students at the University of South Carolina School of Medicine, Columbia, South Carolina, USA is structured as follows: 1) 4 half-days of outpatient work with an endocrinology faculty member, where the student sees patients in office practice and multifactorial therapy of diabetes is emphasized. The student is expected to develop a systematic diagnostic approach, physical examination, case presentation, and differential diagnosis skills 2) teaching

conferences (grand rounds, basic science and clinical conferences) 3) periodic review of relevant medical literature 4) diabetes and nutrition education classes at the Diabetes Education Program 5) pursue a clinical research project or write a brief review paper with preceptor guidance.
Results: 34 fourth-year medical students have completed the diabetes elective over a 52-month period. The student feedback and responses were evaluated by scores in different areas using the following scale: 1=poor, 2=borderline, 3=average, 4=good, 5=outstanding. The average overall score for the "effectiveness of the rotation for the teaching and practice of clinical medicine" was 4.7, for the "amount of knowledge gained and teaching provided" was 4.6, and for "improving diabetes management skills" was 4.9. In addition, all students wrote a project paper on a topic of their choice with recent references which helped to enhance their literature review and medical writing abilities.
Conclusions: A carefully-structured diabetes rotation for senior medical students is suitable and has a high level of acceptance. Devoting a month-long experience in developing expertise in diabetes, its complications like retinopathy, nephropathy, and neuropathy, and its co-morbidities like hypertension, dyslipidemia, and atherosclerotic disease can form a useful aspect of exposure to clinical medicine in medical school.

A patient-to-patient support program: experiment for improving life among people living with diabetes

G. Raymond[1], M. Rouches[1], C. Avril[1], C. Heritier[1]
[1] Association Française des Diabétiques, Executive Desk, Paris Cedex 11 , France

The French Organization for Diabetes is a patients' association with 130 000 members created in 1938 and state-approved in 1976. French Organization for Diabetes acts to improve quality of life of people living with diabetes, or at risk of developing diabetes, with the help of its 125 local associations.
Its training program enables volunteers of its network to become « patient experts » in order for them to become true qualified expert patients and use their knowledge to help others. They strengthen their skills to listen and inform other patients, talk about their own experience, and help participants to improve their quality of life.
Since 2008, this training program is experimented in 8 French districts, as part of a larger program entitled "Stimulation for a better quality of life for people living with diabetes". 35 volunteers have been trained to specifically intervene and run local peer support activities.
Aims: The program aims at coaching and supporting people living with diabetes to improve quality of their life, using their own experience with the disease.
Description and methods: Based on sharing experiences between patients, this program offers opportunities to participate in free peer support groups carried out by the expert patients trained. Groups are open to anybody living with diabetes, family or friends' circles.

- Peer support groups : a collective and dynamic action allowing participants to talk and share about their life experiences.
- Face to face meetings: individual action which aims at helping someone to find their personal issues.

These meetings focus on participants' environment and personal life projects without intervening in the treatment. It allows patients to express their denials, fears, and questions, and to better accept their condition by managing their daily life.
Results:

- Between June and September 2008 :
  - 35 « Patient experts » volunteers have been trained and skilled to « group meetings management » and to « face to face meetings » methods.
- Between September and December 2008 :
  - 58 peer support groups were organized
  - 246 participants registered
  - 75% of participants confirmed they were in need of such meetings and exchanges with other patients living with diabetes.

Conclusion: By its program, the French Organization for Diabetes confirms the need for peer support activities provided by trained expert patients. The participation is increasing. AFD confims its willingness to respond to a need for coordination of all local experiments which are conducted by all health stakeholders working in diabetes educational and patient peer support.

Spirituality in young people with diabetes: can it be measured?

T. Dunning[1], N. Parsian[1]
[1] Deakin University and Barwon Health, School of Nursing, Geelong, Australia

Background: Spirituality is a coping resource that helps people with diabetes accept the diagnosis, undertake appropriate self-care and develop personally.
Aim: The aim of the study was to develop and validate a tool to assess spirituality in young people with diabetes, the spirituality questionnaire (SQ).
Methods: The original 35 item questionnaire was developed after a review of the literature and discussion with relevant experts. The validation processes used were: content validity, construct validity using factor analysis, test-retest reliability, and internal consistency using Cronbach's alpha correlation coefficient.
Two sample groups aged 18-28 consisting of males and females were recruited:

1. 160 non-diabetic young adults to undertake the factor analysis component.
2. 25 young adults with diabetes to examine test-retest reliability and internal consistency.

Results: After content validity was established three items were removed from the questionnaire. Exploratory Factor Analysis was undertaken on the remaining 32 items. The communalities ranged between 0.54-0.82. Kaiser-Meyer-Olkin (KMO). Sampling adequacy was 0.9 (n=160). After undertaking four-factor solution, three items with loading <0.5 were deleted. Loadings of the remaining items ranged between 0.50–0.84, leaving four factors and 29 items:

1. "Self-awareness" (10 items).
2. "The importance of spiritual beliefs" (4 items).
3. "Spiritual practices" (6 items).
4. "Spiritual needs" (9 items).

Mean Cronbach's Alpha was 0.94: range 0.80-0.91. Test-retest reliability using Wilcoxon matched-pairs test revealed no significant differences between the responses over 8-10 weeks.
Conclusions: The SQ is valid and reliable and measures key aspects of spirituality: inner self, meaning in life, connectedness, and transformation. Diabetic and non-diabetic perceptions of spirituality were similar.

The effect of combined relax and music therapy on blood biochemical characters and blood pressure in patients with type 2 diabetes

F. Khoshkhou[1]
[1] Islamic Azad university of Zahedan, Nursing, Zahedan, Iran

Introduction and objectives: The purpose of this semi-experimental study was to evaluate the effect of combined relax and music therapy on blood biochemical characters and blood pressure on the diabetic patients through 3 months.
Materials and methods: 100 patients with diabetes type 2, according to subjects' characters, were invited to participate if they agreed and were randomized into the intervention and control group. The intervention group was stratified into 10 groups with 5 patients in each group. The intervention programs were carried through 10 sessions (music therapy and relax therapy consist of progressive muscle and breathing relaxation, imagery) and home practice. Intervention duration was 3 months. Blood pressure, total Cholesterol, Triglyceride, HbA1c and FBS were measured before and after the study. All patients also filled out the questionnaire related to biography and some diabetes risk factors before and after the study.
Results: A total of 75 patients (intervention group=30 and control group=45) completed the 3-month study. The result showed that Serum TG levels were similar in both groups at baseline and after study. Although blood pressure, HbA1c and Cholesterol decreased in intervention group, there were no significant difference between two groups. FBS significantly decreased in intervention group compared to control group (p=0.018).
Conclusion: We suggest that combined relax and music therapy is a feasible and effective treatment on diabetes; therefore, adding relax and music therapy to other treatments such as physical activity and diet, in people with type 2 diabetes, can help them to control and manage their diabetes better.

Evaluating the clinical skill in motivational interviewing in the treatment of type 2 diabetes

L. Minet[1], E.M. Lønvig[2], L. Sjøberg[2], L. Wagner[3], J.E. Henriksen[1]
[1] Odense University Hospital, Endocrinology M, Odense C, Denmark
[2] Odense University Hospital, Quality, Odense C, Denmark
[3] University of Southern Denmark, Research Unit of Nursing Institute of Clinical Research, Odense C, Denmark

Aim: To evaluate the clinical skill in the practice of motivational interviewing. This evaluation is a part of the implementation of a randomised control trial studying the effect of a 1 year self care behaviour intervention programme based on motivational interviewing in chronically ill patients with type 2 diabetes.
Motivational interviewing has proved effective in eliciting behaviour change in a broad range of behavioural problems and diseases. Further research is needed to establish knowledge about how motivational interviewing education of health care providers is performed and how the method is used in client counselling.
Method: This evaluation included training of health care provider, supervision, videotaping and evaluation by Motivational Interviewing Treatment Integrity (MITI) Coding System. The evaluation method was used to provide a comprehensive examination of interviewer behaviours and to yield feedback that can be used to increase clinical skill in the practice of motivational interviewing. In the MITI evaluation a random 20-minute segment from videotaped interviews from each health care provider practicing motivational interviewing was assessed to be used in the MITI coding. The training and supervision was carried out by a MI-trainer from the Motivational Interviewing Network of Trainers in Nordic countries.
Result: Prior to the intervention programme 2 diabetes specialist nurses, 1 dietician and 1 physiotherapist were educated in motivational interviewing. The course content 5 days' theoretical introduction to strategies in motivational interviewing, and critical dimensions of motivational interviewing: empathy and the motivational interviewing spirit. The course was followed by 3 practical coaching sessions every 3rd month for 24 months. After the 5 days course the health care providers were individually supervised by the MI-trainer in 10 real patient situations in a period of 18 month. For each health care provider performing motivational interviewing 5 sessions were videotaped in a period of 36 months. In the MITI coding the global interviewers ratings were 4-5 point given on a 5 point Likert scale. The behaviour counts showed that open questions and complex reflection were used.
Discussion: This evaluation demonstrates high competency in using motivational interviewing among the health care providers in a self care behaviour intervention programme in patient with type 2 diabetes. MITI is proposed to be used in the feedback process as a way for health care providers to improve their use of motivational interviewing in clinical practice. This research imply the importance of close supervision of the health care provider performing motivational interviewing since conducting motivational interviewing involve a high dependence on individual agents and individual expertise.

Is depression a serious problem among hospitalized patients with diabetes mellitus?

W. Karnafel[1], A.B. Niebisz[1], M. Jasik[1], A. Cacko[1], M. Cenkier[1], M. Cacko[1]
[1] Medical University of Warsaw, Department of Gastroenterology and Metabolic Diseases, Warsaw, Poland

Introduction: Diabetes mellitus (DM) is a chronic disease which affects patients' mental health. Comorbid depression has a significant impact on metabolic control, quality of life and mortality among patients with DM.
Aims: The aim of the study was to assess prevalence of depression symptoms in population of individuals with diagnosed DM hospitalized in inpatient ward, and to display relation between occurrence of depression symptoms and lifestyle, applied treatment and presence of DM chronic complications.
Methods: Into the study were included 80 patients (40 females, med. age – 58,3 ± 13,9 years) with diagnosed DM hospitalized in Department of Gastroenterology and Metabolic Diseases Medical University of Warsaw. Exclusion criteria were diagnosed malignant, systemic or neurodegenerative diseases. Control group was created by 56 patients (28 females, med. age – 49,1 ± 16,8 years) of Department without diagnosed DM. Obtained, using Beck Depression Inventory, frequencies of depression symptoms among both groups of patients were compared. Next were analyzed selected components of lifestyle, duration of DM, treatment scheme and presence of DM chronic complications among patients with and without depression symptoms.
Results: No important difference in prevalence of depression symptoms between studied and control group was found (77,5% vs 73,2%; p>0,05). Among patients with DM more often were observed symptoms of severe depression (7,5% vs 1,8%) but it was not significant (p>0,05). There were found significant positive correlation between presence of depression symptoms and low motion activity (32,3% vs 5,6%), lack of active interests (56,5% vs 11,1%), low education level and presence of diabetic foot ulcer (22,6% vs 0%).
Conclusions: Symptoms of depression occur in about 3 of 4 hospitalized individuals, proving the problem's generality. Among patients with DM it is particularly important to focus on recognizing severe depression. Symptoms of depression more often occur among patients with diabetic foot ulcer and showing lower life activity.

Phone call as an intervention for improving walking practice in type 2 diabetes

M. Fernandes Jucá[1], C.H.F. Fonceca-Guedes[1], P.L. Bellodi[1], I.J. Benseñor[1], C.R. Carvalho[1], R.M. Daud-Gallotti[1], I.F.L.C. Tibério[1]
[1] HCFMUSP, Internal Medicine, São Paulo, Brazil

Aims: The aims of this study were to investigate the impact of phone call support as a tool for promoting daily physical activity during a period of six weeks in a group of type 2 diabetes patients with poor glycemic control (A_{1C} ≥8%).
Methods: A randomized controlled trial enrolling 48 type 2 diabetic patients with poor glycemic control (HbA_{1C} Hg ≥8%) was conducted at an Internal Medicine ambulatory from January 2008 to October 2008. The intervention patients received phone calls, during six weeks, in order to improve walking activity. Control patients received only one telephone call. The number of steps was recorded every week using pedometers. The outcome was the variation of the number of steps between the first and sixth week of the intervention. Information about clinical, metabolic and demographic data, socio-economic status, personality profile, quality of life and depression symptoms were obtained. All patients were analyzed based on their original assignments as an intention-to-treat analysis.
Results: There were no differences at the baseline values of all clinical, socio-demographic and anthropometric aspects between the two groups as well as for the other possible interfering variables that may modify the response for the stimuli of improving walking activity. The phone call support showed an efficacy of 90%. The relative risk reduction was 75% and it was necessary to give a phone call support for three patients in order to obtain an increment in the number of the steps between the sixth and the first week of the study (NNT=3.0).
Discussion/conclusions: In order to reduce the health impact of type 2 diabetes it is required to focus on optimization of the treatment of these patients and in the primary prevention targets related to improving physical activity. Walking is the most popular leisure time activity. However, these patients naturally walk at a speed that is slower than that associated with minimal intensity required to obtain health benefits. In the present study we showed that the phone call support was an efficient intervention for promoting walking activity during six weeks in type 2 diabetic patients with poor glycemic control.

The effect of diabetes and its control on susceptibility to learned helplessness in streptozotocin-induced diabetes rats

Y. Go[1], H. Kitaoka[1]
[1] Seikeikai Hosipital, internal medicine, Sakai, Japan

Aims: In order to examine the mechanism linking diabetes to depression, specifically whether diabetic rats in good glycemic control versus those in hyperglycemia, or subject to exposed alternative periods of hyper and hypoglycemia, are different at risk of affective disorder. We induced learned

helplessness, as model of depression, is indicated the rate of cognitive processing.
Methods: Using the streptzotocin rats receiving insulin NPH or saline, totally 37 rats, were divided into 4 types of glycemic control groups, Group A (good), B (hypo-hyper), C (untreated), D (controls).
The bodyweight, the blood glucose concentration and HbA1c were measured. And all animals were placed in a learned helplessness paradigm,
Forced swimming test (FST): the scorer would rate the rat's behavior each 5 second period, as one of the following four behaviors: immobility and another action. We examined the differences in the length of immobility (a key marker of learned helplessness) with the analysis using Tukey-Kramer multiple comparison.
Results: Glycemic control: Group A had nearly kept smaller change of blood glucose throughout the day. Group B blood glucose showed a very steep fall from 475.8 ± 193.2 (mean ± SD) mg/dl to 42.8 ± 22.6 mg/dl within three hours after the insulin injection. Mean HbA1c of the diabetic group without insulin treatment significantly increased from 5.9 ± 1.3 to 8.7 ± 4.0 % ($p < 0.0001$). In diabetic groups receiving insulin injection once a day or twice a day, the level of HbA1c significantly decreased from 5.6 ± 1.0 to 3.8 ± 0.6 % and 6.4 ± 1.7 to 3.7 ± 0.5 % respectively. There was no difference in the levels of HbA1c before treatment and after treatment between the groups with one daily injection and two daily injection of insulin.
The bodyweight in A and B groups was not significantly different compared with that in non diabetic control group ($P = 0.001, 0.001$). Group C is significantly low compared with that in Group D (< 0.0001).
FST: There were trends for counts of immobility to be higher in all 3 diabetic groups compared to Group D, especially in Group B, the mean count of immobility is significantly high compared with Group D (< 0.001). There is no significant difference between 4 groups in the mean counts of swimming. The climbing was significantly low in Group C compared to Group D (< 0.001).
Conclusion: The rats which had been exposed to hypoglycemia and hyperglycemia are more likely to develop learned helplessness than good glycemic control rats. These investigations are thought to be interesting to examine the relationship between diabetes and depression, and suggested that acute changes in glycemic control could be the mechanism of susceptibility to affective disorder.

Psychonutritional intervention to improve the level of information, life quality, treatment adherence, self-efficacy and family support in patients with type 2 diabetes

R. Guzman Saldaña[1], Z. Calderon[2], J. Vazquez Olvera[3], T.J. Saucedo Molina[2], M.A. Morales de Teresa[4], A. Peña Irecta[2], A. Omaña Covarrubias[5]
[1] *Universidad Autonoma del Estado de Hidalgo, Area Academica de Psicologia, Pachuca, Mexico*
[2] *Universidad Autonoma del Estado de Hidalgo, Area Academica de Nutricion, Pachuca, Mexico*
[3] *Universidad Autonoma del Estado de Hidalgo, Student of Licenciatura en Psicologia, Pachuca, Mexico*
[4] *Resultados Medicos Desarrollo e Investigacion, Research Director, Pachuca, Mexico*
[5] *Universidad Autonoma del Estado de Hidalgo, Student of Licenciatura en Nutricion, Pachuca, Mexico*

The type 2 diabetes is the main reason of morbi - mortality in the world and particulary in Mexico. The treatment is based on changes in the way of life, this is difficult to achieve in the majority of cases, which is reflected in the therapeutic adherence and in a negative impact in the quality of treatment in general. The support both of the family and of the multidisciplinary health team is fundamental to achieve the control of the disease.
Aims: Determining the effectiveness of the psychonutritional intervention to improve the level of information, the quality of life, the adherence treatment, self-efficacy and the family support, in people with type 2 diabetes and their relatives.
Methods: In this study the subjects of study were recruited in a voluntary way, the only one requirement was that they were present at health center of Actopan and Tizayuca, Hidalgo. It was shaped for 22 persons and it was divided in 2 groups, in the first group the people with type 2 diabetes and their relatives received a psychoeducate intervention - conductual, and the group 2 received the traditional medical treatment.
The instruments were applied: Questionnaire of Information, questionnaire of Quality of Life (DQOL), the Questionnaire of self-efficacy for Diabetics. The Family APGAR and the Instrument to evaluate Family Support in type 2 diabetes. The adherence to the treatment was evaluated indirectly with the evaluation of glycated haemoblobin, the Body Mass Index (BMI) and levels of blood glucose.
Results: The analysis results showed the psychonutritional intervention is effective when we evaluated other variables, for example the level of information in group 2 changed from 6 to 10 points after the intervention, the same situation occured in the type 2 diabetes relatives changed from 6.5 to 9.5 points. The glycated haemoglobin levels decreased until 6.4% after the intervention.
Discussion/conclusion: the psychonutritional intervention in type 2 diabetes patients influence in the treatment and control of disease.

Association analysis of HLA-DRB1 in type 1 diabetes Romanian families

C. Guja[1], L. Guja[1], C. Ionescu-Tirgoviste[1]
[1] *Institute of Diabetes Nutrition and Metabolic Diseases "NC Paulescu", 1st Clinic of Diabetes, Bucharest, Romania*

Background and Aim: Type 1 diabetes (T1DM) is a chronic autoimmune disease conditioned by multiple genetic and environmental factors. The major diabetes genes reported so far belong to the class II MHC region, DQB1 and DRB1 loci. For both these two loci, diabetogenic and protective alleles were described. Our aim was to assess the effect of some HLA-DRB1 alleles on T1DM risk in the Romanian population, one with the lowest reported incidence of T1DM in Europe.
Materials and methods: The study group comprised 1,515 individuals with 439 T1D patients (206 male/224 female) and 1,076 unaffected first degree relatives. On this study group, comprehensive typing of HLA/DRB1 alleles was performed. Genotyping was done by PCR-SSOP. Data were analysed using the Transmission Disequilibrium Test (TDT) using Stata® 8.1 (http://www.stata.com/). Subsequently, primary data were analyzed by conditional logistic regression using the high resolution HLA-DQB1 genotypes for the entire study group.
Results: We previously reported a strong diabetogenic effect for both DRB1*03 and DRB1*04, as for all Caucasian populations. We found a significant decreased transmission to diabetics for HLA-DRB1*07 (25.3% transmission, $p_{TDT} = 6.5x10^{-7}$), DRB1*10 (20% transmission, $p_{TDT} = 0.003$), DRB1*11 (20.15% transmission, $p_{TDT} = 4.81 \times 10^{-12}$), DRB1*12 (5.56% transmission, $p_{TDT} = 0.0002$), DRB1*13 (25.29% transmission, $p_{TDT} = 4.03 \times 10^{-6}$), DRB1*14 (10.26% transmission, $p_{TDT} = 6.91\% \times 10^{-7}$) and DRB1*15 (10.81% transmission, $p_{TDT} = 1.56\% \times 10^{-11}$), suggesting their protective nature. The transmission of the same alleles to unaffected siblings was not significantly different from 50%. Overall the effect of HLA-DRB1 was strongly significant, with a $p = 3.72x10^{-46}$. This effect was reduced (but remained significant) after conditional logistic regression analysis (taking into account the current HLA-DQB1 genotypes) with $p = 9.12x10^{-8}$. After this analysis, DRB1*07 (RR of 0.04), DRB1*12 (RR of 0.03) and DRB1*15 (RR of 0.08) retained an independent protective effect.
Discussion/conclusion: Our results indicate a strong diabetogenic effect of DRB1*03 and DRB1*04 and a possible protective effect of HLA-DRB1*07, HLA-DRB1*12, and HLA-DRB1*15 alleles for T1DM appearance in the Romanian population. We also showed that the effect is independent from the influence of known protective HLA-DQB1 alleles. However, the analysis of a much larger family study group from the Romanian population is required before drawing a final conclusion.

The role of cytokine gene polymorphism, HLA typing and beta-cell autoimmunity in the risk of celiac disease in children with type 1 diabetes mellitus

J. Pedras[1], M. Minkina-Pedras[2], P. Jarosz-Chobot[2], J. Polanska[3], U. Siekiera[4]
[1] *District Specialist Hospital, Department of Cardiology, Tychy, Poland*
[2] *Upper Silesia Centre for Child Health, Department of Paediatric Endocrinology and Diabetes, Katowice, Poland*
[3] *The Silesian University of Technology, Institute of Automatic Control, Gliwice, Poland*
[4] *Regional Blood Center, HLA and Immunology Lab, Katowice, Poland*

Background: Some genetic polymorphisms and immunological associations may significantly modify the risk of celiac disease (CD) in subjects with type 1 diabetes mellitus (T1DM).
Aims: The aim of the study was to evaluate genetic predisposition in class II HLA and by gene polymorphism of TNF-a, IFN-γ, IL-6, IL-10, as well as to investigate relationship between the risk of celiac disease and ß-cell associated antibodies.
Material and methods: After screening in 33 children T1DM with a positive tTG antibodies. histopathology, HLA genes DR, DQ, cytokine polymorphisms and antibodies: IAA, IA2A, GADA were analyzed. The group with celiac disease and T1DM (CDM) was compared to the groups with only: T1DM (DM), CD (C) and healthy controls (K)
Results: Silent CD in 24 (72.72%) and a latent form in 9 (27.27%) cases was diagnosed. The onset of T1DM was 6.41± 3.27 years. CD occurred after 1,28± 1,34 year of T1DM duration. The haplotype DRB1*03 DQB1*02 was presented in 25 children (75.76%), significantly more frequent than in the group DM (p=0,01) and was related to the risk of CD, OR=3,54 (1,28-9,81). GADA (84,84%) were found in the CDM-group more often than IA2A (69.69%) and IAA (57.57%) or GADA in the CD-group (66.67%). Positive statistical significance in genotype in TNF-a was also observed between group CDM and DM (p=0,02). The multiple regression model for risk of CD in children with T1DM prove great importance of genotype TNF-A role in this process (OR=6.67, p=0.004).
Conclusions: The risk of CD in children with T1DM is modified significantly by a variant of allele TNF-a – 308A and presence of haplotype DRB1*03 DQB1*02. Due to their population linkage, it is not possible to determine which of these two is of greater significance. Presence of antibodies GADA seem to be an important factor for the development of CD.

P-1231

Thyroid and coeliac autoimmunity in first degree relatives of type 1 diabetic patients

L. González Rivero[1], E. Cabrera Rode[1]
[1] *National Institute Of Endocrinology, Diabetes Immunology, Ciudad de la Habana, Cuba*

In Cuba, the worldwide proved presence of extrapancreatic autoimmunity in first degree relatives (FDR) of type 1 diabetic patients has not been established yet. Frequencies of silent or subclinical autoimmune thyroiditis (AT) and coeliac disease (CD) among that population remain unknown. However their significance for health is not negligible.
Aims: To determine the frequencies of positive thyroid peroxidase autoantibody (AbTPO) and tissue transglutaminase antibody (AbtTG) among FDR of type 1 diabetic patients in the National Institute of Endocrinology. Also to set up a possible association between their confirmed thyroid and coeliac autoantibodies with previusly non-detected clinical features and with presented glutamic acid decarboxylase-65 (GAD65) and tyrosine phosphatase insulinoma antigen-2 (IA-2) autoantibodies.
Methods: A descriptive, prospective research was developed over a sufficiently large sample of 570 FDR: ages between 2 and 65 years and absence of chronic illness requiring immunosuppressive drugs. A questionnaire was applied seeking for gastrointestinal symptoms and/or thyroid dysfunction. Clinical exam and serum lab tests were performed: AbTPO measured by RIA; AbtTG detected by immunochromatographic assay; GAD65 and IA-2, measured by IRMA. Descriptive statistical analysis was made.
Results: Frequency of AbTPO amoung FDR was 6.15% and AbtTG expressed positive in 3.3% of these subjects. There was no association between found AbTPO and AbtTG with positive pancreatic GAD and IA-2 antibodies. Undetected tachycardia and goiter were significantly associated with positive AbTPO FDR group. No clinical manifestation of CD could be linked with positive AbtTG. Relatives with thyroid autoimmunity were advised for follow-up. Those with positive AbtTG were submitted to intestinal biopsy.
Conclusion: Serological screening amoung FDR may be useful for early detection of CD, which has an accurate treatment in gluten free diet. AT is detectable even before impairment of hormonal function starts. These findings suggested that the screening for thyroid and other organ-specific diseases-related autoantibodies, in type 1 diabetes close relatives, may ensure useful information about the probable clinical course of those entities.

P-1232

The effect of HLA-B on type 1 diabetes genetic susceptibility in Romania

C. Guja[1], L. Guja[1], C. Ionescu-Tirgoviste[1]
[1] *Institute of Diabetes Nutrition and Metabolic Diseases "NC Paulescu", 1st Clinic of Diabetes, Bucharest, Romania*

Background and aim: Type 1 diabetes (T1DM) is a chronic autoimmune disease determined both by genetic and environmental factors. The major diabetes genes currently reported are HLA DQB1 and DRB1 from the class II MHC region. Meanwhile, there is data for an independent effect of some class I HLA A and B alleles. In order to assess the potential independent role of HLA-B on T1DM risk in Romania (country with one of the lowest reported incidences of T1DM in Europe), we performed a high resolution HLA-B typing in 423 nuclear families.
Methods: The study group comprised 1,515 individuals with 439 T1DM patients (206 male/224 female) and 1,076 unaffected first degree relatives. Genotyping was done by PCR-SSOP. Data were analysed using the Transmission Disequilibrium Test (TDT) using Stata® 8.1 (http://www.stata.com). Subsequently, primary HLA-B data were analysed by conditional logistic regression using the high resolution HLA-DQB1 and -DRB1 genotypes for the entire study group.
Results: Primary data showed increased transmission to diabetics of HLA-B*08 (71.3% transmission, $p_{TDT} = 6.5 \times 10^{-7}$), B*15 (69.2% transmission, $p_{TDT} = 0.005$), B*41 (74.1% transmission, $p_{TDT} = 0.0002$), and B*50 (85.7% transmission, $p_{TDT} = 0.00002$) and decreased transmission for B*52 (25.8% transmission, $p_{TDT} = 0.007$). The transmission of the same alleles to unaffected siblings was not significantly different from the expected 50%. Overall the effect of HLA-B was significant with a $p = 7.42 \times 10^{-13}$. However, the conditional logistic regression analysis (taking into account the current HLA-DQB1 and -DRB1 genotypes) did not support an independent effect for the HLA-B locus, the significance being reduced to $p = 0.1928$. After this analysis, the only alleles that retained a degree of independent effect were B*50 with a RR of 2.25 and B*58 with a RR of 4.80. With a RR of only 1.33, we could not confirm the association with B*39, reported for other Caucasian populations.
Discussion/conclusion: We were unable to evidence an independent effect of the HLA-B locus in a large dataset of Romanian T1DM families. However, it is still possible that such an effect exists and could be detected using a much larger Romanian T1DM family cohort.

Association of HLA-DRB1/DQB1 alleles and haplotypes with susceptibility to type 1 diabetes among Tunisians

M. Stayoussef[1], M. Chadli[2], J. Ben Mansour[1], H. Ben Said[3], W.Y. Almawi[4], L. Chaieb[5], T. Mahjoub[1]
[1] *Faculty of Pharmacy, Research Unit of Hematological and Autoimmune Diseases, Monastir, Tunisia*
[2] *Ibn El Jazzar Medical Faculty, Research Unit of Endocrine Genetics, Sousse, Tunisia*
[3] *Farhat Hached Hospital, Pediatric Department, Sousse, Tunisia*
[4] *Arabian Gulf University, College of Medicine and Medical Sciences, Manama, Bahrain*
[5] *Medical school Sousse, Endocrinology, Sousse, Tunisia*

Aims: HLA class II genes contribute to the genetic susceptibility of type 1 diabetes (T1D), and both susceptible and protective alleles and haplotypes were implicated with its pathogenesis. This study investigated the heterogeneity in HLA class II haplotypes distribution among Tunisian T1D patients.
Methods: Subjects comprised 88 T1D patients and 112 healthy controls. HLA DBR1 and DQB1 genotyping was done by PCR-SSP.

Results: Significant DRB1 and DQB1allelic differences were seen between T1D patients and controls, which comprised DRB1*030101 and DQB1*0302 which were higher, and DRB1*070101, DRB1*110101, DQB1*030101, and DQB1*060101 which were lower in patients than in control subjects. In addition, the frequencies of DRB1*030101-DQB1*0201, and DRB1*040101-DQB1*0302, and those of DRB1*070101-DQB1*0201 and DRB1*110101-DQB1*030101 haplotypes were lower in T1D patients than control subjects. Logistic regression analysis revealed the positive association of DRB1*030101-DQB1*0201, and DRB1*040101-DQB1*0302, and the negative association of only DRB1*070101-DQB1*0201 haplotypes with T1D. Furthermore, significantly increased prevalence of DRB1*030101-DQB1*0201 homozygotes and heterozygotes, as well as DRB1*040101-DQB1*0302 homozygotes were seen in T1D subjects than in control subjects.
Conclusion: Our results confirm the association of specific HLA-DR and –DQ alleles and haplotypes with T1D, with similar and unique haplotypes identified that distinguish Tunisians from other Caucasians. These findings highlight the need for evaluation of the contribution of HLA class II to the genetic susceptibility to T1D with regard to specific HLA haplotypes, and also to the ethnic origin and racial background.

Case-control study of polymorphism of CTLA4 +49 A/G gene in type 1 diabetes in Tunisia

J. Ben Mansour[1], L. Chaieb[2], M. Stayoussef[1], M. Chadli[3], H. Ben Said[4], W.Y. Almawi[5], T. Mahjoub[1]
[1] *Faculty of Pharmacy, Research unit of Hematological and Autoimmune Diseases, Monastir, Tunisia*
[2] *Medical school Sousse, Endocrinology, Sousse, Tunisia*
[3] *Ibn El Jazzar Medical Faculty, Research Unit of Molecular Endocrinology, Sousse, Tunisia*
[4] *Farhat Hached Hospital, Pediatric department, Sousse, Tunisia*
[5] *Arabian Gulf University, College of Medicine and Medical Sciences, Manama, Bahrain*

Type 1 diabetes (T1D) is a complex autoimmune disease. Several genetic loci have been implicated in the susceptibility to this illness. Evaluated was the role of the CTLA4 exon 1 A49G polymorphism and its role as a risk factor for T1D in our population. DNA from 120 patients with T1D and 96 control individuals were genotyped for CTLA4 exon 1 polymorphism by polymerase chain reaction (PCR) amplification–restriction enzyme analysis and PCR amplification that used sequence-specific primers, respectively. Patients were nonobese and < 26 years old. The CTLA4 G allele was found to be more frequently present in patients with T1D (36.4%) as compared with its frequency in control individuals (18.5%). The GG genotype was also significantly higher among patients (17.6%) than in controls (7.2%). X^2 analysis and family-based association studies were performed and suggested the association of CTLA4 exon 1 G polymorphism with T1D ($p = 0.02$). This study suggests that CTLA4 is a candidate susceptibility gene for T1D.

Mutations detected in HNF-1a gene in students with diabetes mellitus inheritance by means of the PCR-DGGE-Multiplex method

C. Martinez Lopez[1], A.C. Vargas-Trujeque[1], X.M. Boldo[1], J.L. Cortez-Peñaloza[1]
[1] *Universidad Juárez Autónoma de Tabasco México, Centro de Investigación de la División Academica Ciencias de la Salud, Tabasco, Mexico*

Maturity-Onset diabetes of the Young (MODY) is a monogenic variant of Diabetes Mellitus, this disease is characterized by an autosomal dominant inheritance. It has an early beginning and defect in insulin secretion. The aim was to investigate the frequency of diabetes MODY 3 among the university student population with family diabetes mellitus inheritance, using the PCR-Multiplex-DGGE technique for the diagnosis. We searched the database of the Clinical Analysis Laboratory of the DACS from 2001-2005 and selected 108 young university students between 18 and 35 years old who had some glucose or triglycerides abnormalities in their lab test entrance to medical schoo,l and those who had inheritance of diabetes mellitus type 2 in two or more family generations. The metabolic characteristics were analyzed in young students with mutations and without them. The 15.74% showed alterations in glucose metabolism and 3.70% was diagnosed as DM 2. It was observed that 32.40% of the students presented insulin resistance (HOMA). We did the primers design about the sequence of the HNF-1a gene taken from GenBank (www.ncbi.nlm.nih.gov), and we added a CG clamp of 60 mer to assure the visualizations of the mutations through the DGGE. We implemented a PCR-Multiplex-DGGE-HNAF-1a to amplify exon2, exon3-4 and exon7, which allowed determining that 3.70% of the young university students that were included in this study had some kind of mutations in the exons. Although there are general characteristics of diabetes type MODY 3 we couldn't define a clinically specific mutations, suggesting that the clinical features of each individual depends on the type of mutation and the location of these domains in the gene.

Table. Clinical and metabolic features in student with mutations

Features	Exon2	Exon3-4	Exon7	Exon7
Gender f/m	M	F	F	M
Years old	20	19	22	21
Bmi	28	19	22	21
Glucose (mg/dl)	94	84	90	88
Homa	1.8	0.8	5.6	1.5
Cholesterol (mg/dl)	202	153	139	185
Triglycerides (mg/dl)	92	54	239	348
C-hdl (mg/dl)	47	51	75	52
C-ldl (mg/dl)	136	91	18	63

Peroxisome proliferator-activated receptor-gamma coactivator-1a gene Thr394Thr G/A polymorphism and its relationship to type 2 diabetes and insulin resistance in a Chinese population

Y. Ren[1], J. Song[1], Y. Liu[1], Y. Long[2], H. Tian[2]
[1] *West China Hospital of Sichuan University, Division of Endocrinology and Metabolism, Chengdu, China*
[2] *West China Hospital of Sichuan University, Laboratory of Endocrinology and Metabolism, Chengdu, China*

Aims: to examine the relationship of the Thr394Thr polymorphism of PGC-1a gene to type 2 Diabetes in a Chinese population.
Methods: 307 subjects were enrolled in this study including 151 type 2 diabetic patients and 156 normal glucose tolerant controls (NC). The Thr394Thr polymorphism was genotyped using polymerase chain reaction-restriction fragment length polymorphism (PCR-RFLP). Concentrations of glucose, insulin, lipids were determined in all subjects. BMI, waist circumferences, HOMA-IR and blood pressure were also measured.
Results: 43% of type 2 diabetic patients (66/151) had the AG Thr394Thr genotype compared with 37% in NC group (58/156). The frequency of the A allele of the Thr394Thr polymorphism was 22% in type 2 diabetic patients compared with 18% in NC subjects. There were no significant differences either in genotype or allelic distribution of Thr394Thr polymorphism between the type 2 diabetes and the NC group. Diabetic subjects had higher levels of BMI, waist circumferences, blood systolic pressure, triglycerides and lower levels of HDL-C compared with the control subjects ($P<0.05$). In diabetic patients, subjects with XA genotypes had significantly higher levels of waist circumferences ($p<0.05$) and lower levels of HDL-C ($p<0.05$) than those of patients carrying GG genotype.
Conclusion: The A allele of Thr394Thr (G to A) polymorphism of the PGC-1a gene may not be associated with type 2 diabetes in Chinese population. But we found that type 2 diabetic patients with XA genotypes had significantly higher levels of waist circumferences and lower levels of HDL-C.

Association between polymorphisms in uncoupling proteins and type 2 diabetes in a northwestern population from Colombia

A. Villegas Perrasse[1], L.F. Liliana Franco Hincapié[1], N.G. Natalia Gallego Lopera[1], C.D. Constanza Duque Veléz[1], M.P. Maria Victoria Parra[2], A.R. Andres Ruiz Linares[2], G.B. Gabriel Bedoya Berrio[2]
[1] *Universidad de Antioquia, Endocrinología, Medellín, Colombia*
[2] *Universidad de Antioquia, Genetica Molecular, Medellín, Colombia*

Introduction: The uncoupling proteins belong to the family of anion transporting proteins, which uncouple the ATP production from the

mitochondrial respiration causing proton leakage through the inner mitochondrial membrane and releasing energy as heat. Although its function has not been well established, some polymorphisms in these proteins have been associated with type 2 diabetes mellitus, obesity and insulin resistance.
Objective: To assess the association between the polymorphisms –3826A/G, ID 45, -2723T/A, -1957G/A, -866G/A, -55C/T in uncoupling protein 1, 2 and 3 genes and type 2 diabetes mellitus in a north-western Colombian population.
Materials and methods: 545 cases and 449 controls were genotyped for 14 polymorphisms in uncoupling protein genes by PCR and PCR-RFLP. Single associations were evaluated by chi-square test and bayesian logistic regression analysis was done including as covariates the individual admixture estimates obtained by 54 informative markers for European, African and Amerind ancestry.
Results: Association between type 2 diabetes mellitus and the polymorphisms -3826A (OR=0,78; CI 95%=0,63-0,97; p=0,02) and -55C (OR=1,41; CI 95%=1,04-1,92; p =0,03) and the haplotype D45, -866G, -1957G, -2723T, -55C (OR=1,26; CI 95%=1,02-1,56; p=0,03) were found. These associations were kept after the adjustment using individual genetic admixture estimates.
Conclusion: Some alleles of uncoupling protein genes 1, 2 and 3, and their haplotypes confer risk of type 2 diabetes in a north-western Colombian population.

Objective: To identify a molecular marker of risk for Type 2 Diabetes (T2D) in genes implied in the physiopathology of the obesity and resistance to insulin in a sample of Antioquian population, to be used in early diagnosis of susceptibility to Diabetes type 2.
Methodology: In a group of patients with T2D and control group, using the techniques PCR-RFLP (28 variants in 10 genes) and SNPlex (48 variants in 33 genes and 6 chromosomic regions), evaluated polymorphic variants in genes that take part in differentiation of the adipocyte, lipogenolysis, lipogenesis, secretion and signaling of insulin and regulation of the synthesis of ATP in mitochondria; and positive results of association in genomic sweepings in patients with DM2. In order to eliminate the slant in the results by stratification by mixture, 75 informative markers of ancestry were genotyped, to calculate the degree of triethnic mixture of each individual.
Results: 72 variants in 43 genes in an average of 830 cases and 400 controls were genotyped. Were significant differences in age, weight, index of body mass, measures of waist and hip, in the index waist-hip, and sex. Of the total of analyzed variants, 10 were monomorphics. In the 62 rest, when doing the correction by mixture, was association with diabetes mellitus 2 to 18 variants with 12 genes (PKN2, RBMS1, CALP 10, ADIPOQ, LEP, CDKN2B, TCF7L2, EXT2 UCP 2 and 3, IRS2 and FTO), a region in the chromosome 10 and another one in chromosome 11. Also was association to the index waist hip to 6 variants in 5 genes (RBMS1, SCLC2A2, ENPP1, TCF7L2 and UCP2), when the measurement of body mass index was evaluated I observed no signal.
Conclusions: We manage to identify a group of haplotypes that have demonstrated a P and a significant OR (average 0,01 and 1,02, respectively) in genes CALP 10, ADIPOQ, CDKAL2, LEP, TCF7L2, EXT2, UCP 2 and 3 and FTO. At the moment we are in the stage to calculate the effect of each one of the variants and the haplotypes that showed association to DM2 and the index of waist and hip, under a quantitative model.

Serum adiponectin levels and adiponectin gene ploymorphisms in Tunisian patients with type 2 diabetes

I. Slim[1], M. Chadli-Chaieb[1], I. Maman[2], F. BH Slama[2], R. Zemni[2], M. Zaouali-Ajina[3], L. Chaieb[1]
[1] *Farhat Hached University Hospital, Department of Endocrinology and Diabetology, Sousse, Tunisia*
[2] *Ibn Jazzar Medicine Faculty, Immuno – Genetics Unit 04UR0805, Sousse, Tunisia*
[3] *Ibn Jazzar Medicine Faculty, Department of Physiology, Sousse, Tunisia*

Aims: Low levels of adiponectin, resulting from genetic and / or environmental factors, have been associated to insulin resistance, type 2 diabetes and cardiovascular diseases. Recent evidence also suggested that some polymorphisms (SNPs) of adiponectin are associated to type 2 diabetes and metabolic syndrome and may modify adiponectin concentration and / or activity. Our aim was to assess adiponectin concentrations in Tunisian type 2 diabetic patients and to examine the associations between T45G and G276T SNPs of adiponectin gene, type 2 diabetes and its degenerative complications.
Methods: This case-control study included 302 Tunisian patients with at least a 10-year history of type 2 diabetes and 216 gender-, BMI-, district of residence- matched controls. In addition to anthropometric data and medical history derived from a personal interview, serum leptin, C-peptide and insulin were determined using IRMA method. All diabetic and control subjects were genotyped for T45G and G276T SNPs using PCR – RFLP.
Result: Adiponectin levels were significantly lower in diabetic patients compared to controls (11.27 ± 4.00 vs 16.1 ± 5.90 µg/ml; $p < 0.001$). Adiponectin levels were inversely correlated to age (OR : -0.219 ; $p<0.001$), BMI (OR: -0.271 ; $p < 0.001$) and waist circumference (OR : -0.206 ; p : 0.02) in both groups. Other negative correlation was also found between adiponectin levels and triglyceride concentrations (OR: - 0.257 ; $p < 0.001$) and between adiponectin levels and HOMA-IR in diabetic patients although not statistically significant. We have not found any association between adiponectin levels and the occurrence of diabetic microangiopathy after controlling for potential confounding factors (age, gender, BMI). There was no difference in frequency of T45G and G276T genotypes between patients and controls. Microangiopathy (retinopathy and/or nephropathy) seemed to be associated to G276T SNP with a seven-fold risk of the occurrence of these complications in TT or GT patients compared with GG patients. The presence of T allele was also associated to a 3-fold increase in the occurrence of coronary disease.
Conclusion: In line with previous studies, this work supports the role of low levels of adiponectin in type 2 diabetes and metabolic disorders. We did not found any association between type 2 diabetes and both studied genotypes. However, the T allele of 276 SNP seems to play a role in the occurrence of microvascular and macrovascular diabetic complications. Further studies are necessary to highlight the role of adiponectin in the prevention of these complications.

Familial and genetic investigation of type 2 diabetes in Tunisia

A. Abid[1], I. Arfa[2], S. Nouira[2], N. Ben Halim[2], W. Ghazouani[2], K. Lasram[2], I. Mannai[2], M. Zorgati[2], N. Ben Alaya-Bouafif[3], H. Slama[4], S. Blousa-Chabchoub[1], S. Abdelhak[2]
[1] *Institut National de Nutrition et de Technologie Alimentaire Tunis, Service A, Tunis, Tunisia*
[2] *Institut Pasteur de Tunis, Unité d'Exploration Moléculaire des Maladies Orphelines d'Origine Génétique, Tunis, Tunisia*
[3] *Institut Pasteur de Tunis, Service d'Epidémiologie Médicale, Tunis, Tunisia*
[4] *Centre National de Transfusion sanguine, Laboratoire d'Immunohématologie, Tunis, Tunisia*

Aim: To evaluate the degree of familial aggregation and transmission patterns of type 2 diabetes (T2D) in Tunisia and to investigate whether the ACE (I/D) polymorphism is associated with T2D.
Methods: Family history of diabetes was collected for 206 unrelated type 2 diabetic patients. The medical records were taken for diabetes status in first (parents, siblings) and second degree relatives (aunts and uncles from both maternal and paternal sides). The maternal effect was first tested among parents (mother vs father) and then among aunts and uncles (maternal vs paternal). Comparison of proportions was performed by X^2 test (McNemar). Blood samples were also taken to conduct a case-control study investigating

the involvement of (I/D) polymorphism in the susceptibility to T2D. One hundred forty one unrelated type 2 diabetics and 103 non diabetic controls with normal fasting blood glucose were explored. Genotyping of the I/D polymorphism within ACE gene was performed by nested PCR.

Results and discussion: Data collected for Family study demonstrated that familial aggregation of T2D was prominent: 78% reported at least one diabetic relative. The studied subjects reported more positive history of the disease in their mother than in their father (29% vs 9%). This maternal effect is confirmed in older generations. The genotype distributions and allele frequencies of the (I/D) polymorphism did not significantly differ between T2D subjects and non diabetic controls with normal fasting blood glucose (DD:43%, ID: 46%, II: 11% vs DD:37%, ID: 48%, II: 15%, respectively), (X^2=1.42, p value=0.49).

Conclusion: The present study suggests a strong familial aggregation and excess maternal transmission of T2D. Moreover, our study shows that ACE (I/D) polymorphism is not associated with a higher risk of T2D in the Tunisian studied population.

Adiponectin gene polymorphism and type 2 diabetes mellitus in Ukrainian population

V. Poltorak[1], M. Gorshunska[2], N. Krasova[1], I. Karachentsev[2], T. Tyzhnenko[1], A. Pochernyaev[1], Z. Leshchenko[1], G. Fedorova[1], T. Grinchenko[2], N. Kravchun[2], O. Khizhnyak[2], L. Atramentova[1]

[1] *SI "V. Danilevsky Institute of Endocrine Pathology Problems of AMS of Ukraine", Experimental Endocrinology, Kharkiv, Ukraine*

[2] *SI "V. Danilevsky Institute of Endocrine Pathology Problems of AMS of Ukraine", Clinical Endocrinology, Kharkiv, Ukraine*

Studies of association between adiponectin gene polymorphisms and predisposition to type 2 diabetes mellitus (T2D) have provided contradictory results. The aim of the present study was to search for association of +276G>T single nucleotide polymorphism (SNP) in the adiponectin gene (APM1) with T2D and its related metabolic traits in Ukrainian Caucasians.

Methods: The study groups comprised 115 unrelated T2D patients (M/F 44/71, age 55.7±1.1 yrs, diabetes duration 7.8±0.7 yrs, BMI 32.5±0.7 kg/m^2, HbA_{1C} 8.1±0.2%) and 103 controls (C) without T2D and metabolic syndrome (M/F 62/41, age 55.3±2.1 yrs). +276G>T SNP in APM1 was detected using the restriction fragment length polymorphism technique. ELISA was used to determine plasma adiponectin levels.

Results: In T2Ds allele frequencies for the +276G>T SNP were 0.50 for both G and T allele, and they did not differ significantly from C (G 0.45; T 0.55). No gender difference was observed in allele frequencies in both studied groups. But genotype distributions were different between two groups: it was shown a significant departure from Hardy-Weinberg equilibrium in C (X^2=31.02, p<0.001) and correspondence to it in T2Ds (X^2=2.11, p>0.05). In comparison with C, T2Ds had more homozygotes (GG: 28.8 vs 6.8%, p<0.01; TT: 28.7 vs 16.5%, p<0.05). Relative risk for T2D development in population was for GG 4.23 [95% CI 3.45 – 5.01], p<0.001, and for TT 1.74 [95% CI 1.20 – 2.28], p<0.05; subjects with GT genotype had a significantly lower risk of having T2D: 0.57 [95% CI 0.33 – 0.81], p<0.001. Interestingly, the degree of the increase in serum triglycerides and NEFA levels (metabolic parameters of insulin resistance) was significantly smaller in T2Ds with GT genotype than in those with other genotypes. The T2Ds genotype groups were well matched for age, diabetes duration, BMI, fasting glycaemia and HbA_{1C} levels.

Conclusions: Our findings demonstrate for the first time the potential protective role of GT genotype of adiponectin gene +276G>T SNP for type 2 diabetes development in Ukrainian population.

Comparison of patterns of type 2 DM between native Pakistani and UK immigrant South Asians

A. Ahmed[1], A. Jabbar[1], U.Z.M.A. Raza[1], S.R. Haque[1]

[1] *The Aga Khan University Hospital, Endocrine And Diabetes, Karachi, Pakistan*

Objective: This study was designed to assess whether the pattern of diabetes in native South Asians is different from immigrant South Asians.

Materials and methods: Data on Pakistan based South Asians was collected through non-probability purposive sampling of 100 type 2 diabetics attending out-patient clinic of The Aga Khan University Hospital at Karachi, Pakistan for a cross sectional survey. This data was compared with data from UK based South Asians acquired through a study carried out at Ealing Hospital, London enrolling 889 UK immigrant South Asians.

Results: The age of the native Pakistani diabetic male patients attending clinic at AKUH was significantly less than the UK based south Asian men attending clinic at Ealing hospital (p=0.006). When considering the pattern of disease, presentation and the duration of diabetes, no difference was found. In addition, the age of diagnosis of type 2 DM was also found to be similar. The range of BMI was similar between the two groups of south Asian. Further risk factors such as smoking were significantly more common among Pakistani male patients when compared to their UK counterparts. (26.7% vs. 12%, p=0.010) and predictably this difference was not observed among female patients. Although the prevalence of HTN was found to be more among the Pakistani female patients when compared to UK female diabetics (69.1% vs. 39%,p=0.001), a difference not observed among the male patients. When looking at the degree of control of diabetes among patients, the values for HBA1C were found to be significantly lower among Pakistani male diabetic patients when compared to UK south Asian diabetics (8.7 vs.11.3, p=<0.001 for men & 8.2 vs. 11.9, p=<0.001 for women). The prevalence of IHD was similar between both groups, which have been shown to be higher in south Asians when compared to Europeans in previous studies. Retinopathy prevalence was higher, and significantly so among men, in UK South Asians compared to Pakistani patients, (29% vs.13.3%, p=0.037) although the difference was not significant among female patients.

Conclusion: In conclusion, it appears that besides environmental factors, genetic influence appears to be significant influencing the pattern and mode of presentation of type 2 diabetes among South Asians and it should be a focus of future research.

PC-1 gene polymorphism and type 2 diabetes mellitus

S. Al-Shama[1], S. Abbas[1], H. Al-Gerrah[1]

[1] *Dubai Medical College, Medical, Dubai, United Arab Emirates*

Introduction: Polymorphism of PC-1 (Plasma Cell glycoprotein-1) result either in the overproduction or overactivity of the glycoprotein, which leads to less response to insulin as it has an inhibitory effect on insulin receptor (IR) and is associated with clinical insulin resistance.

The normal genotype is (KK) while the abnormal could either be homozygous (QQ) or heterozygous (KQ). In each case, lysine (K) is substituted by glutamine (Q). Studies in transfected cells has shown that polymorphism of this gene leads to stronger inhibition of IR; and this occurs due to increased physical interaction between the two proteins at the cell membrane leading to increased insulin resistance.

The objective of this study is to find the relation between polymorphism of PC-1 gene and type 2 DM.

Materials and methods: the study group consists of 50 type 2 diabetic patients and 50 non-diabetic control. DNA was extracted from white blood cells by salting-out method first, then PCR for amplification of specific nucleotide sequence is done. Gel electrophoresis for detection is the final step.

Results: interesting preliminary results show that, the carriers of KQ or QQ genotypes of PC-1 gene polymorphism were more prevalent among type 2 diabetic patients compared with non-diabetic control. Sample size is not yet complete to put final statistics and planned to be completed within 3 months time.

Conclusion: preliminary results show that the carriers of KQ or QQ genotypes of PC-1 gene polymorphism are at a higher risk of developing DM-2. Final conclusion is to be made after completion of the sample evaluation and statistical assessment.

Insulin action - carbohydrate, lipid and protein metabolism

P-1244

Role of resveratrol in gluconeogenic genes expression in the liver

J. Park[1], T. Kim[2], J. Bae[2], M. Kim[2], Y. Ahn[2]
[1] *Yonsei University College of Medicine Brain Korea 21 Project for Medical Sciences Yonsei University College of Medicine, Center for Chronic Metabolic Disease Research, Seoul, Korea*
[2] *Yonsei University College of Medicine Department of Biochemistry and Molecular Biology, Center for Chronic Metabolic Disease Research, Seoul, Korea*

Background and aim: Resveratrol (RSV), a naturally occurring polyphenol found in grape and red wine, is known as an activator of silent information regulator 2 (Sir2) which is a NAD^+-dependent histone deacetylase. Recently, it has reported that expression of hepatic gluconeogenic genes, phosphoenolpyruvate carboxykinase (PEPCK) and glucose-6-phosphatase (G6Pase), inhibited by insulin signaling was restored by RSV. However a molecular mechanism of the restoration is not well yet established.
The forkhead transcription factor (FOXO1) is known as a transcriptional activator of genes involved in the gluconeogenesis. In the presence of insulin, FOXO1 is phosphorylated and exported from nucleus to cytosol, losing its ability to activate gene transcription.
In this study, we demonstrated that RSV up-regulates the expression of gluconeogenic gene through deacetylation of FOXO1 by activating SIRT1.
Materials and methods: mRNA level for gluconeogenic genes was measured in primary cultured hepatocytes of rat and mouse by real-time PCR. In the presence of insulin, the effect of activator or inhibitor of SIRT1 was studied using Western-blot analysis using primary cultured hepatocytes. Also its effect was identified by observing the localization of FOXO1 and SIRT1 in Alexander cell lines by using immunofluorescence microscopy. The binding of FoxO1 to the promoter regions of gluconeogenic genes are tested by chromatin immunoprecipitation (CHIP) assay using primary cultured hepatocytes.
Results: Down-regulation of gluconeogenic gene by insulin was reversed by RSV in a dose-dependent manner and its effect was counteracted by Sirtinol. In the presence of insulin, PI3K/AKT and ERK 1/2 pathway was affected by activator or inhibitor of SIRT1. RSV induced the localization of FOXO1 to nucleus by deacetylation causing up-regulation of gluconeogenic genes. CHIP assay showed that nuclear FOXO1 directly binds to the promoter region of gluconeogenic genes causing increase in the mRNA level of gluconeogenic genes.
Conclusion: SIRT1 is known to deacetylate the FOXO1 through direct interaction. In this study, we showed that deacetylation of FOXO1 may decrease the insulin-induced phosphorylation of FOXO1, causing nuclear translocation and as a result, up-regulation of gluconeogenic genes. This observation may help explain how RSV increases gluconeogenic gene expression which is suppressed by insulin.

P-1245

Expression of myostatin in obese and insulin resistant rats subjected to exercise

P. Godoy Bueno[1], D. Gomes Contrera[2], K. Okino Nonaka[1], H. Sobreiro Selistre Araújo[1], A. Leal[2]
[1] *University of São Carlos, Department of Physiology, São Carlos, Brazil*
[2] *University of São Carlos, Department of Medicine, São Carlos, Brazil*

Aims: The objective of this study was to determine the influence of exercise in the expression of myostatin (MSTN) in fat and muscle in rats with obesity and insulin resistance induced by high-fat (HF) diet.
Methods: Adult male Wistar rats were housed under controlled conditions (20-22^0 C, 10-14h light-dark cycle) and were allowed free access to standard rodent chow (control group, CG) or HF diet (58% Kcal from fat, high-fat group, HG) during 12 weeks. Glucose tolerance test (GTT) and insulin tolerance test (ITT) were performed before and at 3, 4, 8 and 12 weeks. After 12 weeks, CG and HG rats were randomly assigned to a swimming training group (CGE and HGE) or a sedentary group (CGS and HGS). CGE and HGE swam individually in water tanks (50x30cm) at 34^0 C, for 45 minutes at 0900h and 1700h, 5 day week^{-1}, for 4 weeks. After this period, rats were submitted again to GTT and ITT and then killed by decapitation. GTT area under the curve was lower in HGE compared to HGS. White gastrocnemius muscle and fat pads were dissected, weighed, immediately cooled in liquid nitrogen and stored at -70^0 C for subsequent analysis. MSTN mRNA was quantified by real time RT-PCR. The animals were maintained according to the local University Committee guidelines for the care and use of laboratory animals.
Results: HG developed insulin resistance according to GTT and ITT tests. Adipose fat pads (epididymal, retropritoneal and mesenteric) were 2-3 times heavier in high-fat fed groups (HGS and HGE) compared to standard chow fed groups (CGS and CGE). In HGS rats, MSTN mRNA levels were significantly ($P<0.05$) higher (~2 times) in mesenteric fat compared to CGS rats. However MSTN mRNA levels were significantly lower in epididymal and brown adipose tissue (BAT) in HGS compared to CGS. Swimming training resulted in a significant reduction of MSTN mRNA levels in gastrocnemius in CGE compared to CGS. However, MSTN mRNA levels were significantly increased in BAT in both CGE compared to CGS. In high-fat fed groups, swimming training did not alter MSTN expression in muscle. However, MSTN mRNA levels significantly decrease in mesenteric and increase in epididymal and BAT.
Conclusion: These data suggest that the expression of MSTN in fat tissues may be involved in metabolic response of high-fat fed rats to exercise.

Acute hyperglycemia affects serum adiponectin concentrations and the endothelium-dependent dilation in subjects with impaired glucose tolerance and in newly diagnosed diabetic patients

K. Koniari[1], D. Tousoulis[1], C. Antoniades[1], A. Nikolopoulou[1], K. Makris[1], M. Noutsou[2], N. Papageorgiou[1], A. Antonopoulos[1], C. Stefanadis[1]
[1] *Hippocratio Hospital University of Athens, Cardiology, Athens, Greece*
[2] *Hippocratio Hospital University of Athens, Diabetes Center, Athens, Greece*

Aims: Adiponectin is an adipokine with beneficial effect on vascular function. Although adiponectin levels are decreased in patients with diabetes mellitus (DM), it is unclear whether impaired glucose tolerance (IGT) affects adiponectin's release, or whether glucose intake modifies its release from adipocytes. We examined the effect of glucose loading on serum adiponectin and insulin levels, and we evaluated its impact on endothelial function. We also compared these effects between subjects with IGT, patients with DM and healthy individuals.
Methods: The study population consisted of 113 subjects: 19 with IGT, 78 patients with DM and 16 controls. All subjects underwent glucose loading (75g oral glucose), and blood samples were obtained at baseline and after 3 hours. Endothelial function was evaluated by gauge-strain plethysmography at baseline and every 1h, and endothelium-dependent dilation (EDD) was determined. Adiponectin and insulin levels were measured at baseline and at 3h.
Results: Glucose loading increased adiponectin levels in healthy (7.01±0.85 to 8.08±1.14 ng/ml, $p<0.05$) and IGT (5.26±0.45 to 6.13±0.65 ng/ml $p<0.05$) but not in DM (5.59±0.35 to 5.68±0.35 ng/ml) individuals. Although insulin was correlated with adiponectin both at baseline ($r=-0.375$, $p=0.0001$) and at 3h ($r=-0.286$, $p=0.006$), insulin variations did not follow the same pattern (healthy: 6.55±0.65 to 9.25±1.17 IU/L $p<0.05$, IGT: 11.6±2.7 to 17.6±4.9IU/L $p<0.05$, and DM: 10.24±0.89 to 20.99±2.37 IU/L $p<0.0001$). There was no association between the changes of insulin and those of adiponectin (p=NS). EDD was decreased after loading in healthy (from 76.6±5.2% to 63.0±6.6%, 57.0±6.5% and 89.3±6.3% at 0h, 1h, 2h and 3h respectively, $p<0.05$ for 0h vs 2h), in IGT (from 92.8±6.4% to 66.9±6.1%, 68.6±6.8% and 85.6±6.1% at 0h, 1h, 2h and 3h respectively, $p<0.01$ for 0h vs 2h) and DM (from 86.1±5.1% to 60.7±2.4%, 54.6±2.3% and 75.2±2.8% at 0h, 1h, 2h and 3h respectively, $p<0.01$ for 0h vs 1h, 2h and $p<0.05$ vs 3h).
Discussion/conclusions: Glucose intake increases adiponectin levels in healthy individuals and subjects with IGT, but not in those with DM. This effect is independent of insulin variations. On the contrary, endothelial function was impaired after glucose intake, an effect which is more profound in patients with diabetes mellitus. These findings provide new insights into the associations between insulin, adiponectin and endothelial function in diabetes mellitus.

Paradoxical behavior of free fatty acid during OGTT in patients with type 2 diabetes and secondary failure to oral antidiabetic medications

M. Noutsou[1], A.K. Thanopoulou[1], A.J. Kofinis[1], E.A. Spanou[1], L.K. Milika[1], B.G. Karamanos[1], A.J. Archimandritis[1]

[1] *Hippokration Hospital, Diabetes Center 2nd Department of Internal Medicine, Athens, Greece*

Aims: The aim of this study was to investigate the changes of FFA during an OGTT in patients with type 2 diabetes (DM) and secondary failure to oral antidiabetic medications in comparison to healthy controls and to explore possible correlations with insulin resistance.

Methods: We studied 30 patients with DM and 30 control subjects (C). All subjects underwent an OGTT with 75g glucose. Blood was drawn at baseline and at 30, 60, and 120 min after the ingestion of glucose. Plasma glucose, insulin and FFA were measured. Areas (AUC) under glucose, insulin and FFA curves were calculated. Various indices of insulin resistance, and insulin secretion were calculated as well i.e.: the homeostasis model assessment of insulin resistance index (HOMA-IR), the insulin resistance indices by Belfiore (IRIGLY and IRIFFA) and the insulinogenic index at 30 min. The rate of FFA decrease (K-value) from 30 to 120 minutes was calculated as percent per minute.

Results: At baseline FFA and fasting glucose were higher in diabetics compared to controls: 39.9vs13.3mg/dl and 179.8vs93.0mg/dl $p<0.001$ respectively, while fasting insulin was lower: 8.9vs12.9mU/l $p<0.01$. Fasting FFA were positively correlated with insulin resistance indices in both groups ie: DM: HOMA $r=0.42$ $p<0.01$, IRIGLY $r=0.44$ $p<0.05$, IRIFFA $r=0.82$ $p<0.001$. Controls: HOMA $r=0.54$ $p<0.01$, IRIGLY $r=0.38$ $p<0.05$, IRIFFA $r=0.85$ $p<0.001$. During OGTT, in diabetics, FFA increased at 30 min above baseline by 97.6% and afterwards gradually decreased up to 120 min: 0′= 39.9, 30′= 57.9, 60′=36.3, 120′= 26.3mg/dl. On the contrary in controls a gradual decrease was observed: 0′= 13.3, 30′= 9.9, 60′= 6, 120= 4.1 mg/dl. In diabetics the change of FFA at 30 min was not related to either insulin resistance or insulin sensitivity indices, while in controls it was positively related to insulin resistance indices (HOMA $r=0.44$ $p=0.01$, IRIGLY $r=0.43$ $p=0.01$). Insulin AUC 30-120 min was significantly lower in DM compared to Controls: 466.1 vs 3883.4 mg/dl*min, $p<0.001$. From 30 to 120 min both in diabetics and in controls the FFA decreased constantly. The rate of decrease from 30 to 120min showed no correlation with insulin resistance and did not differ between the two groups: K-value 0.097 vs 0.098, although, the area under the insulin curve, during this time period, was statistical significantly greater in controls than in diabetics.

Conclusions: During the first 30 min of the OGTT, a paradoxical transient increase of FFA in patients with type 2 diabetes and secondary failure to oral antidiabetic medications has been detected. This phenomenon does not seem to be related to insulin resistance and can not be easily explained.

Introduction: Although insulin attenuates cardiac ischemia-reperfusion injury via activation of cell-survival and metabolic pathways, its association with the inhibition of the renin-angiotensin system has not yet been evaluated.

Aim: To evaluate the effects of insulin and captopril on insulin/angiotensin signal transduction pathways and cardiac function in the isolated heart submitted to ischemia-reperfusion.

Methods and results: Male Wistar rats (n=84, ~320g) were killed (cervical displacement), hearts quickly removed and perfused according to the Langendorff technique (10ml/min), with Krebs-Henseleit (KH) for 25min (baseline). Global ischemia was induced (20min), followed by reperfusion (30min). During reperfusion different solutions were employed: Krebs-Henseleit (KH), KH + insulin (I), KH + angiotensin-I (A), KH + insulin + angiotensin-I (IA), KH + angiotensin-I + captopril (AC) and KH + insulin + angiotensin-I + captopril (IAC). Lipoperoxidation (TBA-RS and chemiluminescence), antioxidant enzyme activities (SOD, GST and catalase), nitrates and $_{cu/zn}$SOD, GST, $_{e}$NOS, $_{phospho}$AKT, $_{phospho}$AMPK and GLUT-4 (immunoblotting) were measured. During recovery, the A group showed a 24% reduction in developed pressure and an increase (~2.7-fold) in end-diastolic pressure vs baseline, effects that were reverted in the AC, IA and IAC groups, and a 24% reduction in rate-pressure product vs baseline, an effect that was reverted by insulin. The perfusion pressure was ~20% higher in all groups (except I) vs KH group. The $_{phospho}$AKT was higher in the I and IA groups vs KH (~47% and ~42%, respectively) and A (~60% and ~55%, respectively) groups. The $_{phospho}$AMPK was ~31% higher in the I, IA and IAC groups vs KH, A and AC groups. The TBA-RS levels were ~73% higher in KH vs other groups; the chemiluminescence was also higher (~2,2 fold) in the KH group vs other groups, and ~35% lower in the IA vs A group. SOD activity was similar between groups, but catalase activity was ~28% higher in the KH vs other groups (except IA, P=0,058). GST activity was higher in A and AC (~45% and ~50%, respectively) vs I. The A, AC and IAC groups showed a lower concentration of $_{cu/zn}$SOD (~40%, ~43% and ~27%, respectively) vs KH. There were no changes in GST and $_{e}$NOS enzyme concentrations, GLUT-4 translocation index and total nitrate levels.

Conclusions: During ischemic heart reperfusion, insulin activates the PI3k-AKT pathway, improves the redox balance, activates AMPK and inhibits the deleterious effects of angiotensin-II actions, changes that were translated into improved cardiac function. These effects were more pronounced with insulin alone than when associated with captopril.

Signalling transduction mechanism of BRL37344 and clenbuterol-stimulated glucose uptake in mouse isolated soleus muscle

R. Ngala[1], C. Stocker[2], M.A. Cawthorne[2], J.R.S. Arch[2]

[1] *Kwame Nkrumah University of Science and Technology, Molecular Medicine, Kumasi, Ghana*

[2] *University of Buckingham, Life Sciences, Buckingham, United Kingdom*

Introduction: In mouse soleus muscle, we have reported that very low concentrations (10 or 100 pM) of BRL37344 and the selective β_2-adrenoceptor

agonist clenbuterol stimulated glucose uptake. Higher concentrations (100nM) of clenbuterol inhibited glucose uptake, but BRL37344 (10nM) displayed a second, more pronounced stimulatory effect. Studies using selective antagonists, suggested that the effects of 10nM BRL37344 and 100nM clenbuterol were mediated through the β_2-adrenoceptor.
Glucose uptake was inhibited by 100nM clenbuterol, and stimulated by 10μM BRL37344 suggesting these agonists affect different signalling mechanisms via the β_2-adrenoceptor. We have already reported that the effect of 10pM clenbuterol increased cAMP levels and 100nM effect decreased cAMP levels, whereas there were no cAMP changes associated with the effect of low and high concentrations of BRL-37344 (Ngala et al., 2008 Br J Pharmacol. Oct; 155 (3): 395–406)
Aim: To investigate the intracellular signalling mechanism associated with the effect of BRL-37344 and clenbuterol on glucose uptake in soleus muscle.
Methods: Isolated soleus muscles from male C57Bl/6 mice were preincubated for 60 min in Krebs-Henseleit bicarbonate (KHB) buffer. 2-deoxy [1-^{14}C] glucose (0.1 μCi/ml) uptake was measured over 45 min in KHB buffer that contained 5.5mM glucose and 0.1nM bovine insulin. Muscles were then digested in 0.5ml 1M NaOH, neutralised with HCl, and 2-deoxyglucose-6-phosphate was precipitated using 1ml of 1:1 2.68% Ba $(OH)_2$: 2.51% $ZnSO_4$. The incubation medium contained various concentrations of the beta-adrenoceptor agonists in the presence or absence of either 1 μM.wortmannin, 1μM LY294002 (PI3K inhibitors), 1 μM compound C (AMP activated protein kinase inhibitor), 20 μM PD98059 (prevents activation of MAPKKinase, 10 μM SB203580 (p38MAPK inhibitor) or 10μM H89 (protein kinase A inhibitor).
Results are means ± S.E. values
Summary: The effect of 10pM clenbuterol was blocked by wortmannin and LY294002 whereas BRL37344 were blocked by wortmannin only. SB203580 (10 mM) blocked the effects of 10pM clenbuterol and 100nM BRL37344. 20 mM PD98059 had no effect on any of the concentrations of agonists. Also, only 10pM clenbuterol was blocked by compound C.
The protein kinase A inhibitor prevented the stimulatory effect of 10 pM clenbuterol on glucose uptake and also inhibited the stimulatory effects of 10 pM and 10 nM BRL-37344 on glucose uptake.
Conclusion:
1. Clenbuterol-stimulated glucose uptake is cAMP dependent and involves the activation of PI3K and p38 MAPKinase.
2. The stimulation at 10pM is AMPKinase dependent.
3. BRL-37344 stimulation may be cAMP dependent. The effect was blocked by H89

BRL37344-stimulated glucose uptake mediated through the activation of PI3K and p38 MAPKinase

P-1250

Regulation of DGAT1 gene expression by XBP1 in hepatocyte

J.S. Bae[1], T.H. Kim[1], M.Y. Kim[1], J.M. Park[2], Y.H. Ahn[2]
[1] *Department of Biochemistry and Molecular Biology & Center for Chronic Metabolic Disease Research, Yonsei University College of Medicine, Seoul, Korea*
[2] *Department of Biochemistry and Molecular Biology & Center for Chronic Metabolic Disease Research & Brain Korea 21 Project for Medical Sciences, Yonsei University College of Medicine, Seoul, Korea*

Aims: Acyl-CoA:diacylglycerol acyltransferase 1 (DGAT1) is one of two known DGAT enzymes that catalyze the final step of triacylglycerol synthesis. Mice lacking DGAT1 have increased insulin sensitivity and energy expenditure and are resistant to diet-induced hepatic steatosis. However, little is known about the regulatory mechanisms controlling DGAT1 gene transcription. This study aimed to investigate the effect of X-box binding protein 1 (XBP1), a key regulator of the unfolded protein response, on transcriptional regulation of mouse DGAT1 gene in hepatocyte.
Methods: Transcriptional activity of mouse DGAT1 promoter by XBP1 was measured by luciferase assay in a human hepatoma cell line (HepG2). In vitro translated XBP1 protein was used in electrophoretic mobility shift assay (EMSA) to show the binding of XBP1 in mouse DGAT1 promoter.
Results: We have localized and characterized XBP 1 binding site in the promoter region of mouse DGAT1 gene. Ectopic expression of XBP1s, an active spliced XBP1, in HepG2 cells activated the promoter activity of DGAT1 gene. Serial deletion/mutation studies localized the XBP1 binding site to a region between bases -293 and -287 of the DGAT1 promoter. The XBP1 binding site in this region was confirmed by EMSA.
Conclusion: These results suggest that XBP1 activates the gene expression of DGAT1 by direct binding on DGAT1 promoter.

The key role of PTP1B in the TNFa-induced leptin and insulin resistance in hypothalamus of rats

P.K. Picardi[1], A.M. Caricilli[1], L.L.F. De Abreu[1], J.B.C. Carvalheira[1], L.A. Velloso[1], M.J.A. Saad[1]
[1] *UNICAMP, Internal Medicine, Campinas, Brazil*

Obesity is accompanied by resistance to insulin and leptin, however the molecular mechanisms underlying these resistances in obesity are not completely understood. PTP1B is a major negative regulator of insulin and leptin sensitivity, acting to dephosphorylate the insulin receptor and the leptin receptor-associated Janus kinase 2. Factors that cause or accompany development of insulin and leptin resistance are attractive potential mediators of PTP1B overexpression in obesity. Evidences indicate that obesity is an inflammatory state, with an increase in pro-inflammatory cytokines. Subclinical inflammation may have an important role in the development of insulin and leptin resistance, however, the role of inflammatory mediators in the regulation of PTP1B in the hypothalamus has not yet been investigated. One factor that plays a role in the development of insulin resistance is the tumor necrosis factor alpha (TNFa). TNFa is a pleiotropic cytokine which occurs in many pathological processes, including inflammation. Recent studies have confirmed an important role of TNFa in the pathogenesis of insulin resistance and obesity in human and in animal models. However its mechanism of action is not fully understood. In the present study, we have associated functional and molecular studies of insulin and leptin to investigate the effect of TNFa on central insulin and leptin signaling in rats pre-treated with PTP1B-ASO (PTP1B antisense oligonucleotide). Cannulated icv rats were treated with PTP1B-ASO for 4 days. At the end of the fourth day, rats were treated icv with insulin, leptin, TNF-a, saline or with combinations of TNF-a with insulin or leptin. Our results showed that central administration of TNFa increases PTP1B protein and activity, together with reductions in insulin and leptin sensitivity and signaling in hypothalamus, suggesting that PTP1B should be included in the group of inflammatory responsive genes. At least in part, this resistance to leptin and insulin depends on the capacity of TNF-a to stimulate PTP1B expression and activity in the hypothalamus, because PTP1B-ASO improves the effect of leptin and insulin on food intake and signaling, with increased activation of IR, IRS1, JAK2, STAT3 and AKT. Therefore, we suggest that PTP1B plays a key role in TNFa-induced insulin and leptin reduced sensitivity and signaling, since hypothalamic PTP1B deficiency ameliorates TNFa-induced leptin and insulin resistance.

Influence of gastric emptying on transport of food and orally administered glucose

Z. Rausova[1], J. Chrenova[1], L. Dedik[1], M. Durisova[2]
[1] *Slovak University of Technology, Faculty of Mechanical Engineering Institute of Automation Measurement and Applied Informatics, Bratislava, Slovakia*
[2] *Slovak Academy of Sciences, Institute of Experimental Pharmacology, Bratislava, Slovakia*

Aim: To develop a simulation mathematical model for identification of influences of gastric emptying process on absorption and/or elimination of food and orally administered glucose in healthy subjects.
Methods: Modeling tools from the linear dynamic system theory and concentration data from measurement over 24 hours meal after a normal diet and from a frequently sampled oral glucose tolerance test (FSOGTT) [1] were used.
Results: The developed model was capable of: 1) determining time profiles of glucose and food retained in the stomach, and 2) simulating influences of gastric emptying rate on glucose and/or food on plasma glucose and insulin concentration-time profiles in all subjects enrolled.
Conclusion: The presented model is theoretically sound, sensitive, and reproducible. It may contribute to the working library of the modeling techniques in diabetes research, since it allows accounting for influences of the gastric-emptying process on absorption and/or elimination of food and on glucose and insulin plasma concentration-time profiles in FSOGTT. It may be one of the important keys to achieve glucose control in diabetes.

High carbohydrate or high fat meals decrease insulin sensitivity two hours after the ingestion

R.S. Campello[1], A.B.T. Alves-Wagner[1], M.M. Okamoto[1], R.C.T. Mori[1], U.F. Machado[1]
[1] Institute of Biomedical Sciences, Department of Physiology and Biophysics, São Paulo, Brazil

Aims: Insulin resistance results from a combination of genetic and environmental factors and may be considered the primary cause for the development of metabolic disorders, such as diabetes mellitus. It is characterized by a reduced ability of the insulin sensitive tissues to respond to normal levels of the hormone. In these tissues, glucose transport stimulated by insulin occurs through the glucose transporter (GLUT4) and alterations in its expression are related to changes in insulin sensitivity. This study evaluated the acute effect of a high carbohydrate meal and a high fat meal on the insulin sensitivity and on the content and distribution of GLUT4 protein (plasma membrane and microsomal-enriched fractions) in the gastrocnemius skeletal muscle and periepididymal white adipose tissue.
Methods: Male Wistar rats fasted for 24 hours, were refed for 1, 2, 4 or 6 hours with one of the three meals: balanced meal (B-group, refed with standard meal); high carbohydrate meal (C-group, refed with toast) and high fat meal (F-group, refed with lard).
Results: Both C and F-groups exhibited insulin resistance after 2 hours of refeeding (Glucose/insulin index lower than B-group). In the insulin tolerance test (ITT), a reduction (~47%) in the insulin sensitivity was observed in C group after 2 and 4 hours of refeeding. In the glucose tolerance test, performed 2 hours after the beginning of ingestion, the relation between the area under the curve of plasmatic insulin and the area under the curve of plasmatic glucose confirmed the insulin resistance in C and F-groups. Although high carbohydrate and fat meals reduced insulin sensitivity, they did not alter GLUT4 protein subcellular distribution.
Conclusion: These results suggest that imbalanced meals with high carbohydrate or fat concentration lead to reduced insulin sensitivity after 2 hours of ingestion and such phenomenon does not involve alteration in GLUT4 content in muscle and adipose tissues.

P-1254

Impaired GLUT4 expression in oxidative muscle affects the glycaemia in SHR diabetic rats

A.B. Teixeira Alves[1], R. Sabino-Silva[1], R.S. Campello[1], R.C.T. Mori[1], U.F. Machado[1]
[1] University of Sao Paulo, Department of Physiology and Biophysics, Sao Paulo, Brazil

Aims: The SLC2A4 gene encodes the GLUT4 protein which is highly expressed in muscular and adipose tissues. In these tissues, glucose uptake is elevated when energy substrate is abundantly available, as in the postprandial state, when insulin levels increase, triggering the translocation of GLUT4 protein to the plasma membrane. Alterations in this gene are correlated with increased or decreased insulin sensitivity. The hypertension associated with diabetes can change the GLUT4 expression. The present study was aimed at investigating the participation of the treatment with insulin or propranolol (ß-adrenergic antagonist) or insulin+propranolol in the regulation of GLUT4 gene expression in soleus muscles and periepididymal white adipose tissue of diabetic normotensive Wistar rats and spontaneously hypertensive rats (SHR).
Methods: Normotensive (Wistar) and hypertensive (SHR) rats with 1 month of diabetes were treated or not with insulin and/or propranolol during 7 days. GLUT4 expression was analyzed by Northern and Western Blotting.
Results: Before treatment, all animals were over 100mg/dl glycosuria, confirming their diabetes. The diabetic rats with insulin treatment increased the body weight and plasma NEFA levels, and decreased glycosuria. Glycemia decreased with insulin treatment in normotensive rats, but did not change in hypertensive rats. Propranolol treatment decreased systolic pressure in SHR rats. In adipose tissue and soleus muscle, insulin treatment increased GLUT4 mRNA in both Wistar and SHR rats, and insulin+propranolol treatment further increased GLUT4 mRNA in SHR rats. Preliminary data show that in soleus muscle GLUT4 protein content varies in accordance with mRNA changes in normotensive rats. However, in hypertensive rats insulin did not change the GLUT4 protein content. On the other hand, when combined with propranolol, insulin treatment seemed to improve the GLUT4 gene expression in SHR diabetics rats.
Conclusion: The improved GLUT4 expression in adipose tissue of insulin treated rats was not enough to decrease glycemia in the hypertensive rats. Moreover, hypertensive rats which were unable to increase GLUT4 protein expression in soleus in response to insulin, could not decrease their glycemia after treatment. These data suggest the hyperglycemia in hypertensive rats is related to impaired insulin-stimulated GLUT4 increase in oxidative muscle fibers.

P-1255

Effect of insulin therapy on glucose homeostasis of insulinopenic diabetic rats: contributions of insulin dose, GLUT4 expression and liver insulin signalling

M.M. Okamoto[1], R. Sabino-Silva[1], G.F. Anhê[1], U.F. Machado[1]
[1] Institute of Biomedical Sciences, Physiology, São Paulo, Brazil

Aim: Insulin resistance involves reduced peripheral glucose uptake and/or increased hepatic glucose output. Hyperinsulinemic states have been associated to insulin resistance. Considering that peripheral hyperinsulinemia is observed in insulin-treated type 1 diabetic subjects, we hypothesize that the treatment might induce insulin resistance thus compromising the therapeutic benefits. The present study investigated in diabetic rats the effect of different doses of insulin on insulin sensitivity, as well as potential involved molecular mechanisms.
Methods: Three month-old rats were rendered diabetic by injection of alloxan (38 mg/Kg). Two weeks later they were submitted to treatment with saline (DS) or NPH insulin in different daily doses 1.5U ($I_{1.5}$), 3U (I_3), 6U (I_6) and 9U (I_9), for 7 days. Non diabetic rats (ND) were studied as a control group. After the treatments we analyzed: a) whole body insulin sensitivity, by analyzing basal glycemia and glucose disappearance rate (kITT) during in insulin tolerance test (ITT); b) GLUT4 protein in plasma membrane (PM) and microsome fractions of epididymal adipose tissue and gastrocnemius skeletal muscle; d) insulin signaling in liver.
Results: I_3-, I_6- and I_9-treated rats increased body and adipose tissue weights ($P<0.01$ vs. DS). The higher doses of insulin (6U and 9U) decreased basal glycemia to ~70% ($P<0.01$) of the DS values, restoring levels of ND rats. However, the kITT value remained lower ($P<0.05$) than the value of ND rats, indicating the presence of the insulin resistant condition. On the other hand, the dose of 3U did not normalize glycemia, but increased kITT value by ~250% ($P<0.001$ vs DS), achieving values higher than the observed in ND ($P<0.01$). Insulin treatments (3U, 6U and 9U) similarly increased the GLUT4 protein (~200%, $P<0.01$) in adipose tissue, which may be related to the similar tissue weight gain. Differently, in skeletal muscle the dose of 3U increased GLUT4 protein by ~20%, as compared to effect of 6U and 9U. Additionally, in liver of I_3-treated rats, increased basal values of phosphorylated- (p)-IRb (~100%, $p<0.01$), p-Akt Ser (~35%, $p<0.05$) and IRS2/PI3-kinase association (~45%, $p<0.05$) were observed, as compared to 6U and 9U.
Discussion/Conclusion: The present study shows that intermediary dose of insulin (3U) improve insulin sensitivity in diabetic rats, and that involves increased GLUT4 protein expression in muscle and enhanced insulin sensitivity in liver. However, this dose of insulin (3U) was not enough to normalize glycemia. On the other hand, tight glycemic control was achieved by using high doses of insulin (6U and 9U), but with these treatments, insulin resistance was observed, probably related to decreased muscle GLUT4 expression and liver insulin sensitivity.

Regulation of GLUT4 expression in skeletal muscle cells by resistin

D. Duque Guimaraes[1], G.A. Lima[1], S.S. Teixeira[1], R.C.T. Mori[1], M.T. Nunes[1], P.C. Papa[2], U.F. Machado[1]

[1] Institute of Biomedical Sciences - USP, Physiology, São Paulo, Brazil

[2] Veterinary Medicine School - USP, Surgery, São Paulo, Brazil

Aim: Resistin is a potential link between obesity and insulin resistance or type 2 diabetes. However, there has been little investigation of the effects of resistin on glucose transporters regulation in skeletal muscle, a key tissue for glucose disposal. The aim of this study was to investigate the effects of resistin on regulation of GLUT4 expression in skeletal muscle cells in different conditions.
Methods: Rat myoblasts (L6) were cultured and differentiated into myotubes followed by stimulation with single commercial resistin (50ng/mL, 24 h) in the presence or absence of palmitate (500µm), hyperglycemic (25mM) or insulin-stimulated (100nM) conditions. GLUT4 protein content was assessed by Western blotting as well as GLUT4 mRNA was assessed by real time PCR.
Results: Treatment of L6 rat skeletal muscle cells with recombinant resistin reduced GLUT4 protein levels (30%) and increased GLUT4 mRNA (59%) only in the presence of palmitate. In the others conditions, skeletal muscle cells have not shown any alteration in GLUT4 expression.
Conclusion: In summary, GLUT4 transcription and translation were altered by resistin in L6 rat muscle cells only in the presence of palmitate.

Effect of some active compounds of Morus alba leaf on glucose uptake and glucose transporter 4 in isolated diabetic rat adipocytes

J. Naowaboot[1], P. Pannangpetch[1], V. Kukongviriyapan[1], A. Prawan[1], U. Kukongviriyapan[2]

[1] Khon Kaen University, Pharmacology, Khon Kaen, Thailand

[2] Khon Kaen University, Physiology, Khon Kaen, Thailand

Aims: To study the effect of four active compounds of Morus alba leaf on glucose uptake and glucose transporter 4 (GLUT4) translocation in fat cells of diabetic rats.
Methods: Male Sprague-Dawley rats (weighing 200-250 g) were induced diabetic rat by a single intraperitoneal (i.p.) injection of STZ (45 mg/kg body weight). After 6 weeks STZ injection, diabetic rats were sacrificed and isolated the epididymal fat pads. Adipocytes were treated with four active compounds (caffeic acid, gallic acid, kaempferol and quercetin) of Morus alba leaf at concentrations of 0.1-100 mM or insulin 1.5 nM. After 30 minutes incubation, adipose cells were determined the glucose uptake and isolated cell fractionation for GLUT 4 translocation by Western blot analysis.
Results: Caffeic acid (1-100 mM) significantly increased glucose uptake into adipocytes by 23±6, 28±8 and 42±7 % of control, respectively. Kaempferol at the same concentrations of caffeic acid, increased glucose uptake significantly by 36±9, 64±10 and 24± 11 % of control, respectively. In the insulin treated adipose cells, the glucose uptake was also significantly higher than that of control glucose uptake by 65±6 %. These results have been associated to improve GLUT 4 translocation affected to increase glucose storage in adipose tissue.
Conclusions: Caffeic acid and kaempferol were found to stimulate the glucose uptake by increasing the translocation of GLUT4 in diabetic rat adipose tissue. These results may, in part, explain the ability of Morus alba leaf in controlling the hyperglycemia in diabetic patients.

P-1258

The thyroid hormone (TH) acutely increases the stability of the glucose transporter GLUT4 mRNA in 3T3-L1 cells

S.S. Teixeira[1], C. Serrano-Nascimento[1], L.L. Poyares[1], U.F. Machado[1], M.T. Nunes[1]

[1] Institute of Biomedical Sciences, Department of Phisiology and Biophisics, São Paulo, Brazil

Thyroid hormone (TH) effects on metabolism, growth, and development depend on its interaction with thyroid hormone receptors present on specific regions of its target genes, by means of which it can inhibit or activate gene transcription. However, some TH actions occur in a short period of time and in the presence of drugs that block gene transcription, as actinomycin D. These actions indicate that, in addition to its well-characterized genomic actions, TH also acts at the posttranscriptional level, by mechanisms that are not completely understood yet. One of the genes that are induced by TH is the one that codifies the GLUT4 protein, the main glucose transporter of the skeletal, cardiac muscle and adipose tissue, which is known to exert important effects on the glucose homeostasis maintenance. While, the genomic actions of the thyroid hormone on GLUT4 gene have been well characterized, there are no evidences about non genomic actions of T3 on GLUT4 expression.
Objective: To evaluate, in 3T3-L1 cells (adipocytes), the effect of the acute exposure (30 min) to T3 on the GLUT4 mRNA content and poly-A tail length, as well as on GLUT4 protein expression, in the presence or absence of previous blockade of the gene transcription, by actinomycin D.
Material and Methods: 3T3-L1 cells were treated under specific conditions until they differentiate into adipocytes. Part of them was kept in T3-depleted medium (TX) for 24 h, after which T3 (10^{-9} M) or vehicle was added, for 30 min. Part of the cells received actinomycin D (2 µg/ml) 1 h before the addition of T3. Control group consisted of cells cultured without any intervention. It was evaluated: the GLUT4 mRNA and protein expression, by real time PCR and western blotting, respectively, and the GLUT4 mRNA poly A tail length, by RT-PCR.
Results: The cells kept in T3-depleted medium (TX) presented a decreased GLUT4 mRNA and protein expression vs control group. T3 addition led to a rapid increase in both parameters, as well as on GLUT4 mRNA poly-A tail length, effects that persisted even in the presence of actinomycin D.
Conclusion: In parallel to its genomic actions, T3 can also act nongenomically increasing GLUT4 mRNA and protein expression. Considering that the stability and the translation efficiency of the transcript are directly related with the poly-A tail length, we can assume that the increased GLUT4 mRNA and protein expression were due to a T3 posttranscriptional action on GLUT4 mRNA polyadenylation step.

Cigarette smoke impaired GLUT4 expression in oxidative skeletal muscle

P.M. Seraphim[1], P.E. Silva[1], T. Alves[1], A.T.S. Fonseca[1], U.F. Machado[2], M.F.S. Teixeira[3]

[1] UNESP - Presidente Prudente, Physioterapy, Presidente Prudente, Brazil

[2] USP - Sao Paulo, Physiology and Biophysics, Sao Paulo, Brazil

[3] UNESP - Presidente Prudente, Physics Chemistry and Biology, Presidente Prudente, Brazil

There is evidence that smoke is related to a decrease in glucose transporters (GLUT4) expression and that exercise can increase the rate of transcription and GLUT4 expression in plasma membrane. This study aimed to quantify the expression of GLUT4 in oxidative skeletal muscle from rats subjected to cigarette smoke and physical exercise on a treadmill. Male Wistar rats were divided in groups: (S) sedentary, (E) submitted to aerobic exercise, (SS) smoker and sedentary, (ES) submitted to aerobic exercise and smoker. The groups SS and ES were subjected to combustion of 4 cigarettes for 30 minutes, twice a day for 60 days. E and ES performed the exercise protocol on a treadmill, 60 minutes a day, under same intensity for 60 days. Quantification of GLUT4 protein was performed by Western Blotting – ECL, after samples preparation with separation in plasma membrane (PM) and microsome (M) fractions. The quantification of GLUT4 mRNA was made by RT-PCR. For data analysis it was used descriptive statistical method and ANOVA test, results are presented as mean ± SEM. Differences among groups were considered significant when $P<0.05$. There was no alteration in body weight (BW) and glycemia (GL) among groups (BW: S:364.7±9.7; E:372.4±7.2; SS:368.9±6.8; ES:376.4±7.8 Kg; and GL: S:148±10, E:131.5±7.05, SS:139.5±9.7; ES:130.6±10.2 mg/dL, n=15 to 19 rats). The results of GLUT4 total protein content in PM fraction showed that cigarette smoke caused reduction compared to S group (S: 112.2 ± 9.5, E: 104.7 ± 13.48; SS: 65.4 ± 9.7 *; ES: 92.05 ± 15.9 expressed as AU, n = 10, * $P<0.05$ vs S). In M fraction, there was an increase in GLUT4 protein only in E group compared to S (S:157.7±20.7, E:287.7±54.4*, SS:207.7±42.5; ES:167.1±43.3 expressed as AU, n =7 to 9, *$P<0.05$ vs S). The results of mRNA showed an increase of GLUT4 expression in all groups compared to S (S:95.3±6.5, E:136.5±6.1*, SS:128,5±6,9*, ES:127.1±5.9* expressed as AU; n=8 to 10; *$P<0.01$ vs S). We can conclude that apparently the exposure to cigarette smoke during 2 months does not change glycemia and body weight, in fact. However, this exposure to cigarette smoke associated or not to exercise training impaired GLUT4 gene expression, affecting the regulation of this gene

at posttranscriptional level, since we can observe a higher mRNA content in both smokers groups associated to a reduced (SS) or maintained (ES) protein content. Thus, the exercise training can improve the GLUT4 expression only in non-smoking individuals.

Beta-cell function in individuals with a family history of type 2 diabetes mellitus

S. Bahendeka[1]
[1] *Saint Francis Hospital, Medicine, Kampala, Uganda*

To examine the susceptibility to develop type 2 diabetes in individuals with a family history of type 2 diabetes, 226 subjects residing in Bushenyi and Kasese districts of Uganda, were enrolled into the study in a matched pair design, between April and December 2006. Of these, 114 (41 men; 73 women), mean age 49 years (range 20 -70), and mean BMI 23.9 kg/m^2, had a family history of type 2 diabetes (FHD group); 112 (45 men; 67 women), mean age 54 years (range 23 – 70), and mean BMI 23.1 kg/m^2, were controls (Control group), who had no family history of type 2 diabetes.
A pair of fasting plasma glucose and fasting plasma insulin was determined in FHD and controls, and used to derive b-cell function and insulin resistance indices using homeostatic model assessment (HOMA). HOMA-%B and HOMA-IR parameters were not normally distributed and a log transformation was used in analysis; however for the sake of interpretation, the non-log transformed values are presented.
The b-cell function index was significantly (P = 0.03) lower in subjects with a family history of type 2 diabetes than in controls; (mean ± SD) %B was 63.0 ± 0.03 and 73.6 ± 1.48 respectively. Insulin resistance index, HOMA-IR was low and not significantly (P = 0.21) different between subjects with a family history of diabetes and controls; (mean ± SD) 0.77 ± 1.724 and 0.69 ± 1.578 respectively.
The prevalence (95% CI) of undiagnosed diabetes in FHD group was 7% (2.7 – 13.3%) and 2.7% (-0.3 – 6.1%) in controls.
The results indicate that there is an early but significant b-cell defect, with normal insulin sensitivity, in subjects with a family history of diabetes in this rural population. This may imply that factors associated with insulin resistance may play a secondary and probably minor role in the early pathogenesis of type 2 diabetes in this population.

Usefulness of an OGTT-derived disposition index in clinical practice

E. Bartoli[1], *F. Corlianò*[1], *E. Colli*[1], *C. Cerutti*[1], *E. Cornetti*[1], *G.P. Fra*[1], *G.P. Carnevale Schianca*[1]
[1] *Clinica Medica Generale AOU "Maggiore della Carità", Dipartimento di Scienze Mediche, Novara, Italy*

Aims: The close and inverse hyperbolic relationship between insulin secretion and insulin sensitivity is widely acknowledged. For a given degree of glucose tolerance, the product of insulin sensitivity times insulin secretion is constant and called "disposition index" (DI). The hyperbolic relationship also means that a change in one variable is mirrored by a reciprocal change of the other. Although this relationship is fundamental to understand the nature of type 2 diabetes, its use in clinical practice is restricted by measurements limited to i.v. infusions. In this study we tested the ability of the standard oral glucose tolerance test (OGTT), supported by measurements of plasma insulin values, to yield a surrogate DI index compatible with the hyperbolic relationship between its components.
Methods: A total of 1276 non-diabetic subjects (581 men and 695 women), who received a standard OGTT, were recruited. Both fasting (FPG) and the 2h plasma glucose (2hPG) concentrations and the corresponding insulinemic values (FPI and 2hPI) were used. We identified normal glucose tolerance (NGT), impaired fasting glucose (IFG), impaired glucose tolerance (IGT), the combination of these (IFG/IGT) and type 2 diabetes. Also, we calculated the estimated insulin sensitivity index (EISI) and the first phase of insulin secretion (1fsPH), as surrogate indexes of insulin sensitivity and secretion, as described by Stumvoll (Diabetes Care 2003), and indicated the product of these two variables as DI_o, the surrogate index of DI.
Results: NGT were 714 (55.9%), IFG 255 (20%), IGT 94 (7.4%), IFG/IGT 111 (8,7%), type 2 diabetes 102 (8%).The plot of EISI against 1fsPH displayed a hyperbolic function similar to that obtained with direct measurements, suggesting that DI_o may represent a good surrogate measurement of ß-cell function. In absolute terms, DI_o fell progressively from NGT (8.86 ± 0.8, mean ± standard deviation) to type 2 diabetes (4.91 ± 1.5, $p < 0.0001$), with intermediate values for the in-between steps of glucose intolerance ($F = 529.7$, $p < 0.0001$ by ANOVA performed with all 5 mean values).
Conclusion: Our results demonstrate that DI_o, obtained from OGTT related measurements of insulin sensitivity and secretion, effectively discriminates ß-cell function among the different groups of patients with glucose intolerance, and between the glucose intolerance group as a whole and normal subjects. These differences, detectable from mean values obtained in different groups, are suitable for population studies.

Liraglutide monotherapy increases mealtime insulin response significantly more than glibenclamide monotherapy in Japanese patients with type 2 diabetes

K. Kaku[1], *P. Clauson*[2], *Y. Katayama*[2], *Y. Seino*[3]
[1] *Kawasaki Medical School, Diabetes & Endocrine Division, Okayama, Japan*
[2] *Novo Nordisk Pharma Ltd, Medical Science Affairs, Tokyo, Japan*
[3] *Kansai-Denryoku Hospital, Division of Endocrinology, Osaka, Japan*

Aims: The once-daily human glucagon-like-peptide-1 (GLP-1) analogue, liraglutide, is associated with sustained improvements in glycaemic control with significant reductions in both fasting (FPG) and postprandial plasma glucose (PPG) levels. The effect on PPG may be modulated by regulation of postprandial insulin secretion by a glucose-dependent pathway. This report compares the effect of liraglutide treatment on HbA_{1c}, and mealtime insulin, glucose and glucagon levels to the effect on these parameters with glibenclamide treatment in Japanese patients with T2D.
Methods: In a 24-week, multi-centre, double-blind, randomised, parallel group trial 411 Japanese subjects (men: 67%, mean age: 58 years, duration of diabetes: 8.3 years, HbA_{1c} 8.3%) were randomised to liraglutide (0.9 mg/day, n=272) or glibenclamide (1.25 to 2.5 mg/day, n=139) once-daily. A meal test consisting of a Japanese breakfast at 08.00 h was performed at Weeks 0 and 24. An ANOVA model adjusted for treatment group, pretrial treatment and baseline values was used to analyse mean change from baseline.
Results: Mean HbA_{1c} reduction with liraglutide was -1.87% vs -1.37% with glibenclamide. For patients receiving liraglutide the mealtime insulin response (0–3 hours) after 24 weeks was significantly greater for subjects receiving liraglutide (n=226, AUC: 74.4 µU/mL*h) compared with glibenclamide (n=117; 66.5 µU/mL*h; p=0.0153). Meal-related plasma glucose profiles at 24 weeks were significantly lower with liraglutide (n=243; AUC: 32.1 mmol/L*h) compared with glibenclamide (n=119; AUC: 37.3 mmol/L*h; p<0.0001). The meal-related glucagon suppression at 24 weeks was significantly greater with liraglutide than with glibenclamide (n=243; AUC: 290.4 pg/mL*h vs n=119; AUC 316.9 pg/mL*h, respectively, p=0.0003).
Conclusion: Compared with glibenclamide therapy, treatment with liraglutide once-daily for 24 weeks was associated with significant improvement in glycaemic control which was mediated, at least in part, through a beneficial effect on postprandial plasma glucose levels. This improvement in PPG appears to be mediated, by improvement in postprandial insulin and glucagon secretion.

Association of compensatory ß-cell dysfunction and obesity and plasma nonesterified fatty acid concentration in Korean young men with normal glucose tolerance

S. Chon[1], Y. Lee[1], M. Choi[1], Y. Hwang[1], S. Oh[1], K. Ahn[1], H. Chung[1], J. Woo[1], S. Kim[1], J. Kim[1], Y. Kim[1], Y. Choi[2]

[1] *Kyung Hee University School of Medicine, Endocrinology and Metabolism, Seoul, Korea*

[2] *College of medicine Pochon-cha University, Endocrinology and Metabolism, Seoul, Korea*

Background and Aim: Obesity is known to increase the risk of the development of type 2 diabetes mellitus (T2DM), and the prolonged elevation of nonesterified fatty acid (NEFA) is also known to be an important factor attributed to progressive ß-cell dysfunction in T2DM. But association of obesity and NEFA with ß-cell function in young healthy people with normal glucose tolerance (NGT) is not well elucidated as yet. This study thus compared compensatory ß cell function according to obesity in Korean young men with NGT.

Methods: Standard 75g OGTT was performed in 362 healthy young men. Obesity was classified based upon the Asia-Pacific obesity criteria (Normal weight:18.5≥BMI<23, Overweight:23≥BMI<25, Obese:BMI≥25). The Whole Body Insulin sensitivity Index (WBISI) and $HOMA_{IR}$, Insulinogenic Index (IGI), and Disposition Index (DI = IGIxWBISI) and NEFA were measured.

Results: NGT was 260 (mean age 25.6±3.3 years). Compensatory ß-cell function (DI) was higher among overweight group than in the normal group (8.86 in overweight vs 7.04 in normal, P=0.055). But in the obese group, Disposition Index was significantly lower than the overweight group (6.46 in obese vs 8.86 in overweight, P=0.045). Regression analysis between BMI and Disposition Index showed a nonlinear relationship in spite of normal glucose tolerance. NEFA concentration was higher in the obese group compared with overweight and normal group, and NEFA had a negative linear regression relationship with Disposition Index (p=0.015). Also, after multiple regression analysis, NEFA showed a negative linear relationship with Disposition Index (p=0.017). In stratified analysis for NEFA concentration, the subject with NEFA more than 400 uEq/L showed significantly lower Disposition Index than subject with NEFA less than 200 uEq/L (p=0.009). And also, normal weight subject and obese subjects with NEFA more than 400 uEq/L had a low Disposition Index (5.84 in normal weight and 5.79 in obese, respectively).

Conclusion: This study suggests that obesity is associated with the decrease of compensatory ß-cell function in Korean young men with normal glucose tolerance. In particular, regardless of general obesity, metabolic obesity, which is status with elevated NEFA, may account for compensatory ß-cell dysfunction in the early stage of the natural history of type 2 diabetes.

Uncarboxylated form of osteocalcin is associated with improved glucose tolerance via enhanced ß-cell function in middle-aged male subjects

Y. Hwang[1], S. Chon[2], M. Choi[2], E. Lee[2], I. Jeong[1], S. Oh[2], K. Ahn[1], H. Chung[1], J. Woo[2], S. Kim[2], J. Kim[2], Y. Kim[2]

[1] *Kyung Hee East-West Neo Medical Center, Department of Medicine, Seoul, Korea*

[2] *Kyung Hee University School of Medicine, Department of Endocrinology and Metabolism, Seoul, Korea*

Introduction: Recent human studies support the notion that serum osteocalcin increases ß-cell proliferation and insulin secretion, and improves insulin sensitivity by regulating the expression of adiponectin. However, no study have examined the effects of serum osteocalcin gamma-carboxylation status on these associations or determined the role of uncarboxylated osteocalcin in glucose metabolism.

Objective and design: The aim of this study was to determine the effects of uncarboxylated osteocalcin on ß-cell function and insulin sensitivity in human. 199 men, aged 25 to 60 years (mean age, 47 yr), who had never been treated with glucose lowering agents, were enrolled in this cross-sectional study. Oral glucose tolerance test (OGTT) was performed and other metabolic parameters, such as body mass index (BMI), blood pressure, lipid profiles, liver function test, and both uncarboxylated and carboxylated osteocalcin plasma levels were measured.

Results: When subjects were divided into tertiles by uncarboxylated and carboxylated osteocalcin plasma concentrations, subjects in the upper tertile of each showed lower fasting and post-challenge glucose levels even after adjusting for age and BMI (P<0.05). Specifically, the upper uncarboxylated osteocalcin tertile was associated with higher HOMA-B% (homeostasis assessment model), which are representative of ß-cell function (P<0.05), and the upper carboxylated osteocalcin tertile was associated with lower HOMA-IR values, which are representative of insulin resistance (P<0.05).

Conclusions: Elevated levels of the uncarboxylated form of osteocalcin were found to be associated with improved glucose tolerance via the enhancement of ß-cell function in middle-aged male subjects.

R325W polymorphism in the zinc transporter-8 gene attenuates the inhibitory action of cyclosporine on insulin secretion

E. Kang[1], I. Kim[2], Y. Kim[3], Y. Ahn[2], C. Ahn[1], B. Cha[1], C. Kim[2], H. Lee[1]

[1] *Yonsei University College of Medicine, Department of Internal Medicine, Seoul, Korea*

[2] *Yonsei University College of Medicine, Department of Pharmacology, Seoul, Korea*

[3] *Yonsei University College of Medicine, Department of Transplantation, Seoul, Korea*

Objective: Recent genome association studies have revealed that the islet specific zinc transporter-8 polymorphism (R325W SLC30A8, rs13266634) is associated with type 2 diabetes and posttransplantation diabetes mellitus (PTDM). However the underlying molecular mechanism was unknown. Here we investigated the effects of this polymorphism on the insulin secretion inhibition by cyclosporine.

Methods: We made mutant type SLC30A8 cDNA by site-directed mutagenesis. Wild-type and mutant-type SLC30A8 constructs were transfected into INS-1E cells. Cells were pretreated with cyclosporine. We analyzed the amount of insulin secretion in response to glucose loading.

Results: There was no difference in amount of insulin secretion between wild-type and mutant when no glucose was loaded. Insulin secretion was reduced in cyclosporine pretreated cells. Cells transfected with mutant cDNA produced more insulin than cells transfected with wild-type SLC30A8.

Conclusions: These data suggested that R325W mutation attenuates the inhibitory effect of cyclosporine on insulin secretion in beta cell. Thereby this mutation is associated with lower prevalence of PTDM.

In vitro testing to investigate the antidiabetic biological activity of Leonotis leonurus

N. Mnonopi[1], C. Frost[1], R.A. Levendal[1]

[1] *Nelson Mandela Metropolitan University, Biochemistry and Microbiology, Port Elizabeth, South Africa*

Insulin resistance and the resultant impairment in glucose tolerance are early signs of diabetes. The malfunctioning and/or death of ß-cells also contribute to the etiology of the disease. Hyperglycemia does not only cause ß-cell exhaustion, but, also impairs one or more key aspects of ß-cell physiology and gene expression. The aim of this study was to determine the anti-diabetic activity associated with Leonotis leonurus extracts in INS-1 cell line.

INS-1 cells were cultured under normo- and hyperglycemic conditions. Commercial marrubiin standard (M), the active agent in Leonotis leonurus, organic (OL) and aqueous (AL) extracts of Leonotis leonurus were screened for anti-diabetic activity in vitro. The stimulatory index of INS-1 cells cultured under hyperglycemic conditions was significantly increased by 60% and 61% ($P < 0.01$; n=5) in cells exposed to the OL extract (10µg/ml marrubiin) and marrubiin (500ng/ml), respectively, relative to the normoglycemic conditions. The gene expression of insulin was significantly increased by 76.5% and 71%, and of Glut-2 by 93% and 92.5% for M and OL, respectively, under the same conditions stipulated above ($P < 0.01$; n=4).The extract and M similarly showed an increase in respiratory rate under hyperglycemic conditions. Preliminary results therefore indicate an increase in oxygen consumption as a possible mechanism for the increased rate in insulin secretion under hyperglycemic condition.

Rhein improved early-phase insulin secretion and reversed glucose intolerance in db/db mice

H. Du[1], J. Shao[1]
[1] Nanjing University, endocrinology, Nanjing, China

Aims: Rhein (4,5-dihydroxyanthraquininone-2-carboxylic acid) is one of the anthraquininone derivatives isolated from rhubarb, a Chinese herbal medicine, which has been found to be of value in preventing the development of diabetic nephropathy. Few studies have examined anti-diabetic effects of rhubarb extracts and their constituents. In the present study, we determined whether rhein have hypoglycemic action and how rhein affect ß-cells in db/db mice.
Methods: Thirty 4-week-old db/db mice were randomized to treatment with rhein (120mg/Kg) (n=10), irbesartan (10mg/Kg) (n=10), and placebo (1% natrium cellulose solution) (n=10) by gavage for 8 weeks respectively. Body weight and non-fasting blood glucose level was measured every week. After 8 weeks' treatment, intraperitoneal glucose tolerance test (IPGTT), immunohistochemical staining of insulin were performed, and beta-cell mass was estimated by insulin-stained section. AUC (area under curve) of insulin levels in IPGTT was calculated to evaluate insulin secretory function, and $AUC_{INS0\text{-}30}$ was calculated as $(INS_{30}\text{-}INS_{0})$?15 to evaluate early-phase insulin secretion. Islet isolation and perifusion were performed to evaluate kinetics of insulin release in vitro, especially first-phase insulin.
Results: In rhein-treated group, the blood glucose concentrations at 0min, 60min and 120min after glucose load were significantly reduced. Simultaneously measured insulin levels at 30min and 60min were significantly higher than those of control, furthermore, rhein group presented a good early-phase insulin response, which indicated by an apparent positive $AUC_{INS0\text{-}30}$. In irbesartan- treated group, the blood glucose concentrations also decreased but only significant at fasting state. And the irbesartan group showed an improved insulin secretion at 60min of IPGTT ($P<0.05$). Perifusion showed that rhein-treated group manifested a notable increase of first-phase insulin secretion. And ß-cell mass was greatly rescued by 8 weeks' treatment by both rhein and irbesartan ($P<0.05$). Staining density of insulin were also notably improved in both rhein and irbesartan group when compared with control.
Conclusions: Rhein treatment initiated almost completely reversed glucose intolerance by significantly improved first-phase and early-phase insulin secretion on db/db mice. While irbesartan showed improved basal insulin secretion and decreased fasting blood glucose. And the characteristic of rhein may make itself a novel therapeutic means for preventing from or curing diabetes in the near future.

Adult nesidioblastosis: an illustrative case and 10 years follow up

P. Fragueiro[1], E. Cohen[1], C. Massano[2], R. Palencia[3], L. Armando[4]
[1] Private University Clinic Reina Fabiola Catholic University of Cordoba Argentina, Endocrinology, Cordoba, Argentina
[2] Private University Clinic Reina Fabiola Catholic University of Cordoba Argentina, Cardiology, Cordoba, Argentina
[3] Private University Clinic Reina Fabiola Catholic University of Cordoba Argentina, Surgery, Cordoba, Argentina
[4] Private University Clinic Reina Fabiola Catholic University of Cordoba Argentina, Pathology, Cordoba, Argentina

Aims: To present a case report
Material and Methods: A 55- year-old female shows symptoms of asthenia, nervousness and neuroglycopenia with loss of consciousness, aphasia and temporary agnosia crises. These crises were at first sporadic, within 3 to 5 postprandial hours, becoming, as time elapsed, more frequent, intense and at any hour of the day. Biochemical assessments were normal. The patient underwent brain CT, MRI and EEG, splenic arteriography and abdominal MRI; all of them were normal. She developed recurrent neuroglycopenic symptoms within 24 hr, including a serum glucose level of 20 mg/dl, which again responded to intravenous 50% dextrose (Whipple's Triad positive). The patient was transferred to our institution. While in a monitored setting, she developed neuroglycopenic symptoms and measurable laboratory abnormalities including a serum glucose level of 30 mg/dl, a serum insulin level of 69 uU/ml and a serum C-peptide level of 4,9 ng/ml. The patient underwent surgical exploration. No specific lesion was palpated in the pancreas and intraoperative ultrasound was normal. The distal pancreas was resected to the left of the superior mesenteric vessels with a splenectomy. The histological picture showed: an increase in the number of endocrine cells in the shape of simple elements or small ones tied together in the center of the exocrine tissue and in some areas close to small ducts. Islets of a bigger size and irregular shape and distribution can also be observed; some of them in contact with the connective tissue, the interlobar ducts solely remaining. Every 6 months in 10 years follow-up the patient has subsequently remained euglycemic and asymptomatic without drugs. Fasting and 6-minute C-peptide values after intravenous administration of 1 mg of glucagon were normal. Pancreatic complications were absent.
Results: Nesidioblastosis is a disorder characterized by neoproliferation and disorganization of islet cells, which bud from pancreatic ducts. Intraoperative ultrasound is the most sensitive method of detecting all islet cell tumors, including tumors smaller than 1 cm not palpated at the time of surgery. The patient satisfied the diagnostic criteria for endogenous hyperinsulinemia: high plasma insulin and C-peptide concentrations during episodes of hypoglycemia.
Conclusions: The importance of this case lies in the low frequency of adult nesidioblastosis. There have been several reports of recurrent hypoglycemia or postsurgical diabetes even after a 95% resection of the pancreas.. We deem advisable to take this pathology into account in the presence of classical symptoms of hypoglycemia and use the detection methods necessary to confirm the disease.

Pancreatic ß-cell function, insulin resistance and glycaemic control in Nigerians with type 2 diabetes mellitus

A.O. Coker[1], O.A. Fasanmade[1], A.E. Ohwovoriole[1]
[1] Lagos University Teaching Hospital, Endocrinology and Metabolism Unit Department of Medicine, Lagos, Nigeria

Background: There is currently limited data on the relative role of pancreatic ß-cell function and insulin resistance together as determinants of glycaemic control in patients with type 2 diabetes mellitus in Nigeria.
Objective: To determine the relationship between pancreatic ß-cell function, insulin resistance and glycaemic control in Nigerians with Type 2 Diabetes Mellitus
Materials and methods: ß-cell function was determined by the measurement of basal and post glucagon C-peptide estimations and the calculation of the Homeostasis Model Assessment of Insulin Secretion (HOMA%B). Insulin resistance was assessed by calculation of the Homeostasis Model Assessment of Insulin Resistance (HOMA-IR). Glycaemic control was estimated using fasting plasma glucose and glycated haemoglobin (HbA_{1c}) in 40 subjects with type 2 diabetes mellitus and twenty control subjects.
Results: Mean ±SEM post glucagon C-peptide (PGCP) was lower in subjects with diabetes compared with the control subjects (2.9 ± 0.22 versus 5.6 ± 0.5 $p<0.05$). Subjects with diabetes had a significantly lower HOMA%B of 47.5±3.6% compared with HOMA%B of 62.7±4.7% in controls. ($p=0.02$).
The Homeostasis Model Assessment of Insulin Resistance (HOMA-IR) in the control subjects of 1.2±0.1 was similar to the subjects with diabetes (1.2±0.1). Of the subjects with diabetes, 27 (67.5%) had good glycaemic control (HbA_{1c} <7%). Multiple Regression analysis showed that HOMA%B was the major contributor to glycaemic control.
Conclusions: Pancreatic ß-cell dysfunction and insulin resistance were positively related to glycaemic control with ß-cell dysfunction being the major contributor.

Liraglutide induces human beta-cell proliferation and counteracts the deleterious effects of low density lipoprotein and IL-1beta

S. Rütti[1], R. Prazak[1], H. Ellingsgaard[1], R. Sibler[1], L.B. Knudsen[2], A. Von Eckardstein[3], M.Y. Donath[1]
[1] University Hospital Zürich, Endocrinology and Diabetes, Zürich, Switzerland
[2] Novo Nordisk, A/S, Malov, Denmark
[3] University Hospital Zürich, Institute for Clinical Chemistry, Zürich, Switzerland

Aims: Glucagon-like peptide 1 (GLP-1) analogs induce ß-cell proliferation and have anti-apoptotic effects in rodent islets. However, the proliferative capacity

of human ß-cell and its modulation by GLP-1 analogs remain to be fully investigated. The aim of this study was to determine whether the GLP-1 analog liraglutide affects ß-cell proliferation and to investigate whether liraglutide is able to counteract the anti-proliferative effect of low density lipoprotein (LDL) and the pro-apoptotic effect of interleukin-1ß (IL-1ß).

Methods: Human islets from cadaveric organ donors were dispersed into single cells and exposed to liraglutide for 2 days and co-stained for BrdU incorporation and insulin, allowing the determination of proliferative ß-cells. The anti-apoptotic effects of liraglutide against 2 ng/ml IL-1ß were tested in human islets cultured for 4 days and analyzed for cell death by the TUNEL assay. Islets obtained from LDL receptor -/- or +/+ mouse were cultured for 4 days in the presence of liraglutide and 3.1 mM LDL, isolated from healthy human plasma. Proliferation was assessed by analyzing BrdU incorporation.

Results: After 2 days incubation, liraglutide increased human ß-cell proliferation (unequivocally identified by insulin staining), in a dose dependent manner up to 3 fold. Moreover, 4 days incubation with liraglutide protected human islet cells from IL-1ß induced apoptosis. LDL decreased mouse islet cell proliferation independently of LDL receptor expression and this anti-proliferative effect of LDL was counteracted by the presence of liraglutide.

Conclusion: These results indicate that human ß-cell can proliferate in vitro in response to liraglutide. Furthermore, liraglutide protects human islet cells from IL-1ß induced apoptosis and counteracts the anti-proliferative effect of LDL in mouse islets, suggesting additional mechanisms for the anti-diabetogenic effects of liraglutide.

Improving the function of microencapsulated islets using co-encapsulation with pancreatic duct cells

G. Langlois[1], J. Dusseault[1], S. Bilodeau[1], S.K. Tam[2], J.P. Hallé[1]
[1] Hôpital Maisonneuve-Rosemont, Centre de recherche, Montreal QC, Canada
[2] École Polytechnique de Montréal, Institut de génie biomédical, Montreal QC, Canada

Islet transplantation has normalized the blood glucose levels in patients with type 1 diabetes. However, this treatment requires the use of potentially harmful immunosuppressive drugs. An alternative to immunosuppression is the use of semi-permeable microcapsules that allow the diffusion of glucose, nutrients and oxygen but protect the transplanted cells against immune reaction. Another important problem is the limited survival of encapsulated and free islet cells.

Pancreatic duct cells have been shown to play an important role in pancreas morphogenesis. The co-incubation of pancreatic duct cells and islets has decreased cell apoptosis and necrosis in the immediate post-isolation period. We have previously shown that incubating islets with IGF-II, the principal peptide that is secreted by duct cells, diminishes apoptosis and necrosis of encapsulated islets and allows the restoration of euglycaemia in diabetic mice using fewer islets.

The objective of this study is to investigate the effect of co-encapsulating islets with pancreatic duct cells on islet cell survival.

Pancreatic duct cells were isolated from C57BL/6 mice and their identity was confirmed by immunohistochemistry using antibodies against cytokeratin 7 (CK7) and IGF-II. The presence of known contaminants (fibroblasts and mesenchymals cells) was investigated by flow cytometry using their common marker: vimentin.

Islets encapsulated alone or co-encapsulated with two different concentrations of duct cells (20 or 100 cells per capsule) were maintained in culture and evaluated at days 1, 7, 14 and 27 post-encapsulation. Islet viability was evaluated using fluorescent dyes (acridine orange and propidium iodide), the percentage of necrotic islets by inverted-microscope analysis and their function by an MTS test.

Duct cells expressed IGF-II and CK7. The cell preparation was pure at >85%. Islets cell viability was between 60-80% for islets encapsulated alone or with duct cells with no significant difference. This co-encapsulation did not have a significant impact on the islets necrosis which remained consistently between 30-40%. Co-encapsulating islets with 100 duct cells had a significant impact on islet function (vs. islets encapsulated alone). This was demonstrated by the MTS test, which showed an absorbance at 492 nm of 0.32 ± 0.06 for co-encapsulated islets (vs 0.09 ± 0.01; $p<0.005$) at day 1 and 0.38 ± 0.12 (vs 0.10 ± 0.02; $p<0.05$) at day 27.

The present study demonstrated that co-encapsulation with duct cells had a moderate effect on islet function, but failed to show a positive effect on islet cell survival. Considering the concordant results of previous studies, the present results were unexpected. Further studies are needed to explain these results and will involve in vivo transplantation in diabetic animals.

The effect of high carbohydrate and high fat diet on rat atherosclerotic process and pancreatic beta-cell apoptosis

D.W. Soeatmadji[1], D. Ismiranto[1], Y.A. Wibisono[1], E.N. Hamidah[1], I. Suryani[1], A. Haidar[1], M. Mutiyani[1]
[1] Dr. Saiful Anwar Hospital, Internal Medicine, Malang, Indonesia

To examine the effect of high carbohydrate diet compared to high fat diet on atherosclerotic process and pancreatic b-cell apoptosis, three groups of Rattus norvegicus Wistar strain were fed with isocaloric high fat diet (GIII), high carbohydrate (GII) and "normal" diet (GI). Proinflammatory cytokines expression in aorta wall were assessed using immunohistochemistry, and foam cells were identified using oil red O and Meyer hematoxylin staining. B-cell density were assessed using hematoxylin eosine staining and b-cell apoptosis were identified using apoptek. Blood glucose level of was significantly higher in GII than GI (281.87 ± 39.66 mg /dl vs 192.5 ± 1.4 mg / dl, $p = 0.002$). Group II and GIII showed higher level of triglyceride compared to GI (138.0 ±47.15 vs 85.5 ± 20.3, $p = 0.02$; 163.62 ± 41.77 vs 85.5 ± 20.3, $p = 0.00$, respectively). Level of LDL was significantly higher in G III than G I (72 ± 35.6 vs 27.0 ± 8,9, p= 0.00). There were no significant difference in level of HDL among the three groups. VCAM-1, PPAR a, eNOS, TNF a, CD4 T helper and NFkB were significantly more expressed in GII and G III than GI ($p = 0.00$). The number of foam cells was significantly higher in G II and G III than in G I (7.18 ± 5.28 VS 1.2 ± 1.4, $p = 0.00$; 9.91 ± 6.26 VS 1.2 ± 1.4, $p = 0.00$,respectively). The pancreatic b-cell density was lowest in GII followed by GIII and the highest one was in GI (p=0.00)The pancreatic b-cell apoptosis was highest in GII, followed by GIII and the lowest was in GI (p=0.00).

We conclude that high carbohydrate diet as well as high fat diet potentially increase the risk of atherosclerosis. During an early stage of atherosclerosis, both diets induce endothelial dysfunction, inflammatory processes and increase foam cell formation. High carbohydrate diet may also increase pancreatic b-cell apoptosis leading to decrease of pancreatic b-cell density.

The role of zinc in the pathogenesis of diabetes mellitus

A.G. Meyramova[1], O.N. DuPont[1], G.G. Meyramov[1]
[1] Private Diabetes Research Group, Diabetes Research Lab, Karaganda, Kazakhstan

It is known that B-granules of pancreatic B-cells of human, rats, rabbits, dogs, mice and hamsters contain a large amount of Zn2+ions, which take part in the storage of insulin in B-cells. Today more than 30 diabetogenic chemicals are known that result in the selective destruction of B-cells and development of diabetes (DM). 19 are diabetogenic zinc-binding chelate active chemicals (DZB) which form complex salts with Zn 2+ions in the cytoplasm of B-cells. 18 belong to diabetogenic derivatives of 8-oxyquinolin (D8OX) and only 1 – Xanturenic Acid (XA) – is formed in human and animals as result of disturbances of tryptophan metabolism.

Aim of work: to evaluate the diabetogenic activity of Dithizone (DZ) and 8 D8OX derivatives – 8-para- (toluenesulphonylamino)quinolin, 8-benzyl (sulphonylamino)quinolin, 8-meta- (sulphonylamino)quinolin, 5-ortho-(toluene)-8-oxyquinolin, 5-amino-8-oxyquinolin, 5-meta- (hydroxyphenylazo)-8-oxyquinolin, 8-oxyquinaldinic acid, 8-oxyquinaldin, 4,8-dihydroxyquinolin-2-carboxylic acid (XA) – and determine the mechanisms of their action, leading to methods for the prevention of the destruction of B-cells.

Results and conclusions: On the basis of data previously obtained by us we conclude: 1) injection of DZB to animals results in binding of Zn+2-ions in B-cells within 2-5 min as evidenced by colored complexes of Zn+2-chelator in the cytoplasm and development of diabetes; 2) binding of Zn+2-ions in B-cells by D8OX and DZ followed by removal of chelator from this complex within first 5 min after formation does not cause death of B-cells and developing of DM in 95% of animals; but binding for 15 min and longer results in complete destruction of B-cells and development of DM in 100% of animals; 3) destruction of B-cells is initiated by destroying B-granules, which contain almost all of Zn+2-ions in the B-cells, that results in the destruction of the cell matrix on 30-40% of cell's surface 15-20 min later and on 90-95% 2h

later; 4) prevention of the formation of Zn+2-chelator complexes in B-cells completely prevents the destruction of B-cells and development of DM in 95-100% of animals; 5) destruction of B-cells may be completely prevented by: a) preliminary non diabetogenic binding of Zn+2-ions in B-cells by Na salt of Diethyldithiocarbamic acid, Cystein and L-Hystidine; b) by complete elimination of Zn+2-ions from B-cells before in vivo administration of DZB; c) by interception of DZB in tissue culture nutrient media by introduction of Zn+2-ions as ZnSO4. For destruction by XA, the preferred preventative is d) prolonged treatment with vit.B6 to inhibit endogenous synthesis of XA.

Inhibition of synthesis of diabetogenic metabolites of tryptophan by pyridoxine (II)

A.G. Meyramova[1], F.A. Mindubaeva[1], A.A. Kikimbaeva[1], O.N. DuPont[1], G.G. Meyramov[1]

[1] Private Diabetes Research Group, Diabetes Research Lab, Karaganda, Kazakhstan

Chronic deficiency of vit.B6 (pyridoxine) in animals and humans results in inhibition of synthesis of Pyridoxal-5-Phosphate which is the direct cause of intensive endogenous synthesis of Xanturenic Acid (XA), a main diabetogenic metabolite of disturbances of Tryptophan metabolism. XA is one of 18 diabetogenic derivatives of 8-oxyquinolin (D8OX) and is synthesized in vit.B6 deficient humans.

Aim of work: try to inhibit endogenous synthesis of XA in rats maintained on diet to stimulate endogenous synthesis of XA (starch-52%, casein–22%, butter-15%, sugar -5%, yeast-3%, mineral salt-3%) for 4 months by the prolonged administration of. vit.B6.

Methods: 2 groups of animals, 18 in each: 1) diet only; 2) diet+vit.B6. Blood glucose control (BG) weekly; Xanturenic acid in urine (XAU) assayed monthly; histology: staining of pancreas sections by aldehydefucshine and of insulin by immunohistochemical method with measuring stain intensity (IG).

Results: 1) before diet: BG-4.7±0.4 mM, XAU-0.035±0.004 mg/ml; 2 months on diet: BG-5.5±0.5 mM, XAU-0.142±0.024 mg/ml; 4 months on diet: BG-10.8±1.2 mM (8.9-12.2 mM), XAU- 0.424±0.076 mg/ml; histology: necrosis and destruction of B-cells on 35-40% of islet's surface in 38 of 51 islets investigated (75%); decreasing of insulin content in B-cells: IG-0.26±0.04 (in intact B-cells-1.00±0.03); 2) 16 animals before diet and treatment by vit.B6: BG-4.6±0.6 mM; XAU-0.028±0.007 mg/ml; 2 months on diet + vit.B6: BG-4.7±0.4 mM; XAU-0.067±0.014 mg/ml; 4 months on diet+vit.B6: BG-5.6±0.6 mM (5.1-6.0 mM); XAU-0.078 ±0.016 mg/ml; histology: partial necrobiosis on 25-30% of B-cell's surface in 29% of islets from 100 investigated; in other 71% without changes; IG-0.87±0.04 (in intact B-cells-1.00±0.04; 2a) 2 animals on diet+vit.B6: before: BG-4.8±0.5 mM; XAU-0.036±0.007 mg/ml; 4 months on diet: BG-4.8± 0.5 mM; XAU-0.036±0.007 mg/ml; BG-8.7±0.7 mM; XAU-0.146±0.027 mg/ml; histology: destruction of B-cells on 12-15% of islet's surface in 28 of 55 islets investigated (49%); IG-0.58±0.04 (in intact B-cells-1.00± 0.05).

Conclusion: In animals maintained on diet stimulating endogenous synthesis of XA, 4 months prolonged administration of vit.B6 resulted in inhibition of XA synthesis, evident decreasing of XA in the urine, and reduction in developing symptoms of diabetes in majority of animals.

Diabetes influences histaminergic regulation of the process of the human amniotic epithelial cells (HAEC) differentiation into pancreatic beta-like cells (PBLC)

D. Szukiewicz[1], M. Pyzlak[1], G. Szewczyk[1], D. Maslinska[2], S. Maslinski[1]

[1] Medical University of Warsaw, General and Experimental Pathology, Warsaw, Poland

[2] Polish Academy of Sciences, Institute of Medical Research Centre, Warsaw, Poland

Aim: Recent studies revealed that histamine is involved in pancreatic beta-cell differentiation and insulin secretion. HAEC resemble stem cells and express both H1 and H2 histamine receptors. HAEC in this study were isolated from the amnions obtained after pregnancies complicated by diabetes class C (after White), (group I/culture I; n=10) and after normal pregnancies (group II/culture II; n=10). We compared (group I vs II) expression patterns of H1 and H2 in HEAC cultured in vitro at different stages of nicotinamide-induced differentiation into PBLC.

Methods: HAEC were cultured in normoxia in 24-well cell culture plates (1.0 million cells per well) in Ham's F12 and Dulbeco's modified Eagle medium with 10% fetal calf serum. Altogether, 60 cultures were established. On Day 5, the medium was supplemented with nicotinamide (10 mM). C-peptide concentration in the culture medium collected every 3 days for 15 days was determined by ELISA as an indicator of differentiation into PBLC. At the same intervals the supernatants were removed and the cultures formalin-fixed paraffin-embedded for H1 and H2 receptors immunostaining. Quantitative immunohistochemistry was used for evaluation of H1 and H2 expression.

Results: C-peptide was detected on Day 6 in both cultures and the concentrations were kept gradually increased until Day 12, then stayed at almost the same level, 4,8-fold and 3,5-fold higher than initially (culture I and II, respectively). Expression of H2 was significantly ($p<0.05$) decreased in culture I and amounted (mean % value, ±SEM) 67,91 ±11.34 at the first measurement. Beginning on Day 9, another decrease was noted during consecutive evaluations in both groups. The mean decline in H2 receptor expression was significantly less in culture I, and amounted (mean % value for the measurements performed on Day 12 and Day 15, ±SEM) 55.37 ±12.02 of the value obtained in culture II. Initial expression of H1 was significantly lower in group I (74,32% ±10.87). The differences in H1 expression were not observed during nicotinamide-induced differentiation.

Conclusion: Considering the role of histamine H2 receptors in cell differentiation and possible effects of diabetes on this process, overproduction of C-peptide by diabetic HAEC differentiating into PBLC may be a consequence of a kind of "preconditioning" in proinflammatory environment with unstable glycaemic control.

Expression of Dexras1 in pancreatic b-cells is modulated by prolactin and glucocorticoid pathways

C.L. Santos[1], G.F. Anhe[1], T.C. Nogueira[1], C.R. Bromati[1], A.R. Leite[1], T.S. Yamanaka[1], A.C. Boschero[2], S. Bordin[1]

[1] Institute of Biomedical Sciences, Physiology and Biophysics, São Paulo, Brazil

[2] Institute of Biology, Physiology and Biophysics, Campinas, Brazil

Increased glucose-induced insulin secretion is a trademark of maternal pancreatic b-cells adaptation during pregnancy. This adaptation is believed to be a result of increased STAT5 activation due to high levels of prolactin (PRL). Glucocorticoids (GCs) are known to counteract PRL action and suggested to account for the rapid return of maternal endocrine pancreas to the non-pregnant state. To date, the precise molecular mechanism underlying GCs action is poorly understood. Dexras1 is a member of small G-protein family that is strongly and rapidly regulated by dexamethasone (DEX). It has been suggested that Dexras1 is involved in the regulation of cell morphology, growth and neuronal secretion. So far, the expression and putative function for Dexras1 in pancreatic b-cell has not been settled. The present study was undertaken to examine Dexras1 expression in insulin secreting cells and whether it is correlated to the functional changes of the maternal endocrine pancreas. Additionally, we assessed the possible participation of PRL and GC crosstalk signaling pathways in Dexras1 expression. In order to achieve this goal, gene expression was assessed by RT-PCR and protein content was analyzed by Western Blotting, both in pancreatic islets isolated from 19 day pregnant (P19) and three day lactating (L3) rats and in RINm5F cells treated with PRL (500ng/mL), DEX (100nM) or PRL+DEX. STAT5 interaction to glucorticoid receptor (GR) was assessed by co-immunoprecipitation. Dexras1 was knocked-down by specific siRNA and STAT5b binding to Dexras1 promoter was analyzed by chromatin immunoprecipitation assay (ChIP). Insulin secretion was measured by RIA in MIN6 after Dexras1 knockdown. Dexras1 expression is decreased in pancreatic islets from P19 and increased in that from L3 rats. As expected, DEX increased Dexras1 expression in the presence or in the absence of PRL. DEX induced a rapid STAT5/GR association. ChIP analyses revealed that STAT5 binds to Dexras1 promoter. PRL decreases and DEX increases STAT5 interaction to Dexras1 gene. The combination of PRL and DEX exhibited no effect when compared to untreated cells. STAT5 binding to Dexras1 was diminished in P19 and augmented in L3 islets. Dexras1 knockdown led to an increase in cumulative insulin secretion. Our results show that Dexras1 is expressed in pancreatic beta cells. Dexras1 expression is positively modulated by DEX which is likely to account for the increased DEXRAS1 in L3 pancreatic islets.

Our data suggest that Dex-induced Dexras1 expression results somehow from increased STAT5 binding to Dexras1 promoter, probably bound to GR. Finally, the increased insulin secretion induced by Dexras1 knockdown points to an important role of this protein in maternal pancreatic islet physiology during the peripartum.

Pancreatic antibodies and fasting C-peptide in children with type 1 diabetes mellitus from Romania

A. Vlad[1], V. Serban[1], R. Timar[1], M. Rosu[1], A. Sima[1], L. Diaconu[1]
[1] University of Medicine and Pharmacy "Victor Babes", Diabetes Clinic, Timisoara, Romania

Aims: In order to develop methods for preventing type 1 diabetes mellitus (T1DM), it is very important to know its pathogenic mechanisms. The aim of this work was to characterize a cohort of children with T1DM regarding pancreatic antibody (PA) positivity and fasting C peptide concentrations and to evaluate the influence of disease duration on these parameters.
Methods: The study group comprised 117 children with T1DM, 61 boys (52.1%), mean age ± SD 12.7 ± 3.1 years (range 4 – 18 years), mean disease duration ± SD 1.8 ± 1.6 years (range 0 – 11.4 years), admitted in „Cristian Serban" Clinical Medical Center from Buzias (Romania) in year 2006. Islet cell antibodies (ICA), GAD65 antibodies (GADA), IA-2 antibodies (IA-2A) and fasting C peptide were measured. Results were expressed as units of optical density (UOD) for ICA, units/ml (U/ml) for GADA and IA-2A and ng/ml for fasting C peptide. The threshold for PA positivity was considered 97.5th percentile from a control group (n=73), matched for age and sex: 0.67 UOD for ICA, 3.7 U/ml for GADA and 4.83 U/ml for IA-2A. Normal values for fasting C peptide were between 5th and 95th percentiles from the control group: 0.57 – 4.17 ng/ml. The statistical methods used were unpaired t test and Fisher's exact test.
Results: Taking into account the duration of T1DM, the study group was divided into 4 subgroups: 0-1 year (n=33), 1-2 years (n=34), 2-3 years (n=20) and >3 years (n=30). The positivity for the 3 PA and the values of fasting C peptide are shown in the table.
Table. PA positivity and fasting C peptide values in children with T1DM

Parameter	Study group (n=117)	Disease duration (years)			
		0-1 (n=33)	1-2 (n=34)	2-3 (n=20)	>3 (n=30)
PA+, n (%)	51 (43.6)	17 (51.5)	18 (52.9)	7 (35)	9 (30)
ICA+, n (%)	17 (14.5)	7 (21.2)	7 (20.6)	2 (10)	1 (3.3)
GADA+, n (%)	17 (14.5)	5 (15.2)	6 (17.6)	4 (20)	2 (6.7)
IA-2A+, n (%)	31 (26.5)	10 (30.3)	9 (26.5)	5 (25)	7 (23.3)
Fasting C peptide Mean±SD, ng/ml Normal C peptide, n (%)	0.27 ± 0.46 17 (14.5)	0.44 ± 0.57 9 (27.3)	0.24 ± 0.31 3 (8.8)	0.23 ± 0.67 2 (10)	0.14 ± 0.21 3 (10)

From the 51 patients PA+, 39 (33.3%) were positive for 1 PA, 10 (8.6%) were positive for 2 PA and 2 (1.7%) were positive for all the 3 studied PA. The positivity for PA and for ICA was significantly lower in patients with disease duration >2 years, compared with the rest: 16/50 (32%) v. 35/67 (52.2%) (p=0.03) and 3/50 (6%) v. 14/67 (20.9%) (p=0.03), respectively. The positivity for GADA and IA-2A did not depend on disease duration. Mean fasting C peptide concentrations and the percentage of patients with normal C peptide decreased significantly 1 year after the diagnosis of T1DM was established: 0.20±0.40 ng/ml v. 0.44±0.57 ng/ml (p=0.03) and 8/84 (9.5%) v. 9/33 (27.3%) (p=0.02), respectively.
Conclusion: In children with T1DM, the positivity for PA and for ICA decreases significantly 2 years after the diagnosis of T1DM, the positivity for GADA and IA-2A lasts longer and fasting C peptide decreases significantly 1 year after the onset of the disease.

Dual-oxidase 2 (DUOX-2) as an important regulator of insulin receptor signaling

A.K. Chowdhury[1], D.K. Singh[2], Z. Siddique[2], R. Krishnan[2], K.V.S. Rao[2]
[1] BIRDEM, Dept. of Immunology, Dhaka, Bangladesh
[2] ICGEB, Immunology Group, New Delhi, India

Aims: The strength of receptor signaling is centrally controlled through a cooperative loop between Ca^{2+} and an oxidant signal and dual oxidase 2 (Duox-2) is the source of that reactive oxygen species (ROS). Therefore, we undertook the present study to see the role of Duox-2 in insulin receptor signaling.
Methods: A-20 and NIH-3T3 cell lines were transfected with siRNA and shRNA. Western blot (WB) analysis with isolated RNA performed to see the phosphorylation activity of different molecules involved in insulin signaling. Proliferation assay, fixed confocal microscopy (Bio-Red MRC-1024/Radiance 2100) and confocal live cell imaging (Nikon TE-2000-E) were performed on siRNA and ShRNA treated and non-treated A-20 and NIH-3T3 cells.
Results: Production of ROS (H_2O_2) in A-20 and NIH 3T3 cells (as evidenced by DCF fluorescence) is more in recombinant insulin stimulated normal cells than siRNA and shRNA transfected cells. Fluo-4 AM fluorescence, where cells were transfected with shRNA against Duox, shows considerable decrease of Ca^{2+} mediated fluorescence after recombinant insulin stimulation. WB analysis with cytoplasmic lysates from NIH 3T3 cells, under shRNA mediated knock-down of Duox for 24 hours as well as non-knockdown cells showed reduced signaling in shRNA knock-down cells as reflected by decreased level of phosphorylation. The magnitude of signaling was significantly reduced in active signaling molecules like molecules of MAPK pathway (pRaf, pERK, pJNK) as well as pSrc416, pPLC, pPKC, pPKD and pIκB relevant to insulin signaling. Proliferation assay suggested that Duox knock-down causes drastic reduction in cell proliferation and stimulation of the cells with recombinant insulin does not rescue the inhibitory effect.
Conclusion: Duox-2 is at least one of the important enzymatic sources of ROS that has important role in insulin receptor signaling pathway.

Ghrelin is expressed in non- insulin, non-glucagon cells within the adult human pancreas and stimulates insulin secretion in INS1 beta cells through a mechanism involving NO

S. Nelson[1], Y. Anini[1]
[1] Dalhousie University, Physiology and Biophysics, Halifax, Canada

Ghrelin is a multifunctional hormone that has been shown to regulate glucose homeostasis, although this effect is controversial, with reports of both stimulation and inhibition. We have found ghrelin expression in adult human pancreatic islets that is not co-localized with insulin or glucagon. This population of ghrelin cells may regulate nearby beta cells. The aim of the current study was to investigate the actions of ghrelin using the beta cell line INS1. Binding experiments revealed that INS1 cells have ghrelin specific binding sites, representing GHS R1a, as GHS R1a antagonist [D-Lys^3] GHRP6 competed with ghrelin for the same sites. One hr treatment of INS1 cells with ghrelin in the presence of 11mM glucose stimulated insulin secretion (0.01nM ghrelin: 53% increase, 46.27pg/mg protein ±8.2 (SEM), 10nM ghrelin: 50% increase, 45.23pg/mg protein ±8.3 vs control 30.13pg/mg protein ±2.9) as measured by insulin RIA. Inhibition of NO synthase inhibited the stimulatory actions of ghrelin on insulin secretion, while blockade of Kv channels had no effect. Quantitative RT PCR analysis of INS1 cells treated with ghrelin for 16hr indicated a 55% decrease of proinsulin transcript. These results indicate that ghrelin plays a divergent role in regulating insulin secretion and expression.

Screening for diabetes mellitus type 2 in urban native and alien populations of the Republic of Khakasia

S. Dogadin[1], S. Boyko[2], N. Rossova[2]
[11] Krasnoyarsk State Medical University and Krasnoyarsk Territory Clinical Hospital, Endocrinology centre, Krasnoyarsk, Russia
[2] Ministry for Health Care of Khakasia Republic, Endocrinology Department, Abakan, Russia

The Republic of Khakasia is the part of Russian Federation and situated in the southwest part of Eastern Siberia. The total area of Khakaia is 61,900 sq.km. The population is 583,200 and represented by natives (khakases, 11%) and aliens (caucasians, 89%). The climate of Khakasia is distinctly continental.
Aims: to screen for diabetes mellitus type 2 (DM2) in native and alien inhabitants of the Abakan, the capital of Republic of Khakasia.
Methods: The target cohort of this study was selected randomly from 120,514 residents with age 20+. There were 4,955 residents (518 natives-4% of total native population and 4,437 aliens- 3.7% of total alien population of Abakan) participated in the study. Two-step strategy was used. The blood glucose was determined at random time. Those with glucose > 5,5 were examined with 75g oral glucose tolerance test (OGTT). WHO (1999) diagnostic criteria were used to determine the diagnoses of diabetes and impaired glucose regulation.
Results: OGTT examination (response rate 98.3% for aliens and 100% for natives) found DM2 in 62 persons and impaired glucose tolerance (IGT) in17 persons. DM2 was found in 53 aliens (16 men and 36 women in 36-75 year age group, mean: 57±10 years) and in 9 natives (1 man and 8 women in 46-75 year age group, mean: 58±10 years). IGT was found in 16 aliens and only 1 native. All residents with newly diagnosed DM2 and IGT had risk factors. All native persons with detected DM2 and IGT were obese.
Conclusion: Our screening program for DM and IGT implemented in Abakan town indicated that the prevalence of undiagnosed DM2 in urban population in Republic of Khakasia among native inhabitants is 1.74% (95% CI: 0.61 - 2.87), among alien inhabitants is 1.20% (0.88 - 1.54). The prevalence of undiagnosed IGT in urban native population is 0.19% (0-0.56), and in urban alien population is 0.36% (0.18-0.54). According by State register for DM in Republic of Khakasia the prevalence of diagnosed DM2 in population with age 20+ is 2.13%. Our data shows that the real prevalence of DM2 in Khakasia Republic perhaps two times higher.

[3] St. Michael's Hospital, Endocrinology, Toronto, Canada
[4] Ottawa Health Research Institute, Population Health, Ottawa, Canada
[5] Public Health Agency of Canada, Health Promotion and Chronic Disease Prevention Branch, Ottawa, Canada
[6] Citizenship and Immigration Canada, Research, Ottawa, Canada
[7] Institute for Clinical Evaluative Sciences, Primary Care and Population Health, Toronto, Canada

Aims/background: Diabetes prevalence is increasing in both the developed and developing world, the latter contributing a large percentage of recent immigrants to Canada. We undertook a population-based study of immigrants to Ontario to establish whether diabetes prevalence was higher than in the general population, and to identify high-risk groups.
Methods: Provincial administrative health and immigration records were linked and used to calculate age-specific and age-adjusted point prevalence rates for men and women (aged 20+) on March 31st 2005, by immigration status. Rates were compared for 1,122,771 immigrants by country and region of birth, and for long-term residents. Logistic regression was used to identify and quantify diabetes risk factors among the immigrant population.
Results: After controlling for age, immigration category, education, income and time since arrival, diabetes risk in male and female immigrants respectively from South Asia was OR=4.01 (95% CI: 3.82-4.21); OR=3.22 (95% CI: 3.07-3.37), Latin America and Caribbean OR=2.18 (95% CI: 2.08-2.30); OR=2.40, (95% CI: 2.29-2.52); and sub-Saharan Africa OR= 2.31 (95% CI 2.17 – 2.45); OR=1.83 (95% CI 1.72-1.95).
Increased risk started at an early age (35-49) and continued in older age groups.
Diabetes rates in immigrant women were similar to their male counter-parts.
Conclusions: Immigrants to Canada of South Asian and African ethnic origin have rates that are 2-4 times higher than those of immigrants of European origin. In these high risk groups diabetes develops at a very young age and the high risk continues throughout the adult life-course. Contrary to studies conducted in North American and European populations where risk has been found to be higher in men, men and women of South Asian and African racial ancestry have equally high rates. Health professionals and policy-makers need to be aware of the increased risk for diabetes and opportunities for prevention in women and young people belonging to specific ethnic groups.

P-1282

Linking health care administrative data and laboratory data to study differences in progression of diabetic renal disease in first nations people and other Saskatchewan residents

R. Dyck[1], N. Sidhu[2], H. Klomp[2], P. Cascagnette[2], G. Teare[2]
[1] University of Saskatchewan, Medicine, Saskatoon, Canada
[2] Health Quality Council, Quality Measurement and Analysis, Saskatoon, Canada

First Nations People (FN) with diabetes have higher rates of end stage renal disease (ESRD) compared to other Canadians but the underlying reasons are unclear. The purpose of this study was to compare demographic features and selected laboratory indicators of diabetes care in FN and other Saskatchewan residents (OSK) sub-divided by pre-ESRD chronic kidney disease (CKD) stage and requirement for renal replacement therapy (RRT).
Prevalent cases of diabetes for 2005/06 were identified using the Canadian National Diabetes Surveillance System case definition in Saskatchewan health care administrative data. De-identified cases were linked with laboratory data from laboratories in the two largest health regions in Saskatchewan. Diabetic FN and OSK subjects were sub-divided by CKD Stage using eGFR (MDRD equation) based on serum creatinine, age, and sex (Normal - eGFR 90+/ negative urine microalbumin [MA]; Stage 1 - eGFR 90+/positive MA; Stage 2 - eGFR 60-90; Stage 3 - eGFR 30-60; Stage 4 - eGFR 15-30; Stage 5a - <15/ no RRT; Stage 5b - RRT). Differences in age, sex, and quality indicators (from practice recommendations for A1C, LDL and MA in the Canadian Diabetes Association 2003 Clinical Practice Guidelines) were compared between groups. We identified 2,321 FN and 21,886 OSK with diabetes in the two health regions. From those, eGFR was calculated in 992 FN (42.7%) and 14,054 OSK (64.2%). Overall, 56.6% of FN had positive MA compared to 48.4% of OSK. FN were younger than OSK (mean age 52.7 vs 64.2 years) and more likely to be female (59.6% vs 45.4%). Mean A1C was significantly higher in FN (8.2% vs 7.4%) but mean LDL was identical (2.7 mM). When sub-divided by CKD Stage, 49.4% of FN and 24.9% of OSK were normal or Stage 1. In contrast, there were larger proportions of OSK in Stages 2 (52.4% vs 37.6%) and 3 (20.8% vs 10.6%). Finally, there were more FN than OSK in Stages 4 and 5a (2.4% vs 1.9%) and on RRT (2.3% vs 0.8%). Subjects in Stages 3-5a were older (mean age OSK 73.3; FN 62) than those receiving RRT (mean age OSK 61.1; FN 55.2). This was particularly evident for OSK who also displayed the largest age differential.
Despite poorer glycemic control and higher rates of microalbuminuria, a larger proportion of diabetic FN have normal kidney function or Stage 1 CKD compared to OSK who are older and predominately clustered in CKD Stages 2 and 3. The excess burden of diabetic ESRD among FN may be due in part to age/sex-related lower mortality allowing a larger proportion of those with early CKD to progress through the CKD Stages. We are currently conducting survival analyses to study this hypothesis.

Fasting insulin levels higher among adolescents than adults: an erosion of public health

M.L. Chateau-Degat[1], E. Counil[1], A. Ferland[1], E. Louan-Sidi[1], E. Suhas[2], R. Teyssou[2], E. Dewailly[1]

[1] CHUL- Research Centre Laval University, Public Health Research Unit - CHUQ, Québec, Canada

Populations in dietary transition are characterized by a gradual abandonment of traditional-local foods towards an increased consumption of imported store-bought foods. They show, most of the time, an increased prevalence of Type 2 diabetes and obesity. As a result, many Pacific islanders are already suffering the consequences of their dietary transition, particularly obesity.

Aims: We examine the health transition between rural and urban population in French Polynesia, and how far the transition was implemented across age.

Methods: Maohi adolescents aged 12 to 17 years (n=117) and adults 18 year old and over (n=98) from four French Polynesian islands - Tahiti (urban area; capital of French Polynesia), Tubuai, Raivave and Rapa (rural; Austral Islands) - were invited to participate in the cross-sectional "Dietary and health transition in French Polynesia" study. Anthropometric measurements (body weight, waist and hip circumference) were obtained by standardized protocol; body composition was assessed by bio-impedance analysis and fasting plasma insulin (FPI) and blood glucose (FBG) levels were also obtained.

Results: Among adult participants, 59% reported BMI=30kg/m^2 while 54 % of adolescents were identified with a significant likelihood of persistence of obesity into adulthood, and among them around 28% had BMI ≥95th percentile (CDC growth charts). No difference between gender or island of residency was detected. Among adults, T2D was self-reported by 17% of participants and impaired fasting glucose was detected in 26%. Surprisingly, adolescents had higher FPI concentrations than the generations of their parents and grand-parents did. FPI decreased significantly with age, as presented on Figure (P-value<0.0001), with no difference according to residency. In the meanwhile, adolescents had significantly lower FBG than adults (P-value<0.0001) and generally showed normal glucose values (9% of impaired FPG only). Adolescent also showed median energy intakes (2753 kcal) higher than adults (2612 kcal among 18-49 years old and 2217 kcal among over 50 years old; P-value =0.012) as well as higher carbohydrates consumption (345g vs 291g among 18-49 years old and 242g among over 50 years old; P-value <0.0001).

Conclusion: We observed an inverted trend of fasting insulin level across age, and this needs to be further explored with appropriate measurement of insulin resistance. These findings, along with high frequency of overweight among adolescents, might be the first indicator of a drastic increase of type 2 diabetes among French Polynesian youth.

Romani population in Serbia at an increased risk for diabetes

T. Beljic[1], S. Prgomelja[2], R. Zivkovic[2], M. Marjanovic[1], D. Ackovic[3], T. Ignjatovic[4], I. Soldatovic[2]

[1] Zvezdara University Medical Center, Division of Endocrinology, Belgrade, Serbia

[2] Diabetes Association of Serbia, Belgrade Diabetes Association, Belgrade, Serbia

[3] Roma Community Center, "8 April", Belgrade, Serbia

[4] Diabetes Association of Serbia, Pirot Diabetes Association, Pirot, Serbia

The prevalence of diabetes in Serbia according to the IDF Diabetes Atlas is 5.6%, but according to the National Registry is 6.7%.

Aim: to investigate the prevalence of diabetes in the Romani population of Serbia.

Methods: Diabetes Association of Serbia screened 11 urban and 8 rural Romani communities in Serbia. Blood glucose values, name, age, presence of diabetes, presence of obesity and family history were noted.

Results: Statistical analysis was performed on 1465 Romani subjects (825 in urban, 641 in rural settlements) with complete findings. Mean age of the subjects was 42.2±15.7 years. Obesity was present in 577 (39.4%) people. Some 87 of the 1465 Roma subjects (5.9%) already had diabetes. Additional 76 new cases of diabetes type 2 (5.2%) were discovered. Romani people with diabetes were significantly older (F=28.33; p,0.01). Family history for diabetes was positive in 1/3 of the Roma subjects. Obesity was significantly more prevalent in Romani people with diabetes (X^2= 32.555; df=3; p,0.01). Diabetes was significantly more present in urban communities (X^2=25.205; df=2; p<0.01).

Discussion: The prevalence of diabetes in Roma people is unknown. They live in closed communities with frequent migrations. However, family ties are strong, which may explain the positive family history for diabetes. Obesity is connected to poverty. Roma people living in urban settlements have greater stress and everyday survival challenges. Future work should aim at diabetes care delivery.

In conclusion, Romani population may have a higher prevalence rate than the general population of Serbia. The risk factors for diabetes are middle age, family hsitory, obesity and life in urban communities.

Diabetes and My Nation: a model program for diabetes teaching and treatment in aboriginal communities

K. Dawson[1], H. Nabih[2], L. deGoeij[3], R. Joseph[4]

[1] University of British Columbia, Medicine, Vancouver, Canada

[2] HN Consultants Ltd, Diabetes and My Nation, West Vancouver, Canada

[3] Kitimat Living Well Program, Diabetes and My Nation, Kitimat, Canada

[4] Indian Resident Schools Society, Diabetes and My Nation, North Vancouver, Canada

Diabetes and my nation: a community based health management program (model) to achieve evidence-based outcomes for the prevention and management of type 2 diabetes (T2DM) in First Nations communities by applying culturally appropriate and holistic methods integrated with Western Medicine and computer based technologies. Essential components include: Bridging between all stakeholders; Awareness and screening; Education (classroom / interactive technology); Lifestyle modifications ; Monitoring (conventional / e-health); Treatment (conventional / e-health); Community capacity building and health structure change (based on the Expanded Chronic Care Model). This provides the basic elements of: understanding traditional healing methods including the medicine wheel (physical, spiritual, mental, and emotional) the introduction of western medicine, and addressing the impact of Residential Schools.

Screening included: blood sugar, blood pressure, A1c (if BS is over 11.1 mmol/L), weight, height, and waist circumference.

Education: Consisted of three programs:

1. The Circle of Diabetes Self-Management (adults). The circles formed reviewed one of the ten Diabetes and My Nation DVDs every month with a diabetes nurse educator (or guest speakers). Participants monitored their blood sugar level on a regular basis; the local nurse collected their meters once a month and discussed the results. A1c, lipids and other indicators were monitored in accordance with the CDA Guidelines. Blood pressure was measured. Local nurse advised family physicians and provided advice to patients. A diabetes specialist had one-on-one visits with patients during the circle meetings or via internet contact. The nurse consulted with the specialist on specific cases. Considerable health improvement was seen, particularly with cases that started insulin. Communities were also visited by a Mobile Telemedicine Diabetes Clinic.
   The program utilized "diabetes and my nation.com" educational materials (DVDs and website) which included 26 hours (10 DVDs) of diabetes information. The majority of contributors were Aboriginal physicians, nurses, health educators, traditional healers, nutritionists and community members.
2. Our Spirit Lives: A youth program for ages 15-20, learning about diabetes and its preventiont through cultural activities, sports, and production of their own DVD.
3. Health Warriors: A school program for children ages 10-15, learning about diabetes; gaining knowledge and sharing it with the community and their families.

Outcome assessment demonstrated satisfaction of health care workers and patients, increased awareness in the community, changes in lifestyle (physical activity and diet), and lowering of A1c, BP, and Lipids.

Conclusion: This program was a remarkably successful model for assisting the reduction in diabetes' adverse effects in First Nations communities.

Simulation model of the intra- and inter-generational impact of gestational diabetes on the diabetes epidemic in Saskatchewan First Nations People

N. Osgood[1], R. Dyck[2], W. Grassmann[1]
[1] University of Saskatchewan, Computer Science, Saskatoon, Canada
[2] University of Saskatchewan, Medicine, Saskatoon, Canada

Gestational diabetes (GDM) may lead to increased risks for type 2 diabetes in both affected women and their offspring (intra- and inter-generational effects). The goal of this research was to use simulation modeling to evaluate the contribution of GDM to the diabetes epidemic in Saskatchewan, and to compare these effects between First Nations people (FN) and other Saskatchewan Residents (OSK).

We constructed a dynamic simulation model that replicated the evolution of diabetes in Saskatchewan over time. To characterize the demographics of the province, we classified the total FN and OSK populations by age (children 0-14, reproductive age 15-44 and post-reproductive age 45+), sex, presence of overweight/obesity and diabetes (yes/no). To capture the impacts of diabetic pregnancies, women in the model were categorized by pregnancy status (yes/no), presence of GDM or pre-existing diabetes, and history of GDM. Second, we classified individuals by birth weight and intra-uterine exposure to diabetes. The model was initialized to the estimated status of the FN and OSK populations in 1956, and the model simulated the evolution of diabetes in the populations over 50 years. Parameter estimates were taken from the literature and from author-derived primary data. Less known parameters were estimated via calibration to historical data related to demographics, vital statistics, and the epidemiology of diabetes in Saskatchewan.

The model closely reproduces historical trends of population size, mortality and birth rates, diabetes prevalence and incidence, and reported rates of GDM. The model shows that while the intra- and inter-generational effects of GDM have made only modest contributions to the diabetes epidemic amongst OSK, they are responsible for a significant fraction (>40%) of all diabetes cases amongst FN. The results further suggest that the intra-generational effect appears rapidly and largely accounts for the disproportionately elevated rates of diabetes currently observed in FN women compared to men. In contrast, the inter-generational effect builds more slowly over decades but may eventually surpass the intra-generational impact.

GDM appears to be a major contributor to the diabetes epidemic amongst FN and possibly other populations. This creates unique opportunities for primary prevention initiatives for adolescent females and reproductive age women that are enhanced by the high degree of motivation, short time span and close contact to the health care system that are characteristic of pregnancy. Programs designed to prevent and screen for GDM, optimize management of diabetic pregnancies, and provide follow-up initiatives for women who have experienced GDM, have potential for reducing T2DM rates in both mothers and their offspring.

A culturally sensitive community-based obesity prevention program targeting Latino-Canadian children: a pilot study

M. He[1], E. Harvey[2], D.S. Battram[3], G.E. Mandich[4], C.L. Clarson[5], S.B. Harris[6]
[1] University of Texas at San Antonio, Department of Health and Kinesiology, San Antonio Texas, USA
[2] St. Joesph's Health Care London, Primary Care Diabetes Support Program, London, Canada
[3] Brescia University College, Department of Food and Nutritional Sciences, London, Canada
[4] Middlesex-London Health Unit, Research Education Evaluation and Development Services, London, Canada
[5] Children's Hospital of Western Ontario, Paediatric Endocrinology, London, Canada
[6] University of Western Ontario, Centre for Studies in Family Medicine, London, Canada

Aims: Worldwide, rates of childhood obesity continue to rise, especially among new immigrants in developed countries. This is a result of rapid "westernization", which includes changes in dietary intake and a shift towards a more sedentary lifestyle. Compounding this issue are the additional challenges facing these families including cultural barriers and social constraints that limit access to healthy foods, recreational activities, and health promotion programming. The complexity of the issue demands an interdisciplinary approach to develop innovative interventions for these high-risk populations. In partnership with key local stakeholders, we have designed and piloted a culturally and linguistically sensitive community-based obesity prevention program that targets overweight and obese Latin-Canadian children (6-12 years) and their families.

Methods: The program consisted of two principle components: I) obesity screening and II) a 6-month intensive obesity risk management intervention. Community-based obesity screening evaluated children's diabetes risk profile based on their body mass index (BMI) and family history of diabetes. The intensive 6-month intervention was designed to address the unique challenges and needs of migrant overweight and obese children and their families. The program, delivered by trained lay health advisors, promoted and educated families about healthy eating and active living; improved access to healthy foods and physical activity opportunities; enhanced the self-efficacy of families; addressed cultural, social, and economic determinants of health; and stimulated community capacity. Changes in BMI Z-score; percent body fat; fitness level; physical and sedentary activity levels; dietary intake; and self efficacy at baseline, three months, and six months of the program were evaluated.

Results: 178 Latin children were screened, 71 (40%) of these children were identified as overweight and obese, and 67 were enrolled into the 6-month intensive obesity risk management intervention. The intervention demonstrated favourable changes in children's lifestyle and BMI (n=56). Specifically, statistically significant increases in children's physical activity level (+46 min per day) and fruit and vegetable consumption (+1.1 servings/day); and decreases in screen-related activities (-55 min/day), junk food consumption (-3.3 times/week), and BMI Z-score (-0.1) were observed. No changes were observed in other outcome measures.

Discussion/conclusion: A culturally and linguistically sensitive community-based intervention that targets not only unhealthy behaviours, but key social and economic issues facing new immigrant families, offers a promising strategy for screening and engaging high-risk migrant families for childhood obesity prevention.

Risk factors of type 2 diabetes among migrants and native populations of Spain: DE-PLAN and VIVA-Minorities Studies

R. Gabriel[1], M. Alonso[1], N.C. Barengo[2], T. Acosta[1], S. Vega[3], A. Segura[4]
[1] Hospital Universitario La Paz, Clinical Epidemiology, Madrid, Spain
[2] University Of Helsinki, Department Of Public Health, Helsinki, Finland
[3] Centro De Salud El Espinar, Segovia, Spain
[4] Consejeria Sanidad C-m, Instituto De Ciencias De La Salud, Talavera De La Reina Toledo, Spain

Aims: Spain has one of the highest rates of migration in Europe (13%). Migrants are at higher risk of developing type 2 diabetes (T2D) than the native Spanish population due to an unfavourable risk factor profile and lifestyle habits. The aim of this study was to compare the risk factors of T2D between migrant and native populations in Spain.

Methods: A population-based survey in five provinces of Spain (Madrid, Toledo, Segovia, Burgos and Avila) was conducted in 2008. A proportional random sample of 1.184 Spanish natives (53% women) and 224 first-generation migrants (62% women), 45-64 years old, was selected from the population registers. The overall response rate was 70%. The risk of T2D was assessed using the FINDRISC questionnaire. A score of more than 14 points was considered as high risk of T2D (>20% 10-year risk for diabetes). Weight, height and waist circumference were measured following a standard protocol.

Results: There was no statistical significant difference in the prevalence of high risk of T2D between the native Spanish and the migrant population. The proportion of high risk of T2D was 22% in men and 27% in women in the Spanish population, whereas the respective figures were 15% (men) and 22% (women) in the migrant group. No statistical significant difference was found in body mass index (BMI), waist circumference and use of antihypertensive drugs in men between the two population groups. Women of the migrant group, however, had a statistically significant higher prevalence of central obesity (waist circumference > 88 cm; 68% versus 50%; p-value <0.001) and obesity (BMI > 30 kg/m^2; 40% vs. 30%; p-value 0.03). Despite not significantly different, the native population showed higher self-reported daily physical activity and vegetable and fruit consumption than migrants.

Conclusions: The migrant male population has similar lifestyle habits and risk factors of T2D as the native Spanish men. However, migrant women have higher prevalence of obesity and central obesity than their Spanish counterparts. Special attention may be needed for this vulnerable population group.

Visiting "in" Peru: a comparison of anthropometric and metabolic parameters between diabetic patients and non-diabetics in Abancay, Apurimac, Peru

A.C. Bossi[1], A. Bossi[2], G. Crotto[1], C. Gnasso[1], M.E. Huanca Amable[2], P. Salvatore[2], J. Lizarraga[3]

[1] *Treviglio-Caravaggio Hospital, Metabolic Diseases and Diabetes Unit, Treviglio (BG), Italy*

[2] *Treviglio-Caravaggio Hospital, Associazione Diabetici Bergamaschi ong, Treviglio (BG), Italy*

[3] *Centro Medico Santa Teresa, Health Direction, Abancay Apurimac, Peru*

Aims: Ethnicity is a well known risk factor for diabetes, and Latin Americans are particularly susceptible; a low socioeconomic status is a predictor of non-communicable disease among adults in Peruvian cities, but few data are available about diabetic patients of the Andean region of Peru. Our team of voluntary health-care professionals was asked to co-operate with C.M. Santa Teresa - Abancay, Apurimac. Our aim was to evaluate some clinical and metabolic parameters of the local population, with emphasis on diabetics and "pre-diabetics".

Methods: We worked in Abancay, in Curahuasi, and in Pueblo S. Mateo, a small centre in a mountain area. The following data were collected with standardized procedures: height (m), weight (kg), BMI; fat mass (%), detected by a portable bio-impedance meter; blood glucose (fasting or post-prandial) (mg/dL), using reflectance meters. Electrocardiograms were performed with a Cardiette-micro appareil (Elettronica Trentina, Italy); funduscopic evaluations were obtained by our Orthoptic specialist. Finally, complete clinical evaluations were performed.

Results: We report data expressed as median values ± SD from 423 native Peruvians (F: 263; M: 160). Normo-glucose tolerant (NGT) Peruvians (n: 312; F: 204; M: 108) showed: median age 50.5±17.0; BMI 26.6±4.3. Waist circumference was 93.8±12.4 cm (F: 93.5±12.9 cm; M: 95.2±11.3 cm). Fat Mass resulted 32.1±7.6% (F: 34.8±6.7%; M: 27.1±6.7%). Fasting glucose (mg/dL) was 88.1±10.9; post-prandial glucose revealed 105.9±17.4. Peruvians suffering from Diabetes Mellitus (DM) (n: 111; F: 58; M: 53) showed: median age 57.5±12.2; BMI 27.0±4.5 (F: 28.1±4.0; M: 25.9±4.7). Waist circumference was 98.7±11.8 cm (F: 99.2±11.2 cm; M: 98.3±12.5 cm). Fat Mass resulted 32.4±8.2% (F: 36.8±6.2%; M: 27.2±7.4%). Fasting glucose (mg/dL) was 184.9±94.7; post-prandial glucose revealed 286.5±137.3. Background retinopathy was detected in less than 2% of Peruvians DM. More than 16% of Peruvian diabetics showed abnormalities in ECG evaluations.

Discussion: NGT were younger in comparison with DM Peruvians; BMI was higher in DM women. A higher deposition of abdominal fat in diabetics is confirmed by waist circumferences, stating a real burden for cardiovascular disease for Peruvian diabetics, specially for women. We were surprised by the very high levels both of fasting and post-prandial glucose in DM Peruvians.

Conclusion: In our short period of activity in the Apurimac region, a typical Andean land of Peru, and probably one of the poorest, we found a low attention to diabetes and non-communicable disease. Most people didn't know what diabetes is, neither the burden of overweight and obesity, nor the risks connected with diabetic chronic complications.

Diabetes and relatedness in an Aboriginal settlement in Central Australia

F. Dussart[1]

[1] *University of Connecticut, Anthropology, Storrs, USA*

Grounded in ethnographic research conducted in 2006-2007 and 2009 on how Aboriginal people in Central Australia cope with diabetes mellitus, this paper discusses the importance of creating pragmatic and culturally sensitive long-term health promotion programs for the chronically ill. An analysis of participant-observation and semi-structured interviews with 84 diabetic patients and their kin show how an understanding of contemporary life-style embedded in a post-colonial demand-sharing economy, the traditional nexus between Aboriginal notion of personal autonomy and relatedness, as well as Aboriginal engagement with several healing practices, is key to rethink a desired and sine qua non partnership among patients, their kin, and health-care personnel. An in-depth discussion of sharing practices and healing beliefs and practices provides a basis on which to ground much-needed culturally-sensitive health promotion program in the socio-political complex environment of Central Australia.

Subscapular thickness is strongly associated with blood glucose and insulin levels than waist circumference and BMI in the mixed ancestry population of South Africa

R. Erasmus[1], M.S. Hassan[2], T. Matsha[3]

[1] *University of Stellenbosch, Chemical Pathology, Cape Town, South Africa*

[2] *Cape Peninsula University of Technology, Nursing and Radiography, Cape Town, South Africa*

[3] *Cape Peninsula University of Technology, Biomedical Sciences, Cape Town, South Africa*

Background: Obesity, particularly central obesity is strongly associated with the development of insulin resistance and type 2 diabetes. On one hand, subscapular skinfold thickness has previously been found to be better than BMI and WC in identifying hyperinsulinemia in Asian Indian males. Because the mixed ancestry population of South Africa is a combination of European settlers, the indigenous Africans and the Indians we investigated the relationship between measurements of obesity and fasting blood glucose and insulin levels in the mixed ancestry population of South Africa.

Methods: In a cross-sectional study, fasting blood was obtained from 600 subjects within the age group of 35-65 years who were randomly selected through multistage random sampling within the Bellville South area of Cape Town. Blood glucose was measured using a routine chemistry auto-analyser whilst insulin was analysed using a commercial immunoassay. Waist circumference, hip circumference, Body Mass Index (BMI), subscapular, supra-iliac, mid-upperarm, triceps and bicepc thickness were measured on all participants.

Results: Obesity as measured by BMI was significantly more prevalent in females, $p < 0.05$. In a linear regression analysis waist circumference, subscapular and age were positively associated with fasting blood glucose and insulin levels, $P < 0.001$ whilst the triceps were negatively associated with insulin levels, $P = 0.018$. On the other hand BMI was not significantly associated with insulin levels, $P = 0.075$, but not with fasting blood glucose levels.

Conclusion: Central adiposity is considered to be an accurate anthropometric method to estimate truncal adiposity, a key predictor of insulin resistance subsequently type 2 diabetes. However, differences in obesity phenotype have resulted in different cut-off values for different populations with Caucasians having higher cut-off values than Asians. This study suggests that subscapular thickness in addition to waist circumference can be used to predict insulin resistance risk in this population group.

P-1292

Diabetes, gender and neighbourhood ethnicity: inequalities in healthcare resource utilization

R. Fang[1], J. Lu[2], A. Kmetic[1], J. Millar[1], L. Drasic[1]

[1] *Provincial Health Services Authority, Population & Public Health, Vancouver BC, Canada*

[2] *Vancouver Coastal Health, Richmond Health Services, Richmond BC, Canada*

Aims: Lower utilization of medical resources by immigrants is often observed in self-reported surveys and usually interpreted as the so-called healthy immigrant effect. However, whether the lower utilization rate by immigrants is solely a reflection of better health or is indicative of barriers to accessing the health system is not clear. In this study, we examine the gender-specific differences in healthcare resource utilization between neighbourhoods with varied immigrant density based on patients' medical records.

Methods: For healthcare planning purposes, the entire population of Richmond, BC, Canada is geographically grouped into five neighbourhoods with similar population size: South Arm, Richmond Centre, Blundell, Steveston

and East Richmond. The expected health resource dependency for each resident was assessed using the Johns Hopkins University Adjusted Clinical Group (ACG) case-mix system that accounts for his/her morbidity, complexity and costs of care with the overall Richmond rate as baseline. For each neighbourhood we aggregated the observed hospital bed-days and primary care physician use across all ACG categories and compared them with the corresponding expected values obtained by applying Richmond's ACG-specific rates. The resulting differences are used to signal if resources are under or over used for that neighbourhood. Healthcare use due to pregnancy, obstetrics and relevant complications were excluded as they preclude gender based comparisons.

Results: Overall, diabetic women were more likely to visit their primary care physicians and less likely to stay in hospitals compared to diabetic men. No obvious neighbourhood variations in the use of primary care physicians both among diabetic women and among diabetic men were observed. Taking the entire Richmond female population as baseline, however, we found great neighbourhood differences in hospital use by diabetic women. Diabetic women from the two neighbourhoods with the lowest proportion of immigrants had the greatest use of hospital resources (18.5% higher in Blundell and 5.2% higher in Steveston) whereas diabetic women from the neighbourhoods with the highest proportion of immigrants used less hospital resources (18.6% lower in East Richmond and 10.5% lower in Richmond Centre) than expected. No such effect was observed for diabetic men.

Conclusions: In this study we demonstrated that diabetic women from neighbourhoods with a high density of immigrants used less hospital acute care. This could indicate the existence of potential barriers of gender, language, and ethno-culture to immigrant diabetic women. The results can be used to help health authorities and policymakers respond to the needs of immigrant women by addressing potential barriers to the access of health care.

Has waist-thigh ratio stronger association with type 2 diabetes mellitus than BMI or waist circumference? The case of the Brazilian Xavante Indians

A.L. Fabbro[1], L.J. Franco[1], D.S. Sartorelli[1], A.S. Silva[1], L.F. Franco[2], R.S. Moisés[2], J.P.B. Vieira-Filho[2]

[1] *School of Medicine of Ribeirão Preto USP, Department of Social Medicine, Ribeirão Preto, Brazil*

[2] *Federal University of São Paulo, Department of Medicine, São Paulo, Brazil*

Introduction: Presently, the Brazilian Xavante Indians are undergoing an intense and fast cultural change towards the general Brazilian society, and as a consequence are presenting high prevalence of obesity and diabetes mellitus. Objective: To investigate which anthropometric measurements of fat distribution have a stronger association with the presence of diabetes.

Methods: A cross-sectional study was conducted among 351 Xavante Indians aged 20 years or more in October 2008 and January 2009. After signing an informed consent form, all individuals underwent clinical and anthropometrical examination and submitted to a 75g oral glucose tolerance test. Using WHO criteria, diabetes was diagnosed in 74 (21.1%) individuals, obesity (BMI > or = 30 kg/m^2) in 157 (44.7%) and overweight (BMI > or = 25 and < 30kg/m^2) in 133 (37.9%). According to receiver-operating characteristics analysis, waist-thigh ratio had a better profile to identify individuals with diabetes than BMI, waist-hip ratio or waist circumference. The cut-off point which best predicted the presence of diabetes has sensitivity and specificity around to 70%.

Conclusion: The use of the waist/thigh ratio provides an easy and practical marker that is better associated with the presence of type 2 diabetes. With further studies in other ethnic groups, the waist/thigh ratio may be useful tool for clinical practice and epidemiological research.

The insulin insensitivity is a diminished in the biological function of the insulin characterized by need for high level of plasma insulin for maintenance of the metabolic homeostasis.

The present is a descriptive transversal analytical epidemiological study of a point that determines the prevalence of the Insulin resistance, evaluated through Homeostasis Model Assesment (HOMA IR) in a Shuar Community in the Ecuadorian Amazonia. In this ethnic group had been observed a high prevalence of chronic metabolic disturbance, this fact is consider it outstanding, since previous studies have reported ethnic differences with regard to the insulin sensitivity. The analyzed variables are: Age, Gender, Body mass index, waist circumference, blood pressure, fasting plasma glucose, fasting plasma insulin, Homa IR. It was done in the Tsuraku community, located to 51 kilometer at the distance of the Capital of the Province of Pastaza-Ecuador is constituted by a shuar ethnic nationality.

The randomized 34 individuals more than eighteen years old the insulin resistance was determined through Homeostasis Model Assesment (HOMA IR). We found a global prevalence of 11,8 % of insulin resistance. 26,7 % in the females. The average of age was of 30,35 years ± 12,94, in females 26,67 years ± 9,56. The average of body mass index was 25,5 ± 3,11, in females 24,02 ± 2,78. The average of waist circunference was 80,77 cm ± 8,94, in females 77,42 cm ± 7,32. It is being evidenced an important the resistance insulin prevalence mainly in women in spite of being young and with normal anthropometry. Whatsoever could be related with lower levels of waist circumference in this population.

Screening indigenous communities for diabetes and its complications: 5 year results from a mobile diabetes outreach service in Alberta, Canada

E. Toth[1], K. Ralph-Campbell[1], R. Oster[1], T. Connor[1], M. Pick[1], M.D.S.I. Field Team[1]

[1] *University of Alberta, Medicine, Edmonton, Canada*

Aims: The Mobile Diabetes Screening Initiative (MDSi) provides diabetes and complications screening to Métis [1], off-reserve Aboriginal [2], and other remote communities in Alberta. MDSi aims to mediate access barriers and empower clients and providers to more active risk factor, diabetes and complications management.

Methods: Two vans with health staff and portable screening technology travel to 24 communities. Anthropometrics and clinical parameters (BP, FPG, A1c, cholesterol, triglycerides, microalbumin) are collected on clients at risk for diabetes. Diabetic clients receive eye, foot, cardiovascular and kidney screening, and complete a survey assessing diabetes knowledge, diabetes management and access to diabetes care services. Screening results take 6 minutes and counseling is provided. Results are sent to clients' physicians.

Results: The population seen by MDSi identifies as 56% Métis, 20% Status/ Non-Status Aboriginal (First Nations), and 24% non-Aboriginal. Since 2003, MDSi has screened 2102 at-risk clients for diabetes (1760 adults; 343 children ages 6-17). 65% of children screened were overweight/obese, and 38% were identified with pre-diabetes. 364 diabetic clients were screened for complications.

Adults screened for diabetes		
BMI	Overweight/Obese	80%
FPG	Pre-diabetes	46%
	Probable diabetes	5%
Total Cholesterol	Abnormal	32%
Blood Pressure	Abnormal, no treatment	15%
	Abnormal, on treatment	6%

Diabetic clients		
BMI	Overweight/Obese	95%
A1c (diabetes control)	Good	45%
	Poor	55%
Total Cholesterol	Abnormal	28%
Blood Pressure	Abnormal, no treatment	22%
	Abnormal, on treatment	42%

Survey: 245 diabetic clients completed the survey. 82% said their family doctor was their main diabetes care provider; 65% saw their main provider 3+ times in the past year; 29% had A1c tested in the past 6 months. 36% never had an eye assessment; 81% had never seen a podiatrist; 10% never had a cholesterol test; 60% had a urine test in the past year. Only 49% had seen a dietitian. 68% of respondents used pills to control diabetes; 16% used diet alone. When asked how often A1c, cholesterol, feet and eye testing is recommended for people with diabetes (CDA-CPGs, 2008), most respondents answered correctly.
Discussion: MDSi screening identifies high diabetes risk in Indigenous communities. Baseline survey data shows few clients receive testing at appropriate intervals, despite most clients seeing their main diabetes care provider 3+ times in a year. Our findings are consistent with similar studies on health care gaps for Aboriginal and non-Aboriginal people in remote areas of Alberta. (Toth, 2003; Oster, forthcoming 2009). [1] The Métis issued from mixed marriages during the period of Canada's colonization, and evolved a distinct culture and are recognized as a distinct Aboriginal group in Canada's Constitution. [2] A different screening program serves on-reserve Aboriginal (First Nations) Communities.

Insulin, hydrocortisone and lipid changes among native and alien patients with obesity and newly diagnosed type 2 diabetes in the Republic of Tyva

S. Dogadin[1], B. Mongush[2]
[1] *State Medical University and Krasnoyarsk Territory Clinical Hospital, Endocrinology centre, Krasnoyarsk, Russia*
[2] *1st Hospital of Republic of Tyva, Endocrinology Department, Kyzyl, Russia*

The Republic of Tyva is a part of Russian Federation with the area 168.6 square km. It is situated in the South of the Eastern Siberia in the geographic center of the Asia. The climate is sharply continental. Total population is 308,500 and represented by natives (tyvinians, 77%) and aliens (caucasians, 23%). The native peoples still continue to follow their traditional lifestyle and nutrition. The diabetes 2 type prevalence for native population with age 20+ was 2.67 (95%CI: 2.63-2.71) /1,000 and for aliens was 11.52 (10.50-11.52)/1,000 inhabitants.
Aims: To compare serum insulin, hydrocortisone and lipid levels and their relationships in native and alien persons with obesity and firstly diagnosed (fDM2) in Tyva Republic.
Methods: Natives and aliens: with normal weight (27, 22), overweight (17, 24), obesity (14, 23) and fDM2 (36, 14) were studied. Waist circumference, BMI, blood glucose, serum insulin and hydrocortisone levels before and after 75 g glucose load, HOMA-IR, lipid profiles were measured.
Results: Among native peoples the body mass gain was accompanied by increase of insulin, hydrocortisone and total lipids without changes in lipid profile. Native patients with fDM2 had a lipid profile disturbances with a high level of triglycerides and rise of atherogenic index. Serum Insulin and hydrocortisone were higher among fDM2 patients than in subjects with normal BMI. Among alien peoples the body mass gain was accompanied by increase of insulin and total cholesterol without changes of hydrocortisone levels. Aliens with fDM2 had high cholesterol and triglycerides levels. HOMA-IR was higher in native fDM2 patients than in alien fDM2 patients. There was a negative correlation between insulin and glucose levels in natives and aliens with fDM2. In natives with fDM2 there was a positive correlation between glucose and triglycerides. However in aliens with fDM2 there was negative correlation between glucose and total lipids and total cholesterol. Only in native subjects with fDM2 there was a negative correlation between hydrocortisone and insulin, hydrocortisone and HOMA-IR.
Conclusion: The revealed data indicate the important role of hydrocortisone in the regulation of glucose and lipid levels in obese and fDM2 native inhabitants of Tyva Republic.

Screening

P-1297

Effective uptake of screening blood-tests for diabetes in Canada

C. Robinson[1], M. Abdel-Motagally[1], H. Morrison[1], Y. Shi[1], L. Vardy[1]
[1] *Public Health Agency of Canada, Centre for Chronic Disease Prevention and Control, Ottawa, Canada*

Aims: To describe the extent of diabetes (DM) screening blood tests for various target groups in Canada, in order to identify potential areas where there may be benefit from refocused screening efforts. Also, to enable comparisons between physician and general population perspectives.
Methods: Self-reported data from PHAC's 2009 National Prediabetes Survey consists of two separate arms: i) a stratified random digit dialling (RDD) phone survey of the general population, ages 30 to 75 (GenPop n=1755); and ii) a combined phone/fax survey of Family Physicians (FP n=500). The GenPop arm was weighted by age, sex and province; the FP arm, by age, sex and payment mechanism.
Results: According to the GenPop survey (response rate of 15%) 49% of adults over age 40 without DM said they had received a screening blood test for DM sometime during their life; 58% of these had been within the previous 12 months. The testing rate for males (45%) was lower than for females (53%), and testing did not increase with age. 7% of females had received their most recent test during pregnancy. The testing rate was 57% among those reporting hypertension and 56% among those reporting dyslipidemia. Overall, 68% of those tested reported that their results had been explained to them. OGTT testing was 18% overall – with higher rates for females (24%) than males (11%). According to the FP survey (response rate of 8%), physicians order an average of 30 DM screening blood tests per week: 17 FPGs, 11 A1c, and 1.5 OGTTs. 93% of FPs reported they always (80%) or usually (14%) order a screening blood test for DM when doing an annual exam for adults 40 yeras and over. Among physicians, 93% said they screen for DM among hypertensives, and 86% said they screen for prediabetes.
Discussion/Conclusion: Persons with dyslipidemia or hypertension were more likely to report being screened for DM, suggesting that those at high risk of cardiovascular events are being given priority. DM screening and OGTT use among females was relatively high. This reflects the near universal screening of pregnant women using a modified OGTT in Canada.
With regular testing by FPs, overall GenPop rates of screening in the general population are expected to increase with age – but this was not observed. This incongruence may reflect recent increases in actual DM screening efforts aimed at younger ages, recall bias or other inherent limitations with self-reported survey data.
Significant screening effort is being expended across various target groups, relying mainly on FPG and haemoglobin A1c. Although most FPs reported screening for prediabetes, such screening is problematic given their modest use of OGTT: over half of all prediabetes cases will be missed if the OGTT is not used. This relates to ADA's 1998 recommendation to de-emphasize the use of the OGTT for routine screening.

eZscan, a new non-invasive technology that enables early detection of carbohydrate metabolism abnormalities may also be able to detect ethnic differences

R. Hu[1], J.P. Deslypere[2]
[1] *Huashan Hospital, Endocrinology, Shanghai, China*

Aim: To determine the ability of eZscan to detect prediabetes and diabetes mellitus (DM) in populations not known to have the conditions.
Methods: Two cross-sectional studies were conducted in Chennai, India with 200 subjects and in Shanghai, China with 102 subjects. All subjects had their medical history recorded, with presence of risk factors according to the

ADA criteria, followed by a medical examination, a 2-hr OGTT and lipid panel lab tests. They were then tested with the eZscan, which is a newly patented technology which uses low level DC inducing reverse iontophoresis, together with chronoamperometry to evaluate the functions of tissues in specific locations of the body. A reading of >40% was considered positive on the eZscan. The ADA criteria were used for the cut-off values of the OGTT. The AHA/updated NCEP criteria were used to define metabolic syndrome

Results: Of the 200 subjects from India (mean age:43.2 years; BMI:28.2; 50% male), 101 had NGT, 57 had metabolic syndrome (MS) and 24 had DM. The subjects from China (mean age: 58.6 years; BMI:25.3; 29% male) had 52 cases of NGT, 29 with MS and 21 with DM. The sensitivity of the eZscan for MS and DM in the Indian data was 75% and 83% and that of the Chinese was 94% and 80.9% respectively.

Discussion/conclusions: The eZscan appears to be a sensitive tool to detect prediabetes and diabetes when compared to the OGTT. The eZscan may also be able to detect differences in carbohydrate metabolism abnormalities in different ethnic groups.

[8] *General Health Care Services Center of Kawagoe City, N/A, Saitama, Japan*

[9] *Jichi Medical University, Saitama Medical Center, Saitama, Japan*

Aims: Measurement of urinary myoinositol (UMI) requires a urine sample, but no drawing of blood. This reduces burdens on both the patient and medical staff. We have previously reported the usefulness of UMI increment between before and 2h after glucose loading (deltaUMI = UMI_{2h} - UMI_{0h}) to detect glucose intolerance. With this measurement, urine samples have to be collected twice (before and 2h after glucose loading) and a wait of 2h is required. To measure UMI more easily and comfortably, the present study examined the ability to detect glucose intolerance between UMI at 2h after glucose loading (UMI_{2h}) and deltaUMI.

Methods: A total of 392 volunteers underwent 75g glucose tolerance testing. We collected blood samples before, 1h and 2h after glucose loading and measured plasma glucose (PG) levels. Urine samples were collected before and 2h after glucose loading and both UMI and creatinine were measured simultaneously using enzymatic methods. Based on PG values and following the 2003 American Diabetes Association (ADA) criteria, we divided subjects into five groups: normal glucose tolerance (NGT); impaired fasting glucose (IFG); impaired glucose tolerance (IGT); IFG/IGT; and diabetes mellitus (DM). We then performed receiver operating characteristic (ROC) analyses of UMI_{2h} to examine the ability to distinguish NGT and IFG from other groups (IGT, IFG/IGT and DM). To confirm differences in ROC curves between UMI_{2h} and deltaUMI, we next compared areas under the ROC curve in both indices. Moreover, we compared the positive rate for UMI_{2h} in each groups with that of deltaUMI.

Results: All subjects were classified according to ADA criteria, with: 193 NGT; 70 IFG; 29 IGT; 55 IFG/IGT; and 45 DM. From the ROC curve, the optimum cutoff value for UMI_{2h} to detect glucose intolerance was 30 mg/gCr. With a UMI_{2h} cutoff value of 30 mg/gCr, sensitivity and specificity were 74% and 72%, respectively. As for deltaUMI, however, with a cutoff value of 10 mg/gCr, sensitivity and specificity were 79% and 72%, respectively. Sensitivity and specificity were almost the same in both indices. Both areas under the ROC curve were nearly equal (UMI_{2h}, 0.813; deltaUMI, 0.823) and no significant differences were found (p=0.763). Positive rates for UMI_{2h} were 19.7% in NGT, 50.0% in IFG, 44.8% in IGT, 76.4% in IFG/IGT and 91.1% in DM. Conversely, positive rates for deltaUMI were 19.7% in NGT, 50.0% in IFG, 55.2% in IGT, 81.8% in IFG/IGT and 91.1% in DM, respectively.

Conclusion: UMI_{2h} and deltaUMI display almost equal ability to detect abnormal glucose tolerance. Therefore, both deltaUMI and UMI_{2h} provide useful markers for mass screening in the early detection of glucose intolerance.

P-1300

The use of HbA1c as a screening tool for the diagnosis of diabetes mellitus in a local South African community

A.E. Zemlin[1], R.T. Erasmus[1], M.S. Hassan[2], Z. Mohammed[2], T. Matsha[2]

[1] *National Health Laboratory Services (NHLS) and University of Stellenbosch, Chemical Pathology, Cape Town, South Africa*

[2] *Cape Peninsula University of Technology, Biomedical Sciences, Cape Town, South Africa*

Introduction: HbA1c has been the gold standard measurement of chronic glycaemia for over two decades. Diabetes mellitus (DM) may be diagnosed using WHO or ADA criteria – both use either a 2 hour or a fasting glucose level. This would require a fasting sample, thus leading to inconvenience for the patient and requiring an early morning appointment with the physician. There is a need for a more convenient screening test for DM or impaired glucose tolerance (IGT), which can be performed on a random blood sample. For a test to be an effective screening tool, a high sensitivity is required. Previous problems with HbA1c assay standardization, as well as its large biological variation, meant that it was not an effective screening tool. However, with the recent advances in standardization of the assay, there have been suggestions that HbA1c may be an effective screening tool.

Method: Six hundred participants in a community-based study were included. Seventy-eight were excluded as they were known diabetics. Five hundred and twenty-two patients not known with DM were screened for DM during a local community study using an oral glucose tolerance test according to both ADA and WHO criteria. HbA1c levels of >7% (n = 27), 6.5%-7% (n = 36) and < 6.5% (n = 459) were then correlated to DM or absence of DM.

Results: An HbA1c value < 6.5% excluded DM correctly in 93.9% of patients diagnosed according to ADA criteria (431/459) and in 91.7% of those diagnosed according to WHO criteria (421/459).

An HbA1c value of 6.5-7% was of limited use when distinguishing between DM or not (69.4% and 30.6% respectively using ADA criteria and 58.3% and 41.7% respectively using WHO criteria).

An HbA1c value of >7% as suggested, showed that using the ADA diagnostic criteria, 85.2% (23/27) of patients were correctly identified and 88.9% (24/27) using the WHO criteria.

Conclusion: It appears that that HbA1c may indeed be an effective screening tool for the presence of DM diagnosed according to both the ADA and WHO criteria in our local population.

P-1301

First trimester hemoglobin A1c and its correlation with abnormal GCT and subsequent development of gestational diabetes

B. Menezes[1], T. Perretta[1], P. Friedmann[1], J.B. Menezes[1]

[1] *Beth Israel Medical Center, OB/GYN, New York, USA*

Background: Diabetes with onset during pregnancy and resolution postpartum is termed gestational diabetes. The current standard of care is screening for patient by a glucose challenge test (GCT) at 24-28 weeks gestation with further GTT testing if indicated. Data regarding the association between HbA1c and GCT is conflicting.

Objective: We set out to describe the normal values of first trimester HbA1c and see if it correlates with an elevated GCT in the second trimester.

Methods: We conducted a prospective descriptive study of 52 healthy, pregnant women between 18 and 45 years in the first trimester who come to Beth Israel Medical Center for routine prenatal care. Exclusion criteria included patients with diabetes mellitus. An HbA1c was sent with the initial prenatal labs and demographic data was collected. GCT at 24-28 weeks gestation and, if applicable, the GTT values were recorded retrospectively. The subsequent development of gestational diabetes, birthweight and the complication of a shoulder dystocia were also recorded.

Data Analysis: Data was analyzed using the SAS system for data analysis. Continuous variables are reported as means with standard deviations.

Categorical variables are reported as frequency counts and percent. Pearson correlation coefficients were computed to assess the correlation between HbA1c and GCT, BMI and age. P-values less than 0.05 are considered statistically significant. Correlation coefficients of 0.4 to 0.6 are considered moderate.

Results: 52 patients were enrolled. 50 patients had an HbA1c tested with their prenatal labs. 10 patients transferred care after the initial labs were drawn. 5 patients delivered at outside institutions. The remaining 35 patients comprised the study population available for analysis. For these patients, the mean HbA1c was 4.99 (st. dev.=0.29, range 4.3 to 5.6). The mean age was 29 (st.dev.=6.12), range 18 to 44). The mean BMI was 25.7 (st.dev.=5.6, range 19 to 37). The mean GCT was 96 (st.dev.=22.8, range 69 to 187). The mean birth weight was 3354 (st.dev.=659, range 900 to 4880). One subject had an abnormal GCT and subsequently a diagnosis of gestational diabetes. The Pearson correlation coefficient (r) between HbA1c and GCT was 0.41 (p=0.015). The correlation between HbA1c and BMI was r=0.24 (p=0.166). Correlation between HbA1c and age was r=0.32 (p=0.059). Correlation between HbA1c and birthweight was r=0.31 (p=0.068). No shoulder dystocias occurred in our study population.

Conclusion: Hemoglobin A1c in the first trimester is moderately correlated with GCT conducted in the second trimester of pregnancy. This correlation is statistically significant. Further research is warranted.

P-1302

Predictive value of waist-to-height ratio for the development of type 2 diabetes and impaired glucose tolerance: comparison with other anthropometric indices

J. Perreault[1], G. Dagenais[2], B. Abdous[3], P. Poirier[2]

[1] *Hôpital Laval, Université Laval-Médecine sociale et préventive, Québec, Canada*

[2] *Hôpital Laval, Cardiologie, Québec, Canada*

[3] *URESP, Medecine sociale et préventive, Québec, Canada*

Background: Although body mass index (BMI), waist circumference (WC) and waist-to-hip ratio (WHR) have been used to predict type 2 diabetes (T2D) and glucose intolerance, waist to height ratio (WHTR) has not been well studied. We compared the value of WHTR with those of BMI, WC and WHR to predict T2D and impaired glucose tolerance (IGT).

Method: A total of 294 women and 219 men, all Caucasians, are included in this study. Each participant had the following measurements: weight, height, waist and hip circumference, lipid profile as well as fasting and 2h post 75 g oral glucose test (OGTT) plasma glucose. IGT was defined as plasma glucose concentration ≥ 7.8 and < 11.0 mmol/L. whereas diabetes was defined as plasma glucose ≥ 7.0 or ≥ 11.1 mmol/L after the OGTT. We performed logistics regression to evaluate the best anthropometric measurement that predicts (separately or combined) T2D and IGT and also to find relationships between anthropometric indices of obesity and age, sex, triglyceride (TG) and fasting plasma glucose (FPG) levels. Model had been adjusted for confounding factors such as sex and age, and ROC curves for sensitivity and specificity determinations have been calculated.

Results: Men and women were 55±10 and 52±10 yrs respectively; 54 had T2D and 118 IGT. The waist to height ratios (WHTR) were 0.59±0.07 in men and 0.55±0.08 in women. Ninety one percent of the men and 74% of the women were over the 0.50 boundary. The WHTR was the best predictor of combined T2D and IGT (p= 0.0022) vs. BMI (p=0.0097), WC (p=0.0177), and WHR (p=0.0802). WHTR correlated with BMI (r=0.88), WC (r=0.93) and WHR (r=0.66). WHTR increment correlated also with increasing age, TG and FBG. The specificity and sensitivity of WHTR were 77.7% and 78.6%, respectively.

Conclusion: WHTR is a simple parameter that can easily be used by physicians to predict T2D but also IGT. Our results suggest that WHTR may be a better predictor of T2D and IGT than BMI, WC and WHR, but our findings need to be confirmed in a larger population study.

P-1303

Metabolic disease in psychosis: addressing physical illness in the marginalised

R. Chen[1], J. Snars[2], T. Lambert[3]

[1] *Concord Centre for Cardiometabolic Health in Psychosis, Department of Endocrinology and Metabolism, Concord Repatriation General Hospital*

[2] *Concord Centre for Cardiometabolic Health in Psychosis, Concord Centre for Mental Health, Sydney, Australia*

[3] *Concord Centre for Cardiometabolic Health in Psychosis, Concord Centre for Mental Health Brain and Mind Research Institute University of Sydney, Sydney, Australia*

Introduction: Patients with mental illness, particularly psychosis, have a significant increase in the risk of cardiovascular disease (CVD), cerebrovascular disease and diabetes. Data from the Western Australian linkage database (2001) indicates that the mortality rate ratios are at least doubled for diabetes related deaths and more than three times for cerebrovascular disease in this group of patients. This significant increase is reinforced in more recent studies. Patients with schizophrenia and other psychoses have an increased risk of diabetes and metabolic disease which appears to be over and above the rise observed in the" normal" population, attributed to the mental illness itself, poorer lifestyle resulting in enhanced CVD risk factors and to the use of antipsychotics. Yet, the physical care of these patients has largely remained suboptimal.

Aims: The aim of this study was to establish the prevalence of cardiometabolic risk factors in an inpatient psychiatric population, within an integrated tertiary cardiometabolic monitoring centre, comprising multidisciplinary care from endocrinology and psychiatry health care workers.

Methods: Inpatients at the Concord Centre for Mental Health were screened with history (personal and family history of psychosis, cardiovascular disease, obesity, diabetes, hypertension, smoking, physical activity and dietary habits) physical examination (weight, height, body mass index, waist circumference and blood pressure) and biochemical testing (HDL, LDL, triglycerides, fasting glucose) specifically tailored to screen for cardiometabolic risk. The prevalence of metabolic syndrome using IDF criteria was determined.

Results: The mean age was 41.8 years (females) and 39.8% (males). 65% were current smokers, 31% and 46% had a family history of diabetes and CVD respectively. 40% had at least 1 parent of "at risk" ethnicity for diabetes. Waist circumference was elevated by IDF criteria in 82%, with a mean of 101.5 cm (females) and 103.2 cm (males). BMI was in the obese or overweight range in 68.4%. 20% had impaired fasting glucose or impaired glucose tolerance; 7.3 % had diabetes. High triglycerides and LDL were found in 59% (>1.7 mmol/L) & 47% (> 3mmol/L) respectively and low HDL (< 1mmol/L) in 68%. 36% were hypertensive. 50% had metabolic syndrome.

Discussion: Cardiometabolic risk factors are significant in patients suffering from schizophrenia and other psychoses. This data is sobering particularly in light of the relative young age of the subjects. These risk factors potentially would lead to high CVD morbidity and mortality.

Conclusions: Patients suffering from psychoses warrant active screening and management of these risk factors. Our data reinforce the need for multidisciplinary care for patients with psychosis in an integrated physical-mental health assessment centre.

Improvement in weight management and lifestyle behaviors in elementary Argentinean school children

V. Hirschler[1], K. Oestreicher[2], C. Molinari[3], G. Maccallini[4], C. Aranda[4]

[1] *Hospital Durand, Nutrition, Buenos Aires, Argentina*

[2] *University of Buenos Aires, Public health, Buenos Aires, Argentina*

[3] *University of Biology of Buenos Aires, Statistics, Buenos Aires, Argentina*

[4] *Hospital Durand, Laboratory, Buenos Aires, Argentina*

Background: There is growing interest in understanding the role of lifestyle behaviors in children's weight status. While intensive lifestyle programs can have positive clinical outcomes in adults, few studies have reported successful interventions in children.

Objective: to determine if there were any changes in lifestyle behaviors, in weight status and/or in cardiovascular risk factors in school children after receiving a minimal lifestyle education. We further evaluated the efficacy of the program in the obese (OB) children in comparison to the non-OB group.

Design/methods: In a prospective one-year study, 210 children, were recruited from three schools in September 2007. Approximately 30% (n=64)

of subjects were randomized to study group and were examined at baseline and after 12 months in September 2008. All families were asked to attend 3 educational talks during one year about lifestyle education. Questionnaires about their children's lifestyle behaviors were done at baseline and after a year. BMI, waist, Tanner, lipid profile, and glucose were determined at baseline and a year later. Weight management success in obese children was defined as delta BMI percentile≤ 0 after a year.

Results: Sixty four (33 boys) children aged 8.44±1.37 were randomly selected to be evaluated 1 year later, because financial constraints did not make it possible to examine the whole group. There was not a significant difference in the mean BMI, (17.9 vs 18.0 ; p=0.76) and age (years= 8.4 vs 8.8; p=0.24) between the randomized group and the entire group. The children's mean age at baseline was 8.4±1.3 y, z-BMI = 0.4± 1.1, and waist 62.1±10.4cm. The prevalence of OB was 22% (n=14). The prevalence of children at Tanner 1, 2 and 3 was 85.2% 11.5% and 3.3% respectively. All families were in the lower socio-economic class: 72.4 % of parents had an elementary education or less. There were no significant differences between the OB (n=50) and non-OB groups (n=14) in age, Tanner, gender, HDL-C, and blood pressure at baseline. There was a higher mean level of triglycerides (p=0.03) in the OB group than in the non OB group. Eighty five percent of OB children had improvement in weight status after a year. There was a lower but not significant mean triglyceride (92.2 ±31.9 vs. 105.4 ±62.9, p = 0.4), and total cholesterol (148.1 ±21.8, vs.154.3 ±25.3 p = 0.3) after 1 year in the OB group. The BMI percentile was lower in the OB group after 1 year (96.6 ±2.2, vs.98.0 ±1.2 p = .002).No significant changes of BMI percentile were found in the non-OB group. Sweet beverage consumption decreased in the OB group (Mean 3.7 vs 3.1 glasses ;p=0.01) and in the entire group (3.14 vs 3.31; p=0.03) after a year. TV viewing decreased in the OB group (mean 3.14 vs 3.73 hrs ; p=0.02) after a year.

Conclusions: The reduced rate of weight gain in OB children and the improvement in lifestyle behaviors seen in this group after a minimal intervention suggest that the development of future metabolic disease could be avoided.

A variation of serum creatinine is related to type 2 diabetes

J. Lee[1], J.S. Yoon[1], K.C. Won[1], H.W. Lee[1], K.H. Song[2], Y.B. Ahn[2]
[1] College of Medicine Yeungnam University, Internal Medicine, Daegu, Korea
[2] The Catholic University of Korea, Internal Medicine, Seoul, Korea

Aims: Creatinine is a break-down product of creatine phosphate in muscle, and is usually produced at a constant rate depending on muscle mass. It is well established that skeletal muscle is one of the major target organs of insulin action, and is associated with the pathogenesis of type 2 diabetes. So, we investigated whether serum creatinine is related to developing of type 2 diabetes and other risk factors of diabetes.

Methods: The study subjects were composed of 2735 non-diabetic patients who visited health care center from 01 January 2001 to 31 December 2003 and were followed up after 4-5 years, and were investigated retrospectively. The patients with higher baseline serum fasting glucose (=126 mg/dL, n=61) and higher serum creatinine (= 2 mg/dL, n=2) were excluded. Type 2 diabetes was defined as serum fasting glucose of =126 mg/dL, history of type 2 diabetes, or taking the oral hypoglycemic agents. A variation of serum creatinine (ΔCre) was defined as a difference between follow-up and baseline creatinine. Body composition analysis was included in follow-up examination.

Results: 60 subjects (male=43) developed type 2 diabetes. In patients group (who developed type 2 diabetes) and control group, baseline serum creatinine was 0.89±0.16 mg/dL vs 0.93±0.15 mg/dL (p<0.05). After 5 years later, serum creatinine in each group was 0.93±0.17 mg/dL vs 0.93±0.17. There was significant difference in ΔCre between patients developed diabetes and controls (p<0.05). Lower ΔCre was associated with an increased risk of type 2 diabetes after adjustment for age, sex, fasting glucose, HbA1c, ΔGTP, and Lipid profiles (Odds ratio 2.074 (1.040-4.137, 95% CI)). In 1601 male patients, lower follow-up serum creatinine significantly increased risk of type 2 diabetes (Odds ratio 5.140 (1.915-13.796, 95% CI)). Serum creatinine was positively correlated with muscle mass and negatively correlated with percent of body fat after adjustment for BMI.

Discussion/conclusion: Serum creatinine may reflect body muscle mass and may be regarded as one of risk factors of type 2 diabetes. This study is retrospectively observational study and has limitations such as small numbers of participants and low incidence of diabetes. So, further investigation will be needed.

The predictive value of normal fasting glucose levels for the appearance of impaired fasting glucose

O. Mosenzon-Ninio[1], T.A. Herskovits[1]
[1] Western Galilee Hospital-Nahariya, Endocrinology Diabetes and metabolism, Nahariya, Israel

Background: Impaired Fasting Glucose (IFG), defined as a glucose level of 100-125 mg/dl, is a known risk factor for developing Type 2 diabetes and cardiovascular disease. It has not been established, however, whether a higher glucose level within the normal range (i.e. glucose <100 mg/dl) is a risk factor for developing IFG.

Methods: Demographic data, laboratory results, and physical examination results were collected from 195 subjects (135 males and 60 females, average age 42.67 years). Each subject was examined twice, five to ten years apart (1st and 2nd time points), at the Periodic Examination Center, Western Galilee Hospital, Nahariya, Israel.

Results: A statistically-meaningful relationship was established between the glucose levels at the 1st and 2nd time points for all subjects: the entire population (Spearman correlation, rs=0.559, P<<0.001); subjects with glucose < 126 mg/dl (rs=0.49, P<<0.001, N=184); and subjects with normal glucose (rs=0.363, P<<0.001, N=139).

Subjects with normal glucose levels were divided into three groups according to their glucose level at the 1st time point: <87 mg/dl; 87-90 mg/dl; and 91-99 mg/dl. At the 2nd time point, IFG was found at 14.8%; 21.1% and 47.5% respectively (Cramer's V=0.341 P<0.001).

When different variables and their relation to the glucose level at the 2nd time point were examined, the strongest correlation was found with the glucose level at the 1st time point (0.363 P<<0.001). Other variables that were found to be significantly related to the 2nd glucose level (in subjects with normal glucose level at 1st time point) were: Body Mass Index, Triglycerides, Uric Acid, and systolic, diastolic and average blood pressure.

Following an examination of the relationship and relative influence among the above-mentioned variables, and their impact on glucose level at the 2nd time point, a multi-variant logistic regression model was applied. According to this model, a subject with glucose level of 91 mg/dl at the 1st time point is 3.2 times as likely to develop IFG compared to a subject with glucose level 86 mg/dl at that point. (Linear regression model P<<0.001, R=0.466).

Conclusion: Higher glucose levels within the normal range, are a risk factor for the development of IFG. More studies should be done in order to assess the extent of this risk factor and its clinical implication.

Prevalence of gestational diabetes mellitus in pregnant women in Ahvaz

M. Samimi[1], H. Shahbazian[1], A.L.I. Yarahmadi[1]
[1] Ahvaz Jundishapour University of Medical Sciences, Diabetes research center, Ahvaz, Iran

Introduction: Gestational diabetes mellitus (GDM) is defined as any degree of glucose intolerance with onset or first recognition during pregnancy and is associated with increased feto-maternal morbidity as well as long-term complication in mothers and offspring. The aim of this study was to determine the prevalence of gestational diabetes mellitus in pregnant women in Ahvaz.

Material and methods: In this study, universal screening for gestational diabetes mellitus was performed for 678 pregnant women who had referred to two gynecologic and obstetric clinics in Ahvaz from April 2004 till March 2005. Screening was performed with 50g oral Glucose challenge test (GCT). with 140mg/dl cut-off point, then a diagnostic 100g oral Glucose Tolerance Test (OGTT) was done according to Carpenter and Coustan criteria.

Result: The prevalence of GDM and IGT were 7.4% and 4.3%, respectively. The average age of patients with GDM (30.32±5.27 years) was higher than healthy women (26.25±4.94years) obviously (p<0.001).The average number of pregnancies of patients with GDM (2.4±1.1) was higher than healthy women (1.9±1.1) obviously (p<0.003).Previous abortion frequency in women with GDM (30%) was higher than healthy women (13.85%) (p=0.002).The frequency of previous GDM in women with GDM (10%) was significantly higher than healthy women (0.33) (p=0.0001). Pervious history of macrosomia in women with GDM (6%) and in women with IGT (10.34%) were significantly higher than normal pregnancy (0.5%) (p=0.003 and p<0.001; respectively). There was no relationship between the prevalence of GDM and IGT with

previous congenital abnormalities, or still birth and number of parities. There was no relationship between the maternal age, number of pregnancies, previous abortion and previous GDM with prevalence of IGT.

Conclusion: According to result of this study, it seems that gestational diabetes mellitus has high prevalence in Ahwaz and screening should be done for all pregnant women without consideration of risk factors.

No conflict of interest

P-1308

A population survey to study the association between microalbuminuria and erectile dysfunction among patients with cardiovascular risk factors

A. Lemaire[1], B. Alexandre[1], C. Lemaire[2], A. ElHajj[3], C. Bernardeau[3], F. Barbu[3]
[1] Adirs Association Dr lemaire, sexology, Lille, France
[2] Association Prevart, prévention cardiovasculaire, Béthune, France
[3] Bayer Schering laboratory, medical, Lille, France

Aim: The primary objective of this study is to determine if microalbuminuria (MA) is associated with erectile dysfunction among patients with hypertension or other cardiovascular risk factors.

The secondary objective of this study is to analyze the prevalence of erectile dysfunction among patients with arterial hypertension or central obesity in comparison with data from the literature.

Methods: Patients members of regional associations whose goal is to manage patients with cardiovascular risk factors (hypertension, type 2 diabetes, hyperlipemia, obesity, tobacco) and to prevent cardiovascular events, were proposed to enter in the survey. Sociodemographic and clinical data were collected by trained nurses (weight, height, waist circumference, cardiovascular estimation by SCORE scale). A detection of MA on a morning collection (urine strip, Clinitek-Siemens company; strips are read on Clinitek status analyzer) were performed. MA is indicated as a ratio result of 30-300 mg/g of creatinine. Erectile dysfunction was evaluated with the IIEF questionnaire (short version) which is a 6 items questionnaire: when the score is equal or above 25, it means there is no erectile dysfunction. Statistical analysis was performed by CRESGE (INSERM unit; LILLE, FRANCE)

Results: The survey started in September 2008. 273 male patients have been enrolled in this ongoing study by December 2008.

In this group of patients, 60 had MA. Among these 60 patients, 51 had lower IIEF score (<25).

The relation with age has been studied: IIEF score significantly decreases with age (group with IIEF score <10; mean age = 69±9 versus group with IIEF score >25: mean age = 54±11 ; p<0,001).

The IIEF scores are lowest among patients with hypertension when compared to patients without hypertension (group with hypertension: IIEF score =14,4±8,25 versus group without hypertension: IIEF score =18,8±8,25 p<0,001).

Waist circumference appeared to be inversely correlated with IIEF score (linear regression: p<0, 05).

Conclusion: These preliminary results did not allow to confirm a significant relationship between IIEF score and the presence or not of MA. More patients are now enrolled in this study and it is highly probable that these results will be confirmed.

P-1309

Validation of screening procedures for gestational diabetes mellitus in a population of Cameroonian women

A.P. Tchatchoua[1], F. Tumasang[2], L. Fezeu[3], R. Bell[4], E. Sobngwi[5], J.C. Mbanya[5], C. Muchi Ditah[5]
[1] Yaoundé Central Hospital, Diabetology/Endocrinology, Yaounde, Cameroon
[2] Yaoundé Central Hospital, Gynaecoogy/Obstetrics, Yaounde, Cameroon
[3] yaounde Central Hospital, Public health, Yaounde, Cameroon
[4] University of Newcastle, Public health, Newcastle, United Kingdom
[5] Yaounde Central Hospital, Diabetology/Endocrinology, Yaounde, Cameroon

Aims: The diagnostic test for gestational diabetes mellitus, GDM, 2h 75g oral glucose tolerance test (OGTT), recommended by the WHO is lengthy, costly and unaffordable to the majority of women and health systems in developing countries. Consequently, many do not do this test. To significantly reduce the number needing this test, thereby making it affordable, cost effective screening tests are needed. These will enable early and appropriate diagnosis and treatment which will reduce the incidence of complications. Performance and cut-off values for existing screening tests may vary from one ethnic group to another. It is therefore important to validate these screening tests in different ethnic groups before recommending them to the general population.

Methods: On a sample of 200 pregnant non-diabetic women in the North West region of Cameroon with gestational age between 24 and 28 weeks, RBG, FBG, 1h 50g oral glucose challenge test (OGCT), urine dipstick, and 2h 75g OGTT were done in two days for every participant. Sensitivity (Se), specificity (Sp), positive predictive value (PPV) and negative predictive value (NPV) calculated for each test using cut-off values found in literature against the 2h 75g OGTT as the gold standard were used to evaluate each screening test.

Results: Fourteen out of 200 screened women had gestational diabetes. Family history of diabetes was unknown in 50%, pre-pregnancy weight was unknown in 68.5%. Sensitivity and specificity were not calculated for these clinical variables. OGCT using a threshold of 140mg/dL had Se 64.3%, Sp 67.8%, PPV 13.2% and NPV 96.1%. Urine dipstick (positive or negative) had Se 14.3%, Sp 92.9%, PPV 13.3 and NPV 93.4%. FBG using a threshold of 86mg/dL had Se 57.1%, Sp 73.8%, PPV 14.3% and NPV 97.7%. RBG using a threshold of 144mg/dL had Se 28.6%, Sp 98.9%, PPV 66.7% and NPV 98.4 %.

All of the screening tests had lower sensitivities in our study population compared to those obtained by other authors in Caucasians. However, OGCT was a better option among our participants and urine dipstick the worst. A study in a larger sample in order to derive population-specific cut points is therefore warranted.

Frequency of risk groups in teenagers and young adults identified by the Findrisk survey

H. Garcia-Alcala[1], O. Hirales-Tamez[1], C. Genestier-Tamborero[1]
[1] Universidad Popular Autónoma Del Estado De Puebla, Internal Medicine, Puebla, Mexico

Background: The International Diabetes Federation has established as a first step to prevention of Diabetes the identification of persons at risk through the Findrisk survey. The frequency of teenagers and young adults at risk identified by this survey is unknown in our country.

Aims: Describe the frequency and clinical characteristics of teenagers and young adults at risk to develop Diabetes identified by the Findrisk survey.

Methods: To all Juniors in our University, as part of the admission process a medical exam was performed. A medical history and the Findrisk survey were assessed. Glucose, cholesterol and triglycerides were measured. The students were categorized according to the score obtained through the survey as: low risk: (0 to 6 points) slightly elevated (7 to 11 points), moderate (12 to 14), high (15 to 20) and very high (>20 points). Clinical characteristics and laboratory results were compared amongst the groups. The continuous variables are described as mean ± SD and the categorical in percentage. The T and Chi-squared tests were used any place where needed, as well as the lineal correlation analysis between the continuous variables.

Results: 698 students were studied (female n=396, 56.7%), mean age 18.4±1.12 years, the frequency of the groups was: low risk 75.1%, slightly elevated 21.3%, moderate 2.6%, high 1% and very high 0%. There were no differences in the frequency of groups among sexes. The mean of points was: 4.85±3.27, 5.16±3.23 and 4.45±3.28 in total group, female and male respectively (p<0.05 women vs men). We found a positive correlation (p<0.05) between the total amount of points and the cholesterol and triglycerides levels (not the glucose), the main difference was at the point of comparing the groups of low and moderate risk (triglycerides 96.41±47.04 vs 165.5±106.85 mg/dl, cholesterol 161.34±27.14 vs 183±39.8 mg/dl, p< 0.05 in both). We found a statistically significant difference when comparing the frequency of hypertriglyceridemia among the groups of low and moderate (11.1% vs 44.4% p<0.05).

Discussion: Our results show that even though in stages considered of low risk, patients that should undergo a thorough scrutiny in search of diabetes and disorders of glucose tolerance can be found. Also, we found a statistically significant correlation between the score of the survey and the cardiovascular risk factors such as hypertriglyceridemia and hypercholesterolemia. The increase in the frequency of elevated triglyceride we believe is related to insulin resistance that is certainly present in students with a higher score

Diabetes risk questionnaire: results of online survey

S. Prgomelja[1], T. Beljic[2]
[1] Diabetes Association of Serbia, Belgrade, Serbia
[2] Diabetes Association of Serbia, President, Belgrade, Serbia

There are some 500 000 people with diabetes in Serbia. The new National Strategy Program for Early Detection of Diabetes type 2 was officially announced in 2008. A Diabetes Risk Questionnaire was placed on the web site of the Diabetes Association of Serbia, www.diabeta.net.
The aim was to analyze the frequency of Questionnaire usage, type of people concerned about diabetes and incidence of high risk for diabetes.
Methods: The Questionnaire was placed on the web site in September 2008. Analysis was done on 27th March 2009.
Results: The questionnaire was filled by 1458, but only 1226 were valid. Interest was mostly shown by participants younger than 45 years of age (776 -63.3.%), than by the middle aged (45/54 years, 242 – 19.7%), older (55-64 years, 172 – 14%) and least by elderly people (>64 years, 36 – 3%). Obese individuals were the ones mostly concerned (1215 - 99.1%). Waist circumference (WC) was measured and 487 participants (39.7%) reported having normal WC, according to the IDF criteria. Some 434 (35.4%) participants had WC 94-108cm for male and 80-88cm for females. Waist circumference greater than 102cm (male) or 88cm (female) was present in 305 (25.3%). Recreation for at least 30 minutes, walking included, was practiced by 743 (60.6%) participants. Fruit and vegetables was consumed every day by 797 (65%) of subjects. Antihypertensive therapy was used only by 27.2% of subjects. A blood glucose measurement was never performed in 695 (56.7%) of subjects. Family history was present in 57% of participants, with 37% having diabetes in first line relatives. Risk calculation revealed that 180 subjects (14%) had low risk for diabetes. It was slightly elevated in 387 (31.6%) and considerably elevated in 248 (20.2%) of subjects. High risk for diabetes was discovered in 336 subjects (27.4%),while very high risk was present in 6.1%.
Conclusion: Diabetes Risk Questionnaire was approached mostly by younger people, familiar with internet usage, who considered themselves obese and had positive family history. Waist circumference measurement can be imprecise in obese subjects. Blood glucose testing should be motivated in younger subjects. Questionnaires on diabetes related web sites are a good method of discovering individuals with risk for diabetes.

Evaluation of diabetic patients treated in first and second degree medical centers: first survey report of north-west region of Turkey

K. Ukinc[1], S.u. Gol[1], S. Gur[1]
[1] Canakkale Onsekiz Mart University Faculty of Medicine, Endocrinology and Metabolism Diseases, Canakkale, Turkey

Aims: In order to prevent the development of diabetic micro and macrovascular complications, all metabolic parameters and blood pressure levels should be in target ranges. In any level, all clinicians should be treating their patients dynamically.
Methods: Canakkale University Faculty of Medicine was founded five months ago and it is the first education hospital in north-west of Turkey. We wanted to assess the condition of diabetic patients admitted to our endocrinology and metabolism outpatient clinics who had been followed by general practitioner or second level hospitals in our city previously. Five hundred (male=235; 47% and female=265; 53%) type 1 (n=35; 6,9%) and type 2 diabetic patients (n=465; 93,1%), were evaluated for the metabolic parameters, hypertension, dyslipidemia, micro and macrovascular complications.
Results: Treatments of the patients were as follows; only diet (n=35; 7%), oral anti-diabetics (OAD) (n=330; 66%), only insulin (n=40; 8%), and combination of insulin and OAD (n=95; 19%). Only a few patients with type 1 (n=6; 17%) and type 2 (n=68; 14.6%) diabetes had reached the HbA1c target of lower than 7%. Target blood pressure level of <130/80 mmHg was achieved in 25 (71%) type 1 and 102 (35%) type 2 diabetic patients. In the whole group, LDL-cholesterol<100 mg/dl and HDL-cholesterol >45 mg/dl levels were achieved in only 95 (19%) and 120 (24%) patients, respectively. Type 2 diabetic patients were mostly obese (BMI>30 kg/m2) (n=354; 90%). Microvascular complications were observed in 220 (44%) patients. In this group, retinopathy (n=77; 35%), neuropathy (n=103; 47%), and nephropathy (n=18; 40%) were present as microvascular complications. Also macrovascular complications, cardiovascular disease (n=100; 20%), peripheral vascular disease (n=25; 5%), and stroke (n=10; 2%) were determined.
Discussion/conclusions: Diabetic patients who were treated and followed by first and second line heath care centers, had uncontrolled diabetes (86,4%), uncontrolled hypertension (75%), hyperlipidemia (81%), obesity (90%), and almost half of them had at least one of the microvascular complications. Clinicians in first and second line medical centers follow more diabetic patients than medical schools and professional diabetes centers. Educational programme targeted to these clinicians should be increased and they must be encouraged to use more dynamic and new treatment modalities for their diabetic patients.

Sixty-second screening identifies persons at risk for diabetic foot ulcers

B. Ostrow[1], R.G. Sibbald[2], K. Woo[2], M.G. Rambaran[3]
[1] University of Toronto, Office of International Surgery, Guelph, Canada
[2] University of Toronto, Women's College Hospital, Toronto, Canada
[3] Georgetown Public Hospital Corporation, Medical and Professional Services, Georgetown, Guyana

Aim: To develop and apply a low-tech screening tool for risk status of developing diabetic foot ulcers in a resource-poor setting.
Methods: The 60 second screening tool identifies high risk status on the basis of history, examination of the foot for lesions or deformity, monofilament loss of protective sensation, joint stiffness and the absence of a pedal pulse. The tool was applied in a weekly medical diabetic clinic at Georgetown Public Hospital Corporation, (Guyana's only referral and teaching hospital). The clinic has a population base of more than 2000 patients. High risk status was defined as a single positive score on the tool. Identified high risk patients were referred to the Diabetic Foot Centre for further assessment to prevent foot ulcers through patient education and the supply of appropriate footwear and orthotics.
Results: Audit of initial screened1000 patients: 70% of screened population is female; 40% of total screened population is at high risk; 13% had previous ulcers; 5% previous amputation; 8.5% an absent foot pulse; 7.7% an active ulcer. The tool profiles the frequencies of risk factors in the population. Inter- and intra-rater reliability of the tool will be presented. High risk patients referred to DFC form a cohort to determine the effects of patient education, follow-up concerning foot care and the wearing of appropriate footwear on ulcer prevention.
Discussion/conclusions: Screening of people with diabetes for high risk status is an essential component of comprehensive diabetes care. It focuses preventive practices and reduces workload for the treatment of foot ulcers and their complications. It also identifies unrecognized ulcers at an early stage. Screening and patient education to change behaviors are the keys to preventing diabetic foot ulcers. The 60 second tool has been adopted by the Ministry of Health in Guyana.

Family history is strongly associated with diabetes in the mixed ancestry population of Cape Town, South Africa

T. Matsha[1], J.D. Soita[2], M.S. Hassan[2], R.T. Erasmus[3]
[1] Cape Peninsula University of Technology, Biomedical Sciences, Cape Town, South Africa
[2] Cape Peninsula University of Technology, Nursing and Radiography, Cape Town, South Africa
[3] University of Stellenbosch, Chemical Pathology, Cape Town, South Africa

Background and aims: Diabetes has been recognized as a global epidemic with its prevalence increasing at a rapid rate both in developed and developing countries. The mixed ancestry population has been shown to have one of the highest incidence of diabetes in South Africa. A positive family history has been hypothesized to be a significant risk factor in the development of type 2 diabetes. The objective of the study was to determine factors that may contribute to the high prevalence of diabetes in the mixed ancestry population of South Africa.
Methods: In a cross-sectional study, 600 subjects within the age group of 35-65 years who were randomly selected through multistage random sampling within the Bellville South area of Cape Town underwent an oral glucose

tolerance test. Diabetes, IGT and IFG were determined using the revised WHO criteria. Subjects underwent several anthropometric measurements and demographic, family, health, lifestyle data were extrapolated by use of a questionnaire. Smoking and alcohol consumption were assessed by means of a questionnaire. To validate subjects' responses, urine cotinine and serum GGT levels were measured for tobacco and alcohol consumption.

Results: Overall the crude prevalence of diabetes was 25.6 % of which half were newly diagnosed whilst the other half were self reported diabetics. IGT was present in 4.0% whilst IFG was in 3.5%. Self-reported smoking correlated with urine cotinine levels. Though alcohol consumption was significantly higher in females, gamma-GT levels of males were significantly higher than females, $p< 0.05$. Only 5.1% of individuals with a family history of diabetes did not have either diabetes, IFG or IGT. Females were significantly more obese than males in all age groups 35-45, 46-55 and 56-65, $p=0.002$ and 0.000 and 0.031 respectively. 57% of diabetic individuals were obese whilst 27.6% were overweight. In a multinomial logistic regression analysis that adjusted for factors such age, sex, family history of diabetes, nicotine and GGT levels, weight and lipid levels, the father's family history of diabetes was strongly associated with the development of diabetes (odds ratio = 2.092, 95% CI 1.109 – 3.949, $p = 0.023$). HDL cholesterol levels and younger age were negatively associated with diabetes.

Conclusions: Our results suggest that there has been a sharp increase in the prevalence of diabetes with many being undiagnosed. In view of the strong association between a positive family history and the number of undiagnosed diabetics it is suggested that screening for diabetes, particularly in those with a positive family history, at each and every primary health care visit, may result in earlier treatment thereby controlling diabetic complications.

Diabetes screening in Thai community drugstores: effectiveness, unit cost and provider payment method

C. Ploylearmsang[1], T. Soondon[1]
[1] *Faculty of Pharmacy Mahasarakham University, Social Pharmacy Research Unit, Maha Sarakham, Thailand*

Diabetes Mellitus (DM) is a crucial health problem in Thailand. More than 60% of people with high risk diabetic factors in community are not aware about diabetes and have never been screened. Drugstore as a primary care provider that is stood close to the community could enhance their disease awareness and increase the diabetes screening coverage.

This cross-sectional, descriptive study is aimed to study the effectiveness of diabetes screening in community drugstores and to investigate unit cost and to propose the rational provider payment method for screening service. 11 accredited community drugstores in three provinces: 3 in Nakorn Ratchasrima, 6 in Khon Kaen and 2 in Maha Sarakham were followed during October 2008-February 2009. People aged more than 35 years, indentified as the risk person were screened. Unit cost of the diabetes screening was investigated in provider perspective, including labor cost, material cost and capital cost.

Total of 1663 people aged more than 35 years were screened for their diabetes risk factors. A drugstore could screen average 30-60 cases per month. 9% with high risk factors were referred to the community medical units (CMU) for checking their fasting blood sugar and seeing physician for early diagnosis. During screening, people were informed about diabetes and its sign and symptom and given the leaflets by community pharmacist. Unit-cost of a diabetes screening was 41 Baht per service (1.16 USD) composed of 37% of labor cost, 58% of material cost, and 5% of capital cost. The rational payment mechanism for screening service in accredited drugstore is fee-for-service with 41 Baht per service. Drugstore could reimburse money from the budget of promotion and prevention community-based services (P&P-COM budget). This budget is managed by the contracting unit for primary care (CUP) of National Health Security Office (NHSO) which organizing the Universal Coverage Scheme in Thailand.

It can be concluded that diabetes screening by pharmacist in the accredited drugstore could promote community awareness on diabetes and support the coverage of screened people with risk factors. Community pharmacist as a primary care provider could reimburse his money with the rational payment that could increase their incentives to provide the service.

Organisation of seamless and reliable management of diabetic retinopathy screening through teleophthalmology

M.C. Boucher[1]
[1] *Hôpital Maisonneuve-Rosemont, Ophthalmology, Montréal, Canada*

Aims: Teleophthalmology for screening for diabetic retinopathy (DR) has shown significant visual health results and savings of medical resources in urban and remote communities. Although data and image capture and their electronic transfer are relatively straightforward, management and overview of the screening process are necessary to monitor and ensure quality of all steps, from creation of appointments to follow-up with an ophthalmologist and yearly patient recall.

Methods: Management tools are needed to ensure retrieval of any scheduled patient who has not followed on examination, prompt interpretation of data by the ophthalmologists with an automated redistribution towards other ophthalmologists when delays for interpretation are not met, to flag amongst a large volume of patients any diabetic presenting with a condition dictating intervention or surveillance. Overviewing of timely and appropriate follow-up for each screened diabetic as well as quality control of the medical diagnostics are also needed. Any screening program must ensure security and confidentiality, easy management of protected levels of access for specific tasks for imagers, ophthalmologists, computer technicians, administrators as well as tracing of all actions to all individuals who intervene. Continuing care needs be ensured by systematic transmission of screening results to medical doctors involved in the care of the diabetics and by feedback to and recall of screened diabetics. Organized and easily retrievable data for public health analysis providing a prospective DR registry is also pertinent. Management tools need be compatible with any camera used for screening and be usable in conditions with no immediate access to internet. Using specially developed software with all of the above characteristics, screening for DR through teleophthalmology has been performed since 2005 in urban, semi urban and remote communities in over 8,000 diabetics through mobile and permanently located cameras, with and without immediate access to internet.

Conclusion: Such management software permits easy overview and reliable, safe management of patients screened for DR, monitoring every step of the screening process from the creation of a screening appointment to follow-up with an ophthalmologist to yearly patient recall while ensuring quality control and access to epidemiological data. It could be advantageously used in any public health care screening program for DR.

High prevalence of metabolic syndrome in a group of hypertensive patients in Haiti

N. Charles-Larco[1], E. Jean-Baptiste[1], P. Larco[1], S. Chauvet[1], R. Charles[1]
[1] *Fondation Haïtienne de Diabète et des Maladies Cardiovasculaires, Clinique d'hypertension artérielle, Port-au-Prince, Haiti*

Aims: The prevalence of arterial hypertension is high (47%) among people aged ≥ 20 years in the metropolitan area of Port-au-Prince, according to a previously published study. Hypertension is one of the main components of the metabolic syndrome (MS). A high frequency of MS in hypertensive patients can strongly suggest a high prevalence of this syndrome in the same population. The purpose of this study is to evaluate the prevalence of MS and to analyze the relationship between its components among patients of a hypertension outpatient clinic in Port-au-Prince.

Methods: A total of 119 consecutive hypertensive patients referred to the hypertension clinic, over a period of 3 months, were assigned to the study group. Hypertension was defined as Blood Pressure ≥ 140/90 mmHg or treatment of previously diagnosed hypertension. Demographic data and anthropometric measurements were collected. Fasting blood glucose and lipid profile were performed by venous sample for each participant. Metabolic Syndrome was defined using the IDF criteria.

Results: Mean age was 58.0 ± 11.6 years, with 77.3% women. Median duration of hypertension was 4 years, and all the patients were receiving oral medications. MS was found in 64.7% of these hypertensive patients. In 74.8% of the patients, hypertension was associated with at least 2 factors of MS. A total of 78 (65.5%) hypertensive subjects had also abdominal obesity and only 1 patient with abdominal obesity did not have MS. In patients with MS, 80.5%

had 4 of the 5 diagnostic components, and the frequency of the components associated with abdominal obesity and hypertension was: reduced HDL cholesterol (97.4%), raised fasting glucose (79.2%) and raised triglycerides (27.7%).Furthermore, 81.5% of hypertensive patients with reduced HDL cholesterol versus 11.1% with normal HDL cholesterol have also abdominal obesity (p<0.001). Logistic regression showed that reduced HDL cholesterol was independently associated with abdominal obesity (p<0.001).

Conclusions: Our study showed a high prevalence of metabolic syndrome in a group of hypertensive patients in Haiti. This finding associated with the known high prevalence of hypertension in urban Haitian population illustrates the need for screening for MS in hypertensive subjects at initial diagnosis or first medical visit. The very strong association between abdominal obesity and reduced HDL cholesterol in hypertensive patients drastically increases the probability of MS in presence of the combination hypertension and abdominal obesity.

Risk factors for diabetes in Romani population in Serbia

M. Marjanovic[1], T. Beljic[2], R. Zivkovic[3], D. Ackovic[4]

[1] Zvezdara University Medical Center, Division of Endocrinology, Belgrade, Serbia

[2] Zvezdara Univeristy Medical Center, Division of Endocrinology, Belgrade, Serbia

[3] Diabetes Association of Serbia, Belgrade Diabetes Association, Belgrade, Serbia

[4] Roma Community Center, 4th April, Belgrade, Serbia

It is well known that Romani people suffer from respiratory and cardiovascular diseases. It is very possible that they have high prevalence of diabetes, due to the presence of risk factors: poverty, obesity and stress due to frequent and often forced migrations.

The aim of our study was to investigate the risk factors for diabetes in the Romani population in Serbia.

Methods: Diabetes Association of Serbia screened the Romani population for diabetes. Research concentrated on risk factors for diabetes: obesity, knowledge of occurence of diabetes in family members and difference between urban and rural communities.

Results: Some 2015 Romani people were screened for risk factors. Research was done in 11 urban (1130 people) and 8 rural communities (885 subjects). Most subjects (820) were in the age group 31 - 50 years. Slight less were in the age group 51-70 years (631). Least responders were in the age group over 70 years (95) and slightly more in the age group 18-30 years (469). The subjects were subdivided into 4 groups: those with diabetes (87, 5.9%), those with newly discovered diabetes (76, 5.2%), people with borderline blood glucose values (340, 16.9%) and healthy subjects (1450, 72%). Multinominal regression analysis was used to assess the risk for developing diabetes in obese subjects, those with positive family history and those living in urban settlements. Risk for diabetes was 3,48 times higher if a Roma person had positive family history (OR 3.47; 95% confidence interval 2.37-5.1; p<0.01). Obesity was significantly more prevalent in Romani people with diabetes and those with borderline results (X^2=32.555 ; df=3; p<0.01). The risk of diabetes was 2 times higher in obese Roma person than in the non-obese (OR 2.107, 95% confidence interval 1.249 – 3.554; p<0.01). The risk of developing diabetes was 3,649 times higher in Roma people that live in urban settlements (OR 3.649, 95% confidence interval 1.998 – 6.662; p<0.01), compared to rural.

Conclusion: It is difficult to perform screening of Roma people for diabetes. Diabetes should be searched for in those who are obese, have positive family history and live in urban settlements.

Type 2 diabetes mellitus screening in Kathmandu, Nepal – a pilot study

I. Broz[1], I. Shrestha[2], S. Adhikari[2], K. Tandukar[2], M. Ladyr[2], R. Madar[3], G. Dahal[2], P. Adhikari[2]

[1] Charles' Medical University, 3rd Medical Faculty, 2nd Dep Int Med

[2] IHD clinic, Diabetology, Kathmandu, Nepal

[3] University of Ostrava, Faculty of Health Studies, Ostrava, Czech Republic

Aims: Life-style changes in developing countries cause an increase of obesity and type 2 diabetes mellitus. This in combination with health care insufficiency can have serious health and socio-economic impact. Town areas of Nepal belong to those with the highest prevalence of type 2 diabetes mellitus and impaired glucose tolerance in the world. The aim of the study was the screening for type 2 diabetes mellitus among inhabitants over 40 years old in Kathmandu, Nepal.

Methods: three one day screening points were establihed in different parts of Kathmandu. In cooperation with the local authorities (public notice) inhabitants over 40 years were asked to come for diabetes screening. Fasting plasma glucose, BMI, and blood pressure were examined in all patients.

Resultes: we examined 376 inhabitants (259 woman and 117 men), average age 56,2 ± 9,2 year. Among them there were 45 patients (26 woman and 19 men) with known type 2 diabetes. Among the rest 233 woman and 98 men, there were 32 woman (13,7 %) and 20 men (20,4 %) fulfiling type 2 diabetes mellitus criteria (fasting glucose over 7 mmol/l) with average value 10,3 ± 2,3 mmol/l. Frequence of hypertension was significantly higher in patients matching diabetes criteria (20,1% vs. 42,8, p< 0,05), also BMI was significantly higher in this group (25,9 ± 2,2 vs. 1,7, p<0,05).

Conclusion: A method of screening points offers an efficient method of type 2 diabetes screening in Nepal. Our results correspond with previously reported high prevalence of type 2 diabetes in town areas of Nepal.

Healthy children, physical activity and the relation to blood glucose, C-peptide and BMI

K. Huus[1], A. Raustorp[2], J. Ludvigsson[3]

[1] School of Health Sciences, Department of Nursing Science, Jönköping, Sweden

[2] School of Human Sciences, University of Kalmar, Kalmar, Sweden

[3] Div of Paediatrics and Diabetes Research Centre, Department of Clinical and Experimental Medicine, Linköping University, Sweden

Aims: The incidence of type 1 diabetes among children is increasing. This increase could be related to environmental factors such as low physical activity and overweight/obesity among children. The aim was to study if lack of physical activity relates to blood glucose value and insulin sensitivity in healthy children. Another aim was to study if low physical activity is related to overweight/obesity in children.

Methods: As a part of the prospective study 'All Babies In southeast Sweden' (ABIS), 199 children 8 years old participated in this particular study. Weight, height and pedometer steps were registered. The parents answered questionnaires and blood samples were gathered.

Results - The fewer daily steps the child was taking correlated to higher BMI (Body Mass Index) (P= 0.019), to bigger waist circumference (P=0.018) and also to higher fasting serum C-peptide (P= 0.044), HOMA IR (P=0.046) and HOMA ß-cell (P=0.022). The more hours/day the children spent in front of TV/video, the bigger waist circumference (P= 0.033) and higher fasting blood glucose values (P=0.016) they had.

Discussion: When measuring physical activity, it was found that lower physical activity is associated with higher BMI and bigger waist circumference. It was also found that children who were more physically inactive spent more time in front of TV/video. Those with low physical activity measured by step counters also had higher fasting C-peptide and increased HOMA IR index which indicate insulin resistance.

Conclusion: A lifestyle with higher energy intake and low levels of physical activity may in fact already at these low ages increase the ß-cell stress and could, according to the ß-cell stress hypothesis, contribute to an increasing incidence of type 1 diabetes in children.

Conflict of interest:
Advisory board: Dr Anders Raustorp has served as medical advisor for Keep Walking Scandinavia AB. KWS is a company in the wellness sector with online consulting, online distribution of literature and online distribution of pedometers of different brands including the Yamax. To our opinion this has by no means affected the result of this study.
There does not exist any other potential conflict of interest.

P-1321

Cholesteryl ester transfer protein activity and components of the metabolic syndrome in school children

V. Hirschler[1], L. Gomez Rosso[2], G. Maccallini[3], C. Aranda[3], O. Meroño[4], F. Brites[4]
[1] Hospital Durand, Nutrition, Buenos Aires, Argentina
[2] Conicet, School of pharmacy, Buenos Aires, Argentina
[3] Hospital Durand, Laboratory, Buenos Aires, Argentina
[4] CONICET, School of Pharmacy, Buenos Aires, Argentina

Background: Cholesteryl ester transfer protein (CETP) transfers cholesteryl esters from HDL toward lipoproteins of lower-density classes in exchange for triglycerides, enabling the transport of HDL-derived cholesteryl esters back to the liver via VLDL and LDL
Objective: To determine the association of CETP with components of the metabolic syndrome such as BMI, waist circumference (WC), blood pressure, glucose, insulin and lipid levels in children.
Methods: Data were collected cross-sectionally from an elementary school in November 2008. BMI, WC, blood pressure, and Tanner stages were obtained. Fasting levels of lipids, insulin, glucose and CETP activity (radiometric assay) were determined. To measure the strength of association between two variables, a Spearman correlation coefficient was used. Separate linear regression analyses were done using variables with significant relationships in spearman analysis, as dependent variables and CETP, age, and sex as independent variables.
Results: Fifty eight children (31 males) aged 9.0±2.5 y were evaluated. Seven (12.1%) of the children were obese (>95th percentile), and 9 (15.5%) overweight (85-95th) as CDC guidelines. Most of the children (64.9%) were pre-pubertal (TS1: 37/58). There was a higher activity of mean CETP in obese (190.35±39.14%/ml.min) than in overweight (172.71± 27.27) and normal children (137.12±41.11). Spearman correlation showed an inverse association between CETP and HDL-C (r=-0.31;p=0.018), but a positive association between CETP and BMI (r=0.36;p=0.007), WC (r=0.35;p=0.007), total cholesterol (r=0.41;p=0.001), LDL-C (r=0.48;p<0.001), insulin (r=0.35;p=0.007), and HOMA-IR (r=0.32;p=0.02). In contrast no significant correlation was found between CETP and systolic blood pressure, glucose and triglycerides. In separate linear regression models, CETP was independently associated with BMI (B= 0.03; p=0.002) ; WC (B= 0.09; p=0.002) ; HDL-C (B= -0.066; p=0.017) ; total cholesterol (B= 0.32; p=0.001) ; LDL-C (B= 0.25; p<0.001) ; HOMA-IR (B= 0.006; p=0.003) and insulin (B= 0.03; p=0.002) adjusted by sex and age.
Conclusions: Increased CETP activity was associated with higher BMI, WC, total cholesterol, LDL-C, and insulin and with lower HDL-C in school children. These findings suggest that CETP activity might increase the risk of future cardiovascular disease in children. Additional longitudinal studies should be done to further confirm these findings.

P-1322

Obesity and overweight among students as risk factors for metabolic syndrome

S. Galitskaya[1], T. Mokhort[1]
[1] Belarussian State Medical University, General medicine, Minsk, Belarus

Aim: to assess the frequency of body weight disturbances among students; analyze the main lifestyle factors: the level of physical activity and eating behavior; evaluate the presence of insulin resistance in students with and without obesity.
Methods: The study included a questionnaire survey concerning the level of physical activity (International Physical Activity Questionnaire – IPAQ) and diet (special developed questionnaire), an assessment of anthropometric measurement (BMI, waist-to-hip ratio) and blood pressure. Laboratory research was conducted to evaluate insulin resistance in the selected groups with normal body weight and obesity. Insulin resistance was evaluated based on the index HOMA-IR (normal value up to 2.77) with the determination of fasting glucose level and fasting insulin level (enzyme-linked immunoelectrodiffusion essay).
Results: The study included 400 students of Belarussian State Medical and Pedagogical Universities, 86.2% female and 13.8% male, mean age 20.46±1.77 years. Among all examined students 12.5% were found to be overweight (BMI 25-29.9 kg/m^2), 3% - obese (BMI >30 kg/m^2), 13.5% had the deficit of body mass (BMI <18.5 kg/m^2). High waist-to-hip ratio was found in 3%; arterial hypertention (≥140/90 mm Hg) in 5.8% of the students. Students eating behaviour was found to be unregular (only 16.75% of the students eat 4 or more times a day, 87% of students have frequent unhealthy snacks), poor with excessive consumption of carbohydrates and low consumption of fruits and vegetables, despite the presumable awareness of these groups of students about the importance of healthy lifestyle. Analysis with the IPAQ survey showed that 19.5% of students had a low level of physical activity, 65.25% moderate, and only 15.25% of students had a high level of physical activity. There was a significant difference between groups (obese students – 3.16±0.67, normal body weight – 2.33±0.32, p=0.008). 66.7% of the students in the obese group had insulin resistance based on HOMA-IR index. These students are at high risk of development of diabetes mellitus and cardiovascular diseases.
Conclusion: Considering the fact that lifestyle habits are established at young age and have a great influence on future health, there is a need for a comprehensive program on the modification of lifestyle among students, consisting of advice on diet and physical activity to sustain good health. Special attention should be paid to the population of obese young people to prevent the development of diabetes mellitus and cardiovascular diseases.

Glycemic profile of prediabetic outpatients after nutrition intervention in São Paulo, Brazil

A. Sachs[1], S.K. Oku[1], M.C. Ferreira[1], N.C. Santos[1], M.Q. Freire[1], L.C. Coelho[1], L. Asakura[1]
[1] UNIFESP/EPM, Preventive Medicine, São Paulo, Brazil

Guidelines regarding nutrition therapy to prevent diabetes and its complications are imperative in developed and underdeveloped countries.
Objective: to evaluate glycemic profile in prediabetic outpatients after nutrition intervention.
Methods: data were collected from patients entering the Nutrition Ambulatory from the Nutrition Unit – Department of Preventive Medicine – Federal University of São Paulo between 2007 and 2008. Information was obtained through patients´s records containing the results of fasting blood glucose tests. There were selected only patients under the criteria of prediabetes (American Diabetes Association, 2008) and who had at least 1 blood glucose test result 1 year prior to nutrition intervention and another one within 7 months after nutrition intervention. When entering the nutrition ambulatory patients received general nutrition guidelines and an individualized plan aimed at prediabetes treatment and prevention of comorbidities.
Results: from February/2007 till October/2008 373 patients entered the nutrition ambulatory and 9.65% (36) were diagnosed as prediabetics. Age range was 21 to 70 years and 23 women and 13 men had pre-intervention fasting blood glucose (FBG) result and at least 1 FBG result up to 7 months after intervention. It was observed that from the overall patients 75% (28) showed reduction in the glycemic profile after intervention and 56.14% reached normal levels of fasting glucose.
Conclusion: general and individualized nutritional intervention in prediabetic patients shown to be effective in the reduction and normalization of glycemic profile, helping to prevent complications due to prediabetic state development.

Overweight and obesity in students – risk for metabolic syndrome in adults

P. Gatseva[1], S. Vladeva[2]
[1] Medical University, Dept of Hygiene and Ecomedicine, Plovdiv, Bulgaria
[2] Medical University, Clinic of Endocrinology, Plovdiv, Bulgaria

Background: Incidence of overweight during childhood is reaching higher levels in the recent years in Bulgaria. Different studies observe an interrelationship between this problem and the appearance of metabolic syndrome in later age.
Aim: To assess incidence of overweight and obesity among students.
Subjects and methods: 274 boys and 209 girls aged 8 to 15 years have been examined. We used Cole's criteria about classification of overweight and obesity, approved in 2000. Questionnaires, prepared especially for the study, show the physical activity and the eating habits of the students.
Results showed overweight at 12,81% and obesity at 7,25% among the examined students. 9,18% of them have increased arterial pressure. In most of the cases these are children with overweight or with obesity. The results revealed diminished physical activity and unhealthy eating habits among more than 50% of the students.

Conclusions: There are strong enough arguments for serious recommendations what concerns the physical activity and the eating habits of the teenagers. The achievement of this goal probably could help for the prevention of the metabolic syndrome in later age.

Diabetes and primary healthcare setting: referral and first responsibility in developing countries

S. Joshi[1], K. Panday[2]
[1] District Public Health, PHC, DHI, Nepal
[2] Community Health and Environmental Society Nepal, Health, KTM, Nepal

Aim: Diabetes patients usually come to primary health care setting in their first visit. Usually these patients never aware about diabetes information. To analyze the general clinical characteristics of a population of type 2 diabetic patients referred from primary health care to higher center.
Methods: The study was carried out in the last 132 patients referred from primary health care setting. Consideration was given to: age, gender, time since diagnosis, body mass index, glycosylated haemoglobin, diagnosed hypertension, hypercholesterolaemia, ischaemic heart disease and treatment prior to referral. SPSS software was used for the statistical calculations.
Results: Of the 130 patients seen, 62 were female and 68 male. Mean age: 66.73 ± 11.60 years (range 28–87). Mean time since diagnosis: 9.95 ± 9.34 years (range 0–40). HbA1C: 8.20 ± 1.99% (range 4–16.20). BMI: 30.59 ± 5.56 kg/m2; (range 19.7–60), with 13.4% presenting normal weight, 38.4% overweight, 29.6% grade I obesity and 18.5% obesity with a BMI in excess of 35. On the basis of the ATPIII criteria, 70.8% presented hypercholesterolaemia and 65.4% hypertension. Ischaemic cardiopathy was seen in 12.3%. Only 5.6% were referred just after diagnosis without treatment;13.1% were on a diet, 53.5% took oral antidiabetes drugs (10.7% on acarbose, 46.4% on sulfonylureas, 25% with sulfonylureas and metformin, 10.7% on metformin, 7.1% on acarbose and sulfonylureas and none was receiving glitazones or meglitinides), 13.6% were on insulin and 14.1% on insulin and metformin.
Conclusions: (i) Type 2 diabetic patients referred from primary health-care are patients in advanced middle age, with a long mean time from symptoms until they are referred to the higher center, with a clear dominance of overweight and obese patients with poor metabolic control and added cardiovascular risk. (ii) It is important to stress early and continuing education in diabetes, the basis for medical treatment, promoting physical exercise and appropriate eating habits for each patient in order to lose weight and try to diminish from the outset their insulin resistance, promoting also the use of oral antidiabetes drugs capable of preserving the beta function of the pancreas. (iii) These results leads to thoughts on who should direct treatment of type 2 diabetes from its outset, as the start of therapy is the basis for less exhaustion of the pancreatic function and the degree of glycaemic and metabolic control from the moment of diagnosis is going to avoid, or delay as far as possible, the development of microvascular and macrovascular complications.

P-1326

Obesity and the metabolic syndrome in developing countries: how it related with diabetes

R. Bhandari[1], S. Bhattarai[1]
[1] NMC teaching Hospital, Community Medicine, KTM, Nepal

Aim: Prevalence of obesity and the metabolic syndrome is rapidly increasing in developing countries, leading to increased morbidity and mortality due to type 2 diabetes mellitus (T2DM) and cardiovascular disease.
Methods: Literature search was carried out using the terms obesity, insulin resistance, the metabolic syndrome, diabetes, dyslipidemia, nutrition, physical activity, and developing countries, from PubMed from 1966 to December 2008 and from web sites and published documents of the World Health Organization and Food and Agricultural Organization.
Result: With improvement in economic situation in developing countries, increasing prevalence of obesity and the metabolic syndrome is seen in adults and particularly in children. The main causes are increasing urbanization, nutrition transition, and reduced physical activity. Furthermore, aggressive community nutrition intervention programs for undernourished children may increase obesity. Some evidence suggests that widely prevalent perinatal undernutrition and childhood catch-up obesity may play a role in adult-onset metabolic syndrome and T2DM. The economic cost of obesity and related diseases in developing countries, having meager health budgets, is enormous.
Conclusions: To prevent increasing morbidity and mortality due to obesity-related T2DM and cardiovascular disease in developing countries, there is an urgent need to initiate large-scale community intervention programs focusing on increased physical activity and healthier food options, particularly for children. International health agencies and respective government should intensively focus on primordial and primary prevention programs for obesity and the metabolic syndrome in developing countries.

The influence of adipocytokines, muscle and hepatic lipid content on insulin resistance in Japanese

E. Yoshimura[1,2], H. Kumahara[1], T. Tobina[1], S. Matono[1], A. Kiyonaga[1], M. Kimura[3], H. Tsukikawa[5], S. Kawano[5], T. Etou[4], S. Irie[3], K. Anzai[2], H. Tanaka[1]
[1] Fukuoka University, Fukuoka, Japan
[2] Fukuoka University Hospital, Fukuoka, Japan
[3] Kyushu Clinical Pharmacology Clinic, Fukuoka, Japan
[4] PS Clinic, Fukuoka, Japan
[5] Hakata Clinic, Fukuoka, Japan

Introduction: Recently, the prevalence of type 2 diabetes mellitus is increasing in Japan. Some studies has demonstrated that a reduction in the blood adiponectin concentration, an increased production of adipocytokines which induces lipotoxic effects, an excessive accumulation of muscle and hepatic lipid contents and increased visceral fat were all risk factors for type 2 diabetes. Although those factors induced insulin resistance, it is unclear precisely which factor most strongly influenced insulin resistance. This study investigated which factors most strongly influence insulin resistance.
Methods: Thirty-eight obese Japanese subjects (19 males, 19 females; age 40 -75 years) who demonstrated risk factors regarding the diagnostic standards of the Japanese committee on MS. The percentage of whole body fat was measured by the underwater method. Computed tomography was determined to evaluate the abdominal fat area (visceral fat area (VFA) and subcutaneous fat area (SFA)) and low-density muscle area (LDMA) and liver fat (LF). All subjects underwent blood examinations after fasting for 12 hours.
Results: GIR/I significantly correlated with the fat mass (FM) ($r = -0.56$, $p<0.05$), VFA ($r = -0.60$, $p<0.01$), LDMA ($r = -0.69$, $p<0.001$), LF ($r = 0.59$, $p<0.01$). FM significantly correlated with VFA ($r = 0.48$, $p<0.01$), SFA ($r = 0.83$, $p<0.001$), LDMA ($r = 0.82$, $p<0.001$). VFA significantly correlated with LDMA ($r = 0.42$, $p<0.01$), LF ($r = -0.51$, $p<0.01$), but the correlation between LDMA and LF was not significant based on the results of a stepwise regression analysis which was performed with GIR/I as the dependent variable and with FM, VFA, SFA, LDMA, LF as the significant independent variables. LDMA was adopted in Step 1 ($R^2 = 0.42$, $p=0.002$), LF also was adopted in Step 2 ($R^2 = 0.60$, $p<0.001$). In addition, it's performed with GIR/I as the dependent variable and with high-molecular-weight adiponectin, TNF-a, PAI-1, leptin, IL-6 as the significant independent variables. According to these results, PAI-1 was only adopted in Step 1 ($R^2 = 0.29$, $p<0.05$).
Conclusion: The current study indicated LDMA and LF to be closely related with insulin resistance in comparison with the other types of fat distribution. In addition, PAI-1 was also related to insulin resistance. For this reason, both LDMA and LF were confirmed to be important target factors for improving insulin resistance.

Iranian National Diabetes Research Network (INDIRAN) project: background, mission and outcomes

S. Amiri-Moghaddam[1], R. Heshmat[1], B. Larijani[1]
[1] Tehran University of Medical Sciences, Endocrinology and Metabolism Research centre, Tehran, Iran

Aim: Diabetes is a public health disorder that opens important areas of research on prevention and early intervention. Since research without systematic planning dissipates material and intellectual investments, Endocrinology and Metabolism Research Centre (EMRC) developed a national research network and invited local (provincial) research centers in Iran who were active in diabetes surveys to join this infrastructure for research in diabetes.
Methods: Iranian National Diabetes Research Network (INDIRAN) was designed to perform research projects on diabetes in collaboration with research centers throughout the country. This network was formed officially in 2002.
Results: Some considerable outcomes of INDIRAN are: Implementation of Iranian Diabetes Guidelines, arrangement of supporting society for diabetic patients, launching Iran diabetes education website and designing and conducting National projects such as "Diabetes Education and Prevention Program".
Conclusion: We report our qualitative and quantitative findings, the lessons learned from our experience, the obstacles we encountered and future directions.

International World Diabetes Day activities in Bafang rural area

C. Nono[1], P. Fokumlah[2], J. Leumale[3]
[1] District Hospital Bafang, Private Medical Ward, Bafang, Cameroon
[2] Training School for Health Personnel, School for State Registered Nurses, Limbe, Cameroon
[3] District Hospital Bafang, Epidemiology, Bafang, Cameroon

Introduction: The Bafang branch of Cameroon Diabetes Association celebrated World Diabetes Day in order to raise awareness about the diabetes pandemic last 13th-14th November 2008 with the global awareness focus of childhood and adolescent diabetes. The crucial point remained on how we could organize a celebration in a society that does not receive allocations and is made up of people that can hardly afford their treatment!
Objectives: Raising awareness among the rural population, screening for diabetes age risk factor and registering new members into the local diabetes association.
Methods: Fund raising for screening materials, Radio announcements, Counselling and free screening (using ADA criteria), March for diabetes, Education.
Results: Fund raising gave us ¤16 instead of ¤229 needed for the organisation. We received 100 strips and 100 lancets for the screening from a local member of the association. Education pamphlets, posters, 1 BP apparatus and 100 lancets were donated by Sanofi Aventis.
We did one week of radio advertisement through the local station plus 2 hours interview. We counselled pupils a day prior to screening test and gave them consent forms for their parents. From primary school, 17 (aged 9-14 years old) pupils responded: 16 had FPG < 100mg/dl, only 1 pupil had IFG between 100-125mg/dl. From secondary school 22 (aged 15-20 years) students responded: majority, 17 (77.27%) had FPG <100mg/dl, 2 (9.09%) had IFG between 100-125mg/dl and 3 (13.64%) had IFG >126mg/dl. From adults, 60 responses of which majority; 16 (48.48%) with FGP <100mg/dl were aged 25-34 years old. Majority, 5 (45.45%) with IFG between 100-125mg/dl and majority, 6 (37.5%) with IFG >126mg/dl were aged 45-54 years old, followed by those aged 55-64 (4 (36.36%) and 5 (31.25%) respectively).
20 people marched; all registered members of the local diabetes association wearing T-shirts with the blue circle "Unite for Diabetes" insignia and slogans of the year's theme.
32 people attended the education session which was presented in the local vernacular and by a film projection.
Feedback/evaluation: We had 8 new registered members: 7 with diabetes and 1 nurse. IFG can be slightly detected among pupils but is common with adult above 45 years old; risk ratio being here 2.92. We need a wider screen to identify the impact of the pandemic among children in this rural area. There is a need for local resources including diabetes education and self-management activities in this rural area and in particular for translation of diabetes education in the local vernacular.

[2] Ministry of Health Labor and Social Affairs, Abkhazia, Tbilisi, Georgia

The GUDEAS (foundation year - 1992, IDF membership since 1994) continues its activity. Its mission is "High Quality Diabetes Care / Education and Defense of Rights of People with Diabetes (PWD) in Georgia". A mixed type NGO opens doors to all organizations that share its goals and bye-laws. Past triennium was rather active. One of the most significant activities was UNR campaign, where GUDEAS took active part both internationally (European WG, EEC) and nationally (local Parliament, key persons). This work was quite successful, locally full support was received. In the field of education (PWD and HCPs) our activity has increased: diabetes magazine is published; 7 new guidelines – translated and published; manual on DM in Pregnancy (Georgian/Russian) – published; color book for children with DM translated, passed to MA from EEC; more intensive involvement in medical students and HCPs education; active work with state key persons. In 2007 together with the Ministry of Health of Abkhazia (MoHA) we traveled to Kodori Gorge where we had a symposium for local HCPs and free patient counseling/testing. A branch of the Union was founded, number of its members reached >8000. After August events there are>300 000 refugees; though Georgia managed to go through crises without insulin deficit – all people were receiving the drug. We are working together with local/International charity organizations and MoHA to support these people. New projects/programs are being prepared, some – implemented. Conclusion: Events of the past triennium, both International and local, showed that together we are a great power.

Training of health care professionals has vast divergences between educating schools in Finland

S. Koski[1]
[1] Finnish Diabetes Association, for the working group, Tampere, Finland

Background: Health care professionals who are knowledgeable about the diabetes care process and are skilled in managing the complex needs of persons with diabetes are an important resource for the quality of care. In Finland we don't have enough specialists to serve all the needs of persons with diabetes. Therefore all health care professionals need some basic skills to manage the diabetes care.
Methods: Finnish Diabetes Association observed the situation of diabetes training of various health care professionals during basic and advanced training in Finland. The observing material consisted of web-based survey for schools that educate the professionals, web-based survey for health care labour unions, education curriculums, descriptions of studies, recommendations for health care training and other documents.
The web-based survey was sent to schools which educate the following health care professionals: medical doctor, nurse, practical nurse, podiatrist, dietician, physiotherapist, dental assistant, psychologist, bioanalyst, occupational therapist and pharmacist. Altogether 93 surveys were sent to schools and 61 answers (65%) were received. To health care labour unions we sent 12 surveys and received 11 answers (91%).
Results: We observed that diabetes training of health care professionals varies a lot from both quantity and contents point of view. In training of practical nurses the schools differs most from each other. The quantity of diabetes training varies from 4 hours to 40 hours of education in whole training period. There is significant variation also with dietetics training with various health care professionals.

Conclusion: The quality of diabetes care is in great extent based on training and diabetes-related skills of the health care professionals. The quality of care of persons with diabetes as such is in Finland marked by regional and local divergences. The vast differences in training increases the divergences even more. In order to diminish the divergences, more attention has to be paid to the basic and advanced diabetes training of health care professionals in future.

P-1332

Characteristics of cardiometabolic risk factors in patients with type 2 diabetes mellitus in Bulgaria according to the definition for metabolic syndrome of International Diabetes Federation

P. Kamenova[1]

[1] *University Specialized Hospital for active treatment in Endocrinology "Acad. Iv. Penchev", Department of Diabetology, Sofia, Bulgaria*

The assessment of cardiometabolic risk factors is the first and crucial step to the aim for reduction of cardiovascular risk in patients with type 2 diabetes mellitus (T2DM). The aim of the study was to assess the characteristics of cardiometabolic risk factors in patients with T2DM according to the definition for metabolic syndrome (MetS) of International Diabetes Federation (IDF). Three hundred and eighty three T2DM patients (194 females, 189 males) from different regions of the country, attending Department of Diabetology of the University Specialized Hospital for active treatment in Endocrinology "Acad. Iv. Penchev" of age 62.2±10.4 yr, duration of DM 7.6±6.7 yr, HbA1c 7.5±1.4%, BMI 30.8±4.8 kg/m2 (mean±SD), participated in the study. The presence of the MetS and the assessment of cardiometabolic risk factors were defined applying the definition for MetS of IDF. Metabolic syndrome was established in 76.5% of patients with T2DM (82% females, 70.9% males). Females with MetS were significantly younger than females without MetS and males with MetS were with a significantly shorter duration of DM in comparison to the males without MetS. One hundred and ten of 293 patients with MetS (37.5%) had all 5 components of the MetS. Considering all T2DM patients, the prevalence of central obesity, expressed by the waist circumference, was the same as that of the MetS-76.8%, whereas as an individual risk factor it was present only in 11 of 90 patients without MetS (12.2%). The most common cardiometabolic risk factor, excluding central obesity as a necessary component of the MetS, was arterial hypertension (75.1%). It was at the first position in females with MetS (84.9%) and at the second position in males with metS (63.4%). The prevalence of arterial hypertension in all T2DM patients was 66.3%. Reduced HDL cholesterol was at the second position in patients with MetS (63.5%) and in all T2DM patients (55.4%). It was the most common cardiometabolic risk factor in males with MetS (76.9%). Raised triglycerides were found in 62.5% of the patients with MetS and in 53.7% of all T2DM patients. Combined dyslipidaemia (raised triglycerides, reduced HDL cholesterol) was with the lowest prevalence considering patients with MetS (42.3%) and all T2DM patients (33.9%). In conclusion, T2DM patients included in our study were presented with multiple cardiometabolic risk factors and their cardiovascular prognosis is driven by combinations of these factors which are more potent than expected by their sums. Screening for MetS should be done in all T2DM patients. Treatment of all risk factors is required for reduction of global cardiometabolic risk.

Dyslipidemia and chronic kidney disease in diabetes mellitus patients, data of an outpatients diabetes care center in Western Romania

M. Munteanu[1], *A. Schiller*[2], *L. Ionutiu*[3], *O. Constantinescu*[4], *G. Negrisanu*[5]

[1] *Timisoara University of Medicine, Diabetes Clinic, Timisoara, Romania*

[2] *Timisoara University of Medicine, Nephrology Clinic, Timisoara, Romania*

[3] *Policlinics "Dr. Citu", Diabetes, Timisoara, Romania*

[4] *Emergency Clinical Hospital, Dialysis, Bucharest, Romania*

[5] *University of Medicine and Pharmacy, Diabetes, Timisoara, Romania*

Aims:CKD and dyslipidemia (DL) are highly prevalent in DM patients. DM, CKD and DL are also major risk factors for cardiovascular disease (CVD). This cross section study explores the effects of CKD, DL and CVD on DM patients from an outpatient diabetes survey unit from western Romania.

Method: 646 DM patients (105 DM 1, 441 DM 2), out of 21000 in evidence in a western Romania county have been randomly assigned to the study (349 female, 297 male, average age 57.75 +/- 13.07 years). In the investigated group the average duration of DM was 10.39+/-8.70 years and the average HbA1c was 9.09+/-2.27%. The group was assessed for CVD (i.e. coronary artery disease (CAD), congestive heart failure (CHF), peripheral vascular disease (PVD), history of stroke) and for CKD according to K/DOQI 2002 (GFR was estimated with MDRD 4 formula). Biological data have been retrieved from the centre database. Two-group comparisons were performed using the t-test and the Fisher exact test, as appropriate and correlation have been evaluated with Pearson tests. Data have been processed using SPSS 16.

Results: CKD was identified in 45.51% and DL in 68.13% of DM patients (18.73% hypercholesterolemia, 19.50 % hypertriglyceridemia and 30.34% mixed dyslipidemia). CVD was evidenced in 46,42% of the patients (13.77% CHF, 37.77% CAD, 15,47% PVD and 5.26% history of stroke). The prevalence of CVD was significantly higher in CKD patients as compared to no CKD (CAD 49.65% vs. 27.87%, p<0.0001; PVD 21.08% vs. 10.79%, p=0.0001; stroke 7.14% vs. 3.69%, p=0.018) but the prevalence of DL did not significantly differ in the two groups.

In no-CKD DM patients GFR correlated negatively with age (r=-0.3144, p<0.001), cholesterolemia (r=-0.1844, p=0.001) and BMI (r=-0.1064, p=0.048). The GFR of DM patients with CKD correlated negatively with age, total cholesterolemia (r=-0.1298, p=0.027) and proteinuria (r=-0.1771, p=0.002).DM patients have been divided into four groups (no DL, hypercholesterolemia, hyper triglyceridemia and mixed DL). The highest prevalence of CKD was evidenced in the mixed DL and the highest prevalence of CVD in the hypercholesterolemia group.

Conclusion: DM patients present a high prevalence of CKD correlated with significantly high prevalence of CVD and a high prevalence of DL. We found a negative correlation between GFR and total cholesterolemia, in both CKD and non-CKD diabetic patients. Our results strongly sustain the recommendations of statins use for both cardio and renoprotective purposes.

Heroes against diabetes in Africa

W. Githire[1]

[1] *Hadia, Administrative, Wading River, USA*

Heroes Against Diabetes In Africa was founded in 2008 in the State of New York by parents of a child with diabetes. We understand only too well the joys and sorrows of living with diabetes. Our mission is to foster cross continental commitment to addressing the needs of children in Africa and advocate for effective solutions. We seek to help, design, develop and deliver low cost life saving tools for all in need. This includes access to diabetes supplies and insulin for all.

There are more than 246 million people worldwide living with diabetes, a number that is expected to grow to almost 400 million within 20 years. The African region has not been spared the debilitating and threatening complications of this global epidemic. In developing countries, like Kenya, the prevailing poverty, ignorance, illiteracy and poor health consciousness further adds to the problem. Those who cannot afford or do not have bare minimum health care facilities are likely to be diagnosed late and suffer from diabetes related complications.

Methods: Use a grass root strategy to connect people to people cross continentally and find meaningful solutions to solvable problems.

Support existing medical care facilities and individuals with needed diabetes supplies and insulin.

To rally governments to include diabetes care in their budgets and promote proven low-cost strategies that alter diet, increase physical activity and modify lifestyle.

To encourage sustainable development in developing countries through partnerships, collaboration and outreach.

Results: It is easy to obtain optimum blood glucose control for a patient who has access to diabetes supplies and insulin.

When governments act and include diabetes care in their budgets, lives will be saved and economies will grow. A healthy nation is a wealthy nation.

Sustainable developments will help families with diabetic children to be self reliant. Self reliance creates confidence.

Discussion/conclusion: No child should have to endure the many restrictions and complications of diabetes in a world where the technology and capital to combat the disease. Inspired by the courage of children with diabetes we are committed to building relationships with other organizations to realize this vision.

Lasting progress against the potential diabetes epidemic in Africa will take local awareness and international attention. By promoting powerful partnerships, we will work to increase awareness. We seek to foster a cross-continental commitment to addressing the needs of children with diabetes in Africa and advocate for effective solutions.

Prevalence of dyslipidemia among individuals participating physical activity-recreational and educational for diabetics

P. Tarso Siqueira[1], F. Oliveira Magalhães[1], F. Andrade Avelar[1], E. Espínola Leite[1], A. Carolina Martins[1], D. Ribeiro M C Oliveira[1], R. Gimenez C Bomfim[1], S. Pereira Duarte Nunes[1], N. Mesavilla Ferreira[1], A. Paula da Silva[1], S. Messias de Freitas[1], L. Kataki de Oliveira[1]
[1] Universidade de Uberaba, Faculdade de Medicina, Uberaba, Brazil

Introduction: was performed, in the city of Uberaba, physical activity-recreational and educational for diabetics in commemoration of the World Day of Diabetes, during 8 consecutive years. The purpose of this activity was the improvement of conditions of life of these elderly and, consequently the quest for improving the quality of life of these. This improvement is based in the study of the amendments of the metabolism of glucose, lipids and of the co-morbidities and associated complications. The objective of this study was observed the association of diabetes with dyslipidemia among individuals of this gymkhana.
Methodology: performed questionnaire, measured in capillaries fasting glycemia and post-prandial, total cholesterol and triglycerides. Data were analyzed by SPSS 14.0 program and through the chi-square with a significance level of 5%.
Results: 116 persons analyzed, 36 are diabetic (31.0%), 65 (55.6%) has hypertriglyceridemia and 24/100 (24.0%) has hypercholesterolemia. The average statistics – found: age 65.18 ± 1.3 years, fasting glycemia - 112 ± 5.4 mg/dl, glycemia post-prandial - 136, 1 ± 6,8 mg/dl, Body Mass Index (BMI) – 27.1 ± 0.6 kg/m2 SC, waist abdominal – 85.6 ± 1.5 cm, Total cholesterol – 142.9 ± 8.2 mg/dl, triglycerides – 186.20 ± 9.3 mg/dl. There was no relationship between diabetes and hypertriglyceridemia, where 17 People with diabetes have hypertriglyceridemia (28.3 %), and other 17 (34.7 %) with diabetes have normal levels of triglycerides (X2=0.508, p=0.476), nor relationship between diabetes and hypercholesterolemia (X2=2.474, p=0.116).
Conclusion: Through the data found we can infer that it is high index of patients with diabetes and dyslipidemia, mainly hypertriglyceridemia. Thus, we see the importance of adequate nutrition of diabetics, mainly related to lipids, becoming essential the implementation of this type of activity for awareness of the population.

Diabetes Associations

M. Miki[1]
[1] Diabetes Assoiciation, Limbe, Cameroon

Diabetes Associations are a group of persons or a community of people TOUCHED by diabetes. The Diabetes Associations act as the Fire Brigade of diabetes unawareness in our community. The Diabetes Associations commitments are to educate people living with diabetes in respect of daily management of the illness, and to create public awareness to those at RISK by highlighting the immediate warning symptoms of diabetes.
Diabetes Associations brings together type 1 and type 2 diabetes patients, in this regard, they are able to share their individual experience connected to diabetes complications. Through Diabetes Associations, the International Diabetes Federation is able to pass information on recent discovery on diabetes daily management to affected people. Diabetes Associations is a force that can influence an economic intervention of the government to create diabetes centers in hospitals. In Diabetes Associations, diabetes experts and health-care providers can make time outside their routine schedule to give health talks to diabetes patients. Diabetes Associations can mobilize and influence state health policies in respect of drug prices just as the International Diabetes Federation has influenced the U.N to recognize the World Diabetes Day, that diabetes exists and that there is a community touched and living with diabetes.

A case of a poorly controlled diabetes cured after removal of pituitary adenoma

I. Talapatra[1], D.J. Tymms[1]
[1] Royal Albert Edward Infirmary, Diabetes and Endocrinology, Wigan, United Kingdom

A 41 year old gentleman presented to our clinic, in a North-West district town of UK, with uncontrolled diabetes. He was on gliclazide 160 mg bd. He was admitted as an emergency with blood sugar around 27 mmol/l in Congo three years previously and was started on insulin. He persuaded his local doctor in London one year previously to take him off insulin and he was commenced on gliclazide. His random capillary blood sugars were high and his latest HbA1c was 10.7%.
He had strikingly large hands and feet, macroglossia and interdental separation with a BP of 148/102 mmHg. He reported that his hands and feet started to become large 6 years ago. His gliclazide was discontinued and he was commenced on insulin, Humalog Mix 25 10 units bd. Further investigations showed a repeat HbA1c of 11.7%, normal kidney function and calcium level, IGF-1 (Insulin like Growth Factor-1) of 103.7 nmol/l (normal: 8-38) and two high Growth Hormone levels of 79 and 73 mU/l. His pituitary MR scan showed an adenoma (12mmx10mmx8mm). His visual fields were normal. His GAD and islet cell antibodies were negative. His insulin dose was gradually increased and he was referred to a tertiary centre for management of acromegaly.
His GHDC (Growth Hormone Day Curve) showed levels between 45-100 mU/l and the growth hormone level showed no suppression with oral glucose. He was initially treated with somatostatin analogue, Lanreotide injection followed by transphenoidal surgery of the pituitary adenoma, 7 months after his presentation. He remained on hydrocortisone 10/5/5 mg daily and Insulin mixtard 30/70 6 units bd post discharge. With improvement of his blood sugar control, he was able to come off insulin in the next 2 years. He is now on diabetic diet only and his capillary blood sugars range between 4-5 mmol/l.
He presented 4 years later with high BP despite being on ramipril and doxazosin. His urinary catecholamines were normal. However his renin level was undetectable with furosemide (aldosterone of 160 pmol/l and renin activity of < 0.2 nmol/l/hr), but adrenal imaging showed no adenoma or hyperplasia. His general practitioner was requested to prescribe Eplerenone, an aldosterone antagonist.
There are many endocrine causes which can precipitate diabetes such as acromegaly, cushing's syndrome, thyrotoxicosis, glucagonoma and pheochromocytoma. In all cases of diabetes a secondary cause should be looked for. Even a poorly controlled diabetes can be cured if the secondary cause is adequately treated or removed.

How is individualised care achieved among persons with diabetes in Finland?

S. Koski[1]
[1] Finnish Diabetes Association, Development Programme for the prevention and care of diabetes (DEHKO 2000 - 2010), Tampere, Finland

Aims: The aim for diabetes care is to deliver it individualised, continuous and of high quality.
Methods: Finnish Diabetes Association conducted a survey to explore the execution of individualised care in Finland. The survey was web-based and it was sent in Finland to health care professionals who deliver diabetes care. The survey was conveyed by a contact person in every 21 hospital districts in Finland. About 1 000 surveys was sent and slightly over 600 answers (61%) were received. The most answers were from diabetes-nurses (57% of respondents). Other subgroups were medical doctors (29% of respondents) and other health care professionals (14% of respondents), like dieticians, podiatrists and health care leaders.
The individualized care for persons with diabetes was observed by changeability of care. It was asked in survey how often health care professionals assess next activities individually in relation to the needs of the person with diabetes: the

frequency of check-ups, the methods and instruments of care, the instruments of self-care and the combination of specialists who attend the diabetes-care.
Results: 90% of the respondents assess individually the methods of care (98% of medical doctors, 96% of diabetes-nurses and 93% of other professions). 88% of the respondents assess individually the frequency of check-ups. The instruments of care and instruments of self care are individually assessed by 68% of the respondents but only 55% assess individually the need of specialists who attend the diabetes-care.
Conclusions: According to our survey the individualised care is achieved quite well in general outline among persons with diabetes in Finnish health care. Medical doctors seem to have more possibilities than other health care professions to vary activities in question individually in relation to the needs of the persons with diabetes.

Review of practice of referrals from All Wales Diabetic Retinal Screening Service to Tertiary Care Hospital

S. Roy Chowdhury[1], V. Bansal[2], R.L. Thomas[1], G.J. Dunseath[1], S.D. Luzio[1], S.L. Hale[2], D.R. Owens[1]
[1] *University Hospital Llandough, Diabetes Research Unit, Cardiff, United Kingdom*
[2] *University Hospital Wales, Department of Ophthalmology, Cardiff, United Kingdom*

Aim: Diabetic Retinopathy (DR) is a highly specific microvascular complication of diabetes and the leading cause of blindness in people under the age of 60 in industrialised countries. It is also a major cause of blindness in older people. After 20 years from the onset of diabetes, over 90% of people with Type 1 and more than 60% of people with Type 2 will have diabetic retinopathy. If detected and treated earlier blindness can be prevented in up to 90% of subjects with DR. To achieve this aim a Diabetic Retinal Screening Service in Wales (DRSSW) was established in 2003. The practice of referral from DRSSW to an ophthalmology clinic in 2003 was reviewed to determine if it met the relevant clinical standards, to establish the appropriateness of the referrals and determine the various outcomes resulting from the referrals over 6 years. An estimate of costing generated by the referrals was also calculated.
Method: Records from 103 randomly selected subjects referred by DRSSW in 2003 to the Ophthalmology Clinic were examined over a subsequent period of 6 years.
Results: Average age of the subjects was 62 years (21-86) with 59 males and 44 females. Of the available data 76 were Type 2 and 21 were Type1. Mean duration of diabetes was 35 years. The referred subjects generated the following over 6 years with total approximate local costing being £ 28736.80

	Number	Cost per unit (£)	Cost (£)
Clinic appointments	561	25.60	14361.60
Fundus Fluorescein Angiogram	30	97.60	2928.00
Optical coherence tomography	3	39.20	117.60
Pan-Retinal Photocoagulation	53	109.60	5808.80
Focal Laser	39	109.60	4274.40
Grid Laser	9	109.60	986.40
Orbital Floor Steroids	1	260.00	260.00
Total Cost			28736.80

12 subjects were discharged back to the DRSSW following the 1st clinic appointment with diagnosis of 'No/Mild Background DR'.The mean interval from screening to referral was 16.65 days with the advised national screening guideline interval being 14 days. The mean interval between referral and the first clinic appointment for proliferative DR was 19 weeks and for pre-proliferative DR was 24 weeks. National Screening Guidelines recommend 2-4 weeks (70-100% referred) and 13-18 weeks (70-100% referred), respectively. Discussion: This study follows approximately 100 patients screened in the first year in which the screening service was set up, in order to enable comparison to be made in future regarding improvement of services. The percentage of inappropriate referrals was ~12% which was within current national standards (8-12%) however the period of referral to review interval fell below national standards, especially for patients with proliferative DR. The limited costing analysis carried out emphasises the importance of screening for diabetic retinopathy for the early treatment of preventable blindness.

PROCED: diabetes capacity building and community awareness project for Brazilian states and Portuguese speaking countries

R.M. Chaves Fonseca[1], J.J. Solla[2], R.M.S. Carvalho[3], M. Meiners[4], A.D. Guedes[5], J.M. Salles[5], I.L.C. Oliveira[5], O.S. Matos[6], M.G.V. Farias[7], M.C. Rodrigues[6], M.P. Romero[8], F.R. Trujilho[5]
[1] *CEDEBA-Centro de Diabetes e Endocrinologia da Bahia, Administration, Salvador, Brazil*
[2] *SESAB - Health Secretary of Bahia, Administration, Salvador, Brazil*
[3] *Ministry of Health Brazil, Diabetes and Hypertension, Brasilia, Brazil*
[4] *OPAS - Panamerican Health Organization, Non Comunicalble Diseases, Brasilia, Brazil*
[5] *CEDEBA - Centro de Diabetes e Endocrinologia da Bahia, Technical Coordination, Salvador, Brazil*
[6] *CEDEBA - Centro de Diabetes e Endocrinologia da Bahia, Strategies Coordination, Salvador, Brazil*
[7] *CEDEBA - Centro de Diabetes e Endocrinologia da Bahia, Diabetes Education Coordination, Salvador, Brazil*
[8] *CEDEBA - Centro de Diabetes e Endocrinologia da Bahia, Nutrition, Salvador, Brazil*

CEDEBA (Diabetes and Endocrinology Referral Center of the State of Bahia, Brazil), a public health center, has been training primary care professionals using Staged Diabetes Management (SDM) customized protocols for the last 10 years. SDM has demonstrated positive outcomes for both improved metabolic control and reduction in complications is a series of studies conducted outside of Brazil.
Aims: 1)To expand CEDEBA's experience with clinical protocols to other Brazilian States and Portuguese speaking countries; and, 2)develop strategies and implementation plans to increase community awareness using diabetes educational tools.
Methods: Health professionals of 7 Portuguese speaking countries and 6 Brazilian States were invited for 5 day training at CEDEBA in November 2008. The Assessment of Chronic Illness Care questionnaire, Version 3.5 (ACIC - MacColl IHI, 2000) was applied to evaluate the local (state) public health care system for each country. Two strategies were established: diabetes primary care training program and public health system management program. Problem based learning strategies and symposiums were used to introduce SDM customized clinical protocols and public health management tools. Educational materials for diabetes self management were also introduced, and a diabetes education event for the community and participants was developed as part of a dissemination process to improve diabetes care and awareness. Participants from each site developed an action plan applying the knowledge built during the course using the protocols and educational tools. E-learning strategies were developed to maintain connection between participants and CEDEBA staff. Follow-up training will occur in 6 months (May 2009).
Results: 50 health professionals (13 physicians, 27 nurses, 5 social workers, 5 dietitians) from 6 States of Brazil (Acre, Alagoas, Bahia, Mato Grosso do Sul, Paraiba, and Tocantins) and 2 African countries (Guinea-Bissau and Mozambique) were trained at CEDEBA and participated in the diabetes education community event. A high grade of satisfaction was obtained from the participants and facilitators self analysis (94%), and all of them were able to develop their local action plans. Advocacy and capacity building actions were included in almost all the plans. CEDEBA education materials, games samples and protocols were offered to facilitate the development of their implementation strategies. Using the e-learning technology the plans have been followed. Outcome data is being collected currently and will be provided as part of the presentation.
Conclusions: Through this project it has been possible to spread the CEDEBA/ Brazil experience on diabetes care at primary heath care level to other Portuguese speaking countries encouraging them to improve local health care and raise awareness on diabetes.

Knowledge about the risk factors for diabetes and the sources of medical information: A comparison between the Vietnamese and Japanese urban and rural communities

M. Kishimoto[1], S.P. Thai[2], H. Kajio[1], Q.N. Ngoc[2], Y. Matsushita[3], S. Kanagawa[4], H.P.T. Hong[5], Y. Takahashi[1], M. Noda[1], H. Thuy[6], L. Doan[2], V.N. Lan[2]

[1] *International Medical Center of Japan, Diabetes and Metabolic Medicine, Tokyo, Japan*

[2] *Bach Mai Hospital, Cardiology, Hanoi, Vietnam*

[3] *International Medical Center of Japan, Epidemiology and international health, Tokyo, Japan*

[4] *International Medical Center of Japan, Travel medicine, Tokyo, Japan*

[5] *Bach Mai Hospital, Endocrinology and Diabetes, Hanoi, Vietnam*

[6] *Bach Mai Hospital, Allergy Immunology, Hanoi, Vietnam*

Aims: Diabetes mellitus along with its complications add to a significant and growing burden on society, especially in Asian countries. To promote effective health management for the prevention and treatment of diabetes, it is important for health professionals to recognize the level of knowledge about the population regarding diabetes and be aware of the sources of such medical information. For this purpose, we conducted a questionnaire study in Vietnam and Japan.

Methods: A cross-sectional questionnaire-based survey was conducted on a randomly chosen population from both the rural (Thai Binh province) and urban areas (Hanoi) of Vietnam. The participants were asked to identify the risk factors for diabetes and provide the sources of their knowledge via multiple-choice questions. Similarly, the community-dwelling Japanese people from urban areas (Tokyo) and Japanese outpatients of International Medical Center of Japan (IMCJ) were surveyed as well.

Results: Subjects from the rural area (N = 155) and urban area (N = 147) in Vietnam, urban area (N = 102) in Japan, and Japanese outpatients (N = 159) completed the questionnaire. The Vietnamese subjects from rural areas, none of whom were diabetic, marked almost all the listed choices (smoking, obesity, excessive salt intake, excessive sweet intake, fatty food intake, excessive alcohol consumption, aging, lack of exercise, and stress) as risk factors for diabetes at similar levels of risk. The Vietnamese subjects from urban area (5.4% were diabetic) considered excessive sweet consumption, obesity, and lack of exercise as the top three major risk factors for diabetes among the listed choices. The Japanese subjects from urban area (5.9% were diabetic) and the Japanese outpatients from our department at IMCJ (73.6% were diabetic) indicated the same choices as that of Vietnamese urban subjects. As for the sources of medical information, medical staff was the most commonly cited source by the rural Vietnamese subjects, and TV and radio were commonly cited sources by Vietnamese subjects from both the rural and urban areas. The Japanese subjects acquired medical information from medical staff and the mass media, including the Internet, rather than from friends and relatives.

Discussion and conclusions: Certain differences were observed in the level of knowledge regarding the risk factors for diabetes between the Vietnamese urban and rural populations but the same could not be said for the urban populations of both countries. The unique results for the sources of medical information in each area provide effective healthcare promotion strategy for the prevention and management of diabetes. These results also lead to the conclusion that information dissemination regarding the modifiable risk factors must be tailored to suit the subjects in each country and residential area.

The International Diabetes Federation Twinning Initiative – improving diabetes care and increasing awareness of diabetes and non communicable diseases in Mozambique

D. Beran[1], J.S. Yudkin[1], C. Silva Matos[2]

[1] *International Insulin Foundation, International Insulin Foundation, London, United Kingdom*

[2] *Ministry of Health Republic of Mozambique, Non Communicable Diseases, London, United Kingdom*

Introduction: Despite being the largest cause of mortality worldwide Non Communicable Diseases (NCD) do not receive the attention they deserve in many resource poor settings.

The WHO has called for countries to develop National Plans for NCDs. Mozambique is the first country in sub-Saharan Africa to have such a plan approved and the International Diabetes Federation (IDF) Twinning Initiative has played an important role in achieving this milestone. The support from Diabetes UK assisted in this and also in improving diabetes management and the development of the diabetes association (AMODIA).

Methods: Based on the results of the Rapid Assessment Protocol for Insulin Access (RAPIA) carried out by the International Insulin Foundation (IIF) in Mozambique in 2003, a visit was organised for two members of Diabetes UK to see what type of support could be brought to Mozambique. From this visit the following objectives were established for a 3-year programme of support to Mozambique.

Results: A total of 89 healthcare workers have received training in diabetes and hypertension. 10 out of 11 Provinces now have a team of trained healthcare workers in diabetes management. In addition 2 healthcare workers trained in Tanzania on diabetes education.

These trainings will use patient education material that has been developed locally with input from clinicians, the Ministry of Health and AMODIA. 10 patients have been trained as diabetes educators and will now use this to expand the education sessions.

World Diabetes Day events were organised in both 2007 and 2008. These included information, nutritional advice, exercise sessions as well as measurements of height and weight, for calculation of Body Mass Index, waist circumference, blood glucose and blood pressure. These helped raise awareness of diabetes directly in the community.

The National Plan has now been finalised and integrates cardiovascular disease, hypertension, asthma, diabetes, cancer (breast, cervical and prostate) and trauma and violence.

A research project following a cohort of people with diabetes in Maputo has been initiated in collaboration with the University of Kwa Zulu Natal.

Discussion: With traditional donors to resource poor countries not interested in supporting diabetes projects, the Twinning Initiative provides direct support to developing the capacity of a country to cope with the many challenges of diabetes.

One of Diabetes UK's aims is a "world without diabetes" and the Twinning Project contributes to this aspiration.

Establishing accessible, effective and well coordinated diabetes care activities in the Regional Hospital Limbe, Cameroon

P. Oben[1], W. Akam[1], T. Kinge[1]

[1] *Regional Hospital Limbe, Internal Medicine, Limbe, Cameroon*

The Regional Hospital Limbe (RHL) is a secondary, first referral hospital in the South West Region of Cameroon, one of ten such hospitals in each of the ten Regions of the nation.It has 23 doctors including seven General Practitioners but no internal medicine specialist.

Diabetes care activities are already being carried within the RHL.The individual Doctors, especially the General Practitioners, manage most of the diabetic patients individually in their offices, mass screening and education are done intermittently on special occasions like the World Diabetes Day and the laboratory does routine workup. However, all these activities exist as separate packets of care without any purposeful inter-relation and coordination as a whole. There is no unit within the facility serving as a Diabetes Clinic which is necessary given the size and responsibilities of the RHL, neither is there at the moment a Physician or Paramedical staff solely responsible for Diabetes care. Nevertheless, national policy warrants the existence of the Diabetes Clinic in such a facility, but the hospital has had difficulties establishing one over the past years for multiple reasons probably including poor organization and leadership in this aspect within the hospital.

This project seeks to harmonize, coordinate, supervise and continuously improve diabetes care activities in the RHL which eventually should be centered in a discrete infrastructure within the facility as the Diabetes Clinic. Our approach shall follow a preconceived model of "Phase-Step" designed to establish a functional diabetes clinic in a facility without one but with the necessary capacity. The Phases are the clinical settings of care and the Steps are the major actions to cause a change from one phase to another. Our model has three phases. Phase 1 is our current status in which diabetes care activities exist but are disaggregated and uncoordinated (Disorganized Diabetes Care Activities).Phase 2 is the Virtual Diabetes Clinic which is a transitory phase in which the different care activities within the facility are surveyed, connected, coordinated, supervised and improved using what is available, though no care structures yet dedicated solely for diabetes care. Phase 3 is the target phase of

an established Diabetes Clinic. Step 1 is essentially the leadership, awareness and motivation to create the Virtual Diabetes Clinic while step 2, which leads to the Diabetes Clinic, will consist of setting apart or creating minimal structures solely for diabetes care and effective care processes designed within.
This is a team endeavor that will involve national and international partners and is expected to be realized within 6 months starting April 2009.

Training course for school personnel: integrating and assisting children with diabetes in school

I. Gregurincic[1], M. Grubic[1], J. Ille[1], N. Krnic[1], J. Radanovic[1], M. Dumic[1]
[1] University Hospital Zagreb, Department of Pediatrics, Zagreb, Croatia

In order to facilitate coping with complex psychological and psychosocial needs of children with diabetes, teachers must have basic knowledge about diabetes. At The Departement of Pediatrics, University Hospital Zagreb we developed a systematic educational programme for teachers in cooperation with the Ministry of Education.
Aim: to evaluate the outcome of courses for school personnel in terms of changes in diabetes-related knowledge and attitudes towards children with diabetes.
Methods: The courses consisted of lectures about basic knowledge regarding diabetes, active learning about psychological implication of diabetes in children, practicing skills related to diabetes management and discussion with nurses, paediatrician and psychologist. 348 participants completed two comparable versions of questionnaires before and after the course. One evaluated knowledge about diabetes and the other attitudes toward diabetic children. The participants perception of the importance and applicability and their satisfaction with the course was also evaluated.
Results: Diabetes related knowledge increased significantly after the course and the questionnaire score related to the attitudes toward children with diabetes increased significantly (higher score reflects more positive attitudes toward abilities and potential of diabetic children). All participants perceived the course as applicable, interesting and well organised.
Conclusions: The training course for school personnel is useful in improving diabetes-related knowledge and positive attitudes toward children with diabetes. The course helped participants understand the implications of having diabetes, gave them basic knowledge and skills to manage diabetic children and helped them to feel at ease in accepting these children in the school settings.

Community based intervention for non-communicable diseased people: an initiative to reach door to door

S. Talukder[1], S. Khan[2], S. Haque[3]
[1] Eminence, CEO, Dhaka, Bangladesh
[2] Eminence, Assistant Coordinator, Dhaka, Bangladesh
[3] Eminence, Associate Coordinator, Dhaka, Bangladesh

Context: In Bangladesh, regardless of significant improvement on mortality rate, still deaths due to chronic diseases are increasing at an alarming rate with 27.3% caused by all NCD's. The prevalence rate is even higher in urban areas than that of the rural settings mainly due to rapid urbanization, migration, and sedentary lifestyle. Realizing the urgency of this issue Eminence has initiated a pilot project in the urban context of Dhaka to address the curative, preventive, and awareness aspects of NCD's.
Aims: The aim of the project was to create awareness about the risk factors of non-communicable diseases through increasing knowledge to change in habitual fact related to dietary pattern, physical activity, cessation of tobacco, and compliance to timely and proper medication among identified NCD patients in urban population with the help of a community based intervention model.
Methods: The numbers of direct beneficiaries are 213 known cases of diabetes and hypertension patients aged between 22 to 82 years identified from 6000 population by a baseline screening. The intervention is given through a community based service system, which is comprised of three components: Satellite Centre, Home Visit, and Awareness Building Campaign.
Results: The baseline study found that only 38% respondents have had the right knowledge (here the word "right knowledge" means that the participant having knowledge on at least one scientifically proven cause for diabetes; such as 'It is a genetically derived disease', 'its cause is hormonal imbalance') regarding the probable cause of diabetes, and only 10% people knew the maximum allowable level of blood glucose. Among Diabetic patients 44% had measured their glucose level within the last three months and more than 80% patients had been practicing prescribed food habit and exercising to control their blood sugar, on the other hand, 60% patient had been depending on oral hypoglycemic agents and another 25% on insulin. After one year of intervention; 57.5% respondents have the right knowledge regarding the probable causes of diabetes and around 45% people know the maximum allowable correct level of blood glucose. Among Diabetic patients 59% had measured their glucose level within the last three months. Around 90% patients had been practicing prescribed food habit and exercising to control their blood sugar, on the other hand, 77.7% patients had been depending on oral hypoglycemic agents and another 30.7% on insulin.
Discussion: The outcome of the intervention shows that community based intervention among known cases of diabetic patients increases the rate of knowledge and compliance among them.
Conclusion: Lessons and challenges learnt from this kind of pilot project could be replicated nationally.

Clinical pattern of type 2 diabetes in rural Uganda

S. Bahendeka[1]
[1] Saint Francis Hospital, Medicine, Kampala, Uganda

During the period of May 2007 through September 2008, one thousand one hundred sixty eight diabetic patients were registered in a total of 20 diabetes clinics in four rural districts of Uganda, located in the North, South, East and Central regions of the country. The clinics were based on a structured diabetes care program and used structured patient clinic files. The clinics were run by registered nurses who had been given four 3-day courses on a detailed curriculum of management of diabetes. Medical officers who had undergone similar training program supervised the clinics, reviewed and managed complicated cases.
The mean age of diabetic patients was 50 years with duration of 3.9 years of diabetes. The mean BMI was 23.3 kg/m^2 at the start of project and not much changed at the end of one year: 23.5 kg/m^2. Uncontrolled hypertension was observed in 34.7 % at presentation, despite majority of patients presenting with hyperglycaemia. The average fasting blood glucose during first week of the patient presenting at the clinic was 13.1 mmol/l, and 12.1 mmol/l after 12 months of follow up.
The main barrier to control of blood glucose was patient acceptability of insulin, as the majority of diabetic patients presented with body wasting and hyperglycaemia and would require insulin therapy for stabilization.
In rural Uganda, diabetes presents at a young age and patients present late when they have severe hyperglycaemia and body wasting. This increases the need for insulin therapy which may not be readily available and acceptable. Programs aimed at improving diabetes care in the rural areas need to have this in the strategic planning and an important aspect in the diabetes education. Peer education programs might overcome this barrier.

Pharmacist led diabetes clinic in community pharmacies in Croatia

I. Fritsch Zitnik[1]
[1] Dvorzak Pharmacies, Unit: Gajnice Zagreb, Zagreb, Croatia

Aim: to improve health outcomes for patients with type 2 diabetes mellitus and patients suspected of type 2 diabetes mellitus as the main benefit of a pharmacist led diabetes clinic in community pharmacies in Croatia
Methods: screening service – blood glucose screening organised with other health professionals (e.g. nurses) as in Croatia pharmacists are not allowed to take blood samples
patient counselling
- collecting data and counselling patients about the illness and its complications
- referring patients with high plasma glucose concentration to their physicians

- monitoring and setting treatment goals
- glucose meter training

Results: patients with type 2 diabetes as well as patients at risk of type 2 diabetes mellitus were satisfied with the provided care and were willing to cooperate with pharmacists in order to improve their health and quality of life for various reasons: pharmacists are the most accessible health professionals, they work more closely with patients and they are more understanding of their problems and concerns.

We have proved that pharmacists, as the most accessible and most visited health professionals and experts on drugs, have an excellent opportunity to educate and counsel patients as well as monitor their disease, while by doing sequential screening in the pharmacies they can detect a high percentage of patients suspected of diabetes.

Unfortunately, pharmacists do not have an important role in the health care process in Croatia at the moment.

Discussion: Pharmacists must provide new services (e.g. education and consultations) in community pharmacies in Croatia. With this project we have started a new service. The service is very well accepted among patients and also improved clinical outcomes for patients. Therefore we hope this service will be recognised by Croatian Institute for Health Insurance and Croatian Ministry of Health as an important part in the health care process.

Sweet walk at Brasilia's City Park – health prevention and blood glucose monitoring in a walk guided by diabetes education program

J. Dullius[1]

[1] *University of Brasília, Physical Education College, Brasilia, Brazil*

Diabetes mellitus (DM) affects approximately 6% of the population. Its treatment, morbidity and mortality brings high costs. So, it's important to find ways to guide, incite and contribute to the health care, being the right physical activity very important to the therapy and prevention.

Methodology: To celebrate the World Diabetes Day, this diabetes educational program promoted a guided walk with diabetic people and friends in Brasília on a Sunday morning in November. There were overseers of this same program, collaborators of Diabetics Association of Brasilia, The Health Department of city, the firemen brigade etc. Among curious people, friends and other professionals, 39 diabetics attended the event: 6 children, 22 people in insulin therapy (IT), and 11 not in insulin therapy (NIT). More than 70 capillary glycemia (only for diabetics) were measured.

All of them were oriented about the cares to improve and maintain life quality, and about the benefits and attention in the maintenance of physical activities. There were special activities fo children, and also individual orientation, stretching exercises, walking, exchange of experiences, diabetes reports, lecture about diabetics' rights and tai-chi-chuan. The event lasted almost 4 hours.

Results based on averages of Initial Glycemia of everybody and at the end of the activity the Final Glycemia of who participate of some activities, in mg/dl:

Group	Initial Glycemia in arrival			Initial Glycemia	Final Glycemia
	Average all	Min	Max	Sample Averages	
NIT	171	116	316	172	125
T2 - IT	229	112	301	235	174
T1 Adult	170	068	295	213	155
Children	185	116	248	185	082
Average of all	189	068	316	201	134

There was a great reduction of capillary glycemia among the diabetic people that were there. The glycemia average at the arrival (189±28mg/dl) reduced from 201 ± 28 to 134 ± 40. Usually, higher glycemias were founded among the type 2 in insulin therapy (229/235/174) and the lower among the NIT diabetic people (171/172/125). There was not significant hypoglycemic incident. Everybody was informed and motivated to practice oriented physical activities and to take part in educational programs for diabetes.

Conclusion: These kind of events are very important to improve the attention to diabetic condition and to help people with diabetes, and also to empower the role society about health cares, and mainly to highlight physical activities as a means to bring quality of life and awareness.

Long-term experiences evaluation of improved glycemic control and metabolic markers in a 7-year diabetes cohort

S.L. Su[1], *P.Y. Liao*[1], *K.D. Chen*[2], *S.T. Tu*[1], *K.C. Lin*[1], *H.K. Sia*[1], *Y.N. Chang*[3], *S.L. Lin*[4], *S.M. Lin*[4], *H.L. Wu*[5], *C.M. Wang*[4], *P.Y. Cheng*[1]

[1] *Changhua Christian Hospital, Division of Endocrinology and Metabolism, Changhua, Taiwan*

[2] *Chang Gung Memorial Hospital-Kaohsiung Medical Center and Chang Gung University College of Medicine, Center for Translational Research in Biomedical Sciences, Kaohsiung, Taiwan*

[3] *TaiDoc Technology Corp., TeleHealth Business Group, Taipei, Taiwan*

[4] *Changhua Christian Hospital, Diabetes Education Center, Changhua, Taiwan*

[5] *Chang Jong Christian University, Department of Nursing, Tainan, Taiwan*

Aims: The prevalence of diabetes is increasing at an alarming rate, as are the associated personal and societal costs. Therefore, Shared Care of Network for diabetes was advanced by Department of Health (DOH) in Taiwan to promote the integration of basic medical resources, setup of case management procedure as well as education programs for the public health nurses, and improvement of control in diabetic complications. In this study, we reviewed our care system to evaluate the continuous health instructions are helpful to patients on good control of their glucose level.

Methods: This study is to determine the efficacy of government promoted diabetes education by collecting and analyzing information from a cohort of patients with diabetes who attended diabetes education program of Changhua Christian Hospital between April 2002 and December 2008. The efficacy was evaluated by the fasting blood glucose (BG) and HbA1c levels from outpatients with 7-year follow-up, and other metabolic markers were also monitored.

Results: A total of 749 subjects (348 males, 401 females, 21 type 1, 728 type 2), having an average duration of diabetes of 13.7 years, registered into this educational program. In these patients, HbA1c had reduced by 0.422% (absolute reduction); a relative reduction of 5.55% ($p<0.0001$) between 2002 and 2008. Same trend was found upon fasting blood glucose. When checking other metabolic markers, we found most of parameters like systolic pressure; diastolic pressure, total cholesterol, and triglyceride were gone down during the 7-year period. Statistically significant reductions in systolic blood pressure (133.9-131.1 mmHg, $p<0.0001$), diastolic blood pressure (78.3-74.5 mmHg, $p<0.0001$), total cholesterol (191.9-174.6 mg/dl, $p<0.0001$) and triacyl-glycerol (166.6-144.6 mg/dl, $p=0.0004$) occurred between 2002 and 2008. However, HDL (49.9-52.6 mg/dl, $p=0.00015$), weight (66.36-67.40 kg, $p=0.016$) and BMI (25.91-26.43 kg/m2, $p=0.0003$) significantly increased. Although mean values of serum creatinine were significantly increased on the 7-year duration (1.022-1.335, $p<0.0001$), the serum creatinine of the patient cohort had been maintained in the normal range.

Conclusion: We show the quality of diabetes care is improved by the cooperative model. The continuous instructions are truly effective for diabetic patients. This study exhibits good improvement in HbA1c as well as fasting blood glucose levels just after the first year. Although the slope becomes flat from the fourth year, sustained improvements of many risk factors in relation to cardiovascular complications occurred. Since the diabetes care are the complicated combination of care resources, our analysis results could suggest more effective instructions, the monitor mechanism for care quality, and the way to establish the standard data system and indications for the institution.

Modifiable risk factors for cardiovascular disease in the workers at a district hospital in South Africa

L. Nkombua[1]

[1] *Middelburg Hospital, Family Medicine, Witbank, South Africa*

Introduction: Certain risk factors play an important role in a person's chances of developing heart disease. Among these risks some are modifiable. Proactively addressing the modifiable risk factors reduces the chances for a person to develop a cardiovascular disease or die from its complications. Modifiable factors are: smoking or exposure to environmental tobacco smoke, overweight and obesity, sedentary lifestyle, Diabetes Mellitus, high cholesterol/abnormal blood lipids and Hypertension, stress and alcohol. The more risk factors a person has, the greater the likelihood of developing heart disease.

Method: From September 2007 to end of October 2007, workers at Middelburg hospital were invited on voluntary basis to know their "numbers" as far as

the risk for cardiac disease was concerned. The author, echoing the appeal by the South African Medical Association in September 2007 to encourage all South Africans to know their risk for heart disease, advised the Middelburg hospital management that the project be conducted as part of "caring for the carer" programme as it is routinely done by the Occupational Health Unit in the Hospital. Due to cost constraints, cholesterol was not done routinely because the hospital budget could not afford it. A total of 108 hospital workers voluntarily presented themselves at the Occupational Health Clinic for data collection during the two month period.

Results: Of the participants 6% (N=7) had a random glucose of between 7.8 to 11.0 mmol/l and 3% (N=4) had a random glucose of more than 11.1 mmol/l. The abdominal circumference of the majority of the female participants 49% (N=53) was above the normal required for the risk of heart disease and a few male participants had their abdominal circumference above the normal 6% (N=7),. Of the participants 24% (N=26) consumed more than 2 units of alcohol per day. Of the participants 12% (N=14) had grade 1 hypertension, 14 % (N=16) of the participants had stage 2 hypertension and 3% (N=4) of them had severe hypertension. Of the participants 47 % (N=49) had the body mass index above the norms, hence being at risk of heart disease. 88% (N=95) did not engage in any form of physical exercises and 7, 5 % (N=8) were active smokers.

Conclusions: The survey clearly established that the workers employed in a district hospital have the same risk factors for heart disease as anyone in the general population. Some of them who had already a condition that may complicate into a heart disease were not aware of it, because the lack of symptoms or signs related to the said condition, especially hypertension, diabetes, overweight, alcohol consumption and cigarette smoking.

Type 2 diabetes in the elderly in France: control of vascular risk factors and choice of treatments in 2007 (Entred study)

C. Pornet[1], I. Bourdel-Marchasson[2], E. Eschwege[3], P. Lecomte[4], A. Weill[5], A. Fagot-Campagna[1]

[1] *Institut de Veille Sanitaire, Département des maladies chroniques et traumatismes, Saint Maurice, France*
[2] *CHU of Bordeaux, Geriatric Department, Bordeaux, France*
[3] *Institut National de la Santé et de la Recherche Médicale, U780, Villejuif, France*
[4] *CHU of Tours, Endocrinology-Diabetology Department, Tours, France*
[5] *Caisse nationale d'assurance maladie des travailleurs salariés, Statistics Department, Paris, France*

Aims: Aging is a major contributor to the increase in diabetes prevalence in France. We used a national diabetes survey to study the control of vascular risk factors in elderly people with type 2 diabetes.

Methods: In 2007, a random sample of 8926 adults was drawn from the French medical insurance system (covering 75% of the population) among people who were reimbursed from at least 3 deliveries of oral hypoglycemic agents or insulin during the past 12 months. All medical reimbursements and hospital data were extracted for 3 years. Three surveys were undertaken: patient short phone interview and mailed-questionnaire (47% and 48% response rates), and a mailed questionnaire to their physicians (62% response rate). A sub-analysis was performed in elderly people (≥65yrs) with type 2 diabetes (n=2466), with weights taking into account the sample design and response rates.

Results: Among all people with type 2 diabetes, 51% of men and 55% of women were aged ≥65yrs. In the elderly, type 2 diabetes was diagnosed since <5yrs in 20%, and in 15% of those ≥80yrs. Based on reimbursement data, 20% were on insulin, 56% on metformin, 53% on sulfonylurea and 27% on other treatments.

Based on patient reports, 42% of the elderly were overweight and 35% obese; obesity decreased with age from 39% in the age-group 65-69yrs to 24% in those ≥80yrs. Based on provider reports, mean HbA1c was 7.1%. The distribution of people with HbA1c >7% with age was "U" shaped: 65-69yrs 50%; 70-74 yrs 44%; 75-79yrs 40%; ≥80yrs 51%. Mean blood pressure (BP) was 135/76 mmHg. Systolic (but not diastolic) BP increased from 134 at ages 65-69yrs to 136mmHg at ages ≥80yrs. Among people with and without antihypertensive treatment, respectively 15% and 11% had BP>150/80mmHg. Mean LDL cholesterol was 1.04g/L. The proportion of people with LDL≥1.30g/L increased from 19% at ages 65-69yrs to 25% at ages ≥80yrs. Among people on hypolipidemic treatment, 66% had LDL<1.30g/L. The proportion of people with glomerular filtration rate (GFR) <60ml/min/1.73m^2 increased from 21% in the ages 65-69yrs to 36% in those ≥80yrs; 46% of people with GFR <60 ml/min/1.73m^2 were on metformin and 50% on sulfonylurea.

At least 1 and 3 severe hypoglycemia during the past year were observed, respectively, in 10% and 4% of the elderly, which was more frequent with age, and with insulin treatment (1 and 3 severe hypoglycemia: 26% and 11%).

Conclusion: While HbA1c and LDL cholesterol are correctly controlled in the majority of elderly people with type 2 diabetes, BP can be better controlled to protect mobility and cognitive functions. Obesity remains a common risk factor even in the oldest. With aging, kidney function is failing and the risk of hypoglycemia is increasing: the use of treatments needs to be more carefully assessed.

P-1352

Development and implementation of diabetes guidelines for elderly residents in long-term care facilities in Nova Scotia

B. Cook[1], L. Harrigan[1], L. Mallery[2], T. Ransom[3]

[1] *Diabetes Care Program of Nova Scotia, NS Department of Health, Halifax, Canada*
[2] *Dalhousie University, Division of Geriatric Medicine, Halifax, Canada*
[3] *Dalhousie University, Division of Endocrinology, Halifax, Canada*

Background: The Diabetes Care Program of Nova Scotia (DCPNS) works across various sectors of the healthcare system to improve the care provided to people with or at risk of developing DM. The lack of evidenced-based DM guidelines for the elderly population has resulted in both under and over treatment of the frail elderly residing in NS's long-term care (LTC) facilities. Overtreatment may result in increased rates of hypoglycemia—a potentially serious and underestimated clinical problem that has significant morbidity and mortality. Hypoglycemia can lead to poor balance and risk of falls, can be more severe and prolonged, and may precipitate a cardiovascular event. Current clinical practice guidelines set standards of glycemic control that may not be applicable to the residents of LTC facilities.

Aims: To standardize DM management of the frail elderly residing in LTC facilities through the development of reasonable glycemic targets and appropriate treatment of hypoglycemia.

Methods: In 2002, the DCPNS conducted a needs assessment of LTC facilities to explore priorities for standardization of DM care. A multidisciplinary committee was formed to develop and promote safe DM care guidelines. Two priorities were selected: targets for glycemic control and treatment of hypoglycemia. A pocket reference tool was developed and pilot tested in 3 LTC facilities, 1 rural and 2 urban, to determine appropriateness, adequacy, efficiency, and effectiveness of the tool. Eleven nurses in 3 facilities used the reference tool for 4 weeks and provided feedback for necessary revisions. The guidelines received preliminary approval of the DCPNS Advisory Council in 2007, and final amendments were approved in Feb. 2009. A province-wide telehealth session was held Dec. 2008 to provide context for LTC staff, physicians, and DM educators.

Results: The needs assessment was completed by directors/managers and care providers within provincial LTC facilities. A 78% response rate was achieved with 80% of respondents reporting the need for standard DM management protocols. The target population for the guidelines was non-palliative residents for whom DM care interventions are appropriate. Key characteristics of DM care guidelines include flexibility, individualization, and improved quality of life.

Discussion: The pocket reference guide is a highly anticipated resource that will standardize DM care in LTC facilities in NS. Reduction in over-treatment of DM by adherence to the recommended hyperglycemic targets should result in fewer episodes of hypoglycemia, less stringent treatment plans, and improved quality of life for some residents. Adverse events, secondary to hypoglycemia, will be reduced.

P-1353

Comparison of the efficacy and tolerability of the once-daily human GLP-1 analogue, liraglutide, in elderly versus younger patients with type 2 diabetes: a meta-analysis

B. Bode[1], A. Falahati[2], J. Brett[3], R. Pratley[4]
[1] Atlanta Diabetes Associates, Endocrinology, Atlanta, USA
[2] Novo Nordisk, Biostatistics, Bagsvaerd, Denmark
[3] Novo Nordisk, Medical Affairs, Princeton, USA
[4] University of Vermont College of Medicine, Diabetes and Metabolism Translational Medicine Unit, Vermont, USA

Aims: The number of elderly people diagnosed with type 2 diabetes (T2D) is rising. There is limited evidence for efficacy and tolerability of T2D treatments available for this special population. This meta-analysis of the six phase 3 trials for liraglutide (Liraglutide Effect and Action in Diabetes [LEAD]) investigated changes in HbA_{1c}, body weight (BW), systolic blood pressure (SBP) and hypoglycaemia from baseline to 26 weeks in elderly (>65 years) vs young (≤65 years) patients with T2D receiving liraglutide 1.8 mg/day or placebo.
Materials and methods: HbA_{1c}, BW and SBP data from the 6 trials were stratified by age, >65 years (n=474) and ≤65 years (n=2276). The changes in HbA_{1c} and body weight were analysed by age group using ANCOVA.
Results: Reduction in HbA_{1c} from baseline was significantly greater after 26 weeks with liraglutide 1.8 mg vs placebo for both age groups ($p<0.0001$). Reductions in HbA_{1c} with liraglutide 1.8 mg were similar between ≤65-years vs >65-year age groups: -1.39 vs -1.32%, respectively. These reductions in HbA_{1c} with liraglutide brought a high number of subjects below the American Diabetes Association HbA_{1c} target of 7%: 68% in the age group ≤65 years and 60% in the age group >65 years. BW reduced significantly from baseline with liraglutide 1.8 mg in ≤65-year and >65-year age groups (-1.71 and -2.17kg, respectively; both $p<0.0001$ vs baseline) whereas reductions seen with placebo, for both age groups, were not significant (-0.51 and -0.70 kg, respectively; p=NS vs baseline). No significant difference in BW change, between age groups, with liraglutide and placebo were observed. Reduction in SBP from baseline, with liraglutide 1.8 mg, was significant in age group ≤65y (-2.96; $p<0.001$). Improvements in SBP with liraglutide 1.8 mg were more pronounced in the ≤65-year age group vs >65-year age group (-0.86 mmHg: difference of -2.09 mmHg, $p<0.05$) but not with placebo (+0.39 mmHg: difference of -0.71, p=NS). The proportion of subjects reporting minor hypoglycaemia was low and similar between age groups with liraglutide 1.8 mg (13.4% [≤65 years] and 13.9% [>65 years]) and placebo (8.3% [≤65 years] and 8.0% [>65 years]). Adverse events were predominantly gastrointestinal in nature, that is, nausea. The proportion of subjects experiencing nausea with liraglutide 1.8 mg was 11.3% (≤65 years) vs 14.7% (>65 years), respectively.
Conclusions: These data show that the efficacy of liraglutide with respect to HbA_{1c} and weight is independent of age in T2D, and that liraglutide is well-tolerated in patients ≤65 years or >65 years with low risk of hypoglycaemia.

P-1354

Why are older patients with type 2 diabetes treated for dyslipidemia but not for hyperglycemia?

Q. Zhang[1], E. Marrett[1], L. Radican[1], S. Narayanan[2], M. Feinglos[3]
[1] Merck & Co. Inc., Global Outcomes Research and Reimbursement, Whitehouse Station New Jersey, USA
[2] TNS Healthcare, Global TPO & HEOR, New York New York, USA
[3] Duke University Medical Center, Medicine/Endocrinology Metabolism & Nutrition, Durham North Carolina, USA

Aims: Previous research has highlighted the need for earlier intervention in diabetes. This study examined older patients treated for dyslipidemia but not type 2 diabetes (T2DM) for >6 months after T2DM diagnosis, and assessed reasons for non-treatment with antihyperglycemic agents (AHA).
Methods: A survey was conducted in Nov/Dec-2008 among a panel of U.S. primary care physicians. Patients aged >=65 years at time of T2DM diagnosis, who had not initiated AHA therapy for >=6 months after diagnosis, were selected by their physicians. Each physician provided data for 2 patients based on chart review and reasons for not initiating AHA therapy. In this analysis we focused on a subgroup of patients who currently received lipid lowering therapy.
Results: 441 patients (57.3% of 770 older patients with untreated T2DM) were receiving treatment for dyslipidemia; mean (SD) age was 71.4 (5.7) years, 52.6% were male, mean BMI was 30.3 (4.9), and average duration of diabetes was 21.1 (24.0) months. Most recent mean measures were 6.8% (0.6) for HbA_{1c} (with 32.6% not at goal <7%), and 7.1 mmol/L (1.5) for FPG (44.6% were >=7.0 mmol/L). Macrovascular complications were reported in 24.9% of patients, and microvascular in 17.2%. 46.3% of patients had an estimated glomerular filtration rate <60 mL/min/1.73m^2. 79.1% were being treated with an antihypertensive. Median number of current medications used was 4. The distribution of the first ranked physician reasons for not initiating AHA therapy was "try diet and exercise first (D&E)" 53.9%, "mild hyperglycemia" 25.6%, "patient's concerns" 14.8%, "concerns related to AHAs" 3.2%, and "issues with comorbidity and polypharmacy" 2.5%. However, the corresponding proportions of patients with HbA_{1c} >=7% were 27.5%, 25.0%, 59.4%, 50.0%, and 45.5% respectively. Based on most recent measure, HbA_{1c} had increased since diagnosis in 16.4% of all patients and 26.0% of patients with recent HbA_{1c} >=7%. Among 112 patients who were scheduled to be treated with AHA within a month as indicated by their physician, 57% had a current HbA_{1c} above the threshold specified by their physician for medication initiation.
Conclusion: In these older patients treated for dyslipidemia, but not treated with AHA for >6 months since T2DM diagnosis, one third had HbA_{1c} levels above goal and some already had macro-/micro-vascular complications. Reasons for non-treatment with AHA suggest there are substantial barriers to AHA use in real world practice, including physician's perception of "mild hyperglycemia" and the HbA_{1c} threshold for initiating AHA, which should be explored further.

Abnormal carbohydrate metabolism and diabetes mellitus among elderly people of Kyrgyz Republic

S. Asanaliev[1], E. Fuks[1], S. Fomina[1], T. Coi[1], N. Faizulina[1], A. Musambetova[1], N. Salamahina[1]
[1] Kyrgyz-Russian Slavanic University, Medical Department, Bishkek, Kyrgyz Republic

The demographic situation in Kyrgyzstan is characterized by the increased number of elderly people. Considering the fact that the prevalence and features of carbohydrate metabolism abnormalities among the elderly and senile people are not thoroughly investigated, we have examined 217 people in the age group from 60 to 91 using the random sampling research method. People, who had diabetes mellitus diagnosis before, or any other intolerance to glucose, were excluded from the sampling. Anthropometric measurements have been made for every patient (height, weight, waist). Also data concerning the arterial pressure of patients have been collected. Glucose measurements have been made in the whole blood. Diabetes mellitus has been diagnosed in the case of whole blood glycemia (fasting) with ≥6,1 mmole per liter or in case of the capillary whole blood glycemia ≥11 mmole per liter (any time of a day). Also, type 2 diabetes mellitus risk factors have been assessed with the help of the ADA (American Diabetes Association) tests. All patients had the risk of type 2 diabetes occurrence: 14 % - moderate risk, 86% - high risk. The highest probability for type 2 diabetes occurrence has been noticed among the senile group (90.3 %). 78% of the sample had the lipid exchange abnormalities, and out of them 48% had overweight, 30% - obesity. Blood pressure increase has been recorded in 76.1% of the sample. Hypertension has been recorded more often among the senile people than among elderly. Carbohydrate metabolism abnormalities have been recorded in 99 cases (50.5 %), out of them explicit diabetes mellitus diagnosed in 56 cases (28.6%). Diabetes mellitus course has been asymptomatic among the patients; without complains concerning urinary emaciation, pruritus, or the weight loss. In the majority of cases patients' complains concerned the nonspecific issues, such as asthenia, vertigo, memory impairment, and other cognitive dysfunctions. Because of these symptoms the diagnosis of diabetes mellitus has been complicated. Upon the moment of the diagnosis registration, 50% of patients already had micro- and macro vascular complications.

So, taking into consideration the fact that the proportion of the elderly people is growing, some specific activities should be organized within the healthcare system of Kyrgyzstan, dealing with the active detection and treatment of diabetes mellitus, especially among senile and aged people. Heroprotection should be not just about the life prolongation; instead it should deal with prolongation of healthy, high quality life.

A clinical feature analysis of type 2 diabetic inpatients from middle-aged to aged with poorly-controlled plasma glucose problem

Y. Bao[1], H. Qiu[1], H. Li[1], F. Zhang[1], M. Li[1], Q. Li[1], J. Zhou[1], W. Jia[1]
[1] Shanghai Jiao Tong University Affiliated Sixth People's Hospital, Department of Endocrinology and Metabolism, Shanghai, China

Aim: To investigate the clinical features and chronic diabetic complications from middle-aged and aged diabetic inpatients with poorly-controlled glucose problem.
Methods: A total of 449 subjects over 40 years old with type 2 diabetes were enrolled in the study, and the entry level of HbA1c was >= 7.5%. All subjects were divided into two groups according to the medical history: known diabetes (KDM) and diabetes newly diagnosed by the study (NDM), and were further divided into middle-aged subgroup and aged subgroup respectively. Clinical features and chronic diabetic complications were evaluated for all subjects.
Results: 1.In both middle-aged and aged subjects, compared with those who had a definite type 2 diabetes history, newly-diagnosed patients showed a significantly higher level of HbA1c and GA. 2.The incidence rate of diabetic nephropathy, diabetic retinopathy, diabetic peripheral neuropathy and peripheral vascular disease were 19.4%, 32.7%, 17.4% and 52.1% respectively in all study subjects. 3. In 45% of newly-diagnosed diabetic patients, at least one chronic diabetic complication was confirmed at the time they were diagnosed. More than 33% in aged subgroup with definite history of type 2 diabetes suffered from more than 2 kinds of chronic diabetic complications.
Conclusion: Screening should be made as soon as possible to prevent chronic diabetic complication for newly-diagnosed diabetic patients. The aged group has a higher incidence rate of more than 1 kind of chronic diabetic complication. Therefore, risk factors should be intervened comprehensively together with the effective control of glucose level in order to delay the occurrence and development of chronic diabetic complications.

Prevalence and determinants of anemia in type 2 diabetes mellitus in India

A. Gupta[1], S. Jain[2], R. Agrawal[3], A. Agrawal[4], R. Gupta[5]
[1] Jaipur Diabetes Centre, Department of Medicine, Jaipur, India
[2] Jaipur Diabetes Research Centre, Department of Medicine, Jaipur, India
[3] Jaipur Diabetes Research Centre, Department of Nutrition, Jaipur, India
[4] University of Rajasthan, Department of Home Science, Jaipur, India
[5] Fortis Escorts Hospital, Department of Medicine, Jaipur, India

Background and Objective: Presence of anemia in type 2 diabetes is associated with accelerated micro- and macro-vascular complications. To determine prevalence and determinants of anemia in Asian Indian type 2 diabetes mellitus subjects we performed a clinical audit.
Methods: Data of successive patients of type 2 diabetes (n= 1696, men 1059, women 637) presenting to this centre were analysed for demographic and lifestyle factors, prevalence of cardiovascular risk factors, anemia and other complications. Descriptive statistics are reported.
Results: The mean age of the subjects was 53.2±10 years and duration of known diabetes 7.5±6.9 years. Prevalence (%) of smoking or tobacco use was in 346 (20.4), hypertension in 785 (46.3), ischemic heart disease in 152 (9.0), cerebrovascular disease in 25 (1.5), renal disease- creatinine >1.8 mg/dl in 41 (2.4), asthma in 41 (2.4), and hypothyroidism in 62 (3.7). Mild anemia (haemoglobin (Hb) men 11.0-12.9, women 10.0-11.9 g/dl) was in 898 (41.3), men 414 (39.0), women 287 (44.9); moderate anemia (Hb men 8.0-10.9, women 8.0-9.9) was in 84 (4.9), men 28 (2.6), women 56 (8.0) and severe (Hb <8.0) in 13 (0.8). Hb levels correlated (Spearman's rho) significantly with age (-0.23), diabetes duration (-0.23), smoking (0.13), tobacco chewing (0.13), dietary calories (0.19), proteins (0.17), fiber (0.24) and iron (0.25), creatinine clearance (0.33), systolic blood pressure (-0.11), and presence of hypertension (0.12), nephropathy (0.15), ischaemic heart disease (0.11) and hypothyroidism (0.10) ($p<0.05$ for all). Important univariate risk factors for anemia were age (odds ratio 1.04, 95% confidence intervals 1.03-1.05), diabetes duration (1.49, 1.33-1.67), hypertension (1.24, 1.03-1.50), presence of nephropathy (5.50, 2.42-12.50) and low dietary iron (0.91, 0.87-0.97). Significant multivariate determinants of anemia were dietary iron (0.95, 0.91-0.99), diabetes duration (1.04, 1.03-1.06) and presence of nephropathy (4.82, 2.11-11.1).
Conclusions: Mild to moderate anemia is common in Asian Indian subjects with diabetes. Important determinants of anemia are advancing age, increasing duration of diabetes and presence of renal disease. Low dietary iron is an important lifestyle determinant.

P-1358

Correlation of incipient nephropathy and baPWV in type 2 diabetes - a comparative study

R. Kapoor[1], S. Chopra[1]
[1] Carewell Heart & Super Speciality Hospital, Cardiology, Amritsar, India

Background and aims: Microalbuminuria has been identified as a risk factor for cardiovascular disease in diabetic populations. The nature of this relationship is unclear but may involve arterial stiffness, an independent risk marker for CVD mortality. Pulse wave velocity (PWV) is regarded as a marker to reflect arterial stiffness associated with atherosclerosis and also impaired endothelial functions in diabetic patients. Aim of the study is to examine whether microalbuminuria in type 2 diabetes patients is associated with altered baPWV - an early marker of atherosclerosis.
Methods and materials: 800 type 2 diabetes patients were enrolled in the study. Microalbuminuria in all the subjects was estimated and the albumin to creatinine ratio (A:C) determined. Patients were divided into 2 groups. Group A contained 400 type 2 diabetes patients (230 males/170 females) with incipient nephropathy [A:C 30-300 mg/gm]. The mean age was 50.3±10.73 years with mean duration of diabetes 6.71±3.9 years. Group B contained 400 type 2 diabetes patients (183males/217 females) with Normoalbuminuria [A:C<30mg/gm]. The mean age was 53.18±10.42 years with mean duration of diabetes 7.1±6.3 years. baPWV, Blood Pressure, A1c, BMI, ABI of all the subjects in group A and group B were also measured. baPWV was measured with VP-2000/1000-Colin Corporation, (hyayashi komaki Japan). Microalbuminuria was measured Clinitek status Analyzer. (Bayer Health Care)
Results: Correlation of Albumin to Creatinine Ratio with other Atherosclerotic parameters

	Group a Incipient nephropathy		Group b Normoalbuminuria	
	Mean±S.D.	p	Mean±S.D.	p
baPWV (RT)	1905.14±513.13	<.001	1906.39±513.89	NS
baPWV (LT)	1650.07±449.51	<.001	1647.49±449.70	NS
HbA1c	7.2±1.50	<.01	7.28±1.50	<.05
BMI	27.33±6.103	NS	27.33±6.09	NS
S.B.P	151.7±20.44	NS	151.68±20.44	NS
D.B.P	88.1±11.6	NS	88.15±11.60	NS
ABI (RT)	1.09±0.27	NS	10.8±0.27	NS
ABI (LT)	1.05±0.24	<.05	1.05±0.24	<..05

Discussion: Present study showed highly significant correlation of incipient nephropathy with baPWV compared to normoalbuminuric diabetes patients. A similar correlation was also seen with HbA1c and ABI.This implies a higher association of microvascular complications in this group of patients thus necessitating increased detection and control of such complications. The above correlation confirms a strong link between renal and CV disease in the early asymptomatic stage of disease.

The oxidative stress and antioxidant potency determined by Free Radical Analytical System 4 (FRAS 4) are firmly involved in the progression of diabetic retinopathy and nephropathy in patients with type 2 diabetes mellitus

M. Suetsugu[1], K. Hara[1], K. Ito[1], K. Takebayashi[1], Y. Aso[1], T. Inukai[1]
[1] Dokkyo Medical University Koshigaya Hospital, Department of Internal Medicine, Koshigaya, Japan

The pathogenesis of diabetes provokes an oxidative stress through an activation of the NADPH oxidase or the polyol pathway induced by hyperglycemia. An excess of oxidative stress leads to the advance and/or the progression of chronic diabetic vascular complications. The main purpose of the present study is to elucidate the relationship between the oxidative stress determined by Free Radical Analytical System 4 (FRAS 4) and clinical diabetic features and vascular complications in type 2 diabetic patients. Studies were conducted in 51 type 2 diabetic patients and age-matched 20 healthy subjects. We investigated various diabetic features, and then evaluated daily urine albumin excretion (UAE), Achilles tendon reflex, the grade of retinopathy, ABI and PWV, as diabetic complications. The level of serum oxidative stress was measured by Reactive Oxidative Metabolites (ROM) test, while serum antioxidant potency was determined by Biological Antioxidant Potential (BAP) test using RFAS-4 method (Wismerll Inc. Tokyo, Japan). Serum superoxide dismutase (SOD) activity was assayed by the electron spin resonance method. ROM in diabetic patients markedly tended to increase rather than that in healthy subjects. (diabetic patients: 260.3±54.8 U.CARR, healthy subjects: 237.1±39.4 U.CARR). ROM showed a significantly positive correlation with HbA1c levels in diabetic patients (r=0.281, P=0.045). ROM tended to increase according to the progression of diabetic retinopathy. While BAP significantly reduced according to the deterioration of smoking state. BAP also tended to decrease according to the progression of diabetic retinopathy and showed a significantly negative correlation with UAE (r=-0.333, p=0.029). SOD activity remarkably reduced according to the deterioration of smoking state, and significantly reduced according to the progression of diabetic retinopathy (r=-0.337, p=0.017).
Conclusions: The present study suggest that increase in ROM, a surrogate marker for oxidative stress, and decreases in BAP and SOD activity, representative markers for antioxidant potency, could be firmly involved in the deterioration of blood glucose control and smoking state, and also in progressions of diabetic retinopathy and nephropathy in diabetic patients.

Histopathology on renal biopsy in diabetes with overt proteinuria or microalbuminuria: effect of nondiabetic lesions on GFR and proteinuria.

D. Hazra[1], A.K. Gupta[1], M.L. Pursnani[1], R. Bharti[2], V. Kumar[3], B. Singh[1], A. Jain[1], P. Nath[1], S. Prabhu[1], S. Sharma[1]
[1] S N Medical College, Medicine, Agra, India
[2] S N Medical College, Pathology, Agra, India
[3] Medical Centre, Medicine, Mathura, India

Aims: To study the histopathology on renal biopsy in diabetes with proteinuria to compare the amount of proteinuria and creatinine clearance in cases with diabetic or nondiabetic lesions.
Methods: 50 cases of diabetes mellitus with proteinuria were studied. These included 15 cases of type 1 and 35 cases of type 2 diabetes. They were divided into two groups:-
GROUP1-type 1 diabetes mellitus
a) with microalbuminuria (4 cases)
b) with overt proteinuria (11 cases)
GROUP2-type 2 diabetes mellitus
a) with microalbuminuria (11 cases)
b) with overt proteinuria (24 cases)
Their creatinine clearances were calculated using Cockroft Gault equation. They were subjected to renal biopsy with Bard Max Core Disposable Biopsy Instrument under ultrasound guidance and histopathologically evaluated for both diabetic and nondiabetic renal lesions.
Results: Frequencies of various renal parenchymal histopathological lesions demonstrated in our study were :-
a. 70% had diabetic lesions (diffuse diabetic glomerulosclerosis-58% and nodular diabetic glomerulosclerosis.)
b. 18% had non diabetic lesions (renal amylidosis-4%, mesangiocapillary glomerulonephritis-2%, membranous glomerulonephritis-6%, acute glomerulonephritis-2%, chronic pyelonephritis-4%) and
c. 12% had non diabetic lesion superimposed on diabetic lesions (diffuse diabetic glomerulosclerosis+interstitial nephritis-2%, diffuse diabetic glomerulosclerosis+membranous glomerulonephritis-6%, nodular diabetic glomerulosclerosis+interstitial nephritis-4%).

The 24 hour Urinary protein in cases with diabetic lesions was 694.6+-830.4,and in nondiabetic lesions 1928.9+- 1285.4 mg,while in nondiabetic lesions superimposed on diabetic lesions it was 2716.7+-1463.44 mg.The levels in the latter 2 groups were significantly greater ($p<0.01$) than in cases with diabetic lesions alone.
Mean Creatinine clearance in cases with pure diabetic lesions was 70.7+-32.88 ml/min, while this was 37.7+-29.16 ml/min with nondiabetic lesions and in cases of nondiabetic lesions superimposed on diabetic lesions it was 17.5+-5.45 ml/min. The levels in the latter 2 groups were significantly lower as compared to cases with diabetic lesions alone ($p<0.01$).
The differences between the nondiabetic lesion group and the mixed diabetic and nondiabetic lesion were not significant for both these parameters.
Conclusions: It is felt that renal biopsy should be done in cases of diabetes mellitus with proteinuria because the presence of non diabetic renal lesions is not uncommon and these adversely affect renal function and modify clinical management.

P-1361

Insulin resistance in non-diabetic chronic kidney disease patients with chronic renal failure – a new aspect of one old problem

E. Kumchev[1], S. Vladeva[2], D. Dimitrakov[1]
[1] Medical University, Clinic of Nephrology, Plovdiv, Bulgaria
[2] Medical University, Clinic of Endocrinology, Plovdiv, Bulgaria

Background: A state of insulin resistance is present from the early stages of chronic renal failure and has potential implications with respect to the high cardiovascular morbidity and mortality in patients with renal disease.
Aim: To investigate some aspects of impaired carbohydrate metabolism in predialysis patients with chronic renal failure.
Methods: 75 non-diabetic patients with chronic renal failure were investigated. Glycated hemoglobin and levels of immunoreactive insulin were measured in all predialysis patients. Oral glucose tolerance test was performed according to standard protocol. The control group included 30 healthy subjects.
Results: The baseline levels of plasma immunoreactive insulin showed a tendency towards increasing in patients with chronic renal failure as compared with the controls (7.2 ±1.1 IU/ml vs 6.4±0.7 IU/ml). No significant differences were found at the 1st, 2nd or 3rd hour following the ingestion of glucose as compared with the healthy subjects. Five patients had significantly elevated basal insulin levels. Mean level of glycated hemoglobin was 5.9±0.5% in patients with first degree chronic renal failure. There was a trend towards higher levels of glycated hemoglobin in patients with second and third degree chronic renal failure (6.3±0.6% vs 5.5±0.4% in controls). The results of oral glucose challenge test revealed impaired glucose tolerance in 39 predialysis patients - mean 2nd-hour blood glucose level 9.1±1.6 mmol/l. No significant disturbances in carbohydrate metabolism were found in patients with mild chronic renal failure. We found significant correlation between impaired carbohydrate metabolism with severity of arterial hypertension and duration of chronic renal failure.
Conclusions: Changes in carbohydrate metabolism and basal immunoreactive insulin levels which we found suggest insulin resistance includes moderate and advanced insulin resistance. Early detection of these disturbances would contribute to effective prevention of formation and progression of vascular lesions in non-diabetic patients with chronic renal failure.

P-1362

The effect of statins on apoptosis in kidneys of diabetic rats

W. Lu[1], H. Li[1], F. Zheng[1], Y. Ruan[1], F. Zhang[2]
[1] Sir Run Run Shaw Hospital College of Medicine Zhejiang University, Endocrinology and Metabolism, HangZhou, China
[2] Sir Run Run Shaw Hospital College of Medicine Zhejiang University, Sir Run Run Shaw Institute of Clinical Medicine of Zhejiang University, HangZhou, China

Aims: Treatment with hydroxymethylglutaryl coenzyme A reductase inhibitors (statins) may retard the development of diabetic nephropathy. This study was to investigate the effect of statins on apoptosis in diabetic kidneys in rats.
Materials and methods: Eighty Sprague-Dawley rats were divided into four groups randomly: the first group consisted of healthy controls; the second group included the untreated STZ-diabetics; three or six months of simvastatin or xuezhikang (red rice extract,which contains a mixture of statins) treated STZ-diabetics formed the third and the fourth groups, respectively. Terminal deoxynucleotidyl Transferase Biotin-dUTP Nick End Labeling (TUNEL) method was used for detection of apoptosis. Immunohistochemical staining and western blotting for Bax and Bcl-2 expression were also performed.
Results: TUNEL staining showed that apoptotic cells especially increased in the kidney tubuli of untreated diabetic group and a decrease was observed in both groups that received statin treatment. An increase in Bax expression in immunohistochemical staining was observed in the podocytes, mesangial cells, and the tubule cells of the untreated diabetic group after three or six months; both three and six months of simvastatin treatment could significantly decreased the expression of Bax ($p<0.01$); six months of xuezhikang treatment could significantly decrease the expression of Bax ($p<0.01$), but no significant difference was observed after three months of xuezhikang treatment. Up-regulation of Bcl-2 expression was observed in the above cells after three months in diabetic group compared to control group ($p=0.01$), but no difference was found between the two groups after three months; simvastatin up-regulated the expression of Bcl-2 compared with diabetic group time dependently ($p<0.05$ and $p<0.01$, respectively); xuezhikang up-regulated the expression of Bcl-2 only after six months of treatment ($p<0.05$) compared with diabetic group. In addition, three and six months of statin treatment decreased Bax/Bcl-2 ratio ($p<0.05$ and $p<0.01$), which was up-regulated in diabetic group. Western Blotting showed an increase in the expression of Bax in diabetic group after three and six months; both simvastatin and xuezhikang treatment could inhibit the expression of Bax compared to diabetic group. Expression of Bcl-2 detected by western blotting increased to some extent after three months in diabetic group compared to control group, which disappeared after six months; both simvastatin and xuezhikang treatment increased the expression of Bcl-2 compared to diabetic group.
Conclusion: Our results indicate that statins could reduce apoptosis present in diabetic nephropathy and the beneficial effect might partly be attributed to the regulation of Bax/Bcl-2 ratio.

No conflict of interest

Oxidative stress marker and microinflammation in diabetic nephropathy with type2 diabetes

K. Iso[1], K. Kuboki[1], T. Matsumoto[1], M. Miyagi[1], I. Sugino[1], I. Kaoru[1], G. Yoshino[1], E. MUrakami[2]
[1] Toho University School of Medicine, Divion of Diabetes Metabolism and Endcrinology Department of Medicine (Omori), Tokyo, Japan
[2] Toho University Hospital, Department of Clinical Laboratory (Omori), Tokyo, Japan

Background: Oxidative stress and microinflammation play important role in diabetic vasculopathy. The production of reactive oxygen species and microinflammation are increased in both animal models of diabetes and diabetic human subjects.
Objective: The aim of this study was to clarify the predictors of urinary albumin excretion (UAE) from oxidative stress and microinflammation in type 2 diabetic subjects.
Materials and methods: Thirty five outpatients (male 21, female 14) with type 2 diabetes who met the following criteria were enrolled: (1)systolic arterial Blood Pressure (SBP) <160 mmHg, (2) diastolic arterial Blood Pressure (DBP) <110 mmHg, (3) absence of marked hyperglycemia (HbA1c <8.0%). Exclusion criteria were acute and chronic inflammatory disease, current smokers, liver disease, and renal dysfunction (serum creatinine >1.1mg/dl).Plasma levels of high sensitivity C-reactive protein (hs-CRP), creatinine, HbA1c,Plasma glucose (PG), Total cholesterol (TC), Triglyceride (TG) and High density cholesterol (HDL-C), urinary albumin excretion (UAE), 8-hydroxydeoxyguanosine (8-OHdG), and 8-epiprostangine (PGF2-α),and BP were measured. The univariate analysis was performed. The multivariate analysis was performed to urinary albumin excretion. Data were expressed as Mean ± SD. P value of <0.05 were considered as a level of significance.
Results: Of 35, 18 diabetic subjects had hypertension. Of 18, 14 subjects were taking ARBs, 7 were taking Ca channel blockers, 1 was taking ACEI, 1 was taking ß blocker. In diabetic subjects, age, BMI, BP, and duration, were 62±11 years, 26.1±5.7 kg/m2, 129 ±12/77±13mmHg, and 6±6years. Cr, TC,TG,HDL-C,PG, HbA1c,hs-CRP, urinary 8-OHdG, urinary PGF2-α, and UAE were 0.78±0.15mg/dl, 195±33mg/dl, 146±127mg/dl, 51±14 mg/dl, 141±33mg/dl, 6.3±0.6%, 0.141±0.169 mg/dl, 9.0±3.0ng/mg.Cr, 140.6±32.9pg/mg. Cr, and 57.7± 88.3mg/g.Cr. There was a relationship between PGF2-α ($R=0.518$, $R2=0.268$, $p<0.005$) or hs-CRP ($R=0.486$, $R2=0.236$, $p<0.005$)and UAE. On multivariate analysis, Cr, PGF2-α and hs-CRP predicted UAE (multiple, $R=0.674$ $R2=0.455$, $p<0.001$). On the other hand, BP, TC,TG,HDL-C,PG, HbA1c didn't predict UAE. Similarly, 8-OHdG didn't predict UAE.
Discussion: Under relatively controlled hyperglycemia and blood pressure (HbA1c 6.3±0.6%, BP 128 ±11/75±11mmHg) the microinflammation and the oxidative stress may be implicated in the progression to diabetic nephropathy. It seemed that BP didn't predict UAE due to relatively control.
Conclusion: These results suggest that the microinflammation and the oxidative stress are implicated to urinary albumin in type 2 diabetic patients.

Mesoglycan prevents morphological renal alterations in diabetic rats

J. Mok[1], C. Jung[1], M. Rho[1], M. Song[1], C. Kim[1], D. Byun[1], S. Kim[1], K. Seo[1], M. Yoo[1], H. Park[1], Y. Kim[1], S. Kim[2]
[1] Soonchunhyang University, Endocrinology, Bucheon-Si Gyeonggi-Do, Korea
[2] Catholic University, Endocrinology, Bucheon-Si Gyeonggi-Do, Korea

Aims: Diabetic nephropathy forms a serious complication in patients with diabetes mellitus. Morphologically, diabetic nephropathy is characterized by thickening of the glomerular basement membrane (GBM). Major components of basement membrane are heparan sulfate (HS) proteoglycans. A defect in the regulation of HS production by endothelial, myomedial and mesangial cells determines the susceptibility of diabetic patients to developing proteinuria. Numerous reports showed that HS prevents diabetic nephropathy. The aim of this study is histologic analysis of pathologic renal changes in normal and untreated or Mesocan (major component of Mesocan is HS)-treated diabetic rats with albuminuria.
Methods: We analysed pathologic finding of control rats (n=5), untreated-diabetic rats (n=5) and mesocan-treated diabetic rats (n=5) with albuminuria. Daily dosage of mesocan in treated rats was 200mg/kg and period of administration was 5 weeks. Periodic acid Schiff (PAS) and collagen III staining were performed to histologic analysis.
Results: Diabetic rats exhibited an accumulation of PAS-stained mesangial matrix, which was not observed in the control or mesocan-treated animal. The immunohistochemical analysis of collagen III revealed positive staining in the glomerular mesangial matrix of untreated diabetic rats; staining was significantly less extensive in normal glomeruli and in mesocan-treated diabetic rats.
Conclusion: Our data demonstrate that administration of mesocan has a favorable effect on morphological renal abnormalities in diabetic rats.

Increased vascular calcification compared to bone mineral density in diabetic patients on regular dialysis treatment

A. Soliman[1], M. Taha[1], E. Ismail[2], N. Elshimy[3]
[1] Cairo University, Medicine, Cairo, Egypt
[2] Cairo University, Radiology, Cairo, Egypt
[3] Cairo University, Clinical Pathology, Cairo, Egypt

Cardiovascular disease in dialysis patients is associated with increased vascular calcification (VC) and arterial stiffness, both inversely correlated with bone mineral density (BMD). Few studies have correlated VC in diabetic patients

on regular hemodialysis treatment with measurements of BMD and arterial compliance. Data of 90 haemodialysis (HD) patients assessing the prevalence of VC and its associations. Patients had computed tomography scans through abdominal aorta and superficial femoral arteries (SFA) to determine VC, and dual-energy X-ray absorptiometry (DXA) to determine BMD. Patients were divided into diabetic and non-diabetic groups. Patients, 55% male, 40% diabetic, had median age 48 years. Mean aortic VC score 488.1 ± 298 Hounsfield units, with 91% having aortic VC present. In univariate linear regression analysis, aortic VC correlated positively with length of HD (P = 0.01) and diabetes (P = 0.03) and hyperphosphatemia (p = 0.05) and negatively with secondary hyperparathyroidism. In multivariate regression analysis, length of HD and diabetes were significantly associated with aortic VC, whereas age and diabetes were associated with SFA VC. Mean lumbar spine and femoral neck T-scores on DXA were 0.14 and -1.66 respectively but there was no significant difference between diabetic and non-diabetic groups. Univariate linear regression analysis showed inverse correlation between aortic VC and femoral neck T-scores in non-diabetic but not in diabetic hemodialysis patients. Conclusion: Increased VC is common in HD patients. Bone vascular axis is activated in diabetic dialysis and with increasing age resulting in more VC, and greater aortic VC is seen with longer duration of dialysis and lower bone dynamics in diabetes mellitus.

P-1366

Risk factors of normal ankle-brachial index and low toe-brachial index in diabetic patients on regular hemodialysis treatment

A. Soliman[1], M. Taha[1], E. Ismail[2]
[1] Cairo University, Medicine, Cairo, Egypt
[2] Cairo University, Radiology, Cairo, Egypt

The prevalence of peripheral arterial occlusive disease is high in patients with diabetes mellitus, exacerbated in chronic renal failure and thus it is a major problem in those on hemodialysis. A low ankle-brachial index (ABI) suggests the presence of arterial stenotic lesions between the aorta and the ankle joint, while a low toe-brachial index (TBI) suggests stenotic lesions between the aorta and the toes. Therefore, a normal ABI (≥0.9) and a low TBI (<0.6) may indicate the presence of stenotic lesions located only on the peripheral side of the ankle joint. In the present study, risk factors of normal ABI/low TBI were investigated. In 175 patients on maintenance dialysis, the ABI and TBI were simultaneously measured.The background factors and laboratory data of patients with normal ABI/low TBI (L group) and those with normal ABI/normal TBI (≥0.6) (N group) were compared. Patients on regular hemodialysis treatment were divided into two groups; diabetic (D group) and non-diabetic (ND group). Low ankle-brachial and toe-brachial indices were detected in 39% and 22% of the patients, respectively. Comparison of the background factors and laboratory data between groups showed that the ratio of diabetes mellitus, interdialytic body weight gain, and hyperphosphatemia values were significantly higher in the L group than in the N group. It was concluded that uncontrolled diabetes, excess body weight gain and increased blood phosphorus are involved as risk factors in dialysis patients with normal ABI/low TBI.

P-1367

Plasma adiponectin/hs-CRP ratio in type 2 diabetic patients with diabetic nephropathy

L. Diaconu[1], V. Serban[1], R. Timar[1], A. Vlad[1], M. Timar[1], V. Botea[1]
[1] University of Medicine and Pharmacy "Victor Babes" Timisoara, Diabetes Clinic, Timisoara, Romania

Background and aims: Adiponectin is the only adipocytokine known to produce insulin-sensitizing effects and to have anti-atherosclerotic, anti-inflammatory properties. Low plasma levels of adiponectin were associated with insulin resistance, type 2 DM and atherosclerotic cardiovascular diseases. The aim of this study was to investigate the relationship between plasma levels of adiponectin, markers of inflammation and diabetic nephropathy (DN) in patients with type 2 DM.
Material and methods: The study enrolled 115 patients with type 2 DM, 58 men (51.8%) and 54 women (48.2%), with the mean age 59.6 ± 7.2 years. Laboratory analyzes performed in study subjects included serum creatinine, urine albumin/ creatinine ratio, plasma levels of adiponectin, high-sensitive C reactive protein (hs-CRP), interleukin 6 (IL-6), tumor necrosis factor a (TNF-a). Subjects were divided by the presence and severity of DN into 4 categories: I, normoalbuminuria (urine albumin < 30µg/mg creatinin); II, incipient DN (urine albumin 30 – 299 µg/mg creatinin); III, overt DN (urine albumin = 300 µg/mg creatinin); IV, chronic renal failure with serum creatinine = 2mg/dL. Glomerular filtration rate (GFR) was estimated by the Modification of Diet in Renal Disease Study (MDRD) equation: 175 x (serum creatinine mg/dL)$^{-1.154}$ x age$^{-0.0203}$ x (0.742 if female).
Results: Plasma levels of adiponectin were increased in the advanced stages of DN. Also, plasma TNF-a, IL-6 and hs-CRP increased with the severity of DN. Adiponectin/ hs-CRP ratio decreased significantly (p<0.001) with the severity of DN (Table 1).

Table 1: Adiponectin, adiponectin/hs-CRP ratio and inflammatory markers in subjects with diabetic nephropathy

	I. normo-albuminuria	II. Incipient DN	III. Overt DN	IV. Chronic Renal Failure	P (ANOVA)
N	65	27	14	9	-
Adiponectin (µg/mL)	6.5 ± 0.8	7.3 ± 1.2	8.2 ±1.6	9.8 ± 2.1	<0.001
hs-CRP (mg/L)	3.1 ± 0.5	4.4 ± 0.9	5.1 ± 1.3	6.4 ± 1.7	<0.001
Adiponectin/hs-CRP ratio	2.10 ± 0.41	1.66 ± 0.32	1.61 ± 0.29	1.53 ± 0.25	<0.001
TNF-a (pg/mL)	7.8 ± 0.9	8.4 ± 1.4	9.1 ± 1.6	10.3 ± 1.9	<0.001
IL-6 (pg/mL)	3.7 ± 0.6	4.3 ± 0.8	4.9 ± 1.3	5.7 ± 1.5	<0.001
Data are n (%) or mean ± SD.					

Plasma adiponectin /hs-CRP ratio was negatively correlated with urine albumin excretion (r= - 0. 63) and with GFR (r= -0.56) independently. Plasma adiponectin was positively correlated with serum creatinine (r= 0.54) in type 2 diabetic patients with DN.
Conclusions: Plasma levels of adiponectin were positively correlated with the severity of DN. Adiponectin may be enhanced in type 2 DM patients with DN as a physiological counterregulatory response trying to mitigate the endothelial damage. Although adiponectinemia is increased in advanced stages of DN, the adiponectin/hs-CRP ratio is decreasing with the severity of DN, indicating that advanced stages of DN are proinflammatory states.

How important is the presence of microalbuminuria at diagnosis of type 2 diabetes mellitus?

R.E.T. Navarrete[1], A.C. Santomauro Jr[1], T.A.C. Maciel[1], T.C.P. Bonansea[1], S.V. Matsuda[1], S.F.R. Rosenthal[1], R.T. Rienzo[1], T.P.B. Silva[1], R.B. Spolidoro[1], A.T.M.G. Santomauro[1], F.F. Fraige[1]
[1] Faculty of Medicine ABC, Department of Endocrinology, Santo Andre, Brazil

Background: Microalbuminuria (albumin excretion rate between 30-300 mg/24h) is an early warning sign of impending clinical nephropathy and cardiovascular disease in patients with diabetes mellitus. A transitory albumin excretion and hyperglycemia can occur together at the time of diagnosis of type 2 Diabetes Mellitus (T2DM). However, microalbuminuria persistent after adequate glycemic control may also represent incipient nephropathy with a risk of progression to overt proteinuria of 60-80% over 6-14 years.
OBJECTIVE: The aim of this study was to determine the presence of microalbuminuria at diagnosis of type 2 diabetic patients.
Patients and methods: A Cross-Sectional Study of clinical and laboratoy data of type 2 diabetic patients consecutive newly diagnosed on occasion of the campaign developed by the National Diabetes Association (ANAD) for World Diabetes Day in 2007, Sao Paulo, Brazil. Microalbuminuria was estimated by measuring urine albumin/creatinine ratio in an early morning urine sample during the first visit. Blood pressure, body mass index (BMI) and glycated haemoglobin (HbA1c) were also determined. All analyses were performed with the use of Stata software, version 7.0.
Results: A total of 153 patients were studied (57 % female) with a mean age of 51.7±6.3 years. The prevalence of essential hypertension was 23.8%. The BMI were 28.1±2.7 Kg/m^2. The prevalence of microalbuminuria and macroalbuminuria was 17.0% and 3.92%, respectively. Statistically microalbuminuria did not differ significantly in age, gender, BMI or initial blood pressure.
Conclusions: In our study, the prevalence of microalbuminuria at diagnosis of T2DM was 17.0%. The majority of the studies have shown persistent microalbuminuria in 19 to 20 % of the newly diagnosed T2DM. Although

our data are isolated and the diagnosis must be confirmed with 24-h UAE, this finding indicates that albuminuria is still the best test to predict diabetic nephropathy.

Screening of diabetic men for erectile dysfunction

S. Bosseri[1], S. Mohadi[1], R. Arun[1]
[1] Suri Seri Begawan Hospital, Dept of Medicine, Kuala Belait, Brunei

Background: Erectile dysfunction (ED) is one of the commonest complications of diabetes and is associated with co-morbid conditions such as cardiovascular disease, hypertension and depression. ED may also affect quality of life, patient satisfaction, and patient-clinician relationship. Diabetic patients with erectile dysfunction therefore require careful and sympathetic evaluation
The aim of this study is to explore this hidden complication in patients attending our diabetes clinic as very few of them complain of this problem to doctors.
Methods: The subjects are two groups: 1) Patients; 200 consecutive male patients attending the diabetes clinic at Suri Seri Begawan Hospital. They were never treated for sexual problems. 2) Controls; 100 healthy men who are not taking any medication and were screened for hypertension, diabetes and hypercholesterolaemia. (During public screening campaign)
They were asked to answer International Index of Erectile Function (IIEF), to test erectile function, orgasmic function, sexual desire, intercourse satisfaction, overall satisfaction.
The scores of the two groups were compared and a correlation was made between the scores of the patients and their smoking status, BMI, diabetes duration, HbA1c level and the presence of hypertension, hypercholesterolaemia and coronary heart disease
The statistical analysis was done by SPSS Statistics Version 17 software.
Results: The mean age of the diabetic patients was 52±, 9.6. 47% of the diabetic patients were smokers, 85% had associated hypertension and 40% had coronary heart disease.
The diabetic subjects had a lower IIEF score compared with the healthy men, mean 14.65+6.35 vs. 19.17+4.49 (P <0.0001)
The frequency of the different degrees of ED is shown in the table

ED severity	IIEF score	Healthy subjects %	Diabetic patients %
No	1-4	34	19
Mild	5-7	60	47
Moderate	8-11	4	12
Severe	22-25	2	22

The risk of ED was higher in the diabetic patients who are aged more than 50 years; 12.70±6.10 vs. 17.50±5.56 (P <0.0001), diabetes duration of more than 10 years 12.89±6.85 vs. 15.60±5.80 (P 0.009), increased in the presence of associated hypertension; 13.70±6.19 vs. 18.70±5.35 (P < 0.0001) and coronary heart disease 11.06±6.41 vs. 15.76±6.41 (P <0.0001)
There was no significant risk with smoking status; 14.37±0.39 vs. 14.87±6.28 (P 0.617), BMI 14.50±6.13 vs. 14.9±6.63 (P 0.55), HbA1c level 14.57±6.05 vs. 14.73±6.36 (P 0.55) and hypercholesterolaemia 14.54±6.36 vs 14.66±6.17 (P 0.97)
Conclusion: Erectile dysfunction is highly prevalent among the patients attending our clinic, especially among the older patients and those with cardiovascular disease. Therefore every diabetic patient should be screened for ED as few sufferers actually complain of this problem. This is particularly important since there are nowadays a number of effective treatments. Such treatment should become a routine part of any diabetes care service.

Perception about aetiology of sexual problems, health seeking behavior and treatment for sexual problems among type 2 diabetic men

A. Adegite[1], E. Aniekwensi[2], A. Ohihoin[3], F. Puepet[2]
[1] University of Cape Town/ Groote Schuur Hospital, Diabetic Medicine and EndocrinologyDivision, Cape Town, South Africa
[2] Jos University Teaching Hospital, Department of Medicine Endocrine and Metabolism Division, Jos, Nigeria
[3] Jos University Teaching Hospital, Obstetrics and Gynaecology Department, Jos, Nigeria

Background and objective: Sexual problems i.e low libido, erectile dysfunction (ED), retrograde ejaculation and premature ejaculation are common among type 2 diabetic men. These problems are often under-reported and hardly discussed with the patients by care givers largely because of busy clinic schedule and societal inhibition and norms on issues that border on sexuality, especially in the African communities.Sexual problems compromise multiple aspects of a patient's life, including overall quality of life and interpersonal relationships.
This study examines the perception and understanding of type 2 diabetic men about the aetiology of their sexual problem(s).It also assess their health seeking behavior, treatment practise and outcome.
Methodology: Consecutive 66 type 2 diabetic men attending a diabetic clinic in Jos, Nigeria were interviewed with the aid of a questionnaire on the presence of sexual problem(s) i.e low libido, ED, retrograde ejaculation and premature ejaculation.The erectile domain of the international index of erectile function (IIEF)-15 was also used to assess erectile function.Questions relating to health seeking behavior and treatment were asked from patients found with sexual problems.
Results: Any form of sexual problem was reported in 53 (80.3%) patients, with overall prevalence of ED being 51.5% with the aid of the questionnaire but 87.9% with the IIEF-15. Overall prevalence of low libido, premature ejaculation and retrograde ejaculation were 53%,19.7% and 18.2% respectively. Median duration of sexual problem(s) was 3 years, range (0-12years). In 16 (30.2%) patients sexual problem predate diagnosis of diabetes, and sexual problem was the reason for suspicion and diagnosis of diabetes in 3 (5.7%)patients. Diabetes was the perceived cause of sexual problem(s) in 31 (58.5%) patients. Diabetes medication, stress, old age, hypertension were the perceived cause(s) in 9 (17%) while 13 (24.5%) did not know the cause.Twenty four (45.3%) did not seek for help for reasons ranging from shyness, loss of hope, hope of spontaneous improvement etc. Twenty seven (50.9%) sought for help in the hospital while 2 (3.3%) with the herbalist.Twenty six (49.1%) had used medicine for the sexual problem(s) and some improvement was reported in18 (34%) with or without medicine.Aphrodisiac agents,phosphodiesterase inhibitor (PDE-5) and herbal medicine were used in 10 (18.9%), 9 (17%), and 5 (9.4%) respectively. Eleven (20.7%) did not use medicine because they did not know what to use, twelve (22.6%) because of hope of spontaneous improvement, 2 (3.8%) for fear of drug complication and 2 (3.8%) thought there was no hope of improvement.
Conclusion: Type 2 diabetic men in Jos showed poor perception and understanding of their sexual problems.The health seeking behavior of these patients is also poor. The need for a more holistic approach to management of their sexual problems is more necessary than ever.

P-1371

Peripheral neuropathy in diabetes may predispose to distal distribution of atherosclerosis in lower extremities

R. Chawla[1], A. Garg[1], C.p. Ahuja[1], B.b. Chanana[1], S. Gupta[1], H. Punyani[1]
[1] Maharaja Agrasen Hospitalpunjabi Bagh, Diabetology, New Dehli, India

Aim: to study the relationship between peripheral neuropathy in the distal nerves (sural/tibial) and arterial plaque formation, blood flow velocity, thrombosis & pattern of flow in femoral popliteal, posterior tibial & dorsalis pedis arteries.
Material and methods: 60 Type 2 DM patients were enrolled
30 patients with peripheral neuropathy comprised test group & 30 patients without neuropathy acted as controls.

Inclusion criterion

- Type-2 DM with peripheral neuropathy
- Type-2 DM without peripheral neuropathy

Exclusion criterion – HT >140/90mm Hg

- Renal dysfunction – S.CREATININE >1.5 mg%
- Buerger's disease
- Gross dyslipidemia
- Chain Smokers

Patients were matched for age, duration of DM, blood sugars and lipids.
Peripheral neuropathy was documented by NSS (Neuropathy Symptoms Score) and NDS (Neuropathy Disability Score) scores>10 as per "Young et al" criterion. Peripheral Vascular Disease (PVD) was documented with Leg Arterial Doppler Study on common femoral, popliteal, posterior tibial and dorsalis pedis arteries by demonstrating

- Plaque Formation
- Change in velocity
- Loss of triphasic flow
- Presence of thrombosis

Results: 1 /30 (3.3%) patients in control group had PVD. While - 8/30 (26.7%) patients in the test group had PVD (p=.012)
Conclusion: Due to large number of complications related to PVD in DM, we suggest that every patient with DM with significant neuropathy should be screened for PVD.

No conflict of interest

P-1372

Erythrocyte plasmalogenes level decreased in diabetes mellitus

N.A. Akhrarova[1], T.S. Saatov[2], Z. Shamansurova[1], F. Mukhamedova[1]
[1] Endocrinology, Diabetology, Tashkent, Uzbekistan
[2] Biochemistry, Lipids, Tashkent, Uzbekistan

Aims: Cell membranes lipid components are early reflected to changing of homeostasis and conditions and alteration of their content may be early marker of tissue damage. Plasmalogenes presented cell membranes lipid compounds which participate in nerve impulse generation, reception, immune response, transport of substances and present the antioxidant potential of cells. Changing of plasmalogenes level and their significance not clear in Diabetes Mellitus (DM) and present the interest in our study.
Methods: In 67 patients with type 2 DM and 12 healthy subjects (HS), blood glucose fasting (FG) and 2 hour after meal (2HG), HbA1c, total cholesterol (TCh), triglycerides (TG), high and low density lipoproteines (LDL, HDL) levels, blood serum and erythrocytes membranes plasmalogenes (BP, MP) were observed. All patients were examined by neurologist for determining presence and severity of diabetic neuropathy (DN) and divided in groups – with and without DN.
Results: In patients with DM, blood FG, 2HG, HbA1c, TCh, TG, LDL levels were significantly increased and HDL level were decreased in compare with HS and suggest poor glycemic control, whereas BP (11%) and MB (8%) level were significantly decreased in DM patients. Decreasing BP and MP levels had linkage with FG, 2HG, HbA1c, TCh, TG, LDL, HDL levels, and shown dependency from presence and severity of DN, where BP were less in 13.85% ($P<0.05$) and MP – in 9.41% ($P<0.05$) in patients with DN compared without DN. In consider the plasmalogenes rich in nervous tissue this results permit to recommend BP and MP as a biochemical marker of DN.
Conclusion: In patients with DM the levels of BP and MP were significantly decreased and had linkage with glycemia indexes and blood lipids level, and depend from presence and severity of DN.

No conflict of interest

The relation of Body Mass Index and Bone Mineral Density in postmenopausal women with type 2 diabetes

L. Nikoleishvili[1], R. Kurashvili[1], T. Rukhadze[2], N. Bagashvili[2]
[1] Georgian Diabete Center, Functional Diagnostic, Tbilisi, Georgia
[2] Bone and Joint Diseases Diagnostic Center, Diagnostic, Tbilisi, Georgia

Background: The association between the body weight, height and Bone Mineral Density (BMD) nowadays is extensively researched. The aims of our study was to access the relation between Body Mass Index (BMI) and BMD in postmenopausal type 2 diabetic women, with some symptoms of osteoporosis and prevalence of osteoporosis by WHO criteria.
Methods: This study was conducted on 75 postmenopausal diabetic women at the age of 45-65 years without heavy complications of diabetes. They were divided into 3 groups: Group 1- 24 patients with normal BMI <26 kg/m2; Group 2- 24 overweight patients with BMI from 26 kg/m2 to 30 kg/m2; Group 3- 27 obese patients with BMI >30 kg/m2. Bone mineral density was measured in lumbar spine and femoral neck using dual-energy x-ray absorptiometry.
Results: Patients with obesity had lower prevalence of osteoporosis at the hip (10% vs. 15.5%, p=0.005) or femoral neck (35% vs. 44%, p=0.01) when compared to the patients with normal BMI. Patients with obesity had higher BMD at total hip when compared to the patients with normal BMI ($p<0.001$). There was no statistical difference between the groups 2 and 1, between normal and overweight patients. Overweight patients had slightly, but not statistically significant higher femoral neck BMD and lower lumbar spine BMD, when compared to normal BMI patients.
Conclusion: This study suggests the association of elevated BMI with high BMD and simultaneously, lower prevalence of osteoporosis and fracture risk.

The effects of electric stimulation with Techtron in diabetes mellitus patients with neuropathy pain

H. Uribazo[1], S. Turró[1], D. Oliva[1], F. Fuentes[1]
[1] Hermanos Ameijeiras Hospital, Physical Medicine / Rehabilitation, Ciudad de la Habana, Cuba

Objective: To determine the effectiveness of electric stimulation with TECHTRON in the neuropathy pain relief in a group of Diabetes Mellitus patients who were treated in Physical Medicine & Rehabilitation Service at Hermanos Ameijeiras Hospital.
Design: A Clinic prospective research was performed in a group of patients complicated with Diabetes Mellitus type 1 and 2.These patients were sent to the Diabetes Endocrinology Clinic who showed complications as neuropathy pain, confirmed by clinic assessment and electromyography studies. Subjects were randomly assigned in either a control or experimental groups. Analogical Visual Scale (AVS) was applied before and after the treatment in both groups. Low frequency biphasic square wave between 1,1 kHz – 1,6 kHz with TECHTRON equipment manufactured by TECHNO LINK up to 10 minutes daily for 5 weeks was applied in the experimental group1.The control group 2 received TENS current with 200µs/100 Hz up to 10 minutes daily for 5 weeks. Statistical analysis and Mann- Whitney Test were applied.
Result: The mean age was 51,1 in Group 1 and 55,2 in Group 2. The time of evolution of the disease was approximately the double in Group 1 than Group 2 (14,0 and 7,4).Sex in both groups was similar. The prevalence of Diabetes type 2 was relevant in both groups. There is no statistical significance in the average of the percentage of change in the AVS regarding the type of diabetes, sex, age, or the time of evolution of the disease. There was statistical significance (p= 0,03) in the average of the percentages of change in the AVS between treated groups. The lower frequency biphasic square wave with TECHTRON showed more percentage of change for relieve (68%) in the experimental group1.
Conclusion: This study demonstrates that Diabetic Mellitus patients with neuropathy pain are effectively treated with TECHTRON to relieve neuropathy pain.

New onset diabetes mellitus after liver transplantation and hepatitis C virus infection: meta-analysis of clinical studies

T. Chen[1], H. Tian[1], H.Y. Jia[2], X. Chen[3], H. Zhou[3]
[1] *West China Hospital of Sichuan University, Department of Endocrinology and Metabolism, Chengdu, China*
[2] *Henan provincial people's hospital, Department of Endocrinology, Zhengzhou, China*
[3] *West China Hospital of Sichuan University, Laboratory of Endocrinology and Metabolism, Chengdu, China*

Aims: New onset diabetes mellitus post liver transplantation is very common and may negatively affect patient and graft survival, but its causative mechanism is still unclear. This study was to analyze the connection between Hepatitis C virus (HCV) infection and new onset diabetes mellitus after liver transplantation by systematically reviewing published medical literature.
Methods: We electronically searched databases of MEDLINE, EMBASE and the Cochrane Library from January 1980 to January 2008. Only retrospective studies could be identified. Seven of them were subjected to the meta-analysis. Analysis was performed by using RevMan 4.2 software.
Results: We found that HCV increased the prevalence of new onset diabetes mellitus [OR 2.46,95%CI (1.44,4.19)]. Then, we further analyzed the association between HCV and persistent new onset diabetes mellitus after liver transplantation. The result showed that prevalence of persistent new onset diabetes mellitus was higher in HCV-positive group than in HCV-negative group with marginal statistical significance [OR=1.39, 95%CI (1.06, 1.83)].
Conclusion: The present meta-analysis based on retrospective studies suggested a significant relationship between HCV and new onset diabetes mellitus after liver transplantation, and it seems HCV infection might also increase the prevalence of persistent new onset diabetes mellitus. Multicenter, large sized prospective studies are still needed to further confirm these results.

P-1376

Risk factors for diabetic hand infections

M. Cardino[1], E. Lee[2], M. Estrella[2]
[1] *Philippine General Hospital, Endocrinology, Manila, The Philippines*
[2] *Philippine General Hospital, Orthopedics, Manila, The Philippines*

A case control study of diabetic patients presenting with hand infection in the Philippine General Hospital was performed to determine the correlation of different variables to the development of hand infection in patients with diabetes mellitus (DM). The clinical characteristics and outcomes of diabetic hand infection were described.
Methodology: Clinical characteristics &outcomes of 20 diabetic patients with hand infection (case) were documented. Case patients (N=20) were compared to 60 age and sex-matched diabetic patients without hand infection (control) in terms of educational attainment, occupation, body mass index (BMI), blood pressure, duration of DM, Type 1 vs Type 2 DM, diabetic treatment regimen, blood sugar level control (HbA1c), alcohol intake, tobacco use, incidence of peripheral neuropathy of contralateral hand, presence of arteriovenous (AV) fistula, and intake of immunosuppressants. The odds ratio (OR) and 95% confidence interval (CI) were computed. All variables with P<0.1 identified by bivariate analysis were evaluated by multiple logistic regression analysis to identify independent risk factors for infection (P<0.05).
Results: Case patients had a mean age of 48.65 +/- 7.59 years and a 1:4 female to male ratio. Ninety-five percent were manual laborers with type 2 diabetes for a median of 3 years. Seventy percent were being maintained on oral hypoglycemic agents. Only 10% had adequate glucose control. The nondominant hand was infected in 45% of patients. Infection in 85% was localized to a single digit but was deep in 80% of cases. The median treatment delay was 15 days. All patients had to undergo surgical debridement at time of presentation. An average of 2.1 surgeries were done for each patient. Average time to wound healing was 8.5 days +/- 6.19. Amputation rate was 80%. Average length of hospitalization was 17.4+/- 10.3 days.
Significant variables identified after bivariate analysis were college education, BMI ≤/- 20, HbA1c >7, insulin treatment, tobacco use, and alcoholic beverage consumption. After multivariate analysis, tobacco use was identified as an independent risk factor (OR=30, CI= 1.3, 691.5, P<0.034). Low BMI (P<0.08) and poor glucose control (P<0.08) were strongly associated with infection but did not reach statistical significance.
Conclusion: Diabetic hand infection in the local population was associated with significant morbidity. Prevention efforts should be focused on diabetic patients who are smokers and have a low body mass index. Adequate glucose control should be stressed. Patients should be educated to seek immediate consult following minor hand trauma or at the onset of symptoms.

Periodontitis and association of cytokine gene polymorphism in type 2 diabetes in Sri Lanka

N. De Silva[1], C.F. Dalton[1], D.J.S. Fernando[2], P. Heasman[3], P. Preshaw[3]
[1] *Faculty of Health and Wellbeing, Biomedical Research Centre, Sheffield, United Kingdom*
[2] *Department of Diabetes and Endocrinology, Kings Mill Hospital Sutton in Ashfield, Nottinghamshire, United Kingdom*
[3] *Newcastle upon Tyne, School of Dental Sciences, Framlington Place, United Kingdom*

Aims: To examine Periodontal Associated Genotype (PAG) as a risk factor in periodontitis in patients with type 2 diabetes in a suburban population in Sri Lanka
Introduction: PAG defined by the presence of allele 2 of both IL1A +4854 and IL1B +3954 polymorphisms, is a significant predictor for chronic periodontitis in some but not in all populations studied. Type 2 diabetes is also recognised as a risk factor for periodontal disease.
Method: 262 patients with type 2 diabetes and 72 sex and age matched controls underwent periodontal examination. Polymerase chain reaction (PCR) followed by restriction fragment length polymorphism (RFLP) allelic discrimination was employed to genotype (IL1A +4854) and (IL1B +3954) polymorphisms.
Results: 12.6% and 12.5% of subjects were reported to be PAG positive from type 2 diabetes and control groups respectively. The distribution between the two groups was not statistically significant (c^2 =0.983). 38.9% (130/334) of the total cohort were found to be periodontally healthy of whom 13.1% (17/130) were PAG positive. 27.8% (93/334) and 32.3% (108/334) had gingivitis and chronic periodontitis respectively. 16.1% of subjects with gingivitis and 9.3% of chronic periodontitis group were PAG positive. PAG was associated with mean probing depth (p=0.039) and mean loss of attachment (p=0.05). The presence of PAG has no significant association with smoking (p = 0.582).
Conclusions: PAG had no significant association with periodontits in patients with type 2 diabetes and controls. PAG positive percentage (12.6%) is relatively low in this population compared to Caucasians. PAG status as a significant predictor for periodontal disease remains controversial.

Relationship of oral conditions and factors in type 2 diabetes mellitus patients

I. Takei[1], 2. Yamazaki[2], 3. Aikawa[2], 4. Kaida[2], 5. Kuramoto[2], 6. Tonogi[2], 7. Moriya[1], 8. Odanaka[1], 9. Ogawa[1], 1.0. Yamane[2], 1.1. Ishida[3]
[1] *Tokyo Dental College Ichikawa General Hospital, Center for diabetes and endocrinology, Ichikawa city, Japan*
[2] *Tokyo Dental College Ichikawa General Hospital, Department of Oral Medicine Oral and Maxillofacial Surgery, Ichikawa city, Japan*
[3] *Kyorin University School of Medicine, The Third Department Internal Medicine, Tokyo, Japan*

Aims: Type 2 diabetes mellitus was already reported to be correlated pathogenesis of periodontal disease. Furthermore,hyperglycemia may worsen the periodontal disease, caused by infectious condition, immunocompromise and disturbance of microcirculation.Therefore, we have studied the relationship between complications of periodontal status severity and diabetic several factors.
Methods: Seventy six type 2 diabetic out-patients were selected at Tokyo Dental College Ichikawa General Hospital. Clinical and laboratory examinations have observed age, sex, BMI, duration of diabetes, prevalence of retinopathy, existence of hypertension, current treatment for diabetes, level of HbA1c and LDL-cholesterol, HDL-cholesterol, triglyceride. Oral examination and periodontitis condition were evaluated in diabetic patients. Residual teeth,

bleeding on probing (BOP), plaque control record (PCR) and pocketing were observed. Moreover, Panoramic radiograph was used for alveolar bone resorption assessment.
Results: In this study, average of BOP was recognized 37.8% and average of PCR was recognized 44.4%.These percentages of periodontitis were higher in diabetics compared to normal population. Poor diabetic control, examined by HbA1c, was related to increase the periodontitis status and progression of periodontitis. Prevalence of diabetic retinopathy was recognized to have the tendency to worsen the periodontitis.
Conclusions: The existance of retinopathy and poor diabetic control is related to worsening of the periodontal disease in type 2 diabetes mellitus patients.

Diagnostic value of LDH-enzyme and efficacy of treatment with SPS-bacteriophages in children with newly diagnosed type 1 diabetes and gingivitis

E. Chijavadze[1], R. Kurashvili[1], L. Tsutskiridze[1], G. Kurashvili[1], E. Shelestova[1], M. Gordeladze[2], S. Khutsurauli[3]
[1] Georgian Diabetes Center, endocrinology dept., Tbilisi, Georgia
[2] State Medical University, Pediatric dept., Tbilisi, Georgia
[3] High Medical School "Aieti", endocrinology dept., Tbilisi, Georgia

Background and aims: The aim of the present work was to assess the microflora of the mouth cavity; diagnostic value of the LDH-enzyme activity measured in the mixed saliva, and uses of highly effective polyvalent bacteriophages in gingivitis – a periodontal disease in children with newly diagnosed type 1 diabetes (T1DM).
Materials and methods: Totally, 40 children with fresh T1DM (girls 26/boys 14, mean age 10.5±0.75yrs) were enrolled in the study group (Gr.1). Practically healthy children (n=25, mean age 9.1±0.92yrs) were used as controls (Gr.2). Disk – diffuse method was used to determine sensitivity of micro-organisms toward antibiotics, and Fiscal standard method – for SPS bacteriophages sensitivity. SCE method was used to assess LDH-enzyme activity.
Results: Changes in mouth cavity microflora that are expressed in quantitative growth of conditionally pathogenic microbes in association with fungus Candida Albicans, namely St. haemoliticus – 46.6%, and SPS bacteriophages sensitivity – 70% were observed in children with newly diagnosed T1DM. In Gr. 1 LDH-enzyme activity in the mixed saliva was 1426±78 IU/l (p=0.05), while in Gr. 2 it was 339.26±14.75 IU/l.
Conclusion: 1. It is important to enroll in the treatment scheme of the periodontal diseases, namely gingivitis the highly effective, polyvalent, SPS bacteriophages, that are prepared taking into account the microbial strains revealed while investigating the mouth cavity microflora of children with T1DM. 2. It is necessary to add assessment of the mixed saliva LDH-enzyme activity to the algorithm of the periodontal disease examinations in children with newly diagnosed T1DM.

Effect of hepatitis C virus infection on metabolic and cardiovascular risk profiles of diabetic patients

M.N.A. Jadoon[1], M.A. Shehzad[1], R. Yaqoob[1]
[1] Nishtar Medical College, Medicine Unit 3, Multan, Pakistan

Aims: The aims of this study were to:
1. Determine the prevalence of Hepatitis C virus infection in diabetic patients.
2. Elucidate the presence of an association between diabetes and hepatitis by comparing prevalence in diabetics with controls.
3. Determine the effect of Hepatitis C virus infection on metabolic and cardiovascular risk profiles of diabetic patients.

Methods: Five hundred and fifty diabetic patients attending diabetes clinic were enrolled in the study. Patients' data was collected after taking consent. A control group comprising of 550 healthy blood donors who donated blood in blood bank of hospital during the study period were taken as controls. Hepatitis C virus antibody presence was checked using ELISA in both control and study group. Patients' glycemic control was checked and lipid profile was analyzed. Blood pressure, body mass index (BMI) and waist-hip ratio (WHR) were measured. All the ethical requirements were met before starting the study.
Results: The age of patients was 47.58 years and the duration of diabetes was 7.02 years. Out of 550 patients included in study, 304 were female, 428 were from urban locality and 143 had a positive family history of diabetes mellitus. HCV infection was present in 160 (29.09%) diabetic patients as compared to control in whom prevalence was 8.18% (OR=4.60, 95% CI= 3.22-6.57, p<0.01). Patients with HCV infection had significantly lower total serum cholesterol, serum triglycerides, LDL cholesterol, LDL cholesterol/HDL cholesterol ratio and a lower waist to hip ratio as compared to diabetic patients without HCV infection. In contrast, they had significantly higher random blood sugar value. Furthermore, diabetic patients with HCV infection had insignificantly lower HDL cholesterol, fasting blood glucose and HbA_1c level. They also had insignificantly higher systolic blood pressure, diastolic blood pressure and BMI when compared with diabetic patients who tested negative for HCV infection.
Conclusion: The study shows that there is a possible association between HCV infection and diabetes. Although HCV infection is associated with high random blood sugar values, the remaining metabolic and cardiovascular risk indicators show a favorable pattern. It is an intriguing finding as HCV infection has been shown to induce insulin resistance compounding diabetes course but in this case, it had a positive influence on the metabolic and cardiovascular risk profiles of diabetic patients.

Characteristics and outcome of patients with recurrent tuberculosis in diabetic patients

A. Soliman[1], M. Taha[1], N. Eldeberky[2]
[1] Cairo University, Medicine, Cairo, Egypt
[2] National Institute for Chest and Allergy, Chest, Giza, Egypt

Diabetes mellitus is an immunocompromised state that is shadowed infection with tuberculosis. Little data are available regarding characteristics of recurrence in those patients. Thirty eight registered diabetic patients with recurrent pulmonary TB between July 2002 and June 2007 were evaluated. Our aim was to determine 1) the characteristics, management and treatment outcome, 2) timing of the previous episode of TB, and 3) pattern of drug resistance in patients registered with recurrent smear-positive pulmonary TB. Retrospective data collection using TB registers and laboratory culture and drug sensitivity registers were examined. We found that there were 2 years or less between completing and re-starting treatment in 38 diabetic patients. Only 22 patients had sputum sent for culture and drug sensitivity tests. In 21 patients with cultures of Mycobacterium tuberculosis, 16 were fully sensitive, 3 had resistance to isoniazid and/or streptomycin, and 2 had resistance to isoniazid and rifampicin (MDR-TB). We can conclude that diabetic patients with recurrent TB had acceptable treatment outcomes, and most had fully sensitive organisms. Over half had recurrent TB 2 years or less after completing treatment. Ways to prevent recurrence need to be investigated and implemented in the field.

P-1382

Changes in glycosylated hemoglobin levels among managed care dyslipidemia patients with type 2 diabetes treated with niacin extended-release plus statin versus other lipid therapies

S. Balu[1], R. Quimbo[2], M. Cziraky[2], R. Simko[1]
[1] Abbott Laboratories, Global Health Economics & Outcomes Research, Abbott Park, USA
[2] HealthCore Inc., Health Outcomes, Wilmington, USA

Aim: To compare changes in glycemic regulation in patients with type 2 diabetes (T2D) and dyslipidemia treated with niacin extended-release + any statin (NER+S), ezetimibe + any statin (E+S), or statin monotherapy (SM) in a managed care setting.
Methods: Retrospective analysis of the HealthCore Integrated Research Database was performed on patients aged ≥18 years, diagnosed with dyslipidemia and T2D, minimum of 12-month pre- and post-index health plan eligibility, and newly initiating NER+S, E+S, or SM therapy between 1/1/2000-6/30/2006 (index date). Comparisons included mean change in HbA1c level and percent (%) of patients achieving < 7% HbA1c from baseline (12 months prior to index date) to 1-year post-index between the study cohorts. Multivariate regression analysis estimated change in HbA1c level after adjusting for differences in age, gender, prior cardiovascular disease (CVD), hypertension, baseline HbA1c, and pre- and post-index average daily dose of

insulin, oral and other injectable anti-diabetic medications (incretin mimetics).
Results: A total of 2,441 patients were identified, 204 NER+S, 343 E+S, and 1,894 SM. SM patients were significantly younger (51.7 ± 9.7 vs. 54.3 ± 9.4 years; p<0.05), comprised of fewer males (50.8% vs. 69.1%; p<0.05), and were less likely to have had prior hypertension (77.6% vs. 92.2%; p<0.05) and CVD (13.8% vs. 34.3%; p<0.05) versus NER+S patients. E+S patients had similar demography and were less likely to have had prior CVD (23.6% vs. 34.3%; p<0.05) versus NER+S patients. Percent change in average daily dose in oral and injectable anti-diabetic medication use from pre- to post-index period were found to be statistically non-significant between the study cohorts. Except for the E+S group, other treatment groups demonstrated an unadjusted mean reduction in HbA1c level from baseline to 1-year post-index (6.93±1.24 vs. 7.05±1.42: NER+S; 7.33±1.66 vs. 7.29±1.71: E+S; 7.39±1.77 vs. 7.6±2.03: SM). Multivariate analysis showed no statistical difference in the mean change of HbA1c levels between NER+S and other study cohorts (NER+S vs. E+S; p=0.1448 and NER+S vs. SM; p=0.3313). Post-index achievement of HbA1c goal < 7% was observed accordingly: NER+S (61.3%), E+S (51.0%), and SM (51.3%); p=0.0235.
Conclusions: Despite managed care patients with T2D and dyslipidemia receiving NER+S being older, sicker, and thus with potentially more risk factors, comparable changes in mean HbA1c levels and HbA1c goal attainment compared to E+S and SM therapies at Year 1 after initiating therapy even after adjusting for baseline HbA1c and anti-diabetic medication use were seen. Further research on long-term clinical and economic impact of different dyslipidemia therapies in patients with diabetes is warranted.

[2] *Japanese Red Cross Medical Center, Laboratory Medicine, Tokyo, Japan*
[3] *Automobile Federation Health Insurance Society, Industrial Physician, Tokyo, Japan*
[4] *Bnyu Pharmaceutical CO. LTD. Health Management Center, Industrial Physician, Tokyo, Japan*

Objectives: Serum lipid disorder is one of important risk factors that contribute to atherosclerosis. It is shown that postrandial hypertriglyceridemia has a great influence on it. Recently there are a few reports that serum apolipoprotein (ApoB-48) levels reflect serum triglyceride levels after a meal. The aims of this study are to measure fasting serum Apo B-48 levels in the patients with Type 2 diabetes mellitus and to evaluate the relationship between them and diabetic control marker.
Subjects and methods: We measured serum fasting levels of total cholesterol, HDL-cholesterol, LDL-cholesterol, triglyceride (TG), Apo-B48, blood sugar, and hemoglobinA1c (HbA1c) in 579 patients (346 men, 233 women; age 65.2±12.4 years old) with Type 2 diabetes mellitus. ApoB-48 values were measured by chemiluminescence enzyme assay.
Results: We classified the whole of patients into L group with Apo-48 under 13 μg/ml and H group with more than 13 μg/ml, based on a report of Yamashita et al that defined as abnormal when the value exceeds 13 μg/ml, and compared HbA1c and serum triglyceride levels between both groups. Four hundred seventy-four patients were in the L group, 105 patients were in the H group. HbA1c levels were 6.9+1.1 %, 7.3+1.4%, and serum TG levels were 110.5±63.6 mg/dl, 277.3±141.2 mg/dl respectively. Both HbA1c and serum TG levels were significantly higher in the H group than in the L group (P <0.01). We analyzed in patients with normal TG levels under 150mg/dl. Three hundred ninety-two patients were in the L group and 13 patients were in the H group. HbA1c levels were 6.8±1.0%, 7.5±1.5% (P <0.01), and serum TG levels were 89.5±30.1mg/dl, 102.1±26.3 mg/dl (P <0.01)respectively. Both levels were significantly higher in H group.
Discussion: In the whole ApoB-48 high group of patients, there was a lot of both glucose impairment and lipid disorder. In the patients with normal triglyceride levels, a similar tendency was shown. This is suggested that we need to control serum triglyceride levels strictly as well as glycemic contol for prevention of atherosclerosis in the diabetic patients, especially in the patients with ApoB-48 high level.

P-1384

Prevalence of suspected hemoglobin variants amongst patients in the Diabetes Centre at Tan Tock Seng Hospital

M. Jong[1], B. Lim[2]
[1] *Tan Tock Seng Hospital, Dept of Endocrinology, Singapore, Singapore*
[2] *Tan Tock Seng Hospital, Dept of Endocrinology/ Operations Support Services, Singapore, Singapore*

Introduction: Glycated hemoglobin (gHb), measured as hemoglobin (Hb)A_{1c}, provides a common means for assessing long-term glycemic control in patients with diabetes mellitus (DM) and it correlates well with the risk of developing DM-related complications. The number 1c following HbA represents the order in which this hemoglobin is detected on chromatography. The presence of Hb variants can adversely affect the accuracy of HbA_{1c} measurements, providing misleading in formation regarding the state of glycaemic control in the patient. However, the extent of Hb variants remains unclear.
Objective: This study aims to determine the prevalence of suspected Hb variants amongst DM patients from the DM Clinic at our centre.
Methodology: We undertook a retrospective review of patients who had HbA_{1c} test done in the Diabetes Centre at Tan Tock Seng Hospital from 15 May 2008 to 28 February 2009. The inclusion criteria were any patient with DM who had a Point-of-Care HbA1c performed using the fully automated D-10™ Hemoglobin Testing Analyzers from Bio-Rad Laboratories. This test utilizes the High Performance Liquid Chromatography (HPLC) method for HbA_{1c} analysis.
Patient variables such as age, gender, and racial categorizations were captured and the chromatogram generated by the analyzers were obtained. The chromatogram displays the possibility of Hb variant(s) by showing abnormal peaks such as 'unknown' peak after A_0, variant - window peak after A_0, S-window, 'unknown' peak before A_{1b}, 'unknown' peak before A_{1a} of >2%, 'unknown' peak between A_{1a} and A_{1b} of >2% or abnormal increase in HbF.
Results: 3171 patients' HbA_{1c} data were reviewed. The range of HbA1c was 2.1% - 17.7% and mean HbA1c was 8.2%. 53 % were females and the mean age of the patients were 62, and 69% were Chinese,14% were Malay, 12% Indian and 4% of other races.
5.8% of patients had chromatograms with additional or abnormal peaks, indicating the possible presence of Hb variants.
Discussion: This preliminary study suggests that the prevalence of suspected Hb variants among patients with DM in our practice is significant. Most HPLC systems are not able to resolve additional peaks in their chromatograms which may result in results which do not correlate well with the average glycaemic control over the preceding weeks. This has implications for clinicians who are always pushing to get the HbA1c to target. If the Hb variants are contributing to under-reading, we would be too complacent in our management exposing patients to excessive risk. If the variants were contributing to over-reading, we would potentially be exposing patients to the harm of hypoglycaemia. Further studies will be required to confirm the suspected Hb variants present in each chromatogram and the effects of each Hb variant on the %HbA_{1c} value determined by analyzers.

Glycated albumin is affected by hemoglobin concentration and body mass index in adult normal glucose tolerance

I. Shimizu[1], A. Ochi[1], Y. Hara[1], N. Kukida[1]
[1] *Ehime Prefectural Central Hospital, Diabetology, Matsuyama, Japan*

Aims: HbA1c measurement is usually used to reflect time-averaged glycemic control, because HbA1c has been used in a number of studies on glucose control and diabetic complications as a surrogate marker for risk; however, the assays have not been standardized, and commercial laboratories use different methods. Moreover, the amount of HbA1c reflects the glycemic control of a patient during the 6- to 8-week period before the blood sample was obtained. Glycated albumin (GA) is a glycemic control marker, and the assays have been standardized by enzyme assay. GA levels should provide useful information on

glycemic control when monitoring the effects of therapy, because GA reflects the glycemic control of a patient during a 2-week period; however, GA is also influenced by the turnover of serum albumin. To further elucidate the influence on GA, we investigated the influence factors of GA in adult normal glucose tolerance.

Methods: A 75g oral glucose tolerance test was performed using 719 dry-dock subjects without a past history of diabetes. Of those, 534 (male: female = 330:224) with normal glucose tolerance (NGT) were enrolled. The mean subject age of NGT was 51.3 ± 8.6 years, mean body mass index (BMI) 23.2 ± 3.2 kg/m^2, mean HbA1c 5.0 ± 0.3 % and mean GA 14.5 ± 1.2 %.

Glycated albumin was measured with reagents from Asahi Kasei Pharma (Luccia GA-L enzymatic assay; AKP, Tokyo, Japan). Student's t test, analysis of variance (ANOVA), or the Chi-squared test was used where indicated.

Results: Mean fasting plasma glucose (FPG) was 93.8 ± 7.0 mg/dl, mean post-loading plasma glucose one hour later was 135.7 ± 36.3 mg/dl, and mean post-loading plasma glucose two hours later was 106.3 ± 17.9 mg/dl. Fasting serum immunoreactive insulin of NGT was 6.5 ± 3.7 IU/l. In NGT, GA correlated with age (R=0.1807), HbA1c (R=0.1614), BMI (R=-0.3178), IRI (R=-0.2649), HOMA-IR (R=-0.2532), HOMA-b (R=-0.2649), albumin (R=-0.0941), and hemoglobin (R=-0.4092).

Multivariate stepwise linear regression analysis was performed to identify independent determinants of GA levels. In NGT, multivariate stepwise linear regression analysis indicated that hemoglobin (p<0.0001), BMI (p<0.0001), HbA1c (p=0.0303), age (p=0.0004), HOMA-b (p=0.0074), and post-loading 1-hour PG (p=0.0158) were independent determinates of GA. In IGT, multivariate stepwise linear regression analysis indicated only HbA1c (p<0.0001), BMI (p=0.0162). Also in DM, multivariate stepwise linear regression analysis indicated fasting plasma glucose and post-loading 2-hour PG.

Conclusion: Hemoglobin and BMI were more influencing factors than age or PG in adult normal glucose tolerance.

P-1386

Point prevalence of type 2 diabetes mellitus in a Nigerian urban tertiary hospital

U.M. Amaechi[1], P.C. Obi[1], S. Iwuala[1], A.E. Ohwovoriole[2]

[1] Lagos University Teaching Hospital, Department of Medicine, Lagos, Nigeria

[2] College of Medicine University of Lagos, Department of Medicine, Lagos, Nigeria

Background: Type 2 diabetes mellitus (DM) is assuming epidemic proportions worldwide. Its contribution to clinical workload and healthcare cost is enormous and varies from country to country. DM may present to medical, surgical, obstetric/gynaecological or other disciplines. Previous studies have tended to limit the prevalence of DM admission to medical wards.

Aim: To assess the burden of DM to in-patient care in an urban teaching hospital in Nigeria.

Methods: We surveyed on a particular day, all adult patients on admission in a 700-bedded hospital. Information obtained about each patient included age, sex, indication for admission and duration of hospital stay as at time of survey. Paediatric and psychiatric wards were excluded. Results are presented as frequencies (%) and mean (SD). Level of statistical significance is set as $p \leq 0.05$.

Results: A total of 260 patients were on admission as at the time of survey, consisting of 154 (59.2%) females and 106 (40.8%) males. The mean age of the patients was 40.1 (15.5) years. The patients with DM were significantly older than the patients without DM {58.2 (13.9) v 37.8 (14.1), p=0.0000}. The mean duration of hospital stay for all the patients was 28.3 (53.5) days. The overall point prevalence of DM was 30 (11.5 %) made up of 20 (66.7%) females and 10 (33.3%) males. The prevalence of DM patients in the medical wards was 18 (28.1%) while in the other wards the prevalence rates were surgical 6 (5.4%); gynaecology/obstetrics, 4 (7.3%); and accident/emergency (A/E) wards, 2 (7.1%). Diabetes mellitus foot syndrome (DMFS) constituted 9 (30.0 %) of all the DM patients. Three (10.0 %) of the patients had gestational diabetes. The mean duration of stay on admission for the diabetes patients was 13.4 (14.2) days while for non DM patients, it was 30.3 (56.3) days, p=0.1.

Conclusion: The study shows that DM constitutes a major drain on healthcare resources in urban Nigeria. DMFS has the highest prevalence amongst diabetes admissions. The reasons for the high rate of diabetes admissions require further studies.

P-1387

Pattern of admissions in a tropical endocrine in-patient service in Lagos, Nigeria

O.U. Igwe[1], H. Abdulrahman[1], O.A. Fasanmade[1], A.E. Ohwovoriole[1]

[1] College of Medicine University of Lagos, Department of Medicine, Lagos, Nigeria

Background: Diabetes mellitus is the commonest endocrine disorder. It is treated by both endocrinologists and diabetologists. However, we do not know how much of the endocrinologist's time is devoted to diabetes as compared to other medical and endocrine disorders.

Aim: To determine the contribution of diabetes mellitus and related disorders to the in-patient work-load of a medical endocrine service in Nigeria.

Method: We analysed the Unit records for in-patients in a medical endocrine unit over an 18-month period. The information retrieved from the records included age, sex, diagnosis, date of admission, date of disposal and outcome. Results were presented as means (SD) and frequencies (percentages). The level of statistical significance is set at $p = 0.05$.

Results: A total number of 275 patients were admitted during the period of study. Of these, 137 (49.8%) were males and 138 (50.1%) were females. Their mean age was 40.0 years. Endocrine cases accounted for 78 (28.4%) while the non-endocrine cases accounted for 197 (71.6%) of the patients.

Of the endocrine in-patient admissions 70 (91.0%) were for diabetes mellitus. Thirty-six (51.4%) of them were male and 34 (48.6%) werefemale. The mean duration of admission for all patients was 17.8 days, with a range of 1 to 106 days, while the mean duration of stay for diabetic patients was 19.3 days.

The burden of diabetic admissions was 7 (10%) for hyperglycaemic emergencies, 24 (34.3%) for diabetes mellitus foot syndrome, and 39 (55.7%) for other diabetic conditions.A total number of 65 (24%) deaths were recorded. Of these, 7 (9.9%) were diabetic.

Conclusion: Tropical endocrine practice consists of about 50% of general medical problems and about 50% of general endocrine disorders. Of the endocrine disorders diabetes mellitus occupies a preeminent position. It accounts for a large proportion of the disabilities and mortality among endocrine in-patients. Many of the causes of such deaths are preventable. This calls for preventive measures to be instituted.

P-1388

Are we managing inpatient hyperglycemia appropriately?

J.T. Heshka[1], J.C. Malcolm[1], A.J. Forster[1]

[1] University of Ottawa, Department of Medicine, Ottawa, Canada

Background: Improving diabetes control among inpatients is a priority. Diabetes affects up to 40% of hospitalized patients and is associated with poor inpatient outcomes. To date research in the non-critically ill patient population has focused primarily on glycemic control and short-term inpatient outcomes as opposed to process of care and long-term outpatient outcomes.

Objectives: The objectives of this study were to 1) determine whether diabetic care was appropriate for a representative sample of medicine and surgery patients, 2) describe important processes of care for diabetic patients, and 3) determine whether appropriate diabetic care was associated with better post-discharge outcomes.

Study Design: This study was a secondary analysis of the Ottawa-Outcomes After Hospitalization (OATH) Study, a cohort study designed to assess the association of continuity of care with patient outcomes.

Setting: The Ottawa Hospital, a university-based multi-campus hospital located in Ottawa, Ontario, Canada.

Patient Population: 167 medical and surgical patients with type 1 or type 2 diabetes identified in the medical record.

Interventions: Patients were interviewed and their charts reviewed to identify demographics, diagnoses, co-morbidities, functional status and in-hospital diabetes management. Appropriateness of diabetes management was determined by three physicians using a review process guided by implicit and explicit criteria. We performed structured telephone interviews at 1, 3, and 6 months to identify repeat emergency visits, readmissions, and deaths. Univariate and multivariate analyses were used to assess whether appropriateness of diabetes management was associated with post-hospital outcomes (time to

emergency room visit, rehospitalization or death).
Results/Outcomes: 27% of patients were judged as having inappropriate in-hospital diabetes management. Patients with inappropriate care had higher mean blood glucose levels [11.9 mmol/L (10.1-15) vs 8.5 mmol/L (7.3-11.1), p<0.01], more hyperglycemia (blood glucose >11.1mmol/L) [median 51% (IQR 35-72) vs 40% (IQR 14-67), p<0.01], and less frequent adjustment of treatment in response to hyperglycemia (7% vs 29%, p<0.01). 57% (CI 49-64%) of patients had at least one post-discharge outcome, but a diagnosis of type 2 diabetes was the only baseline factor associated with increased post-discharge outcomes. In multivariate analyses, there was a trend towards the delivery of inappropriate care in hospital with time to post-discharge adverse outcome (OR 1.4, p=0.1).
Conclusions: Based on our results, over one quarter of non-critically ill medical and surgical patients have inappropriate in-hospital diabetes management. Further research is needed to determine the association between in-patient diabetic management and post-discharge outcomes.

No conflict of interest

P-1389

Perceptions of sliding scale insulin regimens amongst medical trainees are not reflected in diabetes management in hospital

K. Helmle[1], A. Edwards[1]
[1] University of Calgary, Department of Medicine, Calgary, Canada

Background: Improved glycemic control in hospitalized patients favourably impacts outcomes and reduces complications in those with established or newly-diagnosed diabetes. In-hospital glycemic targets are rarely achieved and increase morbidity and length of stay. Diabetes management in teaching hospitals is often left to medical trainees who frequently use sliding scale insulin (SSI) regimens. Unfortunately, SSI protocols are reactive and often result in erratic glycemic patterns. Regimens using basal insulin prescription may be more effective at achieving glycemic control but are infrequently used.
Aim: To determine medical residents' attitudes to inpatient diabetes management and SSI use, and whether these perceptions are reflected in practice.
Methods: 1. Questionnaires were distributed to Internal Medicine residents on medical teaching units (MTUs) to determine their comfort with treating diabetic patients and opinions on SSI prescribing practices. 2. A retrospective record audit of diabetes management on the MTU over a 3 month period, concurrent with the questionnaire survey was undertaken.
Results: 40/70 questionnaires were completed. 85% of residents were "comfortable" or "very comfortable" managing uncomplicated diabetes in hospital. Substantially fewer residents feel the same managing diabetic patients who were not eating and pre or post-operative (58% and 38%, respectively). SSI was reported as the most frequently prescribed regimen by 73% of residents with only 10% "often"choosing a basal/bolus protocol. 30% of residents felt SSI was "often" used appropriately. 40% of residents felt recommended glucose targets were "rarely met" with the current prescribing practices. Reasons for selecting SSI for diabetes management were recorded.
134 diabetic patients were admitted to the MTU (of 420 total admissions). Over 84% of diabetic patients received SSI (mean duration of SSI=6.9days). The SSI protocol was adjusted once, on average, prior to discharge, and 43% of prescriptions were never adjusted. 63% of patients had an order for basal insulin. Average length of stay was longer if the patient was prescribed SSI (12.0 days) vs all diabetic patients (11.0 days).
Conclusions: Residents feel comfortable managing inpatient hyperglycemia, are aware of glycemic targets and are familiar with different insulin formulations. Residents recognize that SSI are utilized often, though inappropriately and result in poor glycemic profiles. Evaluation of admissions to the MTU revealed that the prescription of SSI exceeds residents' predictions, and that SSI doses are adjusted very infrequently. This may contribute to poor glycemic control while in hospital and appears to negatively impact length of stay.

Impact of an intensive insulin therapy protocol in the blood glucose control of diabetic patients undergoing cardiovascular surgery

H. Sanabria[1], V.I. Martinez[2], M.L. Pomares[3], A. Matrone[3], N.C. Ferrari[3], S. Gonzalez[3], R. Sanchez[3], E.P. Gurfinkel[1], G. Bozovich[1], R. Favaloro[4]
[1] Favaloro Foundation University Hospital, Clinical Cardiology, Buenos Aires, Argentina
[2] Favaloro Foundation University Hospital, Nursing, Buenos Aires, Argentina
[3] Favaloro Foundation University Hospital, Metabolic Unit, Buenos Aires, Argentina
[4] Favaloro Foundation University Hospital, Cardiovascular Surgery, Buenos Aires, Argentina

Background and aims: Hyperglycemia is a predictor for the development of complications in postoperative period of diabetic patients undergoing cardiovascular surgery. Appropriate glucose control in postoperative period would reduce hospital mortality and morbidity. We evaluated a specific protocol of intensive insulin therapy. The primary aim was to determine the impact on the metabolic control and the secondary aim was to evaluate death and morbidity in these patients.
Materials and methods: Two cohorts of inpatients were evaluated. A cohort (control group) of 212 patient with diabetes undergoing cardiovascular surgery from June of 2004 to June 2005 with blood glucose control without algorithm nor objective of control predetermined, and a cohort (intensive insulin therapy group) of 347 patient with diabetes undergoing cardiovascular surgery from June 2006 to June 2008 with objectives of strict blood glucose control (glucose level < 120 mg/dl) through a specific protocol using continuous intravenous insulin infusion in the first 48 hours of the postoperative period and later subcutaneous insulin until discharge.
Results: The intensive insulin therapy group had higher prevalence of male, obesity and higher scores Euroscore. The cardiovascular bypass time was longer compared with the control group. The mean blood glucose level decreased significantly in the cohort intensified in intensive care unit (189,51 +/- 30,97 vs 132,19 +/- 20,52 ; p 0,05) and during the inpatient clinic (183,49 +/- 42,7 vs 141,09 +/- 19,99; p 0,05). There was no significant difference between the two groups in hospital mortality (4, 7% vs 6,3%; p: ns), mediastinitis (4, 7% vs 5,2%; p: ns) as other complications, even after adjustment for Euroscore.
Conclusions: The protocol of intensive insulin therapy was effective in obtaining a better metabolic control in patients with diabetes undergoing cardiovascular surgery. However we could not show any reduction of postoperative complications during the intensive treatment, possibly due to the smaller population. These observations must be validated in a larger population.

The triple - B (Basal-Bolus-Booster) subcutaneous insulin regimen: a user friendly protocol for management of in-hospital hyperglycaemia

A. Harding[1], N. Perera[1], K. Williams[1], V. Carleton[1], L. Simmons[1], L. Molyneaux[2], M. Constantino[1], M. McGill[1], E. Chua[2], S. Twigg[2], G. Ross[1], D. Yue[2]
[1] Royal Prince Alfred Hospital, Diabetes Centre, Camperdown NSW, Australia
[2] Discipline of Medicine University of Sydney and Royal Prince Alfred Hospital, Diabetes Centre, Camperdown NSW, Australia

Aims: Hyperglycemia in hospitalised patients is common, a problem aggravated by intercurrent illness, interference by investigations, changes in oral intake and lack of time and understanding by health professionals. Sliding scale insulin remains the most common treatment, with all its inherent problems. The real challenge is to find a protocol which is possible for hospital staff to follow logistically and safely. We piloted and systematically evaluated a Triple B (Basal-Bolus-Booster) insulin regimen.
Method: Basal insulin (glargine, 0.2 unit/kg/day for Type 1, cardiac or body weight<60kg patients, 0.25 unit/kg/day for others) was given in the evening. Bolus insulin (aspart or lispro 0.2-0.25units/kg/day) was given in 3 equally divided pre-meal doses but withheld in patients not eating full meals. Booster insulin (aspart or lispro) was given up to 4 times daily according to 4 daily BGLs performed at pre-specified times. Inpatients with existing diabetes (n=42, 98% Type 2) were treated for a median of 5 days (IQR 3-7). Their initial HbA1c was 10.4±2.4% (mean, SD) and their in-hospital glycaemic control to require commencement or substantial adjustment of insulin therapy. Another 171

patients were sufficiently hyperglycaemic but not included due to short hospital stay or concurrent conditions thought not suitable at this pilot phase. Patients were allowed to remain on oral anti-hyperglycaemic agents. Education about the Protocol, typically in 1-2 sessions of 15 minutes, was given to the ward staff. A member of the study team evaluated (i) compliance with the protocol {by comparing the number (n) of actual BGL measurements and insulin injections with the number potentially required, adjusted for duration of stay and absence due to investigations} (ii) the safety of the protocol {% of BGL at pre-specified times <4 or >15mmol/L} and (iii) the efficacy according to the mean daily BGL.
Results:

	Compliance			Safety	
	BGL	Basal&Bolus	Booster	BGL<4	BGL>15
Actual (n)	20+7	19+7	9+6	median 0%	median 9%
Potential (n)	21+8	20+7	15+8	mean 2.2%	mean 17%

The BGL (mmol/L, mean±SD) on successive days were: 13.2±4.7, 11.9±3.8, 11.1±2.9, 10.4±3.2, 11.2±3.1, 10.4±3.2, 10.8±2.9 (t_{trend}, p=0.01). There were no hypo or hyperglycaemic crises requiring withdrawal from the protocol.
Conclusion: Treatment of acutely ill diabetic inpatients with this Triple B regimen resulted in significant improvement in glycemic control with minimal adverse events. Staff were able to implement the protocol after just a modest amount of education with good compliance in determining BGLs and in giving insulin at pre-specified times and dosages. However, they were hesitant to give additional insulin to correct for hyperglycaemia. Further education and the use of the Triple B acronym emphasising the Booster component would hopefully improve this. The Triple B regimen seems to be widely applicable, safe and efficacious.

Intensive perioperative glycemic control with glargine in a group of perioperative patients with type 2 diabetes mellitus

N. Li[1], W. Li[1], H. Wang[1]
[1] Peking Union Medical College Hospital, Endocrinology, Beijing, China

Aims: Intensive perioperative glycemic control of patients with type 2 diabetes mellitus is crucial for the prognosis of surgical operation, especially for those who need to be fasting during pre- and post-operative period. Insulin glargine is the most possible replacement of basal insulin because of its surgeless time-action curve Our study is to explore the possibility and advantages of insulin glargine therapy in the perioperative glycemic control of type 2 diabetic patients.
Methods: We retrospectively analyzed the clinical data of 16 type 2 diabetic inpatients treated with insulin glargine (study group) and 16 type 2 diabetic inpatients treated with the conventional intensive insulin therapy (control group). Several days (usually 1~4 days) before the operation, each patient of study group accepted the intensive therapy including insulin glargine at 7 am and regular insulin before each meal, whereas on the operation day, the preoperative dose of insulin glargine was applied only. After the operation, insulin glargine was still applied as basal insulin and its dose was adjusted according to the value of fasting blood glucose. In the control group, patients accepted the intensive insulin therapy including NPH injection at bedtime and regular insulin before each meal. After the operation the continuous intravenous insulin was applied instead of the subcutaneous injection in the control group.
Results: The fasting blood glucose values of diabetic patients in the study group on the operation day and the first 3 postoperative days were 7.5±1.8mmol/l and 8.2±1.8mmol/l, 7.6±1.6mmol/l, 7.2±1.1mmol/l, respectively; while 9.0±2.8mmol/l and 10.4±2.4mmol/l, 8.8±2.7mmol/l, 9.0±2.0mmol/l in the control group, respectively. The fasting blood glucose values in the study group were significantly lower than in the control group on the postoperative day 1 and day 3 (p=0.02 and 0.01, respectively). No hypoglycemia events occurred and all wounds healed well in both groups.
Conclusion: With satisfying fasting blood glucose level and possibly fewer episode of hypoglycemia, perioperative glycemic control by insulin glargine in type 2 diabetic patients is proved safe, effective and convenient.

Is analogue insulin better in hospitalized patients? A non-intervational investigator initiated study in a tertiary care hospital in India

A. Bhattacharyya[1], M. Sehgal[1], J. Sandeep[1], B.S. Narendra[1], R. Menaka[1]
[1] Manipal Hospital, Dept of Diabetes & Endocrinology, Bangalore, India

Background: Glycaemic control plays a paramount role in outcome of the patients admitted to the hospital. We have documented before that diabetes control in hospitalized people is not good in general.
Aims and objectives: The primary objective of the study was to find out whether analogue Insulin is better than conventional in hospitalized patients. Secondary objectives were to compare incidence of hypoglycaemia, duration of stay and Insulin dose.
Materials and methods: Patients were stared on Insulin as required in routine management, every alternate case was started with conventional (regular human, NPH Insulin and premix) and analogue (Aspart, Detemir and premix Aspart) Insulin. For the purpose of this study the target blood glucose were – [80-140 mg% on IV Insulin/GIK regimen and pre-meal 80-120, postmeal and bedtime 120-180 on SC insulin]. We defined 'good control' as 80% or more blood glucose results within the target range, 'sub-optimal control' as 40-80% and rest as 'poor control'. While on SC Insulin, if the control was good for two consecutive days the Insulin regimen was downgraded, i.e. two doses of premix Insulin, be it conventional or analogue. On the other hand if control was poor or if any two sugar value in a day were above 300 mg%, rescue regimen, i.e. three doses of premix Insulin were used. Treatment satisfaction was assessed with DTSQ at the time of discharge.
Results: The current cohort is the first 70 cases (34 conventional, 36 analogue) from the ongoing project. Mean age, sex, duration of Diabetes, sugar and HbA1C at admission did not vary in the two groups. Two received IV insulin (one in each arm, control was good in both), 32 received GIK regimen for an average period of 30 hrs (16 in each arm: 9 of the 16 in the conventional arm had good, 7 suboptimal control while 12 were in good control with analogue Insulin and the rest 4 suboptimal).Average fasting glucose on SC Insulin was 139 with conventional and 140 with analogue (P=NS) Insulin, average premeal glucose was 178 and 157 mg% respectively (P 0.001). Average postmeal glucose was 225 with conventional and 171 mg% with analogue (P 0.0001). In 17% patient in the analogue group mean blood glucose was <140mg while none with conventional. There was no difference in the daily requirement short acting Insulin in the two groups but average requirement of basal Insulin was less with analogue Insulin (13 vs 18 unit, P 0.003). There were 3 cases of mild hypoglycaemia in 3 patients (2 with analogue). Rescue regimen was used in 10 with conventional as opposed to 1 with analogue, the similar number for downgrading was 18 and 14 respectively. Treatment satisfaction did not vary in the groups (DTSQ 25 vs 27, P NS).
Conclusion: Our data suggests analogue Insulin could be better in people admitted to hospital, we need a bigger cohort to substantiate our observation.

Efficacy of a novel nurse driven multidisciplinary protocol for transition from intravenous to subcutaneous insulin after cardiac surgery

P. Terry[1], S. Siu[1], K. Salak[1], D. Lee[1], H. Kamran[2], E. Blanton[3], V. Tak[1], W. Ko[1]
[1] SUNY Downstate Medical Center, Surgery, Brooklyn NY, USA
[2] SUNY Downstate Medical Center, Medicine, Brooklyn NY, USA
[3] SUNY Downstate Medical Center, College of Medicine, Brooklyn NY, USA

Aim: The use of continuous insulin infusion (CII) for glycemic control for at least 3 days after cardiac surgery reduces morbidity and mortality. We aim to study the efficacy of a novel protocol for subcutaneous (SQ) insulin administration in a basal/prandial regimen in cardiac surgery patients, to transition from CII to SQ insulin at the first oral feeding after surgery, with a target blood glucose of a daily mean of ≤ 150 mg/dL. The protocol is novel in that it is driven by usual nursing staff and unspecialized physicians.
Methods: In the protocol, the initial dose of basal insulin is based on the hourly CII rate required for glycemic control during 6 hours prior to transition. Our CII protocol target glucose is 120 mg/dL. Prandial insulin is based on patient weight. Correction supplemental insulin dose is specified. Blood glucose is obtained at mealtimes, 10pm and 3am. A simple algorithm is used once every morning to adjust insulin doses according to point of care blood

glucose results from the preceding 24 hours. We retrospectively analyzed data in 59 consecutive cardiac surgery patients enrolled in the Protocol to evaluate efficacy in achieving a target blood glucose ≤ 150 mg/dL for 5 days after cardiac surgery.

Results: 32 diabetics and 27 nondiabetics were studied. Diabetics had a greater BMI than non diabetics (29.8 vs 26.0 kg/m^2, p<0.004). The mean duration of CII was 26.6 h (range:7-74, SD:12). 71% of patients extubated the day after surgery received SQ insulin within 6 hours of extubation.

The mean CII rate for 6 hours prior to first oral feeding was similar in diabetics and nondiabetics (2.2 vs 2.4 U/h) as were the mean initial doses of basal insulin (35.1 vs 30.2 U) and mean daily basal insulin doses for protocol days 1-5 (34.7 vs 35.3 U) respectively. The mean prandial insulin dose was 6.0 Units in nondiabetics and 6.5 Units in diabetics patients, p=ns for all.

Mean daily blood glucose for all patients for up to 5 days after surgery was 128.8 mg/dL. This was higher for diabetics than nondiabetics on days 1-5 (143 vs 117 mg/dl), day 1 (144.6 mg/dL vs 124.6) and day 2 (144.2 mg/dL vs 121.2 mg/dL), p<0.05 for all.

80% of patients achieved the 5-day protocol target of mean daily blood glucose of ≤ 150 mg/dL. This was achieved in significantly more nondiabetics than diabetics: 97% vs 59 on days 1-5; 94% vs 63% on protocol days 1 and 2. (p<0.05)

Discussion: Our protocol is effective for glycemic control in cardiac surgery patients. Diabetics require a higher initial dose of SQ basal insulin at transition from CII than predicted solely from the CII infusion rate required prior to beginning oral feeding. We incorporated this interesting finding into a modified protocol; an efficacy study of this is currently underway.

Incretin therapies

P-1395

Safety of vildagliptin in patients with mild renal impairment and patients with normal renal function: GALIANT study

B. Francis[1], D. Purkayastha[1], M.A. Banerji[2]

[1] Novartis Pharmaceuticals Corporation, Development & Medical Affairs Cardiovascular Medicine, East Hanover, USA

[2] SUNY Downstate Medical Center, Division of Endocrinology, Brooklyn, USA

Aim: To assess the safety profile of vildagliptin (Vilda) compared to thiazolidinediones (TZD) as add-on to metformin (MET) in patients with type 2 diabetes (T2DM) with renal impairment (RI) and with normal kidney function.

Methods: Adverse event (AE) data from a randomized, 12-week, open-label study comparing Vilda 100 mg and TZD (agent and dose at the investigators' discretion) as add-on therapy in pts with T2DM inadequately controlled (HbA_{1c}: 7–10%) on a stable dose of MET (≥1000 mg/day) monotherapy were analyzed (GALIANT Study). Glomerular filtration rate (GFR) was calculated by the MDRD method (cutoff of >50 to ≤80 ml/min/1.73^2 defined as mild RI).

Results: Of 2627 pts randomized in a 2:1 ratio (Vilda + MET: n=1756; TZD + MET: n=871), 1278 pts in the Vilda + MET and 635 in the TZD + MET groups had normal renal function (mean duration of T2DM: 4.9 years both groups; mean GFR: 136.4 and 135.5, respectively), and 463 in the Vilda + MET and 230 in the TZD + MET groups had mild RI (mean duration of T2DM: 5.6 years both groups: mean GFR: 71.3 and 70.7, respectively). The number of pts with moderate RI (n=14) was too small to allow for a meaningful interpretation. The incidence of the most common AEs (>2% of pts in any treatment group) was:

	Normal renal function		Mild RI	
	Vilda + MET n=1278	TZD + MET n=635	Vilda + MET n=463	TZD + MET n=230
ALL	40.1	34.8	37.8	40.4
Headache	4.4	2.2	3.2	2.2
Dizziness	2.0	2.2	2.8	3.0
URI	2.0	1.4	1.3	3.0
Nausea	2.9	2.0	2.8	2.2
Diarrhea	2.6	2.5	1.5	2.2
Peripheral edema	0.5	2.0	0.6	2.6
Fatigue	1.6	1.7	2.2	0.9
Rash	1.4	0.3	2.2	0
Arthralgia	0.7	1.1	1.1	2.2
Vomiting	0.9	0.8	1.1	2.2
Bronchitis	1.3	1.1	0.9	2.2

A higher incidence of headache and rash was noted in both Vilda + MET groups, while those with mild RI receiving TZD + MET experienced a higher incidence of peripheral edema and URI. The rash observed was mild and resolved while receiving study drug. For 18 and 10 pts with rash receiving Vilda + MET with normal renal function and mild RI, respectively, rash was reported as possibly related to study drug in only 2 (0.2%) pts and 2 (0.4%) pts, respectively. For pts with normal renal function, 26 (2.0%) in the Vilda + MET and 21 (3.3%) in the TZD + MET groups discontinued due to AEs, while in the groups with mild RI 13 (2.8%) and 7 (3.0%), respectively, withdrew due to AEs. A slightly higher incidence of serious AEs was noted in both TZD + MET groups (normal: 2.4%; mild RI: 3.0%) compared with the Vilda + MET groups (normal: 1.6%; mild RI: 2.4%). For pts with mild RI and normal transaminase levels at baseline, there were no significant imbalances noted at the end of the study between the Vilda + Met and TZD + Met groups (ALT: 3.1% and 1.1%, p=0.2365; AST: 3.0% and 1.4%, p=0.2831, respectively).

Conclusion: The safety profile in pts with mild RI was similar to that noted in pts with normal renal function receiving Vilda + MET or TZD+ MET.

[2] F. Hoffmann-La Roche Ltd, Drug Metabolism and Pharmacokinetics, Basel, Switzerland

[3] Ipsen Pharma, Pharma Division, San Feliu, France

[4] University Medical Center, Department of Cell Physiology and Metabolism, Geneva, Switzerland

Aims: Evidence suggests that incretin therapies may have protective effects on ß-cell function, which is progressively lost in Type 2 diabetes (T2D). Here, we evaluated the effect of the novel, long-acting human GLP-1 analogue taspoglutide (R1583) on islet physiology in Zucker diabetic fatty (ZDF) rats, a model of T2D.

Methods: Quantitative analysis of islet morphology and in situ pancreas perfusion were performed to assess islet structure and function after single application of taspoglutide (1 mg, sc, formulated to mimic human exposure) or vehicle to 6-week-old male ZDF rats. Pancreata harvested from 9-week-old animals after 3 weeks of treatment were stained with specific antibodies for insulin (ß-cells) and glucagon (a-cells).

Results: Treatment of ZDF rats with taspoglutide protected islet integrity as demonstrated by 1) reduced number of abnormally enlarged islets [area of islet section (µm^2) >120,000: 9.8% (vehicle) vs 3.7% (taspoglutide); >50,000 and <120,000: 17.6% (vehicle) vs 10.8% (taspoglutide); mean islet area (µm^2): 43,692±2356 (vehicle) vs 23,680±1464 (taspoglutide), p<0.0001. 2) prevention of loss of insulin-staining intensity [pixel intensity: 83±11.3 (vehicle) vs 100.4±1 (taspoglutide), p<0.0001; with relative change from prediabetic 5-week old ZDF rats of -18.5% (vehicle) and -4.1% (taspoglutide)]. 3) prevention of a-cell invasion from islet periphery to core [% invading a-cells to total a-cells: 26.5±1.2 (vehicle) vs 10.6±0.7 (taspoglutide), p<0.001; with relative change from prediabetic 6-week-old ZDF rats of 340% (vehicle) and 76.5% (taspoglutide)]. Pancreas function was improved in 9–10-week-old ZDF rats treated with taspoglutide, as measured by levels of glucose-stimulated insulin secretion by perfused pancreata in low (2.8 mM) or high (16.7 mM) glucose concentration. In particular, basal insulin secretion at 2.8 mM glucose was reduced [88.8±8.6 (vehicle) vs 18.7±7.6 ng/ml (taspoglutide), p<0.01] and Phase I + Phase II AUC were normalized [406±42 (vehicle) vs 214±44 ng/ml•min (taspoglutide), p<0.05].

Conclusion: Single administration of taspoglutide to ZDF rats protected islet architecture and limited decline in islet function. Preservation of islet integrity and ß cell function with taspoglutide might provide substantial benefits in preventing progression of T2D.

P-1397

Two years of treatment with liraglutide, a human GLP-1 analogue, offers sustained and greater reduction with HbA1c, FPG, PPG and weight compared with glimepiride, with lower glycaemic risk, in patients with type 2 diabetes: LEAD-3 extension study

A. Garber[1], R. Henry[2], R.E. Ratner[3], P. Hale[4], C.T. Chang[5], B. Bode[6]
[1] *Baylor College of Medicine, Depts of Medicine Biochemistry and Molecular Biology and Molecular and Cellular Biology, Houston, USA*
[2] *University of California, Endocrinology Department, San Diego, USA*
[3] *MedStar Research Institute, Diabetes, Hyattsville, USA*
[4] *Novo Nordisk Inc, International Medical Affairs, Princeton, USA*
[5] *Novo Nordisk Inc, Biostatistics, Princeton, USA*
[6] *Atlanta Diabetes Associates, Diabetes, Atlanta, USA*

Aims: In the 1-year, randomised, double-blind, LEAD-3 study, patients with type 2 diabetes (n=746) receiving liraglutide monotherapy, 1.2 or 1.8 mg OD, achieved greater reductions in HbA_{1c}, FPG, weight, hypoglycaemia and systolic blood pressure than those taking glimepiride (8 mg OD). The present study, an open-label extension, analysed the efficacy and tolerability of liraglutide, compared with glimepiride, during a further year (2-year extension).
Methods: A total of 90% (n=440) of 1-year completers entered the randomised, double-blind, open-label extension period of the LEAD-3 study, of whom 321 (73%) completed a further year of treatment (2-year completers: mean age=54 years, HbA_{1c}=8.2%; median diabetes duration=3.3 years; BMI=33kg/m^2; diet/exercise only at LEAD-3 entry=36%; 1 OAD=64%) Data presented are for 2-year completers.
Results: Compared with glimepiride, 2 years of liraglutide treatment, (1.8 or 1.2 mg) resulted in significantly greater reduction in HbA_{1c} (-1.1 and -0.9%, vs -0.6%; ANCOVA; p=0.0016 and p=0.0376, respectively) and lower final HbA_{1c} (6.9 ± 1.2 and 7.1 ± 1.2% vs 7.5 ± 1.2%). A greater proportion of liraglutide subjects reached HbA_{1c} < 7.0% (58 and 53% vs 37%; p=0.0054 and p=0.0269, respectively). Liraglutide also reduced FPG more effectively than glimepiride (1.5 and 1.3 vs 0.3 mmol/L, respectively) and achieved lower mean daily PPG (-2.6 and -1.9 vs -1.8 mmol/L; p=0.01 for liraglutide 1.8 mg vs glimepiride and vs liraglutide 1.2 mg) and post-breakfast PPG (p=0.0001 for liraglutide 1.8 mg vs. glimepiride). Weight loss at 1 year associated with liraglutide and weight gain with glimepiride were maintained (-2.7 and -2.1 kg vs + 1.1 kg; p < 0.0001). Hypoglycaemia (BG < 3.1 mmol/L) was reduced by at least 85% with liraglutide 1.8 mg/day (0.28 and 0.16 vs 1.82 events/subject/year; p=0.0001 and p < 0.0001). Differences in HbA_{1c} between completers and the ITT (LOCF) population were comparable; ITT (LOCF) analyses also showed significantly greater reductions in FPG, PPG, weight and hypoglycaemia with liraglutide vs glimepiride.
Conclusion: Two years of liraglutide monotherapy leads to significantly greater reductions in HbA_{1c}, FPG, PPG and body weight than glimepiride, with lower hypoglycaemic risk.

Aims: There have been suggestions that the ability to induce weight loss might explain some of the improvement in HbA_{1c} observed with GLP-1 receptor agonists. Therefore, this meta-analysis compared HbA_{1c} reduction with liraglutide 1.8 mg daily to determine whether the improvement was related to weight loss.
Materials and methods: A meta-analysis of six phase 3 randomised controlled trials including 2739 patients with type 2 diabetes compared HbA_{1c} reduction among patients in different categories of weight change from baseline (weight gain, weight loss ≥0 to ≤3%, weight loss >3 to ≤5%, and weight loss >5%), during treatment with liraglutide 1.8 mg daily or placebo. Endpoints were assessed after 26 weeks.
Results: More patients treated with liraglutide (76%) lost weight from baseline compared with placebo (60%). Twenty-four per cent of patients in the liraglutide group experienced >5% weight loss versus 10% of patients in the placebo group. Weight loss of >3% to ≤5% occurred in 17% of patients in the liraglutide group and in 13% with placebo. Thirty-five per cent and 37% of patients in the liraglutide and placebo groups, respectively, had weight change of 0 to 3%. Liraglutide induced significant reductions in least-squared (LS)-mean HbA_{1c} from baseline in all weight change groups compared with the placebo group (p<0.0001; Table 1). The effect of liraglutide on change in HbA_{1c} was independent of weight loss category (p=0.71).
Conclusions: Liraglutide induced weight loss in a greater percentage of patients than placebo and almost a quarter of patients treated with liraglutide had >5% weight loss. Liraglutide was associated with significantly improved reductions in HbA_{1c} compared with placebo that was independent of weight loss category. Thus, liraglutide independently affects both HbA_{1c} and weight in patients with type 2 diabetes.

HbA_{1c} reductions according to weight change category

	Percentage HbA_{1c} reductions from baseline (patient no., %)			
	Weight loss from baseline category (%)			
Treatment	Weight gain or no weight change from baseline	≥0 to ≤3%	>3 to ≤5%	>5%
Liraglutide 1.8 mg daily	–1.38* (327, 24%)	–1.29* (470, 35%)	–1.43* (224, 17%)	–1.65* (318, 24%)
Placebo	–0.33 (210, 40%)	–0.23 (192, 37%)	–0.16 (65, 13%)	–0.70 (52, 10%)

*p < 0.0001 versus placebo.

[3] *Novo Nordisk, Liraglutide Medical Affairs, Bagsvaerd, Denmark*
[4] *Ruhr University, Funktionsbereich Diabetologia, Bochum, Germany*

Aims: The sulphonylureas (SU), a widely used oral treatment for type 2 diabetes, stimulate release of insulin from pancreatic beta-cells. The newly developed incretin-based therapies, glucagon-like peptide (GLP)-1 agonists, such as liraglutide, differ from SUs in that they promote glucose-dependent insulin secretion from the beta-cells in addition to having beta-cell preserving properties. Treatment with liraglutide is associated with weight loss and a reduced risk of hypoglycaemia compared to SUs. The aim of this report is to compare the efficacy (HbA_{1c}) of liraglutide (1.2 mg or 1.8 mg/day) and the SU, glimepiride in relation to patients' beta-cell function.
Methods: A meta-analysis was performed on HbA_{1c} efficacy data from six randomised controlled 26-week trials in which patients were treated with liraglutide 1.8 mg (n=1362), liraglutide 1.2 mg (n=896) or glimepiride (n=490). An ANCOVA model adjusted by quartile of beta-cell function at baseline (as defined by HOMA-B) and C-peptide was used to compare the effects of drug treatment on HbA_{1c} change from baseline.
Results: In the liraglutide groups the reduction in HbA_{1c} was significantly ($p<0.01$) greater than with glimepiride with reductions of 1.4%, 1.3% and 1.1% for 1.8 mg, 1.2 mg liraglutide and glimepiride, respectively. Both liraglutide doses reduced HbA_{1c} significantly across all quartiles of HOMA-B and C-peptide (1.0% and >1.2%, respectively). When analysed by quartiles of baseline HOMA-B, reductions of HbA_{1c} with liraglutide were significantly greater ($p<0.05$) than with glimepiride in the 2nd (0.23% [SE=0.12], 0.28% [0.11] for 1.2 mg and 1.8 mg vs glimepiride) and 4th quartile (0.42% [0.11], 0.40% [0.11] for 1.2 mg and 1.8 mg vs glimepiride). For quartiles of baseline C-peptide the greatest reductions ($p<0.05$) with liraglutide compared to glimepiride were observed in the 3rd (0.31% [0.12], 0.31% [0.1] for 1.2 mg and 1.8 mg vs glimepiride) and 4th (0.24 % [0.12], 0.40% [0.11] for 1.2 and 1.8 mg vs glimepiride) quartiles. Liraglutide produced the greatest improvements in HbA_{1c} in patients with the highest baseline beta-cell function (Q4). No effect of baseline quartile on HbA_{1c} reduction was seen with glimepiride.
Conclusions: Liraglutide was effective across the range of beta-cell activity. The greatest improvements in HbA_{1c} occurred in patients with the most preserved beta-cell function, supporting that clinical benefit may be gained when treatment is started early in the disease process.

HbA1c reduction with liraglutide in patients with type 2 diabetes is associated with initial HbA1c levels

M. Nauck[1], A. Vaag[2], S. Colagiuri[3], A. Falahati[4], A.D. Toft[5], K. Hermansen[6]
[1] *Diabeteszentrum Bad Lauterberg, Gastroenterology and Endocrinology, Bad Lauterberg im Harz, Germany*

[4] *Novo Nordisk, Biostatistics, Bagsvaerd, Denmark*
[5] *Novo Nordisk, Liraglutide Medical Affairs, Bagsvaerd, Denmark*
[6] *Aarhus University Hospital, Endocrinology, Aarhus, Denmark*

Aim: The once-daily human GLP-1 receptor agonist liraglutide has been shown to be more effective at reducing HbA_{1c} than other OAD therapies. We analysed data from a meta-analysis of six development trials to establish the effect of initial baseline HbA_{1c} levels on subsequent improvement in glycaemic control with liraglutide.
Methods: The meta-analysis was performed on data from the six LEAD trials (n=3967). Patients receiving liraglutide 1.8 mg, TZD, SU, glargine, exenatide or placebo in the LEAD trials were split into six categories according to initial baseline HbA_{1c} level: ≤7.5%, 7.5–8.0%, 8.0–8.5%, 8.5–9.0%, 9.0–10.0%, >10.0%. Reduction of HbA_{1c} compared to baseline for each category was determined and statistical analysis of change in HbA_{1c} from baseline to week 26 was performed by ANCOVA on the LOCF, ITT data set.
Results: At 26 weeks liraglutide 1.8 mg demonstrated reductions in HbA_{1c} relative to baseline for each baseline category, with greater reductions associated with higher baseline HbA_{1c} categories (Table 1). These reductions ranged from 0.89% for the ≤7.5% category to 2.50% for the >10.0% category. Significantly greater reductions were observed for liraglutide 1.8 mg vs TZD in categories 8.0–8.5% (0.40%), 8.5–9.0% (0.86%), 9.0–10.0% (0.96%) and >10.0% (1.14%); vs SU in categories ≤7.5% (0.24%), 8.0–8.5% (0.21%), 8.5–9.0% (0.13%) and >10.0% (0.56%); vs glargine in categories ≤7.5% (0.34%), 7.5–8.0% (0.19%) and 9.0–10.0% (0.15%); vs exenatide in categories ≤7.5% (0.31%) and 9.0–10.0% (0.06%); vs placebo in categories ≤7.5% (0.86%), 8.0–8.5% (1.14%), 8.5–9.0% (1.25%) and >10.0% (1.72%); $p<0.0001$ for each.
Conclusions: Clinically relevant reductions in HbA_{1c} were achieved with liraglutide 1.8 mg for all categories of HbA_{1c} baseline. Reductions in HbA_{1c} were increased in subjects with poorer levels of initial glycaemic control and were significantly greater than active comparators. Liraglutide 1.8 mg can help patients achieve target HbA_{1c} levels at various stages of disease progression.

LS-Mean of change in HbA_{1c} by baseline category of HbA_{1c}						
	Reduction in HbA_{1c} at 26 weeks relative to baseline (%)					
HbA_{1c} baseline (%)	Liraglutide 1.8 mg	TZD	SU	Glargine	Exenatide	Placebo
≤7.5	0.89	0.57	0.65	0.55	0.58	0.03
7.5–8.0	1.11	0.62	0.88	0.92	0.85	0.24
8.0–8.5	1.31	0.91	1.10	1.15	1.08	0.17
8.5–9.0	1.64	0.78	1.51	1.33	1.25	0.39

P-1401

Adding liraglutide to existing therapy improves glycaemic control: evidence from a meta-analysis of six large randomised clinical trials

R. Pratley[1], M. Nauck[2], J. Brett[3], A. Falahati[4], J.J. Holst[5]
[1] *University of Vermont College of Medicine, Division of Endocrinology Diabetes and Metabolism Department of Medicine, Burlington, USA*
[2] *Diabeteszentrum Bad Lauterberg, Gastroenterology and Endocrinology, Bad Lauterberg im Harz, Germany*
[3] *Novo Nordisk Inc, International Medical Affairs, Princeton, USA*
[4] *Novo Nordisk, Biostatistics, Bagsværd, Denmark*
[5] *Panum Instituttet, Diabetes, Copenhagen, Denmark*

Aims: Worsening glycaemic control associated with the progression of type 2 diabetes is typically addressed by adding additional drugs to existing therapy in routine clinical practice. Liraglutide, a once-daily human glucagon-like peptide-1 (GLP-1) analogue, was tested alone or in combination with various therapies, including diet/exercise, in six randomised, controlled phase 3 trials in 4442 patients.
Materials and methods: Meta-analysis using logistic regression of the subset of patients who maintained their pre-trial regimen of oral antidiabetic drugs during these trials (n=1683) investigated the efficacy of adding liraglutide to existing therapy. Only those patients who maintained their pre-trial regimen, and added liraglutide, were included. Existing therapy was diet and exercise in one trial, metformin or SU in two trials, metformin+SU in two trials and metformin+TZD in one trial. The effect on HbA_{1c}, FPG, body weight (BW) and systolic blood pressure (SBP) was assessed for liraglutide 1.8 mg, liraglutide 1.2 mg, and placebo.
Results: ANCOVA analysis of the effect of adding liraglutide 1.8 mg and 1.2 mg to existing therapy showed statistically significant mean reductions in HbA_{1c} from baseline: 1.5% (liraglutide 1.8 mg) and 1.3% (liraglutide 1.2 mg); $p<0.0001$ for both groups. The reduction in HbA_{1c} from baseline with placebo was 0.3% (summary statistics, see Table). As add-on therapy compared to placebo, liraglutide 1.8 mg and 1.2 mg reduced HbA_{1c} by 1.2% and 1.0%, respectively ($p<0.0001$ for both). Liraglutide as add-on therapy reduced HbA_{1c} to 7.0% (liraglutide 1.8 mg) and 7.1% (liraglutide 1.2 mg), while placebo

as add-on reduced HbA_{1c} to 8.0%. Proportions of subjects (with 95% CIs) reaching target HbA_{1c}<7% with liraglutide as add-on were 71% [65%; 75%] for liraglutide 1.8 mg; 59% [51%; 67%] for liraglutide 1.2 mg; and 18% [12%; 26%] for placebo. The odds-ratio of reaching target HbA_{1c} <7% with add-on therapy of liraglutide 1.8 mg vs liraglutide 1.2 mg was 1.7 (p=0.0202). Reductions in FPG were reported for both liraglutide 1.8 mg and 1.2 mg as add-on, and improvements in BW and SBP were also observed (Table).

Conclusion: Liraglutide as add-on to existing therapy leads to greater improvements in glycaemic control than previously observed in individual trials where background treatment was changed in many subjects.

Comparison of liraglutide with placebo, as add-on therapy (summary statistics)					
		HbA_{1c} (%)	FPG (mmol/L)	BW (kg)	SBP (mmHg)
Liraglutide 1.8 mg	Baseline	8.3	9.6	90.0	132.0
	End of trial	7.0	7.7	88.0	129.0
	Change	-1.4	-1.8	-2.2	-2.9
Liraglutide 1.2 mg	Baseline	8.3	9.5	89.3	128.6
	End of trial	7.1	7.7	88.1	127.0
	Change	-1.3	-1.7	-1.4	-1.4
Placebo	Baseline	8.3	9.3	89.1	132.4
	End of trial	8.0	9.8	88.7	131.8
	Change	-0.3	0.5	-0.4	-0.4
Add-on group includes subjects on prior SU in LEAD 1, prior met in LEAD 2, prior diet/exercise in LEAD 3, prior met and TZD in LEAD 4, prior met and SU in LEAD 5, and all subjects in LEAD 6. Data are ITT LOCF.

[7] *Novo Nordisk A/S, GLP-1 Development, Bagsvaerd, Denmark*
[8] *Oxford Centre for Diabetes Endocrinology & Metabolism, Endocrinology, Oxford, United Kingdom*

Aims: In patients with T2D (n=1091), 6 months' treatment with liraglutide, a once-daily (OD) human GLP-1 analogue, vs glimepiride (both combined with metformin) resulted in similar glycaemic control, but lower weight, reduced hypoglycaemia and improved SBP with liraglutide; data from the LEAD-2 1.5-year extension.

Methods: Subjects were randomised to liraglutide OD (0.6, 1.2, or 1.8 mg) +met, met alone [met], or met+glimepiride (4mg OD) [glim]. Met dose 1.5–2 g/day. First 6 months were double blind, double-dummy, thereafter open-label.

Results: 89% (780 subjects) of 26-week completers entered the extension; 529 (68%) completed 2 years (mean age 55 years; BMI 30 kg/m^2; HbA_{1c} 8.2%; diabetes duration 6 years). HbA_{1c} in subjects on 1 OAD before trial entry (35%) was improved and sustained for 2 years. At 2 years, HbA_{1c} (ITT, LOCF) was 7.38%, 7.44%, 7.74% for liraglutide 1.8, 1.2, 0.6 mg; 7.49% for glim and 8.12% for met (p=NS for liraglutide 1.8 mg vs glim). In the total cohort (ITT, LOCF), proportion reaching HbA_{1c}<7.0% at 2 years was 31.1%, 29.9%, 19.7% for liraglutide 1.8, 1.2, 0.6 mg; 23.5% for glim and 10.8% for met (p<0.0001 liraglutide 1.8 mg vs glim). Liraglutide-treated patients also achieved significant and sustained weight loss (1.8 mg: -2.91 kg; 1.2 mg: -3.03 kg; 0.6 mg: -2.07 kg) vs weight gain for glim (+0.7 kg; p<0.0001 vs all liraglutide doses). With liraglutide, waist circumference was significantly reduced from baseline by 1.8–2.8 cm at 2 years vs an increase with glim (+0.2 cm; p≤0.0001). Mean visceral adipose tissue area was reduced by 18 and 13 cm^2 with liraglutide 1.2 and 1.8 mg and increased by 9 and 2 cm^2 with met and glim, measured by single-slice abdominal CT scan (p=NS between groups). Hypoglycaemia with liraglutide was similar to met but only one tenth of that with glim; events/subject year: 0.15 (each liraglutide dose); 0.16 (met) and 1.60 (glim; p<0.0001 vs all liraglutide doses). Odds-ratio for achieving composite endpoint of HbA_{1c}<7.0%, no weight gain and no hypoglycaemia for liraglutide 1.8 mg was 4.9 vs glim and 3.8 vs met (p<0.001 and p=0.0002).

Conclusion: Over 2 years, liraglutide+met resulted in similar improvements in HbA_{1c} as glim+met. With liraglutide, however, this was achieved with only one tenth the hypoglycaemia with glim and sustained ~3 kg weight loss vs a small weight gain with glim.

P-1403

Improved patient-reported outcomes following treatment for type 2 diabetes with liraglutide compared with exenatide, in addition to metformin, sulphonylurea or both

J.S. Christiansen[1], W.E. Schmidt[2], M. Hammer[3], M.J. Zychma[4], J. Buse[5]

[1] *Aarhus University Hospital, Department of Endocrinology and Diabetes, Aarhus C, Denmark*
[2] *St. Josef Hospital Ruhr University of Bochum, Department of Medicine, Bochum, Germany*
[3] *Novo Nordisk A/S, Global Health Economics and Outcomes Research, Bagsværd, Denmark*
[4] *Novo Nordisk, Medical and Science GLP-1 Development, Warsaw, Poland*
[5] *University of North Carolina School of Medicine, Division of Endocrinology, Chapel Hill, USA*

Aims: Complexity in type 2 diabetes (T2D) treatment regimens often eclipses the positive effects of improved glycaemic control on health-related quality of life. Novel T2D therapies should improve both glycaemic control and patient satisfaction. Here, we report treatment satisfaction from patient-reported outcomes (PRO) examined in a clinical trial on patients with T2D randomised to the once-daily (OD) human glucagon-like peptide-1 (GLP-1) analogue liraglutide or the twice-daily (BID) GLP-1 receptor agonist exenatide.

Methods: Liraglutide Effect and Action in Diabetes (LEAD) 6 was a 26-week, open-label study of 464 patients with patients and HbA_{1c} of 7–11%, randomised to liraglutide 1.8mg OD or exenatide 10µg BID on a metformin±sulphonylurea therapy background. A subgroup of 379 patients had PRO examined using two versions of the Diabetes Treatment Satisfaction Questionnaire (DTSQ): status (DTSQs) at Weeks 0 and 26, and change (DTSQc) at Week 26. In a 14-week extension, patients continued or switched to liraglutide 1.8mg; 313 answered the DTSQs at Weeks 34 and 40 and the DTSQc at Week 34.

Results: From Weeks 0–26, liraglutide achieved a significantly greater reduction in HbA_{1c} relative to exenatide, and a significantly lower rate of minor hypoglycaemia. Concurrently, liraglutide increased overall treatment satisfaction on the DTSQs more than exenatide (27.4–32.1 vs. 27.6–29.0, respectively, p<0.0001). Overall satisfaction on the DTSQc increased more with liraglutide than exenatide at Week 26 (p=0.0004). At Week 26, more patients rated themselves 'satisfied' (DTSQs score >24; DTSQc score >6) with liraglutide than exenatide (DTSQs 91% vs. 82%, p=0.0173; DTSQc 94% vs. 86%, p=0.0176). Liraglutide improved all DTSQs and DTSQc items except 'diabetes understanding' significantly more than exenatide by Week 26. Relative to exenatide at Week 26, significant reductions in DTSQc score were seen for liraglutide in perceived hypoglycaemia (-0.88 vs. -0.44; p=0.0193) and hyperglycaemia (-0.99 vs. -0.33; p=0.0007). By the end of the extension at Week 40, DTSQs scores in those switched from exenatide to liraglutide at Week 26 approached scores of non-switched patients, due to a larger rise in score from Weeks 26–40 (p=0.0028). DTSQs scores remained stable in non-switched patients from Weeks 26–40.

Conclusion: Overall treatment satisfaction among patients with T2D is greater with liraglutide than exenatide at Week 26, and increases from Weeks 26–40 in patients switched to liraglutide relative to non-switchers.

P-1404

Liraglutide pharmacokinetic profile following SC dosing is unaltered by co-administration with sitagliptin in Göttingen minipigs

F. Nielsen[1], L. Ynddal[2], C. Rosenquist[3], J. Drustrup[4], L. Bjerre Knudsen[5]
[1] Novo Nordisk A/S, Diabetes & Obesity Pharmacology, Maaloev, Denmark
[2] Novo Nordisk A/S, Adme, Maaloev, Denmark
[3] Novo Nordisk A/S, Assay Technology, Maaloev, Denmark
[4] Novo Nordisk A/S, Preformulation & Delivery, Maaloev, Denmark
[5] Novo Nordisk A/S, Diabetes Biology & Pharmacology Mgt., Maaloev, Denmark

Background and aims: Liraglutide is a once-daily human Glucagon-Like Peptide-1 (GLP-1) analog that has completed phase 3 clinical testing. Liraglutide is a fatty-acid derived analog of human GLP-1 that binds to albumin as its main mechanism of protraction. Liraglutide is also stabilized against the DPP-IV enzyme. However, liraglutide is subject to a minor degradation in vivo, and thus it is interesting if co-administration with a DPP-IV inhibitor leads to increases in liraglutide concentrations. Sitagliptin is a DPP-IV inhibitor that increases endogenous levels of GLP-1, which is the main mechanism for its blood glucose lowering ability. Since both compounds lead to increases in GLP-1-like concentrations (either liraglutide or native GLP-1), we investigated if they could be combined by investigating the pharmacokinetics of liraglutide following co-administration of liraglutide and sitagliptin.
Materials and methods: The study was carried out in minipigs because only pigs have a similar absorption of injectable peptide analogs as compared to humans. Sitagliptin is dosed once daily PO (100 mg) in patients, resulting in a steady state trough plasma concentration of 41 ng/mL. Liraglutide is dosed once-daily SC (1.2 or 1.8 mg). The study was conducted in two parallel groups (+/- sitagliptin) of mini-pigs (n=4). Both groups were dosed SC with liraglutide in a dose of 2 nmol/kg, equivalent to app. 0.6 mg per 75 kg. The sitagliptin group was dosed three times daily in order to obtain a target steady state trough plasma concentration of sitagliptin above 40 ng/mL.
Results: The key pharmacokinetic parameters (mean ±SD) of liraglutide are given in Table 1. Sitagliptin had no significant effect on the pharmacokinetics of liraglutide as evaluated by T_{max}, C_{max}, AUC/Dose and half-life. The mean plasma concentration of sitagliptin was verified to be above 40 ng/mL.
Conclusion: In conclusion, the DPP-IV inhibitor sitagliptin did not alter the pharmacokinetics of liraglutide following SC administration in mini-pigs.
Table 1

Treatment	Tmax [hr]	Cmax [pM]	AUC/Dose [hr·pM/pmol/kg]	T* [hr]
- Sitagliptin	8.5 ±2.5	18000 ±3700	278 ±32	22 ±2.6
+ Sitagliptin	8.0 ±2.8	19600 ±2300	322 ±53	20 ±1.4

Aims: In a 26-week randomised trial in patients with type 2 diabetes inadequately controlled on metformin and/or SU (LEAD 6), liraglutide was more effective than exenatide (both as add-on therapy) in improving HbA_{1c} and beta-cell function, with less hypoglycaemia. This 14-week extension compared the effect of switching from exenatide to liraglutide with continued liraglutide treatment.
Methods: All 389 patients completing LEAD 6 entered the extension phase (97% of these completed the extension). Patients switched from exenatide 10 µg BD to liraglutide 1.8 mg OD (following 0.6 mg OD for 1 week and 1.2 mg OD for 1 week), or continued liraglutide 1.8 mg OD.
Results: Patients switching from exenatide to liraglutide showed significant improvements in several indices of glycaemic control, HOMA-B, weight (BW) and SBP. These improvements were associated with low rates of minor hypoglycaemia and nausea. One major hypoglycaemic event was reported. No pancreatitis occurred.
Conclusion: Switching from exenatide to liraglutide is well tolerated and achieves additional improvements in glycaemic control and cardiovascular risk markers. Liraglutide treatment provides long-term glycaemic, weight and SBP control with low rates of hypoglycaemia and nausea.

P-1406

A novel adaptive dose-finding study to develop LY2189265, a once-weekly GLP-1 analog

M. Geiger[1], Z. Skrivanek[1], B. Gaydos[1], J. Chien[1], A. Thompson[1], S. Berry[2], D. Berry[3], J. Anderson[1]

[1] *Lilly Research Laboratories, Eli Lilly and Company, Indianapolis, USA*

[2] *Berry Consultants, Senior Statistical Scientist, College Station, USA*

[3] *MD Anderson Cancer Center, Division of Quantitative Sciences, Houston, USA*

Aims: LY2189265 (LY) is a once-weekly, glucagon-like peptide-1 (GLP-1) analog being developed for the treatment of type 2 diabetes (T2DM). LY has been shown to improve glycemic control in patients with T2DM, but potential cardiovascular effects might be dose-limiting. An adaptive dose-finding, seamless, Phase 2/3 trial was designed to improve selection of the "right" doses for further development. A Bayesian algorithm will use observed real time effects to adapt the treatment allocation of new patients to LY doses.

Methods: This is a double-blind, placebo-controlled, active comparator study. It is divided into 2 stages based on 2 randomization schemes: an adaptive scheme (Stage 1) and a fixed scheme (Stage 2). The goal of Stage 1 is to select 2 LY doses. Patients are assigned to placebo, active comparator, or 1 of 7 LY doses. A Bayesian adaptive randomization scheme assigns patients to the LY doses and adapts every 2 weeks based on accumulating data of prespecified efficacy and safety endpoints. These measures are transformed into a single metric, a clinical utility index (CUI), to assess relative benefit/risk for each dose over the LY range. New patients have a higher probability of being allocated to LY doses predicted to provide therapeutic benefit (greater CUI) while minimizing exposure to less effective doses (lesser CUI). When sufficient data have accumulated, LY dose selection occurs or the trial will terminate, based on prespecified decision rules. If dose selection occurs, Stage 2 begins. Patients assigned to the selected LY doses/comparator arms in Stage 1 continue seamlessly on their therapies. New patients are randomized to the selected LY doses/comparator arms using a fixed randomization scheme. Final analysis will be based on pooled data from the selected doses/comparator arms in Stage 1 and Stage 2.

Results: Simulation of this design using the most likely pharmacodynamic model illustrates how the Bayesian algorithm adapts treatment allocations to the 7 LY doses in Stage 1 (Table 1). Over time, more patients within this adaptive design will be allocated to doses meeting the prespecified criteria, enabling more information to be gathered on those doses and better data-driven decisions to be made.

Table 1: Randomization Probabilities - Stage 1

Time (months)	Placebo	d1	d2	d3	d4	d5	d6	d7	AC
2	11%	11%	11%	11%	11%	11%	11%	11%	11%
6	20%	7%	11%	9%	11%	9%	7%	7%	20%
9	20%	8%	11%	9%	11%	8%	6%	5%	20%

AC = active comparator; d = dose

Discussion: This adaptive approach is advantageous to patients. Because adaptations are based on both safety and efficacy endpoints, exposure to less beneficial doses is minimized and assignment to more beneficial doses is increased (i.e., ones that have a higher probability of technical success). This improves the quality of decision making to either select the "right" doses or to stop the trial, halting further patient exposure.

P-1407

Effect of combined pioglitazone and exenatide therapy on plasma adiponectin and lipid metabolism in type 2 diabetes

M. Bajaj[1], M. Jogi[1], S. Samson[1], P. Sathyanarayana[1]

[1] *Baylor College of Medicine, Medicine, Houston, USA*

Aims: We examined the effects of combined pioglitazone (PPAR-gamma agonist) and exenatide (GLP-1 receptor agonist) therapy on plasma adiponectin and glucose and lipid metabolism in patients with type 2 diabetes (T2DM).

Methods: 18 T2DM patients on diet and/or metformin (>3 months) received additional treatment with either pioglitazone 45 mg/day for 6 months (n=8, Age= 52±2 y, BMI= 30.1±2.1, HbA_{1c} = 7.9±0.4%) or combined therapy (n=10, 51±3 y, BMI= 32.9±1.7, HbA_{1c} = 7.5±0.4%) with pioglitazone (45mg/d) and exenatide (10 ug s/c twice daily) for 6 months. All subjects met regularly with a dietician and were advised a weight-maintaining diet during the entire study.

Results: Pioglitazone reduced fasting plasma glucose by 17% ($P<0.05$), fasting plasma FFA by 17% ($p<0.05$) and HbA1c (delta=0.7, $p<0.05$), while plasma adiponectin increased by 68% ($p<0.02$). Total cholesterol, LDL cholesterol and HDL cholesterol did not change significantly. Fasting plasma triglyceride decreased by 21% ($p<0.05$) and body weight did not change significantly (delta=0.2 kg, p=NS). Combined pioglitazone and exenatide therapy was associated with a significantly greater increase in plasma adiponectin (delta=181%, $p<0.01$) and a significantly greater reduction in fasting plasma glucose (delta= 33%, $p<0.05$), HbA1c (delta=1.0, $p<0.05$), fasting plasma FFA (delta=41%, $p<0.01$), and fasting plasma triglyceride (delta=37%, $p<0.05$) versus pioglitazone therapy despite the lack of a significant change in body weight (delta=-0.4 kg, p=NS). Total cholesterol, LDL cholesterol and HDL cholesterol did not differ significantly following therapy between the two treatment groups.

Conclusion: In patients with type 2 diabetes, the addition of pioglitazone and exenatide combined therapy is associated with a greater reduction in fasting plasma FFA, triglyceride and glucose levels and a greater increase in plasma adiponectin levels as compared to the addition of pioglitazone alone. These results suggest that exenatide may directly increase plasma adiponectin, lower circulating FFA, and reduce plasma triglyceride levels in the absence of significant alterations in body weight. The molecular mechanism(s) responsible for the effects of exenatide on adiponectin and fat metabolism need to be studied.

Safety and tolerability, pharmacokinetics and pharmacodynamics of albiglutide in Japanese subjects with type 2 diabetes: A comparison with an ethnically mixed population

Y. Seino[1], H. Nakajima[2], H. Miyahara[2], T. Kurita[2], M. Bush[3], F. Yang[4], M. Stewart[4]

[1] *Kansai Electric Hospital, Osaka, Japan*

[2] *GlaxoSmithKline, Development & Medical Affiars Division, Tokyo, Japan*

[3] *GlaxoSmithKline, Clinical Pharmacokinetics, Research Triangle Park, USA*

[4] *GlaxoSmithKline, Alternative Development Program, King of Prussia, USA*

Aims: Albiglutide improved glycemic control in a Phase 2b (Ph2b) trial in an ethnically mixed population when dosed weekly or less frequently. Here, the safety, tolerability, pharmacokinetics (PK) and pharmacodynamics of albiglutide in Japanese patients with type 2 diabetes mellitus (T2DM) were assessed and retrospectively compared with the Ph2b population.

Methods: In this single-blind, randomized, placebo-controlled study, 40 subjects (mean age 54.5 years, BMI 24.5kg/m^2, HbA_{1c} range 6.3–10.3%) received abdominal, subcutaneous injections of 15mg or 30mg once-weekly; 50mg biweekly (every other week); 100mg monthly albiglutide; or placebo for 28 days, and were followed up 15 days later.

Results: Albiglutide significantly reduced FPG (all doses except 100mg monthly) and HbA_{1c} (all doses) vs placebo.

	Albiglutide dose			
	15mg weekly (n=8)	30mg weekly (n=8)	50mg biweekly (n=8)	100mg monthly (n=8)
Placebo-adjusted change from baseline (LS mean difference)				
FPG, mmol/L (day 29/43)	-1.91*/-1.43*	-1.98*/-1.16*	-1.74*/-1.18*	-0.73/-0.29
AUC_{0-4} glucose, mmol/L (day 29)	-2.86*	-3.58*	-2.51*	-1.44
HbA_{1c}, % (day 29/43)	-0.58*/-0.87*	-0.57*/-0.78*	-0.63*/-0.79*	-0.51*/-0.59*
*p<0.05 vs placebo				

Albiglutide had a plasma t, of 5.3 days, CL/F of 68.7mL/hr and V/F of 12.6L. For all dosing schedules of albiglutide, AUC and C_{max} were numerically higher in Japanese patients than predicted in the ethnically mixed population: $AUC_{(0-7)}$ for 15mg weekly and 30mg weekly albiglutide were 218 and 437µg.h/mL vs 159 and 318µg.h/mL, respectively; $AUC_{(0-14)}$ for 50mg biweekly albiglutide was 728 vs 531µg.h/mL, respectively; and $AUC_{(0-28)}$ for 100mg monthly albiglutide was 1456 vs 1060µg.h/mL, respectively. C_{max} in Japanese patients compared with the ethnically mixed population for 15mg weekly, 30mg weekly, 50mg biweekly, and 100mg monthly albiglutide were 1407, 2813, 2839, and 4441ng/mL vs 1070, 2130, 2280, and 3760ng/mL, respectively. Additionally, the change in FPG from baseline at Week 4 following albiglutide was greater in Japanese subjects vs the ethnically mixed population.

Albiglutide was well-tolerated; GI events were lowest in the 30mg weekly group and were comparable with placebo in all doses except 100mg monthly. The most common AEs in the 100mg monthly group were flatulence (n=3, 38%), vomiting (n=3, 38%) and nausea (n=2, 25%). No serious AEs were reported.

Conclusion: Weekly or biweekly albiglutide demonstrated a favorable safety and tolerability profile and significantly improved glycemia in Japanese subjects with T2DM. The therapeutic index for albiglutide may be wider in Japanese vs non-Japanese subjects in part due to differences in its PK.

P-1409

The long-acting GLP-1-receptor agonist albiglutide for the treatment of type 2 diabetes: a time course analysis of gastrointestinal adverse events in patients receiving concomitant background metformin

F. Yang[1], J. Rosenstock[2], J. Reusch[3], M. Bush[4], M. Stewart[1]
[1] GlaxoSmithKline, Alternative Development Program, King of Prussia, USA
[2] Dallas Diabetes and Endocrine Center, Dallas, USA
[3] Denver VAMC, Endocrinology Metabolism and Diabetes, Denver, USA
[4] GlaxoSmithKline, Clinical Pharmacokinetics, Research Triangle Park, USA

Aims: Gastrointestinal (GI) adverse events can limit long-term adherence to GLP-1-receptor agonist therapies. This subanalysis from a Phase 2 trial assessing the efficacy and safety of albiglutide in type 2 diabetes examined the time course of GI events associated with albiglutide in a subgroup of subjects previously treated with metformin in order to more directly compare treatment effects of albiglutide with the clinical reference treatment, exenatide.

Methods: In this randomized, multicenter, double-blind, parallel-group, Phase 2 study, 356 subjects (mean age 54, BMI 32.1kg/m^2) with type 2 diabetes inadequately controlled with diet/exercise or metformin received subcutaneous placebo, albiglutide [weekly (4, 15 or 30mg), every other week (biweekly; 15, 30 or 50mg) or monthly (50 or 100mg)] or non-blinded exenatide twice daily (per label) over 16 weeks. The metformin subgroup included 245 patients.

Results: In the metformin group, despite comparable efficacy with top albiglutide doses in each schedule, the proportion of subjects experiencing at least 1 episode of nausea or vomiting was: 18.2% in 30mg weekly; 47.8% in 50mg biweekly; and 56.5% in 100mg monthly, vs 29%, 54.3%, 55.9% for the respective doses in the entire sample. For placebo and exenatide, proportions were 11.8% and 45.7%, respectively. Of note, the percentage of metformin subjects receiving albiglutide having nausea or vomiting >7 days ranged from 0 to 14.3%, compared with 0 to 15.6% for the entire sample and 31.4% with exenatide. All nausea and vomiting for 30mg weekly albiglutide were mild. The majority of events with 50mg biweekly or 100mg monthly dosing were mild or moderate (>85%). Rates of mild and moderate nausea and vomiting with exenatide were 63.6% and 36.4%, respectively.

Nausea or vomiting correlated with albiglutide exposure and decreased over time. The incidence was lower with more frequent, smaller doses, with no nausea or vomiting reported after week 8 in the 30mg weekly group. Less frequent, higher albiglutide doses were associated with more nausea or vomiting than the 30mg weekly dose. Rates of nausea or vomiting with the 100mg monthly dose of albiglutide increased after each injection, but decreased greatly during the period between injections. Similarly, following uptitration from 5µg to 10µg, an increase in nausea or vomiting with exenatide was noted.

Conclusion: Among patients on metformin, treatment with 30mg weekly albiglutide resulted in favorable GI tolerability, with all events being mild in nature and transient. A numerically smaller proportion of patients on background metformin in the 30mg weekly or 50mg biweekly albiglutide groups experienced nausea or vomiting compared with the equivalent groups in the total patient population.

P-1410

A time course analysis of glycemic improvements with albiglutide, a long-acting GLP-1-receptor agonist for the treatment of type 2 diabetes

J. Reusch[1], J. Rosenstock[2], M. Bush[3], F. Yang[4], M. Stewart[4]
[1] Denver VAMC, Endocrinology Metabolism and Diabetes, Denver, USA
[2] Dallas Diabetes and Endocrine Center, Dallas, USA
[3] GlaxoSmithKline, Clinical Pharmacokinetics, Research Triangle Park, USA
[4] GlaxoSmithKline, Alternative Development Program, King of Prussia, USA

Aims: Variations in FPG in response to pharmacologic therapies may be related to their underlying pharmacokinetics. Albiglutide is a GLP-1-receptor agonist with the potential for weekly or less-frequent dosing ($t_{1/2}$ of ~5 days). A Phase 2 study was conducted to determine optimal dosing and scheduling of albiglutide. The present time course analysis was conducted to examine the relationship between dose, dose schedule, and measures of glycemic control.

Methods: A total of 356 subjects (mean age 54, BMI 32.1kg/m^2) with type 2 diabetes (mean duration 5 years) previously treated with diet and exercise or metformin (mean baseline HbA_{1c} 8%) participated in this randomized, multicenter, double-blind, parallel-group study. Patients received subcutaneous placebo, albiglutide [weekly (4, 15 or 30mg), every other week (biweekly; 15, 30 or 50mg) or monthly (50 or 100mg)], or exenatide twice daily (as per label for clinical reference only; non-blinded) over 16 weeks. FPG was assessed throughout the study so that its time course and relationship to HbA_{1c} could be evaluated.

Results: After 16 weeks of treatment, similar HbA_{1c} improvements were observed with the highest dose of each albiglutide regimen (-0.87, -0.79 and -0.87% for 30mg weekly, 50mg biweekly and 100mg monthly dosing, respectively, vs placebo -0.17%, p<0.005). Exenatide reduced HbA_{1c} by -0.54%. Improvements in FPG were seen as early as the first assessment (2 weeks) in all albiglutide groups. Although there were similar changes in HbA_{1c} in the highest doses of albiglutide within each dosing schedule, the 100mg monthly regimen resulted in marked fluctuations in FPG between each dose. FPG reductions remained the most consistent over time for 30mg weekly, followed by 50mg biweekly albiglutide, and PK/PD modelling showed a clear relationship between albiglutide exposure and FPG reduction.

Change From Baseline FPG (mmol/L)					
Week	Placebo	Exenatide	Albiglutide 30mg weekly	Albiglutide 50mg biweekly	Albiglutide 100mg monthly
Baseline	9.9	9.5	9.6	10.0	9.8
2	-0.2	-0.8	-1.4	-1.1	-1.6
4	-0.4	-1.1	-1.4	-1.4	-0.6
5	-0.4	-1.1	-1.5	-2.2	-2.1
7	-0.2	-1.3	-1.5	-1.9	-1.1
8	-0.4	-1.4	-1.6	-1.3	-1.3
9	-0.3	-1.5	-1.5	-1.7	-2.3
12	-0.3	-1.3	-1.9	-1.5	-1.5
15	-0.4	-1.3	-1.5	-1.7	-1.3
16	-0.1	-0.8	-1.4	-1.3	-1.2

Conclusion: Albiglutide (30mg weekly, 50mg biweekly, and 100mg monthly) resulted in comparable improvements in HbA_{1c} in patients with type 2 diabetes over 16 weeks. The 30mg weekly dose had the least FPG fluctuation, followed by the 50mg biweekly dose. The stability of the FPG profile over time appeared to be related to more consistent exposure to albiglutide in weekly/biweekly regimens compared with monthly administration, which may be of clinical relevance.

P-1411

NICE guidelines on use of exenatide

S. Kadir[1], M. El Bashir[1], A.B. Ahmed[1]
[1] Blackpool Victoria Hospital, Diabetes & Endocrinology, Blackpool, United Kingdom

Aim:
Exenatide, an incretin mimetic is a new class of medication which has been approved by NICE (national institute for health & clinical excellence) for use in Type2 diabetes in conjunction with oral hypoglycaemic agents. British national guidelines (NICE) recommend use of Exenatide if Body mass index (BMI) >35, there is inadequate glucose control (HbA1C>7.5%) with oral agents or specific psychological, physical or biochemical problems arising from weight gain. NICE also recommends that Exenatide should be continued only if there is a 1% reduction in HbA1C at 6 months and weight loss of at least 5% at 1 year.
Method: We did a retrospective audit of 60 patients who were on exenatide. The case notes were reviewed and their medications, BMI and HbA1C documented before and after starting on exenatide. The BMI and HbA1C were compared at each clinical appointment and the response documented.
Results: Total 60 patients were audited. Majority (80%) of them were started on exenatide due to BMI >35 & poor glycaemia control, however a fair number (20%) were started due to poor glycaemia control (HbA1C>7.5%) only. Of the total 53% were male and 47% female. The average age was between 50-70yrs with a mean age of 59.1yrs.37% of the patients were on metformin & insulin prior to starting exenatide.22% were on metformin & sulphonylurea and 10% were on insulin only. After the initial dose adjustments 63% remained on combination of insulin and exenatide. BMI and HbA1C improved in 67% & 65% of patients respectively, however in 30% & 18% they remained the same. Mean BMI prior to going on exenatide was 45.2 which dropped to 38.7.Mean HbA1C was 9.9% and 8.8% pre and post exenatide. The follow up period was 2-12 months.
Discussion: The incretin-based therapies represent a new potential goal-oriented treatment in type 2 diabetes. Exenatide lowers blood glucose through multiple mechanisms, including enhancement of glucose-dependent insulin secretion, suppression of excess glucagon secretion, reduction of food intake and slowing of gastric emptying (1). Exenatide has been tried with insulin and in some studies used as a monotherapy (2).

In our audit exenatide improved glycaemia control and BMI in majority of the patients. Adding exenatide to insulin did not produce any further side effects and these patients did not require additional monitoring. Although we did not note any cause for concern regarding its use in combination with insulin, our sample size was very small and further studies are needed to evaluate it. However patients should be carefully monitored if they are on combination of insulin & exenatide.With the obesity epidemic in the developed and developing world followed by an epidemic of type 2 diabetes, exenatide represents a new and beneficial addition to the medicines used in type 2 diabetes.

Gliptins added to metformin plus gliclazide therapy improves glycemic control in patients with type 2 diabetes inadequately controlled: an observational study

R.E.T. Navarrete[1], A.C. Santomauro Jr[1], D.M. Nazato[1], F.Z. Loureiro[1], M.A. Costa[1], D.G. Farinelli[1], J.P.S. Paiva[1], A.P. Casarotto[1], B. Perotta[1], A.T.M.G. Santomauro[1], F.F. Fraige[1]
[1] Faculty of Medicine ABC, Department of Endocrinology, Santo Andre, Brazil

Objectives: We sought to evaluate the improvement in blood glucose control among type 2 diabetes patients inadequately controlled with gliclazide and metformin after addition of dipeptidyl peptidase-4 (DDP-4) inhibitor (gliptin).
Methods: Observational, cross-sectional, non-controlled study, including patients suffering from type 2 diabetes more than 10 years. They were taking gliclazide 90 mg/day in combination with metformin 1,7 g/day. Results: A total of 104 patients attending the outpatient clinics of Beneficencia Portuguesa Hospital and Faculty of Medicine ABC (Sao Paulo, Brazil) were investigated (46% male). The mean age of the patients was 62,34 ± 4,2 years and the mean disease duration was 14,2 ± 2,5 years. There was a significantly higher reduction of fasting plasma glucose (174,34 ± 12,4 to 118,17 ± 17,2, $p<0,05$) and HbA1c (7,97 ± 1,42 to 6,6 ± 0,42, $p<0,05$) after the triple oral therapy was initiated. Although there was a slight reduction in weight it was not statistically significant (BMI: 29,15 ± 4,13 to 28,12 ± 5,2). No adverse effects were observed.
Discussion: The studies indicate that the greater glycemic control appears to reflect an improvement in islet function when the DDP-4 inhibitor is used, mainly in initial phases of diabetes. However, our findings suggest a beneficial effect on glucose control when DDP-4 inhibitor was added to a previously reported combination and this triple oral therapy may be a good treatment option in diabetic patients who refuse insulin therapy.

Comparative study between vildagliptin and sitagliptin associated with metformin and/or oral hypoglycemic agents and/or insulin in the control of type 2 diabetes

M. Gama[1], A.R.N. Sabbag[1], B.V. Souza[1], R.C. Perraro[1], A.C. Ossowski[1], C.F. Cruzeta[1], C.R. Datilo[1], J.S.C.C. Krause[1], S.L. Camacho[1]
[1] Hospital Universitário Evangélico, Endocrinology and Diabetes, Curitiba, Brazil

Introduction: DPP-4 inhibitors vildagliptin and sitagliptin reduce blood glucose by their effect in protecting the bioactive forms of GLP-1 and GIP. Both enhance the actions of the incretins stimulating post prandial insulin secretion, reduce plasma glucagon levels and also lower fasting glucose levels.
Objective: Compare the effectiveness of two DPP-4 inhibitors (vildagliptin and sitagliptin) associated with metformin and/or hypoglycemic agents and/or insulin in diabetic patients.
Material and method: Sixty-three type 2 diabetics using metformin and/or hypoglycemic agents and/or insulin with irregular control of the disease were evaluated in a six-months prospective study. A twice-daily dose of Vildagliptin (100mg daily) or Sitagliptin (daily dose of 100 mg) was added. These patients were compared regarding age, sex, average time of illness, fasting blood glucose levels (FBG), postprandial glucose (PPG) and glycosylated hemoglobin (A1C). Comparison between the two DPP-4 Inhibitors was also made.
Results: 29 patients used sitagliptin (ST) and 34 vildagliptin (VD). Twenty-seven of them were women and 36 were men, with age average of 62 years. The groups were homogeneous in relation to the age, sex and average time of illness (ST: 7.1 years; VD: 7.7 years). Before the study, the average of FBG was 8.2±2.1mmol/L for sitagliptin and 9.6±3.8mmol/L for vildagliptin, with reduction to 7.9±1.9mmol/L and 8.0±2.7mmol/L, respectively (p=0.28). When

evaluated the average of PPG the values were of 8.0±2.7 mmol/L for sitagliptin and 10.7±5.3mmol/L for vildagliptin with reduction to 7.7±3.0mmol/L and 7.5±2.3mmol/L, respectively (p=0.68). Patients who had used VD had a higher initial PPG (10.7mmol/L). Before the use of medications the averages of the A1Cs were 8.0±1.3% for sitagliptin and 7.9 ±1.1% for vildagliptin, with reduction to 7.4 ±1.2% and 7.0±0.8%, respectively (p=0.28).
Conclusion: The use of both DPP-4 inhibitors associated with metformin and/or oral hypoglycemic agents and/or insulin was effective in reducing the HbA1c, fasting glucose and postprandial glucose levels. Although vildagliptin group presented with higher PPG, no difference was found when comparison between the two drugs was observed.

Exenatide: a novel therapeutic opportunity to change natural history of diabetes secondary failure, our experience

O. Disoteo[1], G.L. Pizzi[1], P. Marenco[2], A. Torri[3]
[1] Niguarda Hospital, Diabetes, Milan, Italy
[2] Salvini Hospital, Diabetes, Garbagnate, Italy
[3] Salvini Hospital, Internal Medicine, Garbagnate, Italy

In most subjects affected by type 2 diabetes mellitus, hyperglycemia results from a failure of ß-cell insulin secretion to compense insulin resistance in peripheral tissues. Results from the U.K.P.D.S suggest that ß-cell failure is a progressive defect even in optimized therapy with diet, metformin, sulfonylureas or insulin. Despite the use of traditional therapies, it is often impossible to achieve and maintain adequate glycemic control in patients with type 2 diabetes. Glucoregulatory peptides, such as incretins, are currently being introduced in therapy for type 2 diabetes. Exenatide is a 39–amino acid peptide incretin mimetic that exhibits glucoregulatory activities similar to the incretin hormone glucagon-like peptide 1 (GLP-1).
Aims: Our study evaluated the effect of exenatide, in a group of out patients, on improving glycemic control in type 2 diabetic subjects unable to achieve adequate glycemic control despite treatment with combined metformin-sulfonylurea therapy.
Methods: One hundred and two subjects (median age 62 range 31-81, 61 M - 41 F) all treated with metformin and/or sulfonylurea (glibenclamide, glimepiride, gliclazide) have been enrolled in three different diabetic centres to adopt exenatide 5 - 10 mcg bis in die.
Results: At baseline fasting plasma glucose concentration was 171 ± 43 mg/dL, BMI 34.3 + 7,5 kg/m^2, waist circumference 112 ± 14 cm, median HbA1c 8.5 %, range 7.5–11.0% (normal value < 6%).
Statistical analysis was performed with MedCalc version 8.2.02 for Windows, significance level P 0.05.
Significant reductions were observed between baseline and 4 months values: HbA1c P 0,0004, BMI
P 0,0001, waist circumference P 0,01, also in fasting plasma glucose concentrations but not significant.
The incidence of adverse events was low, the most frequent was mild or moderate nausea and gastrointestinal pain. Only 5 subjects were lost to follow up.
Conclusion: This study demonstrated that exenatide therapy improved glycemic control in type 2 diabetes patients and was associated with weight loss and a modest reduction in fasting plasma glucose. No important adverse event have been associated with exenatide treatment in our patient. This novel therapy may offer another potential treatment option when two-drug oral therapy fails to maintain adequate glycemic control but should be potentially more effective if adopted as a first step of therapy in type 2 diabetics.

Knowledge, attitudes and practices of doctors in India towards DPP-IV inhibitor therapy

A. Mukherjee[1], R. Rajput[2], A. Ajamani[3], N. Agarwal[4], P. Singh[5], K. Pandit[6], S. Kalra[7], S. Mitra[8]
[1] RGKMCH, Medicine, Kolkata, India
[2] PGIMS, Endocrinology, Rhotak, India
[3] RML Hospital, Endocrinology, New Delhi, India
[4] GR Medical College, Medicine, Gwalior, India
[6] IPGMER, Endocrinology, Kolkata, India
[7] Bharti Hospital, Endocrinology, Karnal, India
[8] USV LTD., Medical Services, Mumbai, India

Aim & objective: DPP-IV inhibitors have recently been introduced in the Indian market, and promise to bring about a paradigm shift in the understanding and management of diabetes. This abstract aims to report on the recently conducted surveys among doctors regarding the use of DPP-IV inhibitors.
Study Design & Methodology: A total 166 doctors were approached during the RSSDI conference at Hyderabad, and the Diabetes India International conference at Bangalore, in 2008 end, to fill up a pretested semi-structured questionnaire. Of these, 21 were graduates, 33 had a postgraduate diploma in diabetes, 75 were internists, 20 had postgraduate qualifications in both diabetes and internal medicine, and 5 were endocrinologists, while 12 possessed other qualifications. The respondents hailed from all parts of the country, but the majority (70%) were from South India.
Results: At the time of the survey, sitagliptin had been available for 6 months, while vildagliptin had just been launched. Total 70.8% were aware of the gliptins, and had prescribed the drug in their practice. 21.2% of respondents were unaware of this class of drugs, while the others had no response. Of the doctors who had used these drugs, 48.9% physicians had experience with sitagliptin, 16.4% had prescribed vildagliptin, and 5.7% had tried both. The commonest indication was in patients with type 2 diabetes mellitus with dual drug combination failure, followed by triple drug combination failure, monotherapy, combination with insulin, and patients with intolerance to conventional oral agents. Doctors who did not use the novel class of drugs mentioned lack of knowledge, relatively high cost, and non-availability as the reasons for this. None of the doctors was aware of the synergistic effect of metformin and vildagliptin as well as vildagliptin co-prescription with insulin reduced the incidence of hypoglycaemia. When asked about the future of the DPP-IV inhibitors, 97.6% doctors replied that there was a tremendous scope for these molecules, and their use would grow rapidly.
Conclusion: This work has highlighted the enthusiasm and positive attitude of doctors in India towards the gliptins, while pointing out a few lacunae in knowledge. The indications for prescription in the users, as well as the reasons for inability or unwillingness to prescribe the drugs in the non-users have been identified, which can be used to monitor changing trends as well.

Inflammation and diabetes

P-1416

Leptin to adiponectin ratio in patients with type 2 DM and non-alcoholic fatty liver disease

R. Timar[1], V. Serban[1], L. Diaconu[1], B. Timar[1], V. Botea[1], A. Trailescu[1]
[1] University of Medicine and Pharmacy "Victor Babes" Timisoara, Diabetes Clinic, Timisoara, Romania

Background and aims: Nonalcoholic fatty liver disease (NAFLD) is a major cause of liver-related morbidity with possible progression to cirrhosis. NAFLD is often presents in persons with insulin resistance and hyperinsulinemia. Insulin resistance states are characterized by elevated production of several adipocytokines (leptin, resistin, TNFa, IL-6, TGFß, PAI-1). Adiponectin is the only known adipocytokine which produces antiinflammatory and antiatherogenic effects.
The aims of our study was to evaluate the prevalence of NAFLD in patients with type 2 DM, to assess plasma leptin-to-adiponectin ratio and proinflammatory state in patients with type 2 DM with and without NAFLD.
Materials and methods: The study enrolled 124 subjects with type 2 DM. The diagnosis of NAFLD was based on detection of fatty liver by ultrasonography with or without chronically elevated aminotransferase levels (ALT>1.5 times the upper normal values for 6 months or more). All subjects had negative

hepatitis B and C viral markers, negative history of alcohol intake, absence of autoimmune hepatits, Celiac disease, no evidence of genetic, drug-induced or cholestatic liver disease.

Results: The prevalence of NAFLD in patients with type 2 DM was 37.09%. NAFLD with elevated aminotransferase levels was present in 22 patients (17.74%) while NAFLD with normal liver enzymes was present in 24 patients (19.35%). Plasma leptin-to-adiponectin ratio were significantly higher in patients with NAFLD with elevated aminotransferase levels than in those with normal liver enzymes and than in subjects without NAFLD. Plasma levels of TNF-a and IL-6 were also significantly higher in patients with NAFLD and elevated aminotransferase levels than in patients with NAFLD and normal liver enzymes and than in subjects without hepatic injury. HOMA-IR was higher in patients with high leptin-to-adiponectin ratio.

Table 1. Characteristics of patients with type 2 DM with and without NAFLD

Parameter	Without NAFLD	NAFLD with normal liver enzymes	NAFLD with elevated aminotransferase levels	ANOVA p
Number	78	24	22	-
Adiponectin (µg/mL)	9.1±1.2	6.8±0.8	5.9±0.6	<0.001
TNF-a (pg/mL)	7.2±1.3	8.7±1.5	9.2±1.9	<0.001
IL-6 (pg/mL)	4.0±0.5	4.9±0.7	6.1±0.9	<0.001
Leptin (ng/mL)	11.3±2.5	15.3±2.9	22.3±3.8	<0.001
HOMA-IR	2.4±0.3	3.2±0.8	3.8±0.9	<0.001
Leptin-to-adiponectin ratio	1.24±0.3	2.28±0.6	3.72±0.9	<0.001
Data are means ± SD.				

Conclusion: The prevalence of NAFLD is higher in patients with type 2 DM than in general population. Although insulin resistance is present in all patients with type 2 DM, those with NAFLD present higher insulin resistance than those without NAFLD. Plasma leptin-to-adiponectin ratio and proinflammatory adipocytokines are higher in patients with NAFLD than in those without liver injury, suggesting a possible contribution of these abnormalities in the pathogenesis of NAFLD.

Cream intake induces socs-3 and tlr-4: relevance to pathogenesis of inflammation and insulin resistance

R. Deopurkar[1], H. Ghanim[1], P. Viswanathan[1], S. Abuaysheh[1], C.L. Sia[1], P. Dandona[1]

[1] Millard Fillmore Health System, Endocrinology, Buffalo, USA

We have previously shown that the intake of macronutrients induces oxidative and inflammatory stress. Since the suppressor of cytokine signaling (SOCS-3) and toll like receptors 2 and 4 (TLR-2 and TLR-4) are induced by inflammation and since they also lead to interference with insulin signal transduction, we have now investigated whether the intake of cream, which has previously been shown to induce oxidative stress, also leads to the induction of SOCS-3 and TLR-4 along with inflammatory stress. Ten fasting normal subjects were given 33g of cream or water to ingest in 2 separate visits, and blood samples were collected at 0, 1, 3 and 5h. Mononuclear cells (MNC) were prepared. Intranuclear NFkB binding (EMSA), SOCS-3 and TLR-4 mRNA and protein expression were measured by RT-PCR and western blots. There was a significant increase in NFkB binding by 57±18% at 3hr following cream intake. In addition, TNFa and IL-1b mRNA expression in MNC increased significantly following cream intake (by 51±10% and 182±34%, respectively) while there was no change in IL-6 expression. SOCS-3 and TLR-4 mRNA increased significantly by 119±22% and 43±16% (P<0.05), respectively, at 3hr following cream intake while there was no change in SOCS-1 and SOCS-7 or in TLR-2. Consistent with the changes at the mRNA level, cream intake induced a significant increase in SOCS-3 and TLR4 proteins in MNC by 39±16% at 3 hours and by 39±16% at 3 hours, respectively (P<0.05). Water intake caused no change in NFkB binding, SOCS-3 or TLRs expression. Thus, the intake of cream not only induces oxidative stress and inflammation but also induces at two proteins key in the pathogenesis of insulin resistance. Repeated intake of saturated fat potentially contributes not only to atherogenesis but also to insulin resistance.

Marker\Hours	1	3	5	P*	P#
NFKB DNA binding	140±16	157±18	141±12	0.026	0.036
TNFa mRNA	120±11	151±10	132±13	0.036	0.031
IL-1b mRNA	225±50	282±34	238±31	0.006	0.015
SOCS-3 mRNA	155±10	219±22	174±18	0.012	0.018
SOCS-3 protein	135±17	143±21	122±15	0.037	0.043
TLR-4 mRNA	127±14	143±16	142±14	0.036	0.04
TLR-4 protein	114±8	139±16	131±14	0.039	0.044

Table 1: Change from baseline (100%) in inflammatory mediators following the intake of Cream (300 Calorie) in 10 normal weight healthy subjects. P*= P value with RMANOVA for within the same treatment comparisons; P# = P value with 2-way RMANOVA compared to water.

Expression of inflammatory markers in Saudi male patients with type 2 diabetes mellitus

N. Al-Daghri[1], O. Al-Attas[1], M.S. Alokail[1], A. Bamakhramah[1], N.A. Shaik[1]

[1] King Saud University, Biochemistry, Riyadh, Saudi Arabia

Aims: Type 2 Diabetes mellitus (T2DM) is a subclinical chronic inflammatory disorder resulting in huge morbidity and mortality in the Saudi male population. In view of the important role of cytokines on the metabolism of glucose, the present study has assessed the association of serum levels of inflammatory markers such as IL6, resistin, CRP, TNF and IGF with the pathogenesis of T2DM.

Methods: This study has recruited 225 Saudi male subjects, consisting of 81 clinically diagnosed T2DM cases and 144 normal healthy, age and sex matched controls. The Fasting blood samples were collected from the subjects and used for biochemical and immunological analysis.

Results: On analysis of results, we found that serum IL-6 and resistin levels were significantly altered in the T2DM cases when compared to the controls ($p < 0.02$, $p < 0.001$ respectively). However, both case and control subjects shown similar levels of cytokines such as CRP, TNFa, and IGF ($p > 0.05$). Step wise linear regression showed that resistin and CRP were positively correlated and can act as independent predictors for serum IL6 levels ($p<0.001$).

Conclusion: The data suggest an association of low serum levels of IL6 and resistin with T2DM cases in Saudi males and further confirms the role of IL6 and resistin in assessing them as risk markers to T2DM.

Increased histidine decarboxylase activity in diabetic placenta correlates with bradykinin B1 receptor expression

D. Szukiewicz[1], M. Pyzlak[1], G. Szewczyk[1], D. Maslinska[2], S. Maslinski[1]

[1] Medical University of Warsaw, General and Experimental Pathology, Warsaw, Poland

[2] Polish Academy of Sciences, Institute of Medical Research Centre, Warsaw, Poland

Aim: Histidine decarboxylase (HDC) is an enzyme that catalyzes the conversion of histidine to histamine. Previously, we showed increased levels of histamine in diabetic placental tissue. Increased levels of bradykinin, a potent vasodilatory peptide for most vessels, except for the placental, have also been reported in diabetes. Expression of bradykinin B1 receptor becomes evident in the course of inflammatory response, whereas the B2 receptor mediates most of the effects induced by kinins. Here we examined comparatively a correlation between placental HDC activity and bradykinin receptors B1 and B2 expression in diabetes class C (after White) versus normal pregnancy.

Methods: Fourteen diabetic placentas were compared with 14 gestationally matched placentas from normal pregnancies (group I and group II, respectively). Tissue activity of HDC was assayed in placental samples obtained in a standardized manner. A modified method, described previously by Endo was applied. Briefly, histamine-free enzyme solution containing HDC has been obtained after homogenization with phosphorylated cellulose and centrifugation. Then, newly formed histamine after incubation of the enzyme solution with histidine (1 mM) was separated by chromatography and quantified fluorometrically as an indicator of HDC activity. Expression of bradykinin B1 and B2 receptors was examined in immunostained paraffin 5 mm sections (n=84 for each group) by quantitative morphometry in analysed

areas matched in mean vascular density. In order to measure the density of placental microvessels, staining with hematoxylin/eosin and computerized morphometry were performed.
Results: Mean HDC activity in group I was significantly ($p < 0.05$) increased compared to controls (3.98 ±0.24 vs 2.87 ±0.16 nmol/h/g ±SEM). Mean expression of bradykinin B1 receptors in Group I was augmented and reached 140.9% of the value for Group II ($p<0.05$). The differences in mean expression of B2 receptors did not reach statistical significance.
Conclusion: Increased HDC activity may explain particular phenomena observed in diabetic placental tissue. HDC-dependent histamine elevation may change locally vascular properties by influence on bradykinin receptors expression. Proinflammatory reactions mediated via B1 should be expected rather than changed vasomotor reactivity related to B2. Angiogenic properties of histamine and kinins should also be considered.

No conflict of interest

P-1420

Fractalkine concentration and fractalkine receptor expression in the human placental compartments – diabetic vs. normal pregnancy

D. Szukiewicz[1], G. Szewczyk[1], M. Pyzlak[1], T.K. Mittal[2], A. Stangret[1], S. Maslinski[1]
[1] Medical University of Warsaw, General and Experimental Pathology, Warsaw, Poland
[2] Medical University of Warsaw, Chair and Department of Obstetrics and Gynecology 2nd Faculty of Medicine, Warsaw, Poland

Aim: The human placenta is a fetomaternal organ and consists of two functionally distinct compartments, the fetal part – developed from chorion frondosum, and the maternal part – from decidua basalis. The placenta contains paternal genes, which makes it a natural semi-allogenic allograft. Fractalkine (CX3CL1), the sole member of the CX3C chemokine family, has demonstrated an important role in inflammatory conditions, allograft rejection and angiogenesis. Most of these activities are mediated principally through fractalkine receptor (CX3CR1). Increased angiogenic and proinflammatory activities were reported in diabetes. In this study we investigated comparatively (diabetic vs. normal pregnancy) CX3CL1 concentration and CX3CR1 expression in the two placental compartments.
Methods: Twelve placentas obtained after pregnancies complicated by diabetes White class C were compared with twelve placentas obtained from gestationally matched normal controls (group I and II, respectively). Placental samples from fetal and maternal compartments have been taken in standardized manner. Fractalkine concentration in placental tissue homogenates was measured immunoenzymatically using Human CX3CL1 ELISA Development Kit (R&D Systems Inc.). In order to examine CX3CR1 expression, paraffin 5 um sections ($n = 72$ for each group) were immunostained with rabbit polyclonal anti-human CX3CR1 (Santa Cruz Biotechnology Inc.). Quantitative computerized morphometry was applied and CX3CR1 expression was analysed in areas matched in mean vascular density.
Results: Higher CX3CL1 levels were detected in the maternal compartments within the groups. Fractalkine concentration in group I was significantly ($p<0.05$) increased in both fetal and maternal compartments, compared to the controls (group II) and amounted (mean values ng/mL ±SEM) 7.24 ±0.46 and 9.33 ±0.57 versus 2.76 ±0.19 and 3.98 ±0.27, respectively. Mean CX3CR1 expression in the maternal compartment was significantly ($p<0.05$) decreased in group I, whereas differences in CX3CR1 expressions between the fetal compartments were not observed.
Conclusion: Advanced glycation end-products and cytokine activation in diabetes may induce fractalkine upregulation and lead to related placental abnormalities, including disturbed angiogenesis. Decreased expression of CX3CR1 in the maternal compartment of diabetic placenta seems to represent a compensatory mechanism against the increase in CX3CL1 concentration.

Periodontal disease with serum C-reactive protein values in diabetics

S. Rahaman[1], F. Akhter[1], R. Tabassum[1], T.K. Ghosh[1], R. Kabir[1], Q. Naushad[1], A. Choudhury[1]
[1] BIRDEMDiabetic Association of Bangladesh, Dentistry, Dhaka, Bangladesh

Aims: The purpose of this study was to evaluate C-reactive protein values in diabetic persons with periodontal disease.
Methods: We randomly selected 250 patients from the dental outpatient department of BIRDEM, a hospital for persons with diabetes. Each of the 250 patients completed a dental check-up that included a questionnaire survey and clinical examination of periodontal status, including gingival bleeding, and evaluation of gingival inflammation and oral mucosa, to determine the person's periodontal health and treatment needs. A blood sample was collected for C-reactive protein values.
Results: The C-reactive protein values of 61.2% in persons with diabetes are within the reference range (< 6 mg/L), and values of 38.8% in diabetic subjects are above the reference range (> 6 mg/L) for persons with periodontal disease. This relationship was found to be statistically significant ($p < 0.016$). Among the 250 participants, 82 males and 71 females were within the reference range (< 6 mg/L), and 33 males and 64 females were above the reference range (> 6 mg/L). Thus, females had higher C-reactive protein values, and this was also found to be statistically significant ($p < 0.0025$). This study showed that there is a significant relationship between C-reactive protein values and periodontal disease in persons with diabetes, where more females having higher values. Chronic infections and inflammatory responses from diseases such as periodontitis may be the reason behind the initiation and progression of atherosclerosis.
Conclusion: High C-reactive protein values with periodontal disease is a predictor of coronary heart disease. Regular dental examination and routine scaling is essential for diabetic patients. This study is of interest to prevent coronary heart disease in diabetic subjects with periodontal disease but more studies with larger group of patients require to confirm this diagnosis.

Inflammatory markers and silent myocardial ischemia in type 2 diabetes

J. Escobedo[1], L.V. Buitron[1], L.F. Zárate[2], F.A. Morales[3], E. Espinoza[4], A. Méndez[4], R. Garcia[4], M. Cruz[4]
[1] IMSS, Clinical Research Center, Mexico City, Mexico
[2] IMSS, Epidemiology, Ensenada, Mexico
[3] IMSS, Cardiology, Mexico City, Mexico
[4] IMSS, Biochemistry Research Center, Mexico City, Mexico

Aims: To measure the strength of association between serum biomarkers of inflammation and silent myocardial ischemia in type 2 diabetes
Methods: The authors have started a screening program for silent myocardial ischemia in asymptomatic subjects with type 2 diabetes in Mexico. A family medical unit from the Mexican Institute of the Social Security has been selected and all diabetics with no symptoms of coronary heart disease have been invited to participate. A graded exercise test was performed according to the Bruce protocol, following the American College of Cardiology/American Heart Association guidelines. Horizontal or descending ST-segment depression of at least 0.1 mV measured 80 ms after de J-point in 3 consecutive cycles was considered a significant sign of ischemia.To date 152 subjects with silent myocardial ischemia have been identified. In a case-control design they were compared with 371 controls. Controls were randomly selected from the same source population. Fasting venous blood was tested for glucose, total, high and low-density lipoprotein cholesterol, triglycerides, glycosylated hemoglobin and inflammatory markers: intercellular adhesion molecule-1 (I-CAM), vascular cell adhesion molecule-1 (V-CAM), E-selectin, resistin, interferon-gamma, interleukin-6 (IL-6), interleukin-10 (IL-10) and high sensitivity C reactive protein. Mann-Whitney U was used to compare median values between groups and odds ratio (OR) with 95% confidence intervals (95% CI) were estimated while classifying inflammatory markers into tertiles. A logistic regression model was employed to control for potential confounders.
Results: Median values of I-CAM, V-CAM, E-selectin, resistin, interferon-γ and IL-6 were significantly higher in cases. In the logistic regression model, adjusting by age, sex and duration of diabetes, an increased risk was observed

in the highest serum values tertile of V-CAM (OR 11.31; 95%CI 5.6–22.9) E-selectin (OR 2.90; 95%CI 1.5–5.4), IL-6 (OR 8.11; 95%CI 3.6–18.4) and resistin (OR 1.85; 95%CI 1.0–3.5). A dose–response effect was observed with these inflammatory markers. No relation was observed between silent myocardial ischemia and metabolic control parameters.

Discussion: Inflammation plays a major role in atherosclerosis and coronary heart disease, particularly in the context of diabetes. The appreciation of the role of inflammation in silent myocardial ischemia in diabetes, provides insights into its pathogenesis, and offers opportunities for diagnosis and prediction of this subclinical and early manifestation of coronary artery disease, a major complication in type 2 diabetes.

Valuation of the thyroid gland function in type 2 diabetes mellitus patients

M.F.V. Cambrea[1], M.P. Tomarchio[1], V.F.D.S. Arruda[1], G.B.C. Costa[1], L.C. Stella[1], A.T. Santomauro[1], F.F. Fraige[1]
[1] Beneficencia Portuguesa, Endocrinology, São Paulo, Brazil

The prevalence of thyroid diseases in diabetics is over 2-3 times than individuals whithout diabetes. In type 2 diabetics we can find 3 to 6% of primary hypothyroidism and 0,3% of hyperthyroidism. The metabolic disturbancess that are observed in type 2 diabetics (DM2) can modify the values of serum TSH, freeT4 and freeT3. The thyroid dysfunctions can change glycemic control, insulin resistance, cholesterol levels and thyroid gland function. Elevated values of serum TSH are associated with elevated concentrations of cholesterol and triglycerides. The hypothyroidism reduces the activity of the cardiovascular system and has atherogenic effects, increasing the macroangiopathic complications in diabetics. The hyperthyroidism (subclinical too), increases the risk of atrial fibrillation to stimulate the cardiac function. This is a observational, retrospective study to evaluate the thyroid gland function in type 2 diabetics, through the analyses of handbooks of patients in the Endocrinology Clinic of the Beneficence Portuguese Hospital in Sao Paulo-Brazil, between June and December, 2006. 169 handbooks of type 2 diabetics with at least one evaluation of thyroid function were selected. The data was obtained through a protocol with sex, age, blood pressure levels, disease duration of DM2, BMI, metabolic syndrome (MS) like criteria of National Cholesterol Education Program (NCEP), family history of thyroid disease or DM2, HbA1c levels, serum glucose levels, serum lipid levels, TSH, free T4, TPOAb, TGAb and TSAb.As well as this, the different treatments for diabetes were inclueded too. Serum TSH levels (2 bands: 0,5 to 2,99µU/mL and 3 to 5,5µU/mL) and thyroid status (TSH and free T4) were crossed with time diagnoses, BMI, MS, family history of thyroid disease and DM2, HbA1c, serum glucose levels and sex, which were analyzed by Pearson correlation. Analysing the clinical and laboratory characteristics, we could observe large prevalence of women in the cohort (55,6%). The age, on average, from the 169 patientes were 61,6 ±11 years; the serum glucose values were 160,7 ±69,7 mg/dL and TSH levels were 3,1±3,9 µU/mL; 39,6% of the patients have BMI between 25 – 29,9 Kg/m^2; 68,3 % were included in the criterias of MS. About family history, 49,1% had positive comorbities with DM2 and 8,3% with thyroid diseases. Results show a weak positive correlation between TSH and BMI: r = 0,07, between TSH and serum glucose = r 0,01; between thyroid status and time of DM2 r=0,15, BMI r=0,09, HbA1c r=0,06 and glucose values r=0,009.The thyroid diseases have correlation with metabolic disturbances, in this study, we could find correlation between serum TSH levels and glucose levels as well as HbA1c levels. So, the most important from this study is that we have to investigate thyroid diseases in all type 2 diabetics.

Increased plasma C-reactive peptide (CRP) in type 2 diabetes (T2DM) with metabolic syndrome

Y. Liu[1], D. Zhao[1], P. Wang[1], X. Song[1], Z. Xu[1]
[1] 306 Hospital of PLA, Endocrinology, Beijing, China

Aim: CRP are usually increased in diabetic patients. But the reason is still not clear.

Subjects and methods: We examined the serum CRP in 418 T2DM when they come to screen their diabetic complications in our diabetic center during July 2003 to Sep. 2008. Their body mass index (BMI), waist/hip (W/H), systolic and diastolic blood pressure (sBP and dBP), fasting and postprandial glucose and insulin levels, HbA1c, plasma lipid, creatinine and urine albumin/serum creatinine (Alb/Cr) were measured in the same time, and compared by normal CRP (NCRP: CRP≤3mg/l) and high CRP (HCRP:CRP>3mg/l).

Results:

1. Only 93 T2DM (22.2%) were HCRP with 5.46±2.07mg/l CRP levels, and 325 T2DM were NCRP with 0.99±0.77mg/l CRP levels.
2. Significant increased BMI (HCRP 26.80±3.75 vs NCRP 25.66±3.59 Kg/m^2, p=0.008), W/H (HCRP 0.94±0.06 vs NCRP 0.92±0.06, p=0.024), sBP (HCRP 139.36±25.27 vs NCRP 132.35±21.02 mmHg, p=0.007), dBP (HCRP 79.38±10.56 vs NCRP 76.68±9.25 mmHg, p=0.017), HbA1c (HCRP 8.36±1.92 vs NCRP 7.84±1.77%, p=0.015) and TG (HCRP 3.02±4,45 vs NCRP 1.90±1.38 mmol/l, p=0.000), but lower height (HCRP 1.62±0.09 vs NCRP 1.62±0.08 m, p=0.033) HDL-C (HCRP 1.38±0.27 vs NCRP 1.46±0.34 mmol/l, p=0.033)were found in HCRP. However CRP levels were not significantly different between the young and the elder T2DM.
3. Correlations were found positively between CRP with age at both screening and diagnosed of diabetes, BMI, W/H, dBP, dBP, HR, postprandial glucose, fasting insulin levels, TG and Alb/Cr, and negatively with height and TG, but not with duration of diabetes.

Conclusions: Increased CRP levels were found in 22.2% T2DM in our study. The HCRP T2DM seems like having metabolic syndrome characters. Whether the aging was the risk factor of higher CRP was not understood.

P-1425

Patient treatment satisfaction after switching to biphasic insulin aspart 30 in the IMPROVE™ study

M. Brod[1], P. Valensi[2], J. Shaban[3], T. Christensen[4]
[1] The Brod Group, Health Outcomes, Mill Valley, USA
[2] Jean Verdier Hospital Paris Nord University, Endocrinology Diabetology Nutrition, Paris, France
[3] Windsor Regional Hospital, Medicine, Windsor, Canada
[4] Novo Nordisk A/S, Market Access, Copenhagen, Denmark

Aims: Treatment satisfaction (TS) is a key patient-reported outcome that may differ between treatments and impacts patient adherence, treatment costs and self-management behaviors. The effect of switching to biphasic insulin aspart 30 (BIAsp 30, NovoMix® 30) and likely confounding factors on TS was examined using data from the IMPROVE study, a multinational, 26-week, open labeled, observational study of the safety and effectiveness of BIAsp 30 for the treatment of type 2 diabetes in routine practice.

Methods: Data from 52,419 patients were available, and 18,823 patients (previously on oral agents or on basal or biphasic human insulin) with both baseline and end of study TS observations were included in the analysis. TS was assessed with the validated DiabMedSat questionnaire which examines efficacy, relief of burden, relief of symptoms and overall TS. Independent ANOVAs were performed to examine the influence on TS of pre-treatment factors (age, gender, country, duration of diabetes, prior treatment, diabetes-related comorbidities) and current treatment factors (reaching HbA_{1c} goal, weight gain, hypoglycemic events).

Results: Patients previously on oral therapy had a mean baseline HbA_{1c} of 9.2% and mean time since diagnosis of 7.4 years; after 26 weeks of BIAsp 30 therapy mean HbA_{1c} dropped to 7.1% ($p<0.01$) and all TS domains improved ($p<0.001$). Patients previously on insulin had a mean baseline HbA_{1c} of 9.3% and a mean time since diagnosis of 10.4 years; after 26 weeks mean HbA_{1c} dropped to 7.3% ($p<0.01$) and all TS domains improved ($p<0.001$). Although the magnitude of improvement differed by country, patients in all countries had significantly improved TS. Examination of the effect of pre-treatment factors found that higher age was associated with greater levels of satisfaction for overall TS ($p<0.001$), efficacy ($p<0.01$) and relief of burden ($p<0.001$). Patients with a longer duration of diabetes reported greater burden relief ($p<0.01$), and those with diabetes-related comorbidities had greater TS for relief of symptoms ($p<0.001$) and burden ($p<0.05$). Analysis of the impact of side effects and reaching HbA_{1c} goal found that weight gain and minor hypoglycemic events were associated with lower TS in all domains ($p<0.001$), and of patients who reached their HbA_{1c} goal, 98% also reported relief of burden ($p<0.05$) and symptoms ($p<0.01$).

Discussion: This analysis shows that BIAsp 30 significantly improved TS, even in patients previously on oral agents, suggesting that improved management of HbA_{1c} with insulin compared with oral therapy may alleviate the perceived treatment burden of daily insulin use. In addition, treatment side effects should

be considered when choosing the preferred insulin as these events significantly impact patient TS.

P-1426

Positive impact of biphasic insulin aspart 30/70 (BIAsp 30) on physician resources: insights from the IMPROVE (TM) study

J. Shaban[1], J.G. Gumprecht[2], V.K. Knudsen on behalf of the IMPROVE study group expert panel[3]
[1] *Windsor Regional Hospital, Department of Medicine Endocrinology and Metabolism, Windsor, Canada*
[2] *Medical University of Silesia, Department of Internal Medicine Diabetology and Nephrology, Zabrze, Poland*
[3] *Novo Nordisk, Department of Statistics, Bagsvaerd, Denmark*

Aims: Regimens that are straightforward to teach and easy for patients to learn offer benefits to physicians, especially where time and resources are limited; this analysis aims to quantify the impact on physician resources of initiating insulin with, or switching patients onto, biphasic insulin aspart 30/70 (BIAsp 30).
Methods: IMPROVE™ is an international, open-label, 26-week observational study designed to evaluate the safety and effectiveness of use of BIAsp30 in everyday clinical care. Patients with type 2 diabetes on a variety of regimens (n=52,419) were recruited and prescribed BIAsp 30 at the discretion of their physician, and in accordance with local practice. In addition to recording standard clinical endpoints, physicians were also given a series of resource utilisation questions, designed to explore their perceptions and time investment when starting patients on BIAsp30 using cartridges or a prefilled pen. This abstract reports data comprising physicians' evaluation for each patient initiated onto BIAsp 30.
Results: The majority of physicians (>80%) found it easy or very easy to introduce BIAsp 30 into their patients' regimen, with most (88%) being satisfied or very satisfied that BIAsp30 enabled them to achieve their preferred HbA_{1c} target. Most physicians were confident or very confident that patients would continue to maintain good glycaemic control, including post-prandial blood glucose control (89% and 90% respectively). The majority of physicians (97%) stated that they would continue to treat patients in the study with BIAsp30 following its conclusion and overall most (96%) preferred or strongly preferred BIAsp 30 to other insulins. When insulin-naïve patients were considered as a separate subgroup (n=42,368), nurses, physicians and other healthcare practitioners were still able to teach patients to self-inject BIAsp 30 in 10 minutes or less (70%, 80% and 65% respectively), with most able to do so in under 5 minutes. Following this introduction, most physicians (87%) were confident that patients initiated onto insulin with BIAsp30 were able to self-inject correctly.
Conclusion: BIAsp 30 can be easily introduced into a regimen: explanations could be made simply, and the majority of physicians were confident that their patients were able to follow their prescribed treatment and maintain good glycaemic control. Most patients were initiated onto insulin without the need for formal referral to a diabetes education clinic, thus saving time and expense. These data suggest that BIAsp30 use may support the management of insulin therapy where time and resources are limited, as in primary care practice.

Acute onset diabetic ketosis in Japanese: clinical course and prognosis

Y. Iwasaki[1], Y. Kawasaki[1], S. Honjo[1], Y. Hamamoto[1], H. Ikeda[1], K. Nomura[1], Y. Wada[1], H. Koshiyama[1]
[1] *The Tazuke Kofukai Medical Research Institute Kitano Hospital, Center for Diabetes and Endocrinology, Osaka, Japan*

Background & aim: Ketosis-prone diabetes (KPD) is a widespread, emerging, heterogeneous syndrome characterized by patients who present with diabetic ketoacidosis or unprovoked ketosis. On the other hand, similar ketosis-onset diabetes, "soft drink ketosis" has been widely recognized in Japan, which refers to a syndrome of acute onset ketosis induced by large consumption of soft drink in subjects with type 2 diabetes mellitus. A striking aspect of these entities is that substantial proportion of patients can successfully discontinue insulin therapy. So far, few studies have analyzed clinical course of these ketosis-onset diabetic patients and predicting factors of successful insulin discontinuation. In the present study, we investigated the clinical characteristics of Japanese patients with newly diagnosed, acute onset diabetic ketosis or ketoacidosis and retrospectively analyzed predicting factors of future insulin discontinuation.
Subjects & methods: The study included consecutive 1296 in-patients, who were admitted to our center during April 2003 to October 2008. Ketosis-onset diabetes was defined as newly diagnosed diabetes mellitus, presenting with ketosis or ketoacidosis. Several factors were compared between the patients with ketosis-onset diabetes who successfully discontinued insulin therapy within six months of diagnosis (group A) and those who continued insulin therapy after six months (group B), including age of onset, body mass index (BMI), HbA1C level, anti-glutamate decarboxylase (GAD) antibody titers, and insulin secretion indices at diagnosis.
Results: In consecutive 1296 in-patients, a total of 25 subjects (16 males, 9 females) were included, who met the inclusion diagnosis of ketosis-onset diabetes. They were divided into group A (n=7), and group B (n=18). There were significant differences between group A and B in sex (male predominance in group A), BMI (group A: 27.7±4.23 vs group B 20.2±5.45 kg/m2, p=0.01), 24-hr urine C-peptide (59.0±32.4 vs 25.7±25.8 μg/day, p=0.03), and fasting plasma C-peptide (1.09±0.42 vs 0.62±0.61 ng/ml, p=0.05) at diagnosis. The rate for positive anti-GAD antibody was not significantly different between the two groups (16.7% vs 44.4% p=0.15). Characteristics of patients without anti-GAD antibodies were similar to those of soft drink ketosis, ie large consumption of soft drink, and mainly male obese subjects.
Conclusions: These results suggest that a significant proportion of Japanese patients with ketosis-onset diabetes subsequently achieve successful insulin discontinuation. Patients with higher BMI, 24-hr urine C-peptide, fasting plasma C-peptide at diagnosis are more likely to discontinue insulin therapy. Clinical characteristics of these patients are similar to those of so-called "soft drink ketosis," suggesting that there is considerable overlap between KPD and "soft drink ketosis."

Insulin VIAject™ but not insulin lispro or regular human insulin can normalize vascular function and endothelial insulin action in patients with type 2 diabetes mellitus

A. Pfützner[1], T. Forst[1], C. Hohberg[1], S. Forst[1], A.H. Pfützner[1], P. Pichotta[2], A. Krasner[2], F. Flacke[2], A. Weise[1], S. Steiner[2]
[1] *IKFE - Institute for Clinical Research and Development, Medical, Mainz, Germany*
[2] *Biodel Inc., Medical, Danbury CT, USA*

Background: Postprandial (pp) insulin delivery has a major impact on pp oxidative stress and endothelial function. This study compared the effect of the ultra-rapid prandial insulin VIAject™ (VJ) with human regular insulin (HI) and insulin lispro (LP) on markers of oxidative stress, endothelial function and post-receptor insulin function in patients with type 2 diabetes mellitus.
Material and methods: Fourteen patients with type 2 diabetes (7 male, 7 female; age 61.5±1.8 years; disease 6.6±4.6 years; HbA1c 7.2±0.5 %; mean±SEM) received a single prandial injection of VJ, HI, and LP in a randomized, cross-over study. At baseline and 10, 20, 30, 60, 120, and 180 minutes after a standardized liquid meal test, the pp increase in asymmetric dimethylarginine (ADMA) levels, nitrotyrosine, microvascular blood flow, skin oxygenation, vascular elasticity and eNOS/MAPK-expression in peripheral monocytes were investigated.
Results: Equal pp glucose control was achieved in all treatment arms. Treatment with VJ showed reduced ADMA generation (VJ: -2.73±2.26; HI: 9.77±2.44; LP: 6.69±3.39 nmol/L; p<0.05 respectively), decreased nitrotyrosine levels (VJ: -0.22±0.17, HI: 0.25±0.15 μg/ml; p<0.05; LP: 0.09±0.07 μg/ml; n.s. vs. VJ). This was associated with improved microvascular blood flow (VJ: 7.1±5.7; LP: 1.9±7.6; HI: 1.2±3.1 AU; p<0.05 respectively) and skin oxygenation (VJ: 2.7±2.4; LP-2.5±1.9; HI-1.9±1.6 %; p<0.05 respectively), and similar central arterial elasticity.
Treatment with HI increased expression of MAPK-1 (60 min +0.4±0.8 AU), and decreased eNOS expression (60 min: -0.4±1.1 AU). In contrast, VJ resulted in opposite results (MAPK-1: -0.2±0.4 AU, p = 0.11, eNOS: +0.4±0.8 AU, p<0.05). The results with LP were between these extremes, but still significantly different as compared to VJ. In this pilot study, treatment with the ultra-fast

regular human insulin formulation VJ resulted in reduced oxidative stress and molecular indications of an improved endothelial function than treatment with LP or HI. These results suggest that the pharmacokinetic profile of insulin may have a major impact on the vascular effects of insulin in patients with type 2 diabetes mellitus, which is independent from glycemic control.

P-1429

Insulin glargine based therapy in type 2 diabetes: From pathophysiology towards achieving glycaemic targets in real life with proper knowledge

F. Pathan[1], F. Khan[2], M. Rahman[2], F. Saleh[3]
[1] *BIRDEM, Dept of Endocrinology, Dhaka, Bangladesh*
[2] *sanofi-aventis Bangladesh Ltd, Dept of Diabetes Cardiovascular & Thrombosis, Dhaka, Bangladesh*
[3] *BIHS, Dept of Community Nutrition, Dhaka, Bangladesh*

Aims: The most recent analysis of the UKPDS have shown that insulin therapy reduces the risk of both micro and macrovascular disease in type 2 diabetes. Given the large number of type 2 diabetic patients that are poorly controlled and the shortage of proper knowledge to initiate insulin therapy with most required insulin regimen, there is a need to develop simple and safe insulin treatment regimens, which focus on empowering the patients with proper knowledge for self management skills. A key component in empowering patients to manage their own diabetes for good glycaemic control is education. The aim of this study was to assess the relationship between glycaemic control with insulin glargine and patient education among Bangladeshi type 2 diabetic subjects.
Methods: A total number of 86 subjects (M 49%, F 51%) were selected purposively from among the patients attending diabetes counseling center (age, 62±12.9 yrs, mean ±SD). Data were collected by a predesigned questionnaire and by examining the patient record books.
Results: The mean (±SD) value of fasting blood sugar (FBS), random blood sugar (RBS) and HbA1c of the study subjects (who received premix based regimen) were 14.9±4.4 mmol/L and 17.2±5.1 mmol/L and 9.5±0.7% respectively. On the other hand, the mean (±SD) value of fasting blood sugar (FBS), random blood sugar (RBS) and HbA1c of the same study subjects (now who receive insulin glargine based regimen) were 7.3±1.5 mmol/L and 9.2±2.3 mmol/L and 7.3±0.6% respectively. Over a 4.6 year period, fasting blood glucose (FBS), random blood glucose (RBS) and HbA1c target (< or = 7%) was significantly better (p=0.05) in the group treated with insulin glargine based regimen than the group receiving premix based regimen. Although 84% subjects knew the ideal level of HbA1c, but only 11% said that diabetes mellitus is not a disease. About 16% believed that proper diet, exercise and medicines affect glycemic control excellent. Almost half of the subjects (45%) knew that skipping meals is the cause of low blood glucose. A significant negative correlation was found between fasting blood sugar and total knowledge score of the subjects (r=-0.45, p=0.0001).
Conclusion: Glycaemic targets can be reached with more physiological/ simple regimens in combination with proper knowledge. And that can only lead to an improvement in diabetes control more strongly. More attention should be paid to such strategies in day to day practice.

[4] *Hospital de Clínicas de Porto Alegre (HCPA), Centro de Tratamento Intensivo Adulto, Porto Alegre, Brazil*
[5] *Universidade Federal do Rio Grande do Sul (UFRGS), Departamento de Biofísica, Porto Alegre, Brazil*
[6] *Hospital de Clínicas de Porto Alegre (HCPA), Serviço de Cardiologia, Porto Alegre, Brazil*

Intravenous insulin infusion is a strategy to maintain tight glycemic control in critical care and coronary unit patients, although it was not evaluated in diabetic patients after coronary angioplasty (PCI), a situation where its antiinflammatory and antioxidant effects could be beneficial.
Aim: To evaluate the effects of intravenous insulin/24h to normalize glycemia on markers of oxidative stress (protein oxidation and total antioxidant defense) and inflammation (CRP and sCD40L) in diabetic patients submitted to PCI with stent.
Methods: Prospective, open label randomized controlled trial, comparing continuous intravenous insulin/24h guided by glycemia (Optium, Abbott), evaluated hourly, targeting values <110 mg/dl (IIT, n=35) to conventional treatment (CT, n=35, glycemia before meals and subcutaneous regular insulin if values >200 mg/dl) in diabetic patients submitted to PCI. Blood samples for glycemia, HbA1c, lipids, inflammatory markers (CRP and sCD40L) and oxidative stress (total antioxidant status - TAS, carbonyl) were collected immediately after the PCI and at the end of insulin infusion. Results were analyzed with ANOVA, Mann Whitney and Student t test.
Results: Patients were 60.5 ± 10 years old, 60% were men, HbA1c 8.1 ± 1.8 (IIT) vs 7.6 ± 1.6% (CT) (p=0.394). Continuous intravenous insulin for 24h determined lower glycemia in the IIT group (160 ± 63 vs 199 ± 98 mg/dL, p=0.006) and higher insulinemia (171 [59-550] vs 25 [11-50] mu/l, p< 0.001). However, no significant change was observed in protein oxidation (carbonyl 0.13 ± 0.12 (IIT) vs 0.12 ± 0.94 nmol/mg (CT), p= 0.70), total antioxidant defense (TAS 1.66 ± 0.23 (IIT) vs 1.63 ± 0.22 mmol/L (CT), p= 0.33), CRP [4.5 (2.1-11.7) vs 6.8 (2.4-10.3) mg/L, p= 0.35] and sCD40L [402 (191-843) vs 610 (230-1200) pg/mL, p= 0.68]. CRP levels increased after PCI in both studied groups (p<0.001). There was a positive correlation between final CRP and glycemia (r = 0.340, p=0.010).
Conclusions: Although continuous intravenous insulin for 24h effectively increased insulin levels and prevented further hyperglycemia episodes, a clear rise in inflammatory markers was observed after PCI in both groups. No effect of treatment was observed on oxidative stress and inflammatory markers.

P-1431

Stem cell therapy in type 1 diabetes

B. Larijani[1], F. Abbasi[1], M.M. Amoli[1], A. Sharifi[1], M. Ghodsi[1], M. Ebrahimi[1], R. Heshmat[1]
[1] *Tehran University of Medical Sciences, Endocrinology and Metabolism Research centre, Tehran, Iran*

Aims: Cell therapy has been considered as one of the most promising superlative potential treatment for type 1 diabetes. In this regard stem cell transplantation (SCT) has been carried out by implantation of live tissue fragments of different organs and tissues, of human (allo-, or auto-) or animal (xeno-) origin, from fetal, neonatal, juvenile, or adult stage as an effective tool in repair of recipient organ tissues.
The aim of this study was to examine the outcome of treatment with fetal stem cells in patients with type 1 diabetes under specific conditions.
Methods: Thirteen type 1 diabetic patients with age between 6-30y, duration of disease up to 1 year, blood glucose less than 15mmol/l and without any refractory complication were selected. Hematopoietic stem cells from human

fetus (6w-12w of pregnancy) were obtained and checked for viral infection including HCV; HBV; HIV and uro-genital infection. Cells maintained by cryopreservation and were injected intravenously within 20-30 min in each patient. Blood glucose monitoring was performed every hour within first 24 hours post cell therapy in all patients. Primary clinical and laboratory data was collected in the day of hospitalization.

Results: Blood glucose levels gradually decreased within 24 hours after treatment in 11 patients. Insulin independence occurred in 4 patients whose insulin requirement was 22-42 unit/day before treatment 24h after cell therapy. Significant decrease in insulin dosage occurred in 8 patients during a 6-month follow-up period (Their insulin requirement was 11-36 unit/day before treatment).

Conclusion: It seems that stem cell therapy in type 1 diabetics could improve hyperglycemic status. Stem cells under injured environments can promote the secretion of a variety of cytokines and growth factors that have both paracrine and autocrine activities. The paracrine function of transplanted cells rather than cell Transdifferentiation may play a crucial role in the hyperglycemic reversal immediately after treatment in our diabetic patients. Further studies with greater sample size and longer follow-up duration are warranted to further evaluate the outcome of cell therapy in patients with type 1 diabetes.

P-1432

Insulin glargine reduces blood glucose level with less hypoglycaemic events

A.B.B. Ascic Buturovic[1], Z.V.A. Zelija Velija Asimi[1], B.H. Becir Heljic[1]

[1] University Clinical Centre Sarajevo, Clinic for Endocrinology Diabetes and Metabolic Diseases, Sarajevo, Bosnia and Herzegovina

Aim: Our aim was to present the effects of insulin glargine on glycaemic control and frequency of hypoglycaemia.

Methods: 35 type 2 diabetic patients (17 male and 18 female) with poor glycaemic control were included in this trail. The study lasted for 6 months. The patients were treated with twice daily premix human insulin + metformin 850 mg after each meal. We switched patients onto once daily insulin glargine + metformin 850 mg after each meal, and followed FBG, PPG, HbA1c and frequency of hypoglycemia. Doses of insulin were titrated separately for each patient (0,7- 1IU/kg). The mean age of patients was 55.09± 5,56 years. The mean diabetes duration was 4,77 ± 1,61. The mean BMI prior the study was 31,70 ±5,45kg/m^2, and at the end of the study it was 30,18 ± 4,90 kg/m^2 p <0,05. The mean number of insulin units on the beginning of the study, with premix human insulin therapy was 56,54 ± 17,22 IU/day, while on the end of the study with glargine therapy was 43,43 ± 13,71 IU/day.

Results: The mean FBG prior the study was 13,50 ± 3,93 mmol/L, after 6 months mean FBG was 7,27 ±1,26mmol/l p <0,05. The mean HbA1c prior the study was 9,33±1,29%, after 6 months mean HbA1c was 6,87 ± 1,34%, p <0,05. Prior the study, frequency of hypoglycaemia was higher 0,82 ±0,77 than after the study 0,2 ±0,4, p< 0,002. Nocturnal hypoglycaemia frequency was 0,77± 0,75 prior the study and after the study 0,08 ± 0,27, p <0,005.

Conclusion: After six months of treatment with basal insulin glargine, significant improvement of FBG and PPG were achieved with significantly lower HbA1c level, with reduced total daily insulin doses and reduced frequency of hypoglycemia. Treatment with insulin glargine improves glycaemic control with lower frequency of hypoglycaemia, compared to treatment with twice daily premix human insulin.

P-1433

Tight blood glucose control in T1DM via continuously-adjusted insulin delivery based on frequent blood glucose sampling

A.G. Gallardo-Hernandez[1], S.A. Islas-Andrade[2], M.C. Revilla-Monslave[2], L. Fridman[1], Y. Shtessel[3], R. Leder[1]

[1] Universidad Nacional Autónoma de México, Posgrado de Ingeniería, Mexico DF, Mexico

[2] Centro Médico Nacional Siglo XX, Unidad de investigación en enfermedades metabólicas, Mexico DF, Mexico

[3] The University of Alabama in Huntsville, Electrical and Computer Engineering Department, Huntsville Al, USA

Aims: Classical T1DM therapy includes three or more blood glucose concentration measurements daily and a similar number of insulin injections. Nevertheless the most important factor for treatment success is the patients' nutritional habits and their acceptance of and adherence to the treatment. Even in the best of cases hypoglycemia episodes can occur. An automatic insulin pump improves therapy results, but a risk of hypoglycemia still exists.

Method: This research is focused on closed-loop insulin pump therapy for T1DM. It includes on line blood glucose (BG) information from a glucose sensor. The approach is to design a mathematical algorithm able to determine the short term insulin requirement using High Order Sliding Mode control. This technique does not require as input any of the patient parameters, such as insulin resistance or glucose effectiveness. It means that is possible to design a universal insulin delivery controller that is suitable for every patient.

Results: A preliminary test of the controller, was conducted with three different mathematical models to generate in silico patients (SP); the Bergman Minimal Model, the Hovorka Model, and the Sorensen Model. For each model three different SP are simulated with insulin resistance 5.5±5 min^{-1}per mU/l. This study simulations lasted 400 minutes, with initial conditions for BG of 130mg/dl. At minute 100, meal ingestion is simulated, and postprandial BG is 180±25 mg/dl. BG for every patient is under 110mg/dl at minute 300, after minute 350 all SP reach the BG target of 90mg/dl.

Discussion/conclusion: This type of designed controller can be used for any patient, due to the fact that it is not designed for any specific parameter set or mathematical model. The success of this therapy depends on an accurate BG sensor and the only input to the controller is BG level which reduces the risk of hypoglycemia. The sensors available are able to measure BG every 10 seconds. In the simulations, pump dynamics and sensor sample rate are considered in order to have an implementable system for a trial in a clinical setting.

Expectations and experiences with insulin therapy in the prandial-basal insulin regimens to improve mealtime glycemia in type 2 diabetes study

L. Ilag[1], X. Mao[2], M. Campbell[3], C. Hayes[4]

[1] Lilly Research Laboratories, Insulins/Devices Medical, Indianapolis Indiana, USA

[2] Lilly Research Laboratories, Humalog & Insulin Devices, Indianapolis Indiana, USA

[3] Lilly Research Laboratories, Diabetes/Endocrine, Indianapolis Indiana, USA

[4] Lilly Research Laboratories, Epidemiology/Health Srvc Research, Indianapolis Indiana, USA

Aims: Knowledge of patients (pts)' expectations and experiences with insulin therapy may help inform clinical practices on insulin initiation and intensification.

Materials and methods: In this 36-wk, parallel group, international RCT, adult pts with type 2 diabetes, no insulin for ≥90 days, HbA_{1c} ≥7.5% and ≤12.0% on at least 2 oral antihyperglycemic drugs (OAD) were assigned to prestudy OADs plus dinnertime insulin lispro mix 50 (LM50) (50% insulin lispro/50% insulin lispro protamine suspension) or morning insulin glargine (G). Injections were added (1-2 more in LM50, 1-3 lispro in G+L) to achieve premeal BG 4.4-5.6 mmol/L. The primary objective was to show noninferiority in HbA_{1c} change from baseline (upper limit of the 95% CI of treatment difference in HbA_{1c} [LM50 group minus insulin glargine+lispro (G+L) <0.3%]). The Expectations About Insulin Therapy Questionnaire (EAITQ) was administered at Week 0; Experiences With Insulin Therapy Questionnaire (EWITQ) at Week 36. Questionnaires consisted of 15 corresponding items (insulin therapy and insulin delivery system) summarized into positive, negative and self-efficacy subscales.

Results: Baseline HbA_{1c} was similar (LM50 9.3; G+L 9.2%; p=.11). The majority of pts (286/469~61%) were on >1 injection at study end (median=2 in both groups). Between-group difference in HbA_{1c} change from baseline to endpoint was 0.17% (95% CI -0.03 to 0.37), not meeting pre-specified noninferiority criteria. No difference was seen in endpoint HbA_{1c} (LM50 7.7; G+L 7.5%, p=.1). Overall hypoglycemia rates (adjusted for 30 days) were similar except at endpoint (LM50 1.6; G+L 2.2, p=.02). The main devices used were HumaPen Luxura (87%) (LM50) and OptiClik, OptiSet, OptiPen Pro 1 or Optipens (82%) (G+L). No EAITQ between–group differences were noted. EWITQ between-group differences are shown below.

Table: EWITQ Subscale Negative Positive Self-efficacy

LM50		G+L		p-value (ANOVA)
n	Mean±SD	n	Mean±SD	
227	2.4±1.3	225	2.6±1.3	.15
227	6.2±0.8	225	6.0±0.9	.02
227	5.8±1.0	225	5.8±0.9	.58

EWITQ items showing between-group differences in overall 7-category rating for LM50 vs G+L were: Taking insulin makes me feel better (79% vs 88% slightly to strongly agree, p=.04); My insulin delivery system is physically painful (77% vs 70% slightly to strongly disagree, p<.01); My insulin delivery system is easy for me to use away from home (87% vs 76% slightly to strongly agree, p=.01); My insulin delivery system is convenient (93% vs 86% slightly to strongly agree, p=.01); It's easy to get the dose I need with my insulin delivery system (93% vs 89% slightly to strongly agree, p=.04).

Conclusions: HbA_{1c} was reduced from baseline with LM50 and G+L but noninferiority in HbA_{1c} was not met. EWITQ scores suggest that LM50 pts may have had a more favorable experience with their insulin therapy that was associated with the insulin delivery system.

Superior outcome of once-daily initiation with BIAsp 30 as compared to insulin glargine in Asian subjects with type 2 diabetes inadequately controlled with oral anti-diabetic drugs: subgroup results of the OnceMix trial

S. Kalra[1], T.P. Que[2], D.K. Kandregulla[3], M. Mumtaz[4], F. Søndergaard[5], P.G. Kozlovski[6], W.M. Wan Bebakar[7]
[1] *Bharti Research Institute of Diabetes & Endocrinology, Endocrinology, Karnal, India*

[6] *Novo Nordisk A/S, Global Development, Aalborg, Denmark*
[7] *Universiti Sains Malaysia, Medicine, Kota BharuKelantan, Malaysia*

Aims: To compare the efficacy and safety of biphasic insulin aspart 30 (BIAsp 30) and insulin glargine (glargine), administered once daily in Asian subjects with type 2 diabetes mellitus (T2DM) inadequately controlled with oral anti-diabetic drugs.

Methods: In the 26-week, open-labeled, randomized, parallel-group, multinational, treat-to-target trial, 155 insulin naïve Asian subjects (at baseline: 76 BIAsp vs. 79 glargine; mean diabetes duration 8.62 vs. 8.60 years, HbA_{1c} 8.47 vs. 8.44%, BMI 26.51 vs. 27.25 kg/m^2, respectively) from a global cohort of 480 subjects were randomized to receive either BIAsp 30 before dinner or glargine at bedtime, both in combination with metformin and glimepiride. Efficacy was assessed by measurements of HbA_{1c} and self-measured plasma glucose (SMPG), while safety was evaluated by incidence of hypoglycaemic episodes and adverse events (AEs), and change in body weight.

Results: After 26 weeks, lower HbA_{1c} was observed with BIAsp 30 (7.25±0.13%) than with glargine (7.60±0.13%). Analysis of change in HbA_{1c} from baseline to end of treatment showed BIAsp 30 was superior compared to glargine (BIAsp 30–glargine = -0.36%, 95%CI [-0.64;-0.07], p=0.015). Mean SMPG at bedtime was significantly lower with BIAsp 30 than with glargine (BIAsp 30 vs. glargine: 7.98±0.34 vs. 9.16±0.33 mmol/L, BIAsp 30–glargine = -1.18 mmol/L, 95%CI [-2.05;-0.32], p=0.0078). Overall hypoglycaemic rates were low in BIAsp 30 (225 episodes, 36 subjects) and glargine (168 episodes, 32 subjects), and mostly minor/symptomatic. Major hypoglycaemic episodes were few in BIAsp 30 (1 episode, 1 subject) and glargine (3 episodes, 2 subjects). There was a trend for slightly increased risk of overall minor hypoglycaemia (BIAsp 30 vs. glargine: 39.5% vs. 30.4%, p=0.081) and daytime hypoglycaemia (BIAsp 30 vs. glargine: 5.3 vs. 3.7 episodes/year, p=0.064). No difference was observed in incidence of nocturnal hypoglycaemia. The occurrence of treatment emergent AEs were comparable in both groups (BIAsp 30 vs. glargine: 56.3 vs. 58%). The majority of AEs were mild in severity: 77 of total 94 events with BIAsp 30 and 101 of total 119 events with glargine. The difference of increased body weight was not significant between the two groups (BIAsp 30 vs. glargine: 0.8 vs. 1.2 kg, p = 0.3556).

Conclusion: In insulin-naïve Asian subjects with T2DM, BIAsp 30 administered once-daily is a more effective and equally safe option for insulin initiation compared to glargine.

Aims: This paper reports the efficacy, results and feasibility of providing good quality diabetes care, including insulin initiation, through a camp based strategy, using trained primary care physician in India.

Methods: The national HbA1c screening and control programme was a prospective study conducted at 77 primary care centres across the country, by physicians who had earlier been trained in diabetes care. 1794 patients who visited free, pre-advertised diabetes camps underwent a baseline fasting (FPG), postprandial glucose (PPG), and HbA1c estimation. They were prescribed appropriate diet, exercise, lifestyle and pharmacological therapy.

Results: 740 patients at 34 centres, including 59.1% men and 40.9% women, with a mean age of 54.5±11.0 yrs and a mean duration of diabetes of 6.91±5.3 yrs, who presented for investigations at repeat camps 3 months later, were taken for analysis.

All patients were given dietary, exercise and lifestyle advice. 20.7% were prescribed insulin monotherapy, 45.5% took oral hypoglycemics and insulin in combination, while 33.7% were advised only oral drugs. The mean dose of insulin was 26.3±11.9 U/d at final visit, with 95% on premixed insulin (35% conventional insulin; 60% premixed aspart), 3% on bolus insulin and 2% on basal insulin. Mean HbA1c got reduced by 0.87±1.75% (Baseline 8.65%; Final visit 7.79%) in the complete cohort (p<0.001). Over 3 months FPG and PPG fell from 157.30 to 136.30 mg/dl (p<0.001) and from 256.70 to 213.80 (p<0.001) respectively in complete cohort. HbA1c reduction was -0.63% in the oral hypoglycemics group, -0.83% in the insulin monotherapy, and -0.91% in the combination group, with all values being highly significant (p<0.001). FPG and PPG reduction were most in the insulin group (-38.29 and -79.31 mg% respectively). The proportion of patients with HbA1c ≤7.0% rose from 38.20% to 59.60% (p<0.001). Of these 31.6% were taking oral drugs, 27.9% insulin monotherapy, and 40.4% were on combination therapy. A total of 63 hypoglycemic events were reported with highest incidence in combination group.

HbA1c reduction was greater in patients on premixed aspart (-1.44%) than conventional premixed insulin (-0.69) (p<0.001), while hypoglycemia was less common in the aspart-treated group. Though the mean daily insulin dose was similar in both groups (26.44 U aspart, 26.5/U conventional), the mode was lower with aspart (20U/d in 14.9% patients) than with conventional insulin (30U/d in 20.8%)

Conclusions: This study highlights the feasibility and effectiveness of camp-based diabetes care and insulin initiation in primary care centres. It demonstrates the efficacy, safety and utility of premixed aspart in such settings.

Average daily dose of analog basal insulins in patients with type 2 diabetes: a matched case control analysis

C. McAdam-Marx[1], J. Yu[1], V. Shankar[2], J. Bouchard[3], M. Aagren[3], D.I. Brixner[1]
[1] University of Utah, Department of Pharmacotherapy, Salt Lake City, USA
[2] SDI Health LLC, Verispan, Plymouth Meeting, USA
[3] NovoNordisk Inc, Health Economics & Outcomes Research, Princeton, USA

Aims: Insulin is a recommended treatment option in patients with type 2 diabetes (T2D) who fail to maintain glycemic control on oral antidiabetic drugs. Insulin dose is patient specific and driven by blood glucose control. The purpose of this study was to compare the average daily dose of insulin detemir to insulin glargine in a matched cohort of patients with type 2 diabetes (T2D) to determine if the mean daily dose in the real-world setting differs between these products.

Methods: Patients with T2D (per ICD-9 code 250.x1 250.x3) were identified in the Verispan Electronic Data Warehouse (SDI, Plymouth Meeting, PA) from 7/1/2006 to 6/31/2007. Verispan data has an open architecture and does not include eligibility data, but filtering techniques were employed to eliminate cohort shrinkage. Insulin naïve patients started on detemir (cases) were matched 1:1 to newly treated glargine patients (controls) for baseline characteristics that could influence dose requirements including gender, age (± 2 years), baseline antidiabetic therapy (by classes of oral agents, and exenatide), and comorbidities including cerebrovascular disease, renal failure, heart failure, heart disease/myocardial infarction, hypertension, neuropathy, and obesity. Patients were not prescribed any other insulin during the observation period. The average daily insulin dose in units was calculated as the number of units dispensed from the first to the second to last prescription in the observation period divided by the elapsed days from the first to last fill. A Wilcoxon rank sum test was used to identify differences in the average number of units per day between detemir and glargine. Changes in antidiabetic therapy by class and number of agents after insulin initiation were identified and compared between cases and controls using chi-squared tests.

Results: Of 2215 newly treated patients with T2D, 1581 (71.4%) were matched to a glargine patient. Mean age of this matched cohort was 59.4 years; 53.5% were female. Metformin (57.1%) and sulfonylureas (51.6%) were the most commonly used antidiabetic agents at baseline; 45% were on 1 or 2 non-insulin antidiabetic agents at baseline. The most common comorbidities were hypertension (57.6%) and heart disease/myocardial infarction (15.4%). The mean (median) of the average daily insulin dose was 35 (26) units per day for detemir and 32 (27) units per day for glargine; which was not significantly different (p=0.15). There were no differences in concomitant antidiabetic drug use from baseline to follow-up which could have influenced insulin dose requirements.

Conclusion: The mean daily insulin dose for detemir did not differ from glargine in patients with T2D matched on baseline characteristics that could influence insulin dose requirements.

P-1438

The need for specific assays of insulin analogues

G. Dunseath[1], S. Luzio[1], N. Williams[1], S. Woodhead[2], D.R. Owens[1]
[1] Cardiff University, Diabetes Research Unit, Cardiff, United Kingdom
[2] Invitron Ltd, Wyastone Business Park, Monmouth, United Kingdom

Aims: Most assays for insulin cross-react to varying degrees with insulin analogues making distinction between insulin analogues and human insulin difficult. Currently there are no commercially available specific assays for the short acting insulin analogues aspart and glulisine. The aim of this study was to compare specific assays for the insulin analogues aspart and glulisine with the results obtained from an immunochemiluminometric insulin assay (Invitron ICMA).

Methods: A total of 66 samples were collected for assay taken from 19 Type 2 diabetic subjects who received subcutaneous injection (0.2U/kg) of either aspart or glulisine on 2 separate study days. Low and high insulin analogue concentration plasma samples were taken on both days. Both the doses of the 2 insulin analogues and the sample timepoints were kept the same to maintain comparability. 33 plasma samples were assayed using a specific aspart assay (Capio/Unilabs ELISA) and 33 using a specific glulisine assay (Linco RIA). All samples were then also assayed using an insulin assay (Invitron). Further samples were also assayed for C-peptide (Invitron ICMA) in order to determine endogenous and exogenous insulin using the initial ratios method: $Insulin_{exogenous} = Insulin_{observed} - F \times C\text{-}peptide_{observed}$ (where F is the ratio of basal insulin and C-peptide levels)

Results:

Analogue	Specific assay result (pmol/L) Mean (SD)	Invitron insulin result (pmol/L) Mean (SD)	Calculated exogenous insulin (pmol/L) Mean (SD)	% Bias-calculated exogenous vs. specific insulin (95% CI)	% Cross reactivity of Invitron vs. specific assay Mean (SD)
Aspart	185.8 (182.3)	340.0 (227.1)	304.0 (255.3)	+58.3 (42.3 to 74.4)%	239.8 (239.7)%
Glulisine	326.0 (231.8)	349.8 (159.3)	315.2 (184.8)	-0.4 (-13.3 to 12.5)%	107.3 (45.0)%

Discussion: Our results showed that when comparing specific assay data for aspart and glulisine, there was a 47.7 (44.6)% difference between the mean concentration of the two analogues, despite the consistency in both the dose administered and the sample timepoints. Conversely, there was only a 9.2 (33.8)% difference between mean concentrations measured in the Invitron assay and only a 2.1 (2.96)% difference between mean calculated aspart and glulisine.

This study highlights the difficulty in comparing insulin analogue levels when assayed using different methods, and that care must be taken when interpreting the results. As the use of insulin analogues increases, including the use of multiple analogues, accurate, robust, specific assays for insulin analogues, with no cross-reactivity to either human insulin or other insulin analogues need to be made available.

Insulin detemir was effective for better control of diabetes and reducing weight among Japanese

H. Fujii[1], Y. Watanabe[1], T. Miyakawa[1], A. Ueki[2], A. Ono[2], M. Kato[3], N. Kato[3], K. Kondo[4], M. Takesue[5], H. Takamura[6], H. Nishimura[7], M. Kitaoka[8]
[1] Tama-Center Mirai Clinic, Internal Medicine, Tama-City, Japan

[5] Takesue Clinic, Internal Medicine, Mitaka, Japan
[6] Takamura Clinic, Internal Medicine, Fussa, Japan
[7] Haru Clinic, Internal Medicine, Nishi-Tokyo, Japan
[8] NPO Nishi Tokyo clinical diabetes study group, Internal Medicine, Kokubunji, Japan

We conducted a multi-centered study of insulin Detemir to verify the effectiveness on controlling diabetes, approved by the ethical committee and performed with informed consent by the patients. Our subjects were type 1 and 2 diabetic patients whose control was stable for the previous 3 months without changing therapy of four or more daily insulin injections. We replaced their basal insulin to Detemir and monitored them for 6 months. The insulin dose was fixed for the first 3 months and adjusted thereafter to achieve the target of HbA1c less than 6.5 %. Also the questionnaire of insulin therapy related Quality of Life (ITR-QoL) was performed before and 6 months after the study. Mean age, 49.9y/o, duration of illness,15.7ys, and BMI was 23.2. HbA1c at beginning was 7.5%. Dose of insulin is 45.6U/d (0.76U/kg), with basal insulin 15.8U/d (35.8%). 56 had used Insulin Glargine, and 38 had used NPH insulin as basal insulin. Mean HbA1c from1 month to 6 months were; 7.6 (n.s. by t test with HbA1c at 0 month), 7.5 (n.s.), 7.6 (n.s.), 7.4 ($p<0.003$), 7.3 ($p<0.003$), 7.3 ($p<0.001$) %, respectively. Significant declines after 3 months were seen only among the group whose previous basal insulin was NPH, but not Glargine. Total dose and the basal rate of insulin significantly increased after 4 months. BMI decreased significantly 4 months later. 19 had injected basal insulin twice and continued to inject Detemir twice daily. 11 who had previously injected basal insulin once daily had to inject Detemir twice daily. Dose and basal rates of insulin were higher among the group that injected twice than the group that injected once. According to QoL indexes, 'emotion of treatment', 'hypoglycemia at bedtime and early morning' and 'control at pre-breakfast' improved significantly when Detemir was used. Pain scores of

injection were significantly higher among the Glargine group than the NPH injecting group, but significantly decreased after administering Detemir. In conclusion, replacing basal insulin from NPH to Detemir improved their control. Detemir tended to decrease body weight even among Japanese people whose average BMI was 23.

Improvement of endothelium-dependent dilation was previously shown in T2DM patients submitted to insulin therapy, but this effect was probably due to improved glycemic control.
Aim: To compare endothelium-dependent dilation in patients with T2DM with good metabolic and blood pressure control using or not insulin as part of their therapy.
Methods: We studied 16 patients with T2DM treated with anti-diabetic agents (C, 8 women) and 8 with insulin alone or in combination with anti-diabetic agents (Ins, 3 women), 60.0 ± 5.6 years-old, body mass index 26.3 ± 2.9 kg/m^2. Both groups had HbA1c < 7.5%, no dyslipidemia or nephropathy and systolic blood pressure lower than 150 mmHg. Endothelial function was evaluated by the dorsal hand vein technique, which measures changes in vein diameter in response to phenylephrine, acetylcholine (endothelium-dependent vasodilation) and sodium nitroprusside (endothelium-independent vasodilation).
Results: Age (p=0.66), body mass index (p=0.33), systolic blood pressure (129.4 ± 11.8 vs 133.8 ± 10.3 mmHg, C and Ins, respectively, p= 0.36), HbA_{1c} (6.6 ± 0.6 vs 6.5 ± 0.8 %, C and Ins, respectively, p= 0.95), total cholesterol (p=0.74), triglycerides (p=0.84) and urinary albumin excretion (9.1 ± 9 vs 10.3 ± 6 mg/24h, C and Ins, respectively, p=0.72) were similar between groups. There were no differences between endothelium-dependent vasodilation of C (59.3 ± 26.5%) vs Ins (51.4 ± 16.4%), p=0.38. Endothelium-independent vasodilation was similar between C (113.7 ± 35.3%) and Ins (116.4 ± 24.9%), p=0.83.
Conclusions: Insulin therapy did not influence vascular function in T2DM patients under stable glycemic and blood pressure control.

Comparison of insulin infusion protocols by using time-dependent insulin action model

M. Matsuda[1], Y. Akiyama[1], M. Tokunaga[1], M. Yazawa[1], E. Omura[1]

[1] *Saitama Med Univ. Saitama Med Center, Dept of Endocrinology and Diabetes, Kawagoe-shi, Japan*

Aims: Insulin infusion has been recommended to use in critically ill patients at an in-patients setting to obtain reasonable plasma glucose concentration. However there are many protocols for insulin infusion. It is difficult to compare insulin infusion protocols, because you cannot re-try in the same setting. We have recorded insulin and glucose infusion rate, and plasma glucose concentration during insulin infusion procedures, and applied this time dependent change to a mathematic model which expressed insulin action by time-dependent two parameters. Using this model, we virtually applied insulin infusion protocols to compare the effectiveness and safety of such protocols.
Methods: The model was expressed by an insulin-dose dependent line which was determined by insulin resistance index (IRI-abs: how many units of insulin per hour is necessary to keep plasma glucose conc.) and insulin sensitivity index (ISI-del: decline of plasma glucose conc. by infusion of one unit insulin per hour). The relation was plotted on a graph (X: insulin infusion rate, Y: delta PG), and ISI-del and IRI-abs (which are time-dependent variables) were identified. Glucose infusion was assessed by the distribution of glucose space, and converted to the difference of PG which is approximated in addition to Y. Mathematically this is written as Y = - (ISI-del (t)) x (X - IRI-abs (t)). Next estimated PG = Current PG + Y. By using this model, Yale Univ. protocol, Braithwaite method, and Davidson's method were compared.
Results: Data from 50 cases (subjects) (age: M/F = 25/25, age = 54 ± 12 y.o., BMI = 24 ± 5 kg/m^2) were re-analyzed. Total time under reconstructed and deconvolution was 3,000 hours. Averages PG were 95, 110, and 97 individually. Frequency of hypoglycemia lower than 50mg/dl of PG were 5, 12 and 8 times individually. In the manual procedure of actual intervention, average PG was 113mg/dl, and frequency of hypoglycemia was twice.
Conclusion: In the protocols analyzed, Yale Univ. protocol was most effective and safe. Despite of its complicated protocol, it may be a choice to use Yale Univ. protocol. Although there is a limitation, it also may be possible to apply a procedure by obverting graphic change of insulin action. Thus manual intervention by obverting graphic change of insulin action would be an alternative choice, and further validation would be conducted.

Characteristics of anti-insulin antibodies on Scatchard analysis and daily profiles of plasma glucose

H. Ryuko[1], T. Fukuda[2], E. Isikawa[2], S. Okazaki[2], A. Nozaki[3], T. Yonei[4], H. Kataoka[5], K. Ikeda[5], N. Koide[5]

[1] *Okayama University Graduate School of Medical and Dentistry, Depertment of General Medicine, Okayama City, Japan*
[2] *Sakakibara Heart Institute of Okayama, Internal Medicine, Okayama City, Japan*
[3] *Tunashimakai Kousei Hospital, Diabetic Center, Himeji City, Japan*
[4] *Mitoyo General Hospital, Internal Medicine, Kanonji City, Japan*
[5] *Okayama University Hospital, General Medicine, Okayama City, Japan*

Aim: We analysed how characteristics of anti-insulin antibodies are related to daily profiles of plasma glucose in insulin-treated diabetic patients.
Objects: We evaluated anti-insulin antibodies by K1 affinity constant at the high-affinity range and bound-to-free (B/F) ratio with Scatchard plot analysis. Antibodies in 4 male and 3 female patients (Mean age:65.4±9.1) with type 2 diabetes complicated by poor glucose control because of anti-insulin antibodies were analyzed. All patients were treated with daily insulin injections.The levels of their fasting immunoreactive insulin (IRI) were very high (270-1900μU/ml), and the levels of non-specific binding capacity of their anti-insulin antibodies were also high (54-95%).
Result and discussion: Our patients with anti-insulin antibodies showed two patterns of glucose levels. Insulin resistance and plasma glucose levels were increased in 4 cases, in which 2 cases had high K1 (>0.14), and the other 2 cases had low K1 (<0.03) and high B/F ratio (>1.0). Glucose levels were unstable with early-morning hypoglycemia and hyperglycemia in the rest of a day in the other 3 cases, who had low K1 (<0.06) and low B/F ratio (<0.8).
Conclusion: These results indicate that the affinity and the binding capacity of anti-insulin antibodies have effects on insulin resistance and glycemic instability of insulin-treated diabetic patients.

Why does diabetes therapy often fail?

S. Sakkal[1]

[1] *Metabolic Care Center, Endocrinology & Metabolism, Mason-Ohio, USA*

Introduction/aims: The total cost of diabetes in the United States will approach $200 billion per year by the year 2020. National guidelines recommend HbA1c to < 7% long term and treating BP and lipids. However, conditions are not currently met. The hard facts: outcomes are still dismal and women with diabetes are still dying hard. Even if they monitor blood glucose they often do not adjust their insulin doses due to fear of hypoglycemia and weight gain. Our hypothesis was using Humalink software system would help

find patient, or provider, or disease related factors which may explain why most patients are still not well controlled.

Methods:

1. Software: Humalink system is a well proven, validated software for better glycaemic control applied in more than 1800 patients.
2. Patients: 87 insulin treated diabetics who were insulin pump therapy candidates because of poor glycaemic control (HgA1c>9%, Gl>250 mg/dl), were offered Humalink software via a touchtone telephone, in preparation for insulin pump therapy.
3. Protocol: Patients were asked to call 4 BGSM values twice weekly. Instantly, the system analyzed their previous glucose profile data (up to 90 days), gave an instant response with modifications on insulin am or pm dose (rapid or intermediate). After patient agreed to the protocol, we quantified before and after 12 months intervention metabolic outcome measures and the following provider/patient outcome measures: 1) Patient related factors: Compliance with the protocol (initiating use of the system), Adherence (persistent regular use after initiation) 2) Provider related factors (patients who became well controlled by the system, after provider inability to achieve optimum control). 3) Disease related factors (patients who continued to have poor control and needed Insulin pump).

Results: Non-compliance was seen in 31% of patients (27 of 87 dropped out soon). Of the 60 compliant patients non-adherence was seen in 10% (6 of 60 did not use the system regularly). Of the 54 adhering patients 97.2% improved in all parameters, indicating provider related factors which was appropriately corrected by Humalink not needing insulin pump. Only 2.% did not improve despite good compliance and adherence indicating disease related factors, and clearly representing the best candidates for insulin pump. Improved outcome measures included decreased: 1) FBS from167 to 140 mg/dl. 2) 2HPP glucose from 194 to 152. 3) HbA1c from 9.7% to 7.9%. 4) Fructosamine from 348 to 294. All changes are significant at P value <0.001. For comparison in the non users of the system HbA1c increased 0.4% with absolute difference of HbA1c :2.2% (for comparison oral agents %.5 -1.1).

Conclusion: The three factors in failure of diabetes therapy are: patient related factors (41%) including non compliance (31%), non adherence (10%), provider related factors (57%), disease related factors (2%) which benefits best from the pump if expense covered. Using Humalink may help decrease cost by billions of dollars while improving quality.

Resource utilization and cost comparison among type 2 diabetes patients using either insulin glargine or insulin detemir: a German claims data analysis

P.K. Schädlich[1], E.G. Hagenmeyer[1], H. Gothe[2], A. Höer[3], W. Landgraf[4], B. Häussler[2]

[1] *IGES Institut GmbH, Health Economics and Outcomes Research, Berlin, Germany*

[2] *IGES Institut GmbH, Health Services Research, Berlin, Germany*

[3] *IGES Institut GmbH, Pharmacoepidemiology, Berlin, Germany*

[4] *Sanofi-Aventis GmbH, Diabetes Care, Berlin, Germany*

Aims: Little is known on resource utilization and costs incurred by type 2 diabetic (T2D) patients treated with basal insulin analogues in Germany. The aim of our analysis was to compare prescription drug use, inpatient days for any reason, emergency services, and related costs in T2D patients using either insulin glargine (GLA) or insulin detemir (DET).

Methods: A retrospective cohort study based on pseudonymized claims data provided by a large German sickfund was conducted using propensity score matching. Propensity scores were quantified via regression analysis using patient and physician characteristics. Patients with an equal propensity score taking either GLA or DET were matched for comparison. The primary outcomes consisted of prescription drug use, the number of inpatient days, and related costs during the period from 1/1/2005 until 12/31/2005. Statistics were performed using the non-parametric Mann-Whitney U test. Differences in outcomes between GLA and DET users were regarded statistically significant with a two-sided p<0.05.

Results: Of the 1,051,842 continuously enrolled beneficiaries of the sickfund, 385 GLA and 382 DET users remained after matching. Outpatient prescription drug use was lower by 228 EUR in GLA users compared to DET users (mean costs 2578 vs. 2806 EUR, p=0.001). Costs of outpatient prescription drugs related to diabetes treatment also differed by 305 EUR in favour of GLA users compared to DET users (mean costs 1275 vs. 1580 EUR, p=0.001). There was no meaningful difference in costs of outpatient prescription drugs unrelated to diabetes treatment between GLA and DET users (mean costs 1303 vs. 1225 EUR, p=0.977). Inpatient days for any reason were not different between the GLA and DET groups (mean 7.65 vs. 9.13 inpatient days, p=0.384). There was a lower utilization of emergency services by the GLA group compared to the DET group with a mean of 0.01 vs. 0.16 days (p=0.029) and with mean costs of 2.91 vs. 27.17 EUR (p=0.029) for drugs prescribed by emergency physicians. Further exploratory analyses showed that GLA users accumulated lower cost for short-acting insulin analogues (mean costs 277 vs. 460 EUR, p<0.001) and for blood glucose test strips (mean costs 288 vs. 363 EUR, p=0.045) compared to DET users.

Discussion/conclusion: This analysis of a real-world setting represented by claims data showed considerably lower costs of all outpatient drugs as well as of drugs related to diabetes treatment per T2D patient per year in the group of GLA users compared to the group of DET users. Resource consumption for emergency services differed also in favour of GLA. Propensity score matching is well suited to adjust for known confounders. Hence, a practice-panel survey should be undertaken to evaluate the impact of those confounders, which might not be covered by the present study design.

[4] *Tabriz University of Medical Sciences, Endocrinology & Metabolic disease Department, Tabriz, Iran*

[5] *Iran University of Medical Sciences, Endocrinology & Metabolic disease Department, Tehran, Iran*

[6] *Yazd University of Medical Sciences, Endocrinology & Metabolic disease Department, Yazd, Iran*

[7] *Novo Nordisk Pars, Medical Department, Tehran, Iran*

Aims: IMPROVE™ study was carried out to evaluate the clinical profile of BIAsp 30 (30% soluble insulin aspart, 70% protamine-crystallized insulin aspart) in type 2 diabetes patients in routine clinical practice. A subgroup analysis of quality of life in Iranian patients is presented in this abstract.

Methods: IMPROVE™ was a 26-week, multinational, open-label, non-randomized study in patients with type 2 diabetes. In Iran, 478 patients (47% male), who were treatment-naïve (0.4%) or previously treated with oral antidiabetic drugs (OADs) (33.3%) and/or insulin (66.3%) participated. Mean (SD) age was 55.2 (11.8) y, mean duration of diabetes was 13.2 (8.2) y and mean body mass index was 28.1 (4.8) kg/m^2. The treatment regimen (dose of BIAsp30 and supplementary treatment if any) was at the physician's discretion.

Results: Quality of life (QoL) was measured using the Diabetes Medication Satisfaction Questionnaire (DiabMedSat) score (0 to 100-point scale with higher scores indicating higher quality of life). QoL scores at baseline and end of treatment (26 weeks) are presented in Table 1. After 26 weeks of treatment with BIAsp 30, the overall score was significantly higher than baseline (75.4 at week 26 vs. 58.1 at baseline). Also the subclass QoL scores "relief of burden", "relief of symptoms" and "effectiveness" significantly increased after treatment, particularly the score for "effectiveness" improved by 30 points (from 42.1 at baseline to 72.6 at week 26). The results were further supported by improvement in HbA_{1c}, which was significantly reduced from 8.6% at baseline to 7.4% at week 26. Similar trends were observed in patients previously treated with OAD only or insulin ± OADs (Table 1).

Conclusion: The results showed a significant improvement in the overall

score for quality of life after 26 weeks of treatment with BIAsp 30. These improvements might help to enhance the patient's adherence to the treatment and encourage them in their self-management of type 2 diabetes.

Table 1: Quality of life - DiabMedSat Score

DiabMedSat Score (SD)	All	OAD only	Insulin ± OAD
Overall			
Week 0	58.1 (12.7)	59.2 (12.6)	57.6 (12.8)
Week 26	75.4 (12.0)	75.6 (11.5)	75.3 (12.2)
Change	+17.3 (16.0)*	+16.4 (15.8)*	+17.8 (16.1)*
Relief of Burden			
Week 0	68.9 (15.8)	71.3 (14.9)	67.7 (16.1)

[8] Dr V Seshiah Diabetes Care & Research Institute, Diabetology, Chennai, India

Background: Evidence suggests that early insulin therapy for glycemic control provides additional benefits over conventional therapy in DM. However, subcutaneous route of administration is a barrier to initiating early insulin therapy in majority of these patients. Postprandial glucose control by buccal route of insulin administration may overcome this barrier, improve glycemic control and provide further benefits.
Objective: This prospective open label phase IV multicentric study in India evaluated efficacy and safety of insulin metered dose buccal spray (Generex Oral-lyn™; Oral Recosulin™) given pre- and post-meal in adult subjects with Type 2 DM that are suboptimally controlled with oral anti-diabetic agent (s).
Methods: 40 Male and female insulin naïve type 2 adult diabetics, suboptimally controlled with oral anti diabetic agents (i.e. 6.5≥ HbA_{1c} ≤8.5) but otherwise in good general health, received insulin in addition to their OHA, by metered dose buccal spray after training, in doses ranging from 4 to 10 puffs at each meal based on their FBG, for the study period of 3 months. The main outcome measures were improvement in glycemic control in terms of changes in HbA_{1c}, and improvement in fasting and post meal glucose from baseline. Safety was assessed by monitoring changes from baseline in clinical and laboratory findings and changes in buccal cytology at the end of 3 months treatment.
Findings: Findings in 40 type 2 diabetic patients on OHA who received metered dose buccal insulin spray showed improvement in glycemic control in terms of improvement in HbA_{1c} values (Mean HbA_{1c} value: 7.8% vs 7.3%) and fall in both fasting and postmeal glucose. No significant changes were observed in clinical laboratory events and buccal cytology. Except for minor hypoglycaemic episodes, transient burning sensations and transient numbness in mouth, no other adverse effects were observed. Recombinant human regular insulin metered dose buccal spray (Generex Oral-lyn™ ; Oral Recosulin™) appears to be well tolerated and highly preferred by patients. The detail data and its finding will be presented in the meeting.
Interpretation and conclusions: Treatment with insulin metered dose buccal spray (Generex Oral-lyn™; Oral Recosulin™) in type 2 diabetes mellitus patients on OHA, resulted in glycemic improvement and was well tolerated. Oral Recosulin had high acceptability in patients.

P-1447

Real-life prescription patterns show fewer treatment changes with pre-mixed insulin analogues compared to pre-mixed human insulin in patients with type 2 diabetes in the Netherlands

T.L. Thomsen[1], E.M. Heintjes[2], F.J.A. Penning-van Beest[2], T.E. Christensen[1], A.W. Plat[2], R.M.C. Herings[2]
[1] Novo Nordisk A/S, Global Marketing, Virum, Denmark
[2] PHARMO Institute, Research, Utrecht, The Netherlands

Aims: Studies have suggested that pre-mixed insulin analogues may improve the balance between glycaemic control and hypoglycaemia compared with human pre-mixed insulin in patients with type 2 diabetes (T2D). This Dutch study aimed to observe prescription patterns of pre-mixed insulin analogues compared to human pre-mixed insulin among patients with T2D by: looking at proportions of patients starting either human or analogue pre-mixed insulins; comparing previous insulin experience; and establishing how many patients changed treatment during the first year of treatment.
Methods: The Dutch PHARMO database includes community pharmacy drug dispensing records and clinical laboratory measurements from approximately 2.5 million patients. Data for patients with T2D who started using pre-mixed insulin in the period 2004–2006 were extracted, and patients were categorised into insulin-naïve users (no insulin in the previous year) and prior insulin users. In addition, the proportion of patients changing treatment within one year was determined.
Results: The study included 3530 new users on pre-mixed insulin, of which 2324 (65.8%) were naïve to insulin. Overall, 2134 (60.5%) started on analogues; the proportion of analogue users was greater among prior insulin users (812 of 1206 = 67.3%) vs. naïve users (1322 of 2324 = 56.9%). In prior insulin users, a significant difference in baseline HbA_{1c} was observed between those using human pre-mixed insulin (8.5%) and pre-mixed analogue (8.0%, p<0.001). Other patient characteristics did not differ between human insulin and analogue users. Within one year, 44.1% of human pre-mixed insulin users and 33.5% of pre-mixed analogue users changed their treatment. The changes made and average time to change were recorded: among human pre-mixed insulin users 20.1% discontinued treatment (230 days), 6.5% added a fast-acting insulin to their therapy (114 days), and 17.6% switched treatment (143 days); among pre-mixed analogue users 14.9% discontinued treatment (245 days), 5.8% added a fast-acting insulin to their therapy (137 days), and 12.9% switched treatment (155 days).
Conclusion: When insulin treatment was initiated, pre-mixed insulin analogues were more frequently prescribed by Dutch physicians than human pre-mixed insulin. Users of pre-mixed insulin analogues neither discontinued nor switched therapy as frequently as human pre-mixed insulin users, suggesting that pre-mixed insulin analogues gave a more sustained and satisfactory result.

P-1448

Blood glucose variability in type 2 diabetic patients on different basal insulin preparations

I. Smirnov[1]

[1] *Kharkov Regional Hospital, Endocrinology, Kharkov, Ukraine*

Background and aims: There are strong evidences of a close linear relationship between average glycaemia during 3 months and HbA1c at the end of this period. However the blood glucose (BG) excursions can considerably differ in patients with the similar HbA1c level. We aimed to find any (if at all) difference in blood glucose variability (BGV) in patients on various basal insulin regimens.

Materials and methods: We studied 61 Type 2 diabetic (T2D) patients on glargine once a day (I, N=18), NovoMix twice daily (II, N=20) or NPH twice daily (III, N=23) with pretty strict glycaemic control (HbA1c<7,5%). Three groups were matched for age, gender, BMI and diabetes duration. No significant differences between groups in HbA1c were found. The BGV was assessed from 3 days continuous glucose monitoring (CGM). CGM system high limit of BG was fixed on 9,0mmol/l, low limit on 4,0mmol/l. Episodes of hypoglycaemia were registered either they were symptomatic and BG below normal range, or asymptomatic and BG below 2,5mmol/l.

Results: The duration of CGM was around 72 hours with no differences in the number of sensor values between groups. In the course of CGM an average BG was 8,5mmol/l, 8,6mmol/l and 8,6mmol/l; BG min-max deviations: 2,7 – 11,5mmol/l, 3,1 – 10,6mmol/l, and 2,2 – 14,6mmol/l in I, II and III group respectively. The table shows CGM results (values are presented as Mean±SD).

see table 1

Hypoglycaemias were rare, no severe episodes were seen. Despite the proved difference in duration of BG below low limit between groups they were comparable in clinically remarkable hypoglycaemic events.

Conclusions: BGV in T2D patients with equal HbA1c could be significant. The minimal BG excursions were found on NovoMix twice daily and the most meaningful were on NPH twice daily. How much BGV is clinically important remains unclear and needs further study.

[9] *Novo Nordisk Pharma Korea, on behalf of IMPROVE-Korea study group, Seoul, Korea*

Aims: To investigate clinical safety and efficacy of biphasic insulin aspart (BIAsp30) administered once- or twice-daily in Korean patients with type 2 diabetes.

Methods: This was a 26-week, open-label, multi-centre, observational study in Korean patients with type 2 diabetes to evaluate the safety and efficacy of BIAsp30 in daily clinical setting. Data were collected at baseline and final visit (26 weeks).

Results: 645 patients (mean age: 56.6 ± 12.5 years, mean BMI: 24.8 ± 4.0 kg/m^2, mean diabetes duration: 11.0 ± 8.6 years, mean HbA_{1c}: 9.7 ± 2.0%) were enrolled. Of which 16.0% were treatment naïve, 35.8% were previously treated with oral antidiabetic drug (OAD) only, and a large portion of patients (48.2%) were treated with insulin ± OAD. After entering into the study, 53.5% and 37.8% of patients were initiated with BIAsp30 only and with OAD, independently. At the final visit, majority (56.4%) of patients were receiving BIAsp30 + OAD. During the study, a total of 10 (1.6%) adverse drug reactions (ADRs) and 6 (0.9%) serious ADRs were reported. Among 9 serious adverse events (SAE), only 6 cases were probably associated with BIAsp30. The proportion of patients who reported major hypoglycaemic episodes decreased over time (baseline vs. final visit: 2.7% vs. 0.2%, p<0.001). In contrast, incidence of minor hypoglycaemic episodes increased from 11.8% at baseline to 24.5% at final visit (p<0.001). HbA_{1c} was significantly reduced from baseline to final visit by 1.24 ± 2.22% (p<0.001). An increase of more than 2 fold was observed in the proportion of patients who achieved the glycaemic target of HbA_{1c}<6.5% (baseline vs. final visit: 2.0% vs. 5.1%), while the proportion of patients achieving HbA_{1c}<7.0% almost doubled (baseline vs. final visit: 5.9% vs. 11.5%). FPG was significantly reduced from baseline to final visit by 2.31 ± 5.05mmol/L (p<0.001). Change of mean body weight was 0.97 ± 3.41 kg at final visit (p<0.001). However, treatment naïve patients took almost part in the increase of body weight. The overall total DiabMedSat score (which indicated patient's quality of life) after 26 weeks of treatment with BIAsp30 was significantly higher (baseline vs. final visit: 63.4 vs. 68.3, p<0.001).

Conclusion: In Korean patients characterized with long duration of type 2 diabetes and poorly controlled even under more intensive therapy, treatment with BIAsp30 significantly improved glycaemic control and quality of life, while not increasing the incidence of major hypoglycaemic episodes.

P-1450

Analysis of glycemic control outcomes vs. baseline in patients treated with analog basal insulin in a real-world setting

C. McAdam-Marx[1], R. Nelson[1], M. Aagren[2], J. Bouchard[2], D.I. Brixner[1]

[1] *University of Utah, Department of Pharmacotherapy, Salt Lake City, USA*

[2] *NovoNordisk Inc, Health Economics & Outcomes Research, Princeton, USA*

Aims: In clinical trials, change in A1C is often associated with baseline A1C; the higher the baseline value the greater the reduction with treatment. Both insulin detemir and insulin glargine have demonstrated improved glycemic control for patients with diabetes mellitus (diabetes) in controlled clinical trials. This study compares A1C outcomes vs. baseline in patients treated with detemir and glargine in a real-world, ambulatory care setting.

Methods: Patients with diabetes were identified from the General Electric electronic medical record (EMR) research database (GE Centricity) from September 1, 2004 to April 30, 2008. Patients were 18+ years, insulin naïve, newly treated with detemir or glargine mono-insulin therapy. Index date was defined as the date of the first detemir or glargine prescription. Patients were continuously active in the EMR for 395 days pre to 270 days post-index date and had no other insulin orders in the follow-up period. Baseline A1C was identified 45 days pre to 15 days post-index date. Both baseline and change

Table 1

Index	Groups			p-value		
	I	II	III	I/II	I/III	II/III
HbA1c (%)	7,21±0,25	7,19±0,24	7,23±0,24	>0,5	>0,5	>0,5
# of sensor values	870,56±11,59	868,60±15,31	872,26±13,76	>0,5	>0,5	>0,4
Duration above high limit (%)	11,28±4,44	8,50±3,36	14,35±3,77	0,04926	0,03112	0,00019
Duration below low limit (%)	20,22±6,45	15,95±5,34	25,00±7,90	0,03122	0,04731	0,00094
Duration within limits (%)	68,50±5,86	75,55±5,29	60,65±9,92	0,01625	0,01938	0,00087

in A1C from baseline to 6 month (±90 days) were compared between detemir and glargine using independent t-tests. A linear regression analysis was used to adjust A1C outcomes for age, gender, region, baseline A1C, diabetes type, baseline BMI, and hypoglycemic events.

Results: Of the 6570 patients who met study inclusion criteria, 308 (4.7%) were started on detemir and 6262 (95.3%) on glargine. Mean (±SD) age was 58.7±12.7 years and did not differ by insulin. A total of 46.4% of detemir patients were female versus 49.6% of glargine patients (p<.001). Of those with A1C data (n=198; 64% for detemir, n=3881; 62% for GLAR) baseline A1C was significantly higher for glargine (9.2±1.9%) than for detemir (8.8±1.9%; p=0.003). Mean change in A1C from baseline to 6 months in those with A1C data was -1.1±2 for detemir vs. -1.4±1.9 for glargine (p=0.12). When controlling for multiple baseline characteristics the mean change in A1C also did not differ between detemir (-1.5%; 95% CI -1.6 – -1.3) and glargine (-1.3; 95% CI -1.4 – -1.3).

Conclusion: Although changes in A1C with antidiabetic drug treatment are often positively associated with baseline A1C in clinical trials, glycemic control outcomes in those treated with the basal analog insulins detemir or glargine in a real-world setting were similar despite higher baseline A1C for glargine patients.

P-1451

Evaluation of first insulinization by administration of basal insulin in Asian patients with type 2 diabetes

S. Tsai[1]
[1] *Veterans General Hospital, Taipei, Taiwan*

Aim: FINE Asia (First Basal Insulin Evaluation in Asia), a multinational, prospective observational study, assessed the use of basal insulin in insulin-naïve Asian Type 2 diabetes (T2D) patients (age≥20y), uncontrolled (HbA_{1c}≥8%) on oral antidiabetic drugs (OADs).

Methods: Basal therapy was assessed at 6 months by doctors (Drs) and patients, on a 4-point scale (not good, moderate, good, very good). Treatment choices were at the Dr's discretion to reflect real-life practice. Patients with both baseline and 6-month HbA_{1c} data were included and analyzed.

Results: 2679 patients from 11 Asian countries: 50% male; mean±SD age, 56±11y; BMI, 26.1±4.7kg/m^2; T2D duration, 9±6y; OAD duration, 9±6y. 2016, 589 and 61 patients started glargine, NPH and detemir, respectively. Results (overall and categories by insulin type) are shown in the Table. Overall reductions in HbA_{1c} (9.8 to 7.7%) and FBG (210 to 129mg/dL) were seen after 6 months of basal insulin; 33.7 and 36.9% patients reached HbA_{1c}<7% and FBG<110mg/dL, respectively. Significant differences between insulins were seen (Table). Significantly higher No. of patients on glargine reached HbA_{1c}<7% and FBG<110mg/dL at Month 6 vs detemir and NPH patients (Table). Patients on glargine had a lower frequency of total, severe and mild–moderate hypoglycaemia vs NPH patients at Month 6 (Table). 72% of Drs and 78% of patients rated insulin treatment as good/very good. More Drs (76%) and patients (81%) rated glargine as good/very good vs other insulins (% of Drs and patients): NPH 58 and 68%; detemir 43 and 51%; significant (p<0.0001) differences were seen for both Drs and patients between insulin type.

Conclusion: Starting insulin treatment with basal insulin was efficient and safe in Asian T2D patients, with significant differences found among basal insulins. As this was a descriptive registry, no sample size calculation was used, leading to large variations in patient No. between groups. Thus, these results should be interpreted with caution.

Insulin pump therapy for children/young people: Impact on condition management in the context of family lives

F.M. Alsaleh[1], *F.J. Smith*[1], *K.M.G. Taylor*[2], *R. Thompson*[3], *K. Agostini*[3], *L. Potts*[3]
[1] *School of Pharmacy University of London, Practice and Policy, London, United Kingdom*
[2] *School of Pharmacy University of London, Pharmaceutics, London, United Kingdom*
[3] *University College Hospital, London, UK*

Background: It has been estimated that around 10%-25% of type 1 diabetes mellitus (T1DM) patients are treated with insulin pumps or continuous subcutaneous insulin infusion (CSII) in the US and other European countries. However, this percentage is much lower in the UK (1%), with only 0.1% of children with T1DM treated with CSII.

In the UK, recent government policy has emphasized that disease management for children should allow them, and their families, to lead normal lives. To date, there is limited evidence from the users' perspective that demonstrates the benefits and problems of insulin pumps in the lives of children and their parents. Such evidence will inform policy regarding recommendations for CSII use in children and young people.

Aim: To examine the experiences of children using CSII, and their parents, including glycemic control, use of pump technology and flexibility in lifestyle for children of different ages and durations of pump therapy.

Methods: The study was conducted in the Paediatric Diabetes Clinic at University College Hospital (UCH), London. All patients (N= 70) using insulin pumps and attending the clinic, and their parents, were invited to participate. Semi-structured audio-recorded interviews were conducted with parents of all children and children aged 5 years and older. Measures of HbA1c values from six months prior to, and after, pump therapy were also obtained from medical records. Quantitative analysis of structured data was undertaken using SPSS. Qualitative data were analyzed by an iterative process employing a constant comparative approach.

Results: Both the parents and the children found it easier to maintain glycemic control within their target range with CSII compared to injection therapy. This was supported by HbA1c measures and reported severity of hypoglycaemic episodes. Whilst patients and the parents generally found the device itself easy to use and more acceptable than injection from the start, variable lengths of time were required to develop confidence in carb-counting and dose calculation. Parents and children reported an overall increase in flexibility in lifestyle and their ability to participate in daily activities. Trends in the independent use of insulin pumps were associated with both children's age and duration of pump use.

Conclusion: Parents and children using CSII found it easier to lead normal lives by being able to maintain glycemic control and accommodate more flexibility in lifestyle, which is a central goal of health policy for children in the UK. This evidence will inform future policy regarding recommendation for CSII use for children with T1DM.

Guiding the optimal use of insulin analogues

B. Leslie[1], D. Belanger[1], B. Shea[1]

[1] Canadian Agency for Drugs and Technologies in Health, Canadian Optimal Medication Prescribing and Utilization Service, Ottawa, Canada

Aims: The Canadian Agency for Drugs and Technologies in Health (CADTH) through its Canadian Optimal Medication Prescribing and Utilization Service (COMPUS) produced a series of Optimal Therapy Reports and related intervention tools aimed at optimizing the use of insulin analogues in Canada. Given the high prevalence and rising incidence of diabetes in Canada, the optimal prescribing and use of insulin and insulin analogues has the potential to positively impact health outcomes for a large number of patients. Given the increasing number of people diagnosed with diabetes mellitus each year, health care providers, consumers, and policy makers require evidence-based information on the optimal use of these agents.

Methods: Research efforts for the comparison of insulin analogues with conventional insulins focused on:

- clinical evaluation (systematic reviews and meta-analyses)
- economic evaluation (cost-effectiveness analyses)
- current utilization analysis
- current practice analysis
- identification of practice and knowledge gaps
- barriers to optimal use
- creation of key messages
- development of intervention tools

Results:

- 16 optimal therapy recommendations were produced
- Three gaps in knowledge and practice were revealed through comparing information from the Optimal Therapy Reports: Current Utilization of Insulin Products in Canada, and Current Practice Analysis with the Optimal Therapy Recommendations for the Prescribing and Use of Insulin Analogues
- Key messages were developed based on the gaps and recommendations
- COMPUS developed several intervention tools that will encourage the evidence-based optimal prescribing and use of insulin analogues

Discussion/conclusion: Uptake of COMPUS key messages on the optimal use of insulin analogues has the potential to positively impact health outcomes for a large number of patients and to provide evidence for decision-makers toward the efficient use of finite health care resources. This presentation will discuss the COMPUS process from clinical and cost-effectiveness evidence to the production of intervention tools designed to improve the prescribing and use of insulin analogues. Key messages on bolus insulin and basal insulin therapy will be highlighted.

Long term evaluation of a programme of intensive treatment with continuous subcutaneous insulin infusion (CSII) in patients with type 1 diabetes

I. González-Molero[1], M. Domínguez-López[1], M.S. Ruiz de Adana[1], S. Gonzalez-Romero[1], F. Soriguer[1]

[1] Hospital Carlos Haya, Endocrinology and Nutrition, Malaga, Spain

Introduction: CSII therapy is an effective treatment to ameliorate metabolic control and quality of life in patients with type 1 diabetes. Nevertheless most of the studies have evaluated only short term results.

Objective: To evaluate the long term results (three years) of CSII treatment in type 1 diabetes.

Material and methods: This is an observational longitudinal study in patients previously treated with multidose of insulin (MDI) who start and continue during at least three years insulin pump therapy. We ruled out pregnant or pregestational patients (32 women) and patients using combined sensor-pumps systems (34 patients). We analyzed in 49 patients the following data: age, sex, duration of the disease, macro and microvascular complications, and reason for starting CSII treatment. Initially and every six months periods during three years were evaluated: dose of insulin, weight, number of self monitoring blood glucose (SMBG), HbA1c, hypoglycemic events, quality of life (DQOL), and medical visits frequency.

Results: We obtained data from 49 patients (26 male and 23 female), with a median age of 34,11+/-11,7 years and 17,59± 7,41 years of diabetes duration. 11,6% had neuropathy, 12,2% nephropathy (4,1% with chronic kidney failure) and 28% retinopathy. The clinical reasons to initiate CSII treatment were: 37,5% bad metabolic control, 40,6% glycemic lability and 21,9% severe or frequent hypoglycemic events. During three years, six patients dropped out of CSII treatment and four pumps were removed by the medical team.

	Basal	6 months	12 months	24 months	36 months
HbA1c	8.11±2,2	7.6±1,3*	7,8±0.9*	7,2±2,6*	8,2 ±0.97
Insulin units /Kg	0,67 ±0,4	0,49±0,29	0,5±0.4	0,48±0,3	0,42±0,32
Weight	69±10,6	69,4±10,7	70,4±10.6*	71,6±11.2*	73,9±11,8*
Severe hypoglycemic events /year	0,43	0.06	0	0	0.03
Number of hypoglycemia events /week	4,5±3	3,3±2,8	2,1±1,7*	2,8±2,2*	2,7±1,6
Ketoacidosis (requiring hospital admission)	0	0	0	0	0
Sensibility factor	37,6 ±17.8	45,3±19.04	40.7±18.9	38,8±18,4	41,3±10,3
Carbohydrate rate	1.05±0,5	0,88±0,44	0.95±0.46	0.97±0,44	1,03±0,29
SMBG	3,6±2.5	3,1±1,99	3,8±1,9	3,7±2,2	3,2±1,4
Number of visits / month		0,62±0,22	0,28±0,14	0,30±0,11	0,30±0,11
DQOL	92± 16,15	80,82± 19,2*	82,12±19,1*	82,5±14,0*	

*P<0,05

Conclusions: CSII treatment improves metabolic control and quality of life in well selected patients. This improvement is evident in the first six months and is mantained during all this period for quality of life but not for HbA1c reduction.

The effect of various insulin regimens on glycemic control and cost-effectiveness

T. Saler[1], N. Sener[2], S. Ucak[2], T. Yesim[3], Z.A. Saglam[4], Y. Altuntas[5]

[1] Haseki Training and Research Hospital, Internal Medicine, Istanbul, Turkey

[2] Sisli Etfal Training and Research Hospital, Internal Medicine, Istanbul, Turkey

[3] Haseki Training and Research Hospital, Endocrinology, Istanbul, Turkey

[4] Haseki Training and Research Hospital, Family Practice, Istanbul, Turkey

[5] Sisli Etfal Training and Research Hospital, Endocrinology, Istanbul, Turkey

Background and aims: We aimed to compare the efficacy of various insulin regimens on glycemic control in diabetic patients using insulin.

Materials and methods: Data of 987 patients (583 female/404 male) were analysed retrospectively. Patients were divided into groups according to insulin regimens as insulin lispro 25 (Lis25), human insulin 30 (HM30) and biphasic insulin aspart 30 (BiAsp30) for twice daily insulin regimens and human regular insulin and neutral protamine insulin Hagedorn [NPH] (HR-HN), insulin lispro and glargine (LisGlar), insulin aspart and glargine (AspGlar) and regular human insulin and glargine (HR-Glar) for intensive regimens. Type of insulin, insulin doses, total and per kilogram body weight, HbA1c levels before and after treatment, body weight, duration of diabetes, duration and onset of insulin therapy were evaluated and compared among groups.

Results: In twice daily insulin regimens glycemic control was achieved in all types of insulin in similar success rates. Glycemic regulation rates were 32,4 %, 44,6 % and 40,4 % in Lis25, HM30 and BiAsp30 groups, respectively, when target HbA1c was defined as <7. Lowest insulin doses per kilogram were used HM30 group compared to Lis25 and BiAsp30 groups (0,37± 0,15 IU/ kg vs 0,49± 2,27 and 1,03± 5,28 IU/ kg, respectively). In intensive insulin regimens, achievements of glycemic control rates were 39,7 %, 17,9 %, 23,7 % and 30 % in HR-HN, LisGlar, HR-Glar and AspGlar groups, respectively. Insulin doses per kilogram used in intensive regimens were 0,55± 0,17; 0,52± 0,14; 0,61± 0,25 and 0,55± 0,26 IU/kg, in HR-HN, LisGlar, AspGlar and HR-Glar, respectively.

Conclusion: Although glycemic control was achieved to some degree with all regimens, HR-HN was effective in smaller doses and cheaper compared to AspGlar. Also in twice daily regimens, all groups were similarly successful in achieving glycemic control, but HM30 was effective in smaller doses and cheaper than Lis25 and BiAsp30 groups. Our data indicate that regimens using human insulin are cost-effective and as successful as insulin analogues.

A user study assessing the performance of a new reusable insulin pen injection device compared with other injection pens available on the market

A. Penfornis[1]

[1] *University of Franche-Comté, Endocrinology-Metabolism and Diabetology-Nutrition, Besançon, France*

Aims: Important practical aspects of insulin injection pen devices for patients with diabetes mellitus (DM) are ease of use and performance. ClikSTAR® (sanofi-aventis) is a new reusable insulin pen device under development for injection of insulin glargine or insulin glulisine.

Methods: In this user study, ease of use and performance of ClikSTAR was compared with 3 available reusable insulin pens: NovoPen 3®, NovoPen 4® (Novo Nordisk) and Lilly Luxura® (Eli Lilly). 654 patients with DM from the US, Canada, UK, France and Germany were included in the study (Oct–Dec 2008). For each pen type, the patient was assessed via a face-to-face questionnaire on the following: fixing/replacing cartridge, hearing/feeling clicks, safety test and dialling/delivering 40 U dose; patients then rated overall usability.

Results: Overall, a higher proportion of patients found ClikSTAR easy to use vs comparator pens (Table 1). For specific categories assessing ease of use, such as replacing cartridge, dialling a dose and feeling the clicks, a significantly higher proportion of patients rated ClikSTAR easy to use vs other pens. Patients using ClikSTAR did not experience any significant difficulties in completing tasks vs other pens (Table 2). The proportion of patients not requiring help completing specific tasks with ClikSTAR was higher or similar vs comparator pens; significantly more patients completed all steps without help vs NovoPen 3 and 4 pens.

Conclusion: At the final stages of ClikSTAR pen development, in patients with DM, ease of use and overall performance of the pen was equal to or better vs other injection pens currently available on the market.

[5] *Hanyang University Medical Center, Internal Medicine, Seoul, Korea*
[6] *Hallym University Kangnam Sacred Heart Hospital, Hallym University Kangnam Sacred Heart Hospital, Seoul, Korea*
[7] *Suwon Ajou University School of Medicine, Endocrinology and Metabolism, Suwon, Korea*
[8] *Seoul St. Mary Catholic Medical Center, Internal Medicine, Seoul, Korea*

Aims: To evaluate clinical safety and efficacy of insulin detemir in Korean patients with type 1 or type 2 diabetes mellitus under normal clinical practice conditions.

Methods: PREDICTIVE™ is an observational, multi-centre, open-label, prospective study to assess the safety and efficacy while using insulin detemir once or twice daily. The results of the 26-week treatment in Korean patients with type 1 or type 2 diabetes are presented, based on an interim analysis of 2005 patients from an expected population of 10,000 patients at completion of the study.

Results: Baseline characteristics: Mean age: 56.0 ± 12.8 years, mean diabetes duration: 9.6 ± 6.1 years, mean HbA_{1c}: 9.2 ± 1.8%, mean fasting plasma glucose (FPG) 10.64 ± 4.12 mmol/L, mean body weight: 63.5 ± 10.6kg. The majority of patients included had type 2 diabetes (97.4%). During the study, the incidence of serious adverse drug reactions (SADRs) including major hypoglycaemic episodes (adverse events considered related to treatment) was 0.3% (six subjects). The incidence of all hypoglycaemic episodes decreased from 4.51 episodes per patient year at baseline to 1.71 episodes per patient year after 26 weeks. The incidence decreased both for diurnal and nocturnal episodes. A corresponding decrease was found for the incidence of major hypoglycaemic episodes from 0.64 per patient year at baseline to 0.01 per patient year at 26 weeks. Fourteen adverse events (AEs) were reported in nine patients and 10 serious AEs were reported in seven patients. Most AEs (92.9%) were classified as 'unlikely' related to insulin detemir treatment. Treatment with insulin detemir was associated with a significant reduction in HbA_{1c} of -0.9% ± 1.8% from baseline to 26 weeks ($p<0.0001$). Insulin detemir also significantly improved FPG (change from baseline to 26 weeks: -2.68 ± 4.21 mmol/L, $p<0.0001$). No difference was observed in body weight from baseline to end of the study (baseline vs. 26 week: 95% CI = [-0.1, 0.1], $p > 0.05$).

Conclusion: In Korean patients with type 1 or type 2 diabetes, treatment with insulin detemir was associated with

- a low incidence of serious adverse events and lowering of hypoglycaemia
- improved glycaemic control and non-significant weight change.

[7] *Yonsei University Wonju College of Medicine, Internal Medicine, Wonju, Korea*
[8] *Seoul St. Mary Catholic Medical Center, Seoul St. Mary Catholic Medical Center, Seoul, Korea*

Aims: To evaluate clinical safety and efficacy of insulin detemir in Korean patients with type 2 diabetes mellitus that transferred to insulin detemir from other basal insulin or oral antidiabetic drug (OAD).
Methods: PREDICTIVE™ is an observational, multi-centre, open-label, prospective study to assess the efficacy and safety while using insulin detemir once or twice daily. Results from 26 week of treatment are presented from an interim analysis of 1672 Korean patients with type 2 diabetes mellitus classified based on previously treated by insulin glargine, neutral protamine Hagedorn (NPH) insulin or OAD only, respectively. This expected study population at completion of the study is 10,000 patients..
Results: Overall, 461 patients previously treated with glargine, 260 patients previously treated with NPH and 951 patients previously treated with OAD only were enrolled in this analysis. Twenty six weeks after transfer to insulin detemir, only a few serious adverse events were reported in the three subgroups (0.9% in glargine group, 0% in NPH group and 0.3% in OAD only group). During the study period, one serious adverse drug reaction including major hypoglycaemic episode was reported in the glargine subgroup and none in the other two subgroups. The proportion of total hypoglycaemic episodes decreased in both groups pretreated with basal insulin (glargine group: from 13.9% at baseline to 6.9% at 26 weeks; NPH group: from 21.2% at baseline to 9.6% at 26 weeks), but increased slightly in OAD only group (from 1.2% at baseline to 5.3% at 26 weeks). No difference was observed in change of body weight from baseline to end of the study in any of these groups. Treatment with insulin detemir was associated with a significant reduction in HbA_{1c} in all three groups (changes from baseline to 26 weeks: -0.3 ± 1.6% in glargine group; -1.0 ± 1.5% in NPH group; -1.1 ± 1.7% in OAD only group; p< 0.05 in all analyses). Insulin detemir also improved fasting plasma glucose (changes from baseline to 26 weeks: -0.13 ± 0.77 mmol/L in glargine group (not significant); -0.79 ± 2.03 mmol/L,in NPH group, p< 0.05; -0.49 ± 0.88 mmol/L in OAD only group, p<0.05).
Conclusion: In Korean patients with type 2 diabetes with poor glycaemic control by other basal insulin (insulin glargine or NPH) or OAD only, insulin detemir improved glycaemic control with less risk of hypoglycaemia. The results show how insulin detemir is efficacious and well tolerated in Korean patients with type 2 diabetes.

P-1459

Evaluation of daily glucose variation using CGMS in CSII and MDI treated patients with long-standing diabetes mellitus type 1

T. Didangelos[1], F. Iliadis[1], A. Zantidis[1], A. Hatzitolios[1]

[1] *Aristotle University, Diabetes Center, Thessaloniki, Greece*

Aim: To evaluate with Continuous Glucose Monitoring System (CGMS) glucose variability, events of hypoglycemia and daily glycaemic control in patients with long-standing Diabetes Mellitus type 1 (DMT1) treated with either Continuous Subcutaneous Insulin Infusion (CSII) using insulin aspart or Multiple Daily Insulin injection (MDI) using glargine once daily and regular three times daily.
Patients and methods: Twenty eight patients with DMT1 (9 women) with mean age 36.7 ± 10.2 years and mean duration of DM 20.3 ± 7.6 years were on treatment with either CSII (n=11) or MDI (n=17). All patients wore a CGMS sensor for six days and hyper / hypoglycaemic episodes and glycaemic control were evaluated.
Results: There were more hypoglycaemic excursions [blood glucose (BG) <or= 60 mg/dl] 4.8±1.0 vs 1.4±1.1, p=0.018 and the average duration of hypoglycaemia was significantly different (8.9 ±2.6 vs 2.4 ±1.7, p=0.048) in MDI than CSII group. Number of measurements within the glucose range of 60-70 mg/dl were not significantly different (90.3 ± 19.9 vs 40.8 ±31.3, p=0.067) for the two groups. Hyperglycaemic excursions (BG >or= 180 mg/dl), glycaemic exposure over 150 mg/dl and maintenance of near-euglycaemia as determined by the average amount of time spent within the glucose range of 80-140 mg/dl were similar between the two groups. HbA1c was significantly better (6.8 ± 0.4% vs 8.2 ± 0.4 % p=0.019) in CSII than in MDI group. Mean age and mean duration of DM did not differ between the two groups.
Conclusion: In present study patients with long-standing DMT1 treated with CSII had fewer hypoglycaemic excursions as evaluated using CGMS and significantly better HbA1c than patients treated with MDI.

[1] *University Clinical Centre of Sarajevo, Clinic of endocrinology diabetes and metabolism disease, Sarajevo, Bosnia and Herzegovina*

Aim: To examine whether the use of insulin glargine alone or in combination with metformin has influence on the reduction of CRP in obese type 2 diabetic patients (T2D). In this 12-months randomized clinical trial, we assessed the comparative effects of metformin and insulin glargine alone or in combination on inflammatory biomarkers, glycemic control, and lipids.
Methods: In beginning of study excluded patients who had coronary heart, kidney disease before, diabetes mellitus type 1 or any inflammatory response before. In study included 83 obese with T2D [43 male and 40 female, BMI = 28.93 ± 2.45 kg/m2, aged 33-65 yr], who had previously been treated with sulfonylurea therapy and who have poor glycemic control (HbA1c>7%) and elevated CRP (>2mg/l). Patients divided in three groups with similar BMI, age and sex. Fifteen patients received glargine s.c. alone once a day (1st group), 38 patients received glargine s.c. in combination with metformin orally at the doses of 3x850 mg/d (2nd group) and 30 patients received metformin alone at the doses of 3x850 mg/d (3rd group). All patients will receive diet and exercise counseling. Markers of glycemic control and inflammation including fasting blood glucose (FBG), postprandial blood glucose (PBG), HbA1c, hsCRP, lipids, basal insulin and C-peptide, were measured at baseline, 3, 6, 9 and 12 months. Clinically, levels of CRP>3 mg/l indicate elevated risk for myocardial infarction and stroke. Percentile, average and correlation analysis have been utilized in statistical analysis.
Results: HbA1c, FBG and PBG were significantly reduced from baseline 3 months after starting treatment in each of the groups (p<0.01), but the best glucose control had 2nd group. Listed reduction was maintained in a similar proportion during the 12 months. HbA1c decreased from 8.98 to 7% in 3rd group, to 6.5% in 2nd group and to 6.79% in 1st group (NS, p=0.31). FBG decreased for 5.2 mmol/l in 1st group, for 6.5 mmol/l in 2nd group and for 4.9 mmol/l in 3rd group. Mean body weight and mean waist circumference significantly reduced in the 3rd group (p<0.05). Mean serum CRP levels (4.38 ± 1.95 mg/l) significantly decreased after metformin treatment (-1.98mg/l, p<0.05) and glargine+metformin treatment (-1.67mg/l, p<0.05) but after glargine treatment CRP decreased not significantly (-0.89mg/l). Level of CRP significantly correlated to level of fasting insulin, C-peptide, to BMI, HbA1c, total cholesterol, and to triglycerides. Total cholesterol and low-density lipoprotein cholesterol levels decreased as well in all three groups.
Conclusion: Reduction levels of CRP in obese patients with type 2 diabetes were more effective after glargine treatment in combination with metformin than after glargine treatment alone.

Patterns of cardiovascular risk and disease amongst people with Type 2 diabetes starting insulin: baseline characteristics in the CREDIT study

L. Blonde[1], P. Home[2], G. Vespasiani[3], K. Admane[4], M. Marre[5]
[1] *Ochsner Clinic Foundation, Department of Endocrinology Diabetes and Metabolic Diseases, New Orleans, USA*
[2] *Newcastle University, Institute of Cellular Medicine – Diabetes, Newcastle upon Tyne, United Kingdom*
[3] *Diabetology and Metabolic Disorders Centre, Ascoli Piceno, Italy*
[4] *Sanofi-aventis, Paris, France*
[5] *Université Paris, INSERM U695, Paris, France*

Aims: Insulin therapy improves long-term glycaemic control, which can reduce the risk of vascular events associated with Type 2 diabetes mellitus (T2DM).
Methods: The Cardiovascular Risk Evaluation in people with T2D on Insulin Therapy (CREDIT) study is a 4-yr, 314 centre, non-interventional trial in North America, Europe and Asia, which includes people with T2DM who had recently started insulin therapy.
Results: At baseline, 3031 patients with T2DM were enrolled (51% male; mean±SD age 61±10 yr; BMI 29.3±6.3 kg/m^2; T2DM duration 11±8 yr). Macrovascular disease was present in 34%; most commonly stable angina (13%), peripheral vascular disease (11%) and prior myocardial infarction (10%). Unsurprisingly, there was a trend for more CV risk factors amongst people with T2D who had at least one cardiovascular disease (CVD) condition, including older age (>=63 yr), male sex, diagnosis of hypertension, family history of CVD and physical inactivity.
Conclusion: Shifting the management paradigm to attempt to prevent rather than retrospectively treat CVD through tight metabolic control is a high priority of diabetes care. As the study progresses, analysis of CVD outcomes stratified by metabolic control on insulin initiation should provide evidence as to the value of timely initiation of insulin to achieve this treatment goal.

[6] *Sir Ganga Ram Hospital, Endocrinology & Metabolism, New Delhi, India*
[7] *Kilpauck Medical College, Medicine, Chennai, India*

Aims: Several studies have shown that hypoglycemia is the most common safety concern with intravenous insulin. However such clinical safety data is minimal for intravenous (IV) use of insulin aspart (IAsp). The aim of this study (ClinicalTrials.gov Id: NCT00700648) was to evaluate the safety and effectiveness of using IV IAsp in the management of in-patient hyperglycemia.
Methods: This is an open label, non-randomized, non-interventional, observational study. IV IAsp was prescribed for managing hyperglycemia among hospitalized subjects, according to routine clinical practice in India. In total 2972 (Male: 62.9%, Female: 37.1%) subjects received IV IAsp during the study period of six months. Two thousand subjects (67.3%) were admitted to ICU and the rest received IV IAsp in non-ICU setting.
Results: Fifty four episodes of major hypoglycemia were reported in 50 subjects: 1/2/3 episodes in 47/2/1 subjects respectively and 162 minor hypoglycemic episodes were reported in 131 subjects: 1/2/3/4/6 episodes in 109/16/4/1/1 subjects respectively. Overall only 1.6% of the subjects experienced at least one episode of major hypoglycemia with IV IAsp (see Table 1). There were no hypoglycemia related complications. There were five serious adverse events (SAEs), unlikely to be related to the study medication, reported during the study.
Conclusions: Intravenous insulin aspart appears to be a safe and well tolerated option for managing in-patient hyperglycemia in ICU as well as non-ICU settings.

Table: Incidence of hypoglycemia during IV IAsp treatment

	Subjects experiencing at least one episode of hypoglycemia		
	ICU (n=2000)	Non-ICU (n=972)	Overall (n=2972)
Major hypoglycemia #, n (%)	37 (1.8%)	13 (1.3%)	50 (1.6%)
Minor hypoglycemia, n (%)	65 (3.2%)	66 (6.7%)	131 (4.4%)
Overall *, n (%)	99 (4.9%)	79 (8.1%)	178 (5.9%)

receiving i) IV dextrose / glucagon and / or ii) blood glucose < 3.6 mmol/L
* Three subjects in ICU group and one subject in Non-ICU group experienced both major & minor hypoglycemia.

P-1463

Insulin therapy: partial knowledge by part of diabetic patients interferes in their adherence to the treatment

J. Dullius[1], R. Fonseca Lima[2], D. Correa de Araujo[2], A. Vaz Machado[2], J. Naves[2]
[1] *University of Brasília, Physical Education College, Brasília - DF, Brazil*
[2] *University of Brasília, Pharmacology School University of Brasília, Brasília - DF, Brazil*

Aims: The aim of this study was to correlate the insulin therapy knowledge of people who have Diabetes Melllitus (DM) and the adherence level of the same individuals to the therapeutics schemes.
Methods: The research was based on semi-structured questionnaire answered by 30 type 1 diabetic individuals. All of them are over 16 years old and attend a regular health education program which deals with DM, health education and

oriented physical activities. Data regarding knowledge, trust and understanding of their treatment was collected as well as their level of adherence, awareness and commitment. It was studied 15 women and 15 men, with the average age of 30 ± 12 and the average time of DM equivalent to 11 ± 8 years. In addition, the average insulin applied daily was of 2.9 ± 1.3.

Results: It was possible to verify that, before attending the program, 53.3% of the participants affirmed their non-adherence, partially or totally, to the treatment as well as their unawareness and non-commitment to the same. This might have reflected in the 76.6% of the individuals who declared not knowing the start of action, the durability of response and the serum peak levels of insulin they used. Moreover, it is believed that it also influenced the 50% of those who declared not trusting and not understanding the treatment. Among the questions made before and after the participation in the program, the clinical question related to 'the knowledge about insulin therapy' was the one which presented the highest absolute average variation (0.97; an increase of 48%). Thus, it suggests a direct influence in the treatment adherence level after the program: 93.3% of the participants affirmed to have now an ideal level of adherence, awareness and commitment to the treatment against 46.6% of the ones who affirmed the same before attending the program.

Conclusion: Nowadays, communicable chronic diseases have been considered one of the main causes of morbidity in population and Diabetes Mellitus is one of them. It is noticeable the existence of individual and contextual factors which may influence the treatment adherence and are essential for the efficacy of pharmacotherapy in diabetic patients. Moreover, it is indispensable that the diabetics have this capacity for managing the insulin schemes by themselves when it is necessary. For doing so, however, it is necessary that the patient understands the treatment and trusts in it, which will directly affect in the treatment adherence.

Characteristics predicting poor blood glucose control at the time of starting insulin therapy; data from the CREDIT study

P. Home[1], L. Blonde[2], M. Marre[3], K. Admane[4], G. Vespasiani[5]

[1] Newcastle University, Institute of Cellular Medicine – Diabetes, Newcastle-upon-Tyne, United Kingdom

[2] Ochsner Medical Center, Diabetes Clinical Research Unit Department of Endocrinology, New Orleans LA, USA

[3] Université Paris, INSERM U695, Paris, France

[4] sanofi-aventis, Paris, France

[5] Diabetology and Metabolic Disorders Centre, Ascoli Piceno, Italy

Aims: The Cardiovascular Risk Evaluation in people with Type 2 diabetes mellitus (T2DM) on Insulin Therapy (CREDIT) study is assessing the effect of insulin on the risk of vascular events.

Methods: CREDIT is a 4-yr, 314 centre, non-interventional trial in North America, Europe and Asia and includes 3031 people with T2DM who have recently started insulin. This analysis aimed to identify factors leading to poor glycaemic control (HbA_{1c} >8.5 %) at the time of starting insulin. Participants were divided into two groups by HbA_{1c} (≤8.5 and >8.5 %) and the baseline characteristics of the groups were compared using Chi square or Wilcoxon rank-sum test. For factors associated with poor glycaemic control, multivariable backward logistic regression analysis was performed, entering all variables with p<0.20 on univariate analysis.

Results: Table 1 presents the baseline characteristics according to HbA_{1c} group. Age, BMI, region, FBG and the diagnosis of retinopathy, peripheral neuropathy and hypertension were identified as potential predictors of poor glycaemic control. Variables remaining in the model with a p value <0.05, and therefore taken as significant predictors of poor glycaemic control, were age (p=0.003), FBG (p=0.000) and region (p=0.000) (Table 2).

Conclusion: Based on the modelling of HbA_{1c} levels of ≤8.5 and >8.5%, at the time of starting insulin, older people appear to have better glucose control (lower HbA_{1c} [≤8.5%]) compared with younger people. Not surprisingly, high FBG was also correlated to high HbA_{1c} levels. There are also unexplained geographical differences in attitudes to starting insulin.

P-1465

Treatment of 212 patients with type 1 and 2 diabetes mellitus with a novel insulin preparation (AI) which is avidly absorbed if instilled into the auditory channel

K. Pirkalani[1]

[1] Mehr Medical Group, Internal Medicine, Tehran, Iran

Aims: To find new routes for insulin "instillation" into the body and to abate the need for injectable insulin or oral hypoglycaemic agents, we developed a novel insulin preparation that can avidly and rapidly be absorbed from the auditory channel with the idea that small molecules in the range of 4500 Dalton are readily absorbable from mucous membranes.

Methods: Different preparations were tested in a phase Zero study for absorption. Both radioactive and bioassays were performed. At phase I, 212 patients with either type 1 (22 patients) or type 2, 190 patients were enrolled to this trial. All previous hypoglycaemic medications, including long acting insulin, were discontinued 24 hours before the study. Based on baseline BS 8-45 Unit equivalent of auditory insulin AI was instilled into the external auditory channel and the patients were let to rest. Blood sugar was tested at 15 minutes and every half hour till 3.5 hours and blood insulin levels were evaluated before and 2.5h after instillation.
Results: No patient developed local or systemic side effects. Insulin is avidly absorbed from the mucosa of the auditory channel. It does not pass the tympanic membrane evaluated with our tools. BS levels decreased substantially in 185 patients (87%) and less pronounced in another 10 (4.7%). A clear cut dose/response curve could be drawn only between 25-45IU. The response was correlated with type 1 diabetes and type 2 diabetes of shorter duration. Patients with type 2 diabetes of longer duration, history of insulin resistance, stress, anxiety during study, generalized anxiety disorder (basedon MCMI-III) and those whose external auditory channel was more grayish than red or pink fared less well than others. Almost all responding patients showed an (absolute or relative) increase of serum insulin matched with their blood sugar. Curiously, instillation of insulin into the auditory channel erased a faster response than IV insulin in 74 (35%) of the examinees. Besides, later till two months control of BS in patients who returned to their oral hypoglycaemic regimen was followed by better control giving the erroneous idea to many of our patients that this treatment might be "curable".
Discussion: This is the first trial of instillation (does not need sophisticated spraying equipments) of insulin into the auditory channel. It is extremely effective and patients respond nearly uniformly. Another trial is presented which uses a piezoelectric pump for continuous control. With clever application and larger trial of longer duration this revolutionary treatment will completely abolish sc insulin, oral hypoglycaemic agents, inhalation insulin and sophisticated therapies such as gene therapy or beta cell transplantation forever.

No conflict of interest

P-1466

Continuous control of diabetes mellitus by infusion of auditory insulin (AI) into the ear via a piezoelectric pump

K. Pirkalani[1], Z. Talaei Rad[1]
[1] Mehr Medical Group, Internal Medicine, Tehran, Iran

Aim: Based on previous studies we tried to design a very small and sophisticated infusion system and evaluate blood sugar control.
Methods: A piezoelectric pump of 2g weight first fed by a 70g electronic device + battery and later by a very tiny feeding electronic machine of less than 8g was used. Twenty type 2 diabetes patients were enrolled to this trial. They received a bolus of crystal insulin IV to reach a BS level of less than 150mg; afterwards, they received escalating doses of AI equivalent to1-5 IU per hour for 16h/24h or 24h/24h. The escalation was done only in case of random BS of >250mg/dl. The electronic device was self controlled and all patients received 0-10 units of insulin equivalents before each meal. Comparison with intermittent insulin, short term BS control and glycosylated albumin were goals of this trial rather than HbA_1C and long term BS.
Results: As predicted, continuous AI is followed by excellent BS control with 100% of random BS under 183mg/dl; 82% below 150 and 76% of below110mg/dl. Attacks of hypoglycaemia never happened, though rarely subjective sense of deranged well-being was encountered with normal BS; a phenomenon familiar to endocrinologists. 8 of 10 patients who were on intermittent insulin showed better control of BS with only 55-70% of the previously needed insulin. This is a great improvement as bolus insulin is the real cause of wide fluctuations of BS. Most patients enjoyed excellent BS control with 1.5-2.5IU/h in the 24h/24hregimen and 2-3.5IU/h in the 16h/24h regimen. At least 60% of the patients probably do not need insulin overnight. The glycosylated albumin showed complete normalization in 18 of 20. Patients' compliance for carrying of the piezoelectric pump with the heavier and tiny electric device was good and excellent respectively, even in patients on oral hypoglycaemic agents as they were convinced of more natural system of treatment with less strict diets.
Discussion: The result of this (not preliminary) trial is extraordinary. After decades of challenge we have developed a therapy which is extremely effective and easy to deliver. The risk of this therapy as is shown in a small number of patients is nil. Clearly, larger double blind trials with long term side effects and long term diabetes control must clarify the state of this therapy in the anti diabetic armamentarium. There were no side effects in short term and a mathematical model with a concomitant drug therapy will abolish long term local side effects (explained elsewhere). Laboratory findings have also shown that insulin does not pass the tympanic membrane and the site of absorption is the mucous membrane of the auditory channel. Continuous instillation is not faced with liquid overload relative to the auditory channel volume and does not jeopardize hearing.

Pregnancy and gestational diabetes

P-1467

Insulin therapy among women with impaired glucose tolerance of pregnancy

A.E. Dawson[1], L.L. Lipscombe[2]
[1] University of Toronto, Internal Medicine, Toronto, Canada
[2] Women's College Hospital, Endocrinology, Toronto, Canada

Background: Women with gestational diabetes (GDM) often require insulin therapy to treat hyperglycemia. Women who have impaired glucose tolerance (IGT) of pregnancy do not fulfill diagnostic criteria for GDM and are traditionally not offered specific treatment, but may also have hyperglycemia-related adverse outcomes. However, the benefit of following these patients is uncertain, as it is unclear what proportion progress to hyperglycemia requiring insulin therapy.
Objectives: To document the proportion of women with IGT of pregnancy who progress to hyperglycemia requiring insulin therapy, and to identify predictors for insulin treatment, in women with IGT and GDM.
Methods: We reviewed the charts of 280 women with a history of IGT or GDM followed at Women's College Hospital from January 2006 to August 2008. Women were diagnosed with IGT if they did not meet criteria for GDM but had one abnormal value on a glucose tolerance test. Patients with IGT were treated according to the standard of care for women with GDM, which involves starting insulin therapy in response to hyperglycemia. We calculated the proportion of women with IGT and GDM who required insulin during their pregnancy. Using univariate and multivariable logistic regression, we also identified predictors of insulin use overall and within people with IGT.
Results: We studied 68 women with IGT (24.3%) and 212 (75.8%) women with GDM. There were no significant differences in baseline characteristics between the two groups. Insulin therapy was started in 33.8% of women with IGT, the mean gestational age at initiation was 32 weeks, and the mean maximum daily dose was 14.5 units. Women with GDM were more likely to require insulin therapy (61.8%, P<0.001), and there was a trend toward earlier treatment (30.3 weeks, p=0.057) and a higher daily dose (31.5 units, p=0.089) compared to women with IGT. On multivariable analysis, overall predictors of insulin use were PCOS (odds ratio, OR 3.36, 95% confidence interval, CI 1.26 – 8.94), family history of diabetes (OR 2.1, 95% CI 1.22 – 3.61), and obesity (OR 2.85, 95% CI 1.39 – 5.83). In the subset (n=171) with available fasting glucose levels, high serum fasting glucose (>=5.3 mmol/L) was the most important predictor of insulin need (OR 6.32, 95% CI 2.94 – 13.59).
Conclusions: Although it is not standard practice to monitor and treat women with IGT of pregnancy, we found that 34% go on to require insulin therapy to treat hyperglycemia. Our findings suggest that women with IGT of pregnancy may need similar care to those with GDM, particularly those with additional risk factors such as high fasting glucose, obesity, PCOS, and family history of DM. This study may have implications for the diagnostic criteria of GDM.

Continuos subcutaneous insulin infusion versus multiple daily injections in pregnant women with type 1 diabetes

I. González-Molero[1], M. Domínguez-López[1], S. Gonzalez-Romero[1], M.S. Ruiz de Adana[1], F. Soriguer[1]
[1] Hospital Carlos Haya, Endocrinology and Nutrition, Malaga, Spain

Introduction: Women with type 1 diabetes who wish to became pregnant need to be intensively treated to avoid undesired effect of bad glucose control. Incidence of complications are still nowadays increased in diabetic women. Insulin pumps (CSII) offer theoretical advantages over multiple daily injections but there are few published studies comparing CSII and multiple daily insulin injections (MDI), and many of them are not recent.

Objective: To compare metabolic control and obstetric and perinatal outcome in women with type 1 diabetes treated with CSII and MDI during pregnancy.
Methods: Retrospective study, including all women treated with CSII during pregnancy in recent years (1999-2008), as compared with a control group of all women with type 1 diabetes treated with MDI in the same period of time in our Endocrinology and Pregnancy Unit. Metabolic control, obstetric and perinatal outcome were compared in both groups. In a second approach we have excluded from MDI group, younger patients and shorter duration of diabetes, obtaining a 2nd control group of MDI, with the same age and diabetes duration as CSII group.
Results: 35 pregnancies in 26 women treated with CSII and 103 pregnancies in 87 women treated with MDI were evaluated. Metabolic control (HbA1c), complications of diabetes during pregnancy (hypoglycemic events, ketoacidosis, progression of retinopathy or nephropathy) and obstetric and perinatal outcome did not differ among groups.
Conclusions: CSII during pregnancy is a safe treatment, and for selected women may be a therapeutic option in planned pregnancies. Obstetric and perinatal outcomes are similar to that achieved with MDI intensive treatment.

Using prophylactic steroid therapy in GDM: lesson learnt

M. Anekal[1], M. Ramprasad[1], A. Bhattacharyya[1], N. Shivashankar[1]
[1] Manipal Hospital, Diabetes & Endocrinology, Bangalore, India

Background: People with GDM at risk for neonatal respiratory distress syndrome are given prophylactic steroid between 28-34 weeks of pregnancy.
Aims: In this study we wanted to see the requirement/increment of the Insulin dose in GDM pregnancies given steroid.
Materials and methods: 22 GDM women given prophylactic steroid (two doses of Betamethasone 12 mg in 24 hours) over the last six months in our hospital constituted this cohort. 14 were on diet only, rest were on Insulin. Pre- and postmeal (2hr) capillary glucose were monitored (six/day) and urine was checked for ketone. Every effort was made to keep the premeal < 100mg/dl and post meal< 140mg/dl.
Results: All 14 on diet required Insulin, average short acting Insulin required was 27 units while basal 31 units/day, everybody required Insulin till delivery. The increment of people already on Insulin were 719% short acting and 838% basal Insulin. One patient required IV Insulin and none had positive urine ketone. All discharged on insulin. The average decrease in insulin dose after one week of steroid therapy was 67% of short acting insulin and 61% of basal insulin, none reached baseline dose. Only one lady on diet did not require insulin after a week of steroid therapy. On follow up, all pregnancies were uneventful and none of the babies had developed neonatal complications.
Conclusion: Management of GDM patients requiring steroid therapy is a challenge to the treating clinician. From our study, we have observed that GDM patients on diet control required average insulin of 26 and 30 units of short and long acting respectively, while already on insulin required a huge increment both in prandial and basal Insulin. A knowledge of this increment in the dosage of insulin in people with GDM receiving steroid will help in the management.

Excess of weight and under weight in the newborn of mothers with diabetes (Study of 1,320 consecutive alive births)

L. Valdes[1], O. Santana[1], B.R. Rodriguez[1], A. Santurio[1], J. Lang[2], A. Marquez-Guillen[2]
[1] Ramon Gonzalez Coro Hospital, Central Service of Diabetes and Pregnancy, Ciudad de la Habana, Cuba
[2] National Institute of Endocrinology, Central Service of Diabetes and Pregnancy, Ciudad de la Habana, Cuba

Aims: The discovery of a nexus among the weight at birth and the development of several illnesses in the mature age has opened new areas to the medical investigations.
Patients and method: We analyze retrospectively the alive born results of 1 320 children of diabetic mothers. 686 were "gestational diabetics", and 634 were "pregestational diabetics".The definition of macrosomic neonate employed was = or > to 4 000g, and for IUGR it was less than 10 percentile of the curve of weight of our institution. We used the X2 test of Fisher for the analyses of the variables and Z for the proportions with a statistical significance $p < 0,05$.
Results: We detect a frequency of macrosomic neonates of 14,2% (181/1320). The frequency of IUGR was 2,4% (32/1320). Differences were not detected on macrosomic frequency between gestational diabetics and Pregestational diabetics.
We detect among the maternal events related with macrosomic neonates: pregestational maternal weight more than 120%, the weight gain during pregnancy bigger than 15 kg, and maternal hyperglycemia. With regard to IUGR neonates, we detect among maternal events: pregestational maternal weight less than 90%, pregnancy induced hypertension and vascular lesion present at ophthalmoscopy in the Pregestational diabetics.
Conclusions: 1.- The frequency of macrosomic neonates can be expected with almost the same frequency from the period of gestational diabetes.
2.- The macrosomic and IUGR neonates of the mother with diabetes have been according with our results multifactorial events.

An office-based "stepped-up" protocol using the PDSA Cycle for management of gestational diabetes mellitus

A. Rizvi[1]
[1] University of South Carolina School of Medicine, Department of Medicine, Columbia, USA

Aims: Strict glucose targets are advocated in gestational diabetes mellitus (GDM) to minimize maternal-fetal complications. In a brief pilot project, we instituted a brisk "stepped-up" approach at our institution involving a multipronged strategy of education, diet, and pharmacologic therapy to achieve glucose control in GDM patients.
Methods: The "Plan-Do-Study-Act" cycle was used for quality improvement. *Plan:* A results-oriented strategy for improving GDM care. *Do:* All patients seen for GDM received preliminary in-office education followed by dietary advice within 5 days of referral from their obstetrician or primary care physician. They were supplied with blood glucose (BG) meters at the initial visit and instructed to monitor their fingerstick readings at least 4 times a day (morning fasting and one hour after each meal). Urinary ketone testing was advised. The patients were asked to use standardized blood glucose flow sheets to record and either fax or call in their BG on a daily basis. Insulin therapy, usually with multi-dose daily injections, was started within one week of the initial visit if lifestyle and diet modifications were inadequate in achieving desired glucose goals. Continued communication with phone/fax 2-3 times per week and office visits once or twice a month was continued for the remainder of the pregnancy.
Results: Over a 12-week period, 17 women with average age 28.6 years (range 19-34) were treated for GDM upon referral from the obstetrics service. The average duration of pregnancy at first visit was 28 weeks. All patients were given a "crash course" of diabetes self-management teaching, diet, with ongoing feedback and guidance. *Study:* 11 patients were managed with lifestyle/nutrition, while 6 required insulin. The average hemoglobin A1c achieved prior to delivery was 5.48% (range 4-7.3). The average fasting and 1-hour postmeal glucose were 91 and 119 mg/dl respectively. 14 of 17 pregnant women reached both the A1c and fingerstick ADA-recommended glucose goals for GDM.
Conclusion: In this pilot study applying the PDSA philosophy, glycemic control in GDM was achieved quickly and safely by employing an aggressive yet supportive approach consisting of office nurse education, self-management and dietary advice, and close, frequent, and ongoing communication between the diabetes center staff and the patient. In the final *Act* phase, further empowerment of the patient to assume and maintain responsibility will be studied. Even in practices with limited resources, GDM can be managed successfully by focusing on and emphasizing the major priorities as outlined above.

Insulin dose, distribution & factors influencing its requirement in gestational diabetes mellitus: Indian experience

S. Gupta[1]
[1] Diabetes Care and Research Centre Pvt. Ltd., Diabetology, Ramdaspeth Nagpur, India

Aim: To evaluate insulin dose, distribution and factors influencing its requirements in Gestational Diabetes Mellitus (GDM) & Decreased Gestational Glucose Tolerance (DGGT)

Material & method: 781 pregnant women with varying degree of glucose intolerance were divided in two groups GDM (as per WHO & ADA criteria) & DGGT (If any 2 hr OGTT value is ≥120mg%, but not meeting the standard ADA or WHO criteria, or if any one value is abnormal in 3hr OGTT]).They were managed till delivery by achieving euglycemia (FBG < 90 mg%, 2hr PPBG < 120 mg%) by therapeutic diet and/or Insulin therapy. Majority of subjects who required < 40IU insulin/day at delivery were evaluated for their insulin dose, relation with meal, age, pre pregnancy weight, pre pregnancy Body Mass Index (BMI), Fasting Blood Glucose and Glycosylated Haemoglobin A1c (GHb%) at diagnosis.

Observation:

- Of total 781 subjects, 382 (48.9%) women required insulin to achieve euglycemia for pregnancy. Amongst 493 GDM women 300 (60.8%) and of 288 DGGT women 82 (28.4%) needed insulin for control.
- 333 subjects (87.1%) were on < 40IU/day insulin and 49 subjects (12.8%) were on ≥ 40IU insulin/day at delivery.
- Women requiring < 40IUInsulin/24hr at delivery were further evaluated as below:
  - Insulin requirement in GDM was 16 ± 9.5 IU /day & in DGGT was 10 ± 7.2 IU/day (P 0.002)
  - There was progressive increase in insulin dose from diagnosis to delivery (P 0.01)
  - GDM women needed 0.25 IU/Kg/day & DGGT women needed 0.17 IU/Kg/day insulin of their Pre-Pregnancy weight.
  - Amongst those on three times insulin doses per day, pre dinner Insulin dose was highest & pre-breakfast was lowest in both the groups and was statistically significant [GDM – (P-0.01), DGGT-(P 0.01)]
  - Insulin dose was positively co-related to Fasting Plasma Glucose at diagnosis (P 0.01), Pre pregnancy weight (P 0.01), Pre Pregnancy BMI (P 0.01), GHb% at diagnosis (P 0.01).
  - Insulin dose could not be co-related to height & age of subject and weeks of diagnosis of pregnancy.

Conclusion: Most of the available literature indicate that insulin treatment of GDM women should be individualized. Our data has shown positive correlation of insulin dose with Fasting Plasma Glucose and Glycosylated Haemoglobin A1c at diagnosis, Pre pregnancy weight & Pre pregnancy Body Mass Index. There was progressive statistically significant increase in insulin requirement from diagnosis till delivery. Unlike others, highest dose requirement in pre-dinner period in our population indicates the probable impact of dietary habit on the insulin dose, which needs further assessment

P-1473

Lipid profile in diabetic pregnancy

H. Sellami[1], F. Chaker[1], C.H. Amrouch[1], M. Hassine[1], F. Mahjoub[1], A. Falfoul[1], S. Chabchoub-Blouza[1]

[1] *Nutrition institute of Tunis, Diabetology nutrition and metabolic disorders, Tunis, Tunisia*

Physiologic pregnancy is associated with a broad series of metabolic adaptations which may also influence the metabolism of lipids.

Aim: To assess the modifications of cholesterol, triglycerides, low density lipid cholesterol (LDL-C) and High-Density Lipoprotein cholesterol (HDL-C) during pregnancy in diabetic women.

Materials and methods: A comprehensive lipid profile was evaluated in 30 diabetic women during physiologic pregnancy (first, second and third trimester). Conventional lipid parameters, including total cholesterol, high-density lipoprotein cholesterol and triglycerides, were evaluated. Low-density lipoprotein cholesterol was quantified by the formula of Friedewald.

Results: We observed that all the lipid parameters tested were significantly modified by the gestational age; in particular, women in the second and third trimester displayed significantly increased total cholesterol, low-density lipoprotein cholesterol, high-density lipoprotein cholesterol and triglycerides.
Advancing pregnancy was associated with an increased prevalence of undesirable or abnormal values for total cholesterol, low-density lipoprotein cholesterol and triglycerides in the second trimester (respectively 15%, 8% and 57%) and for total cholesterol, low-density lipoprotein cholesterol, triglycerides, in the third trimester (respectively 6%, 9% and 20%) compared to parameters in the first trimester of pregnancy.

Conclusion: The results of this study demonstrate that physiological pregnancy is associated with a substantial modification of the lipid metabolism from the second trimester, providing reference ranges for traditional cardiovascular risk predictors throughout the gestational diabetic period.

P-1474

Relation between glycaemic goals used in the management of gestational diabetes and perinatal outcome and the impact of maternal obesity on the rate of caesarean section

M. Khan[1], H. Gray[2]

[1] *Bedford Hospital, Diabetes and Endocrinology, Bedford, United Kingdom*

[2] *Cheltenham General Hospital, Diabetes and Endocrinology, Cheltenham, United Kingdom*

Aims: To assess whether glycaemic goals of Preprandial Capillary Blood Glucose of <6 mmol/L and Post Prandial Capillary Blood Glucose of < 8 mmol/L used at our centre to treat patients with Gestational Diabetes are adequate in preventing perinatal complications and
To assess the impact of Maternal Obesity on the rates of Caesarean Section and Foetal Macrosomia.

Design and methods: This was a retrospective study of 92 patients with a diagnosis of Gestational Diabetes seen in the joint Antenatal-Diabetes clinic between July 2005 to May 2007 at our centre which is a secondary care 450 bedded hospital.
Data was collected on several variables and data such as rates of Caesarean section,Foetal Macrosomia, induction of labour, shoulder dystocia and still birth rate was compared against data from:

- General Maternity population data in England and Wales (from CEMACH study-Maternity Statistics England 2002- 2003) and
- Pregnancy Outcome Data of the intervention group in the ACHOIS study (Australian Carbohydrate Intolerance Study in Pregnant Women).

Results: The median BMI in our study was 27 ± 7.2. 38% of patients had a BMI of > 30 and 14% were grossly obese with a BMI greater than 40.
Total Number of Caesarean Sections were 34.7 % of which 62% were Elective and 38% were Emergency.
25% of elective Caesarean sections were done purely for Foetal Macrosomia.
The median Birth Weight observed was 3505 grams (± 551). 15.3 % of Babies were Macrosomic (birth weight > 4000grams)
5.5% of Babies were severely macrosomic (birth weight > 4500 grams).
64 % of macrosomic babies were born to mothers with a BMI of greater than 30.
There was one case of Shoulder dystocia (1.08 %) and one still birth (1.08 %) observed in this study.Still birth rate in UK is 0.57% and that of Shoulder dystocia is 3%.

Discussion: We found the rate of Caeserean Sections (34.7%) was higher than in the general maternity population but not too different from that observed in the ACHOIS intervention group (31%). The Foetal Macrosomia rate in our study (14.3%) was only slighltly higher than general maternity population in the UK (11%) and ACHOIS (10%).
In our study 38% of patients had a BMI of greater than 30 and 14% were grossly obese with a BMI greater than 40.This could be the cause of the higher caesarean delivery rates compared to the general maternity population.
Comparing the Caesarean delivery and the macrosomia rates seen in our study with that of UK general maternity population and the ACHOIS study, It can be said that glycaemic targets used at our centre which is Preprandial < 6 mmol/L and postprandial <8mmol/L are adequate to reduce the rate of perinatal complications seen in Gestational Diabetes.
Our study also signifies the link between Maternal Obesity and rates of perinatal outcomes such as C-Section and Foetal Macrosomia.

Mother's weight history and its impact on newborn's anthopometry: preliminary data

M.-C. Dube[1], A.-S. Morisset[2], R. Drolet[2], E. Bujold[3], A. Tchernof[2], S.J. Weisnagel[1]

[1] *CHUQ-CHUL, Diabetes Research Unit, Québec, Canada*

[2] *CHUQ-CHUL, Molecular Endocrinology and Genomics, Québec, Canada*

[3] *Laval University, Department of Obstetric and Gynecology, Québec, Canada*

Introduction: Pregnancy is characterized by a physiological state of insulin resistance, which is further magnified in women affected by gestational diabetes (GDM). Low maternal birthweight is associated with a twofold higher risk for GDM, independent of major confounders. However, maternal weight history may have an impact on baby's weight.

Aim: To explore the relationships between mother's weight history and fetal and newborn's anthropometric measurements.

Methods: A 75-g OGTT was administered in 24 Caucasian women: 5 presented gestational diabetes and 19 had normal glucose tolerance. Mother's weight history was documented and body composition measures (height, weight, hip circumference, skinfold thickness) were obtained between 24 to 28th weeks of gestation, at 32 weeks of gestation and 8 weeks postpartum. Fetal measurements were obtained at 32 weeks of gestation (cranial, abdominal perimeters, femur length, estimated weight). Length, weight, cranial and thoracic perimeters were measured in the first hour and at 8 weeks of life of the newborn. Spearman rank correlations were computed to quantify associations between variables.

Results: Reported weight at 20, 30 years old and highest adult weight correlated with newborn's weight (0.41 to 0.45, $P < 0.05$) and there was a trend for a correlation between mother's weight at 32 weeks of gestation and the newborn's weight (0.38, $P = 0.06$). Reported weight at 20, 30 years old and highest adult weight also correlated with newborn's length (0.41 to 0.44, $P < 0.05$). Mother's weight measured between 24th and 28th weeks and at 32nd weeks of gestation also correlated with newborn's length (0.45 and 0.47, all $P < 0.05$).

Conclusions: Our results suggest that women's weight history with or without diabetes is related to newborn's growth measurements.

Differential effects of olanzapine and risperidone on plasma adiponectin levels over time: results from a 12-week prospective open-label study

A. Scheen[1], L. Hanssens[2], M. Wampers[3], R. Van Winkel[3], J. Collette[4], J.Y. Reginser[2], M. De Hert[3]

[1] *CHU Sart Tilman, Division of Diabetes Nutrition and Metabolic Disorders and Unit of Clinical Pharmacology, Liège, Belgium*

[2] *CHU Sart Tilman, Department of Epidemiology and Public Health, Liège, Belgium*

[3] *University Psychiatric Center St Jozef, Katholieke Universiteit Leuven, Kortenberg, Belgium*

[4] *CHU Sart Tilman, Department of Clinical Chemistry, Liège, Belgium*

Aims: Second-generation antipsychotics (SGA), especially clozapine and olanzapine, are associated with an increased metabolic risk. They may induce weight gain, metabolic syndrome (MetS), impaired glucose tolerance/impaired fasting glucose (IGT/IFG) and/or diabetes mellitus. Recent research showed that plasma adiponectin levels, an adipocyte-derived hormone that increases insulin sensitivity, vary in the same way in schizophrenic patients as in the general population according to gender and adiposity. The aim of the present study was to investigate whether different SGAs might vary in their effect on plasma adiponectin levels independent of body mass index (BMI) and MetS status.

Methods: 113 schizophrenic patients (65.5 % males, 32.3 years old, average GAF score 4.5) who were free of antipsychotic medication were enrolled in this open-label prospective single-centre study and received either risperidone (n=54) or olanzapine (n=59). The two groups had similar baseline demographic and metabolic characteristics. They were followed prospectively for 12 weeks. Average daily dose was 4.35 mg/day for risperidone and 17.36 mg/day for olanzapine. Plasma adiponectin levels as well as fasting metabolic parameters were measured at baseline, 6 weeks and 12 weeks.

Results: Baseline BMI (23.7 vs 23.2 kg/m^2), prevalence of MetS (adapted NCEP-ATPIII criteria: 7.4 vs 8.0%), mean fasting plasma glucose (FPG) (86.8 vs 86.9 mg/dl), fasting plasma insulin (FPI) (11.4 vs 12.0 mIU/ml) and plasma adiponectin levels (10154 vs 11280 ng/ml) were similar in the risperidone group and in the olanzapine group, respectively. A significant increase in body weight was observed over time in the olanzapine group as opposed to a numerical increase in the risperidone group (+7 kg vs +3.1 kg, $p< 0.05$). Slight but not significant differences were observed in MetS prevalence (increase from 7.4% to 20.4% with risperidone vs increase from 8.5% to 33.9% with olanzapine), in FPG (from 86.8 to 88.0 mg/dl with risperidone vs from 86.9 to 89.2 mg/dl with olanzapine) and in FPI (from 11.4 to 10.8 mIU/ml with risperidone vs from 12.0 to 14.0 mIU/ml with olanzapine). We observed a significant ($p =0.0002$) treatment by time interaction showing an adiponectin increase in the risperidone-treated patients (from 10154 to 11124 ng/ml) and an adiponectin decrease in olanzapine-treated patients (from 11280 to 8988 ng/ml). This effect was independent of BMI and the presence/absence of MetS.

Conclusion: the differential effect of antipsychotic treatment (risperidone vs olanzapine) on plasma adiponectin levels over time, independent of BMI (and MetS), suggests a specific effect on adipose tissues, as already reported in animal models. The observed specific olanzapine-associated reduction in plasma adiponectin levels may at least partially contribute to the increased metabolic risk of olanzapine compared to risperidone.

P-1477

The prevalence of the metabolic syndrome in a cohort of HIV positive patients on highly active antiretroviral therapy

A.O. Oladejo[1], J.O. Adeleye[1], Y.A. Aken'ova[2]

[1] *University College Hospital, Medicine, Ibadan, Nigeria*

[2] *University College Hospital, Haematology, Ibadan, Nigeria*

Aims: To assess the prevalence and the pattern of the metabolic syndrome in HIV-positive patients attending the anti-retroviral clinic of the University College Hospital, Ibadan and to compare the prevalence and pattern among the HAART exposed, HAART-naive and HIV-negative subjects.

Methods: Two hundred and seventy patients were recruited into the study (119 males and 151 females). The subjects were selected by systematic random sampling; their demographic, clinical and laboratory data were obtained and analysed using the SPSS software version 16.0.

Results: The mean age of the HAART exposed group was 40.1±9.5 while the mean ages for the HAART naive and HIV-negative groups were 37.7±9.3 and 41.9±8.9 respectively. The mean duration of infection from time of first diagnosis for the HAART exposed group was 22.4±15.7 months. The mean weight, BMI, waist circumference, systolic blood pressure, fasting plasma glucose were all higher in the HAART exposed group than the HAART-naive group, $p< 0.05$. The HIV negative group had the highest mean weight, waist circumference, systolic blood pressure, diastolic blood pressure and HDL cholesterol, $p< 0.05$.

The prevalence of the metabolic syndrome in the HAART exposed group based on the International Diabetes Federation definition was 38.1% while the prevalence of the metabolic syndrome in the HAART-naive group and HIV negative subjects was 13.6% and 28.9% respectively, $p< 0.001$. The prevalence was much higher among patients on protease inhibitor inclusive therapy than patients whose drug combination did not contain a protease inhibitor, 42.1% versus 37.0% ($p> 0.05$).

Conclusion: The result of this study has shown a significantly higher fasting blood glucose, waist circumference, body mass index, systolic blood pressure and diastolic blood pressure in the HAART exposed group than the HAART-naive group. The prevalence of the metabolic syndrome based on the International Diabetes Federation defintion was highest in the HAART exposed subjects. Thus, HIV positive patients on HAART may be at an increased risk of cardiovascular events.

P-1478

Glucose intolerance among HIV/AIDS patients in the Plateau region of Northern Nigeria

F.H. Puepet[1], R.J. Mshelia[2], J.A. Idoko[1]
[1] *University of Jos, Dept of Medicine, Jos, Nigeria*
[2] *University of Abuja, Dept of Medicine, Abuja, Nigeria*

Background: HIV/AIDs is an enormous health problem in sub-Saharan Africa. Many persons living with HIV/AIDs have access to Highly Active Antiretroviral therapy (HAART) in Nigeria and these people constitute a 'highrisk' group for developing glucose intolerance (IFG, IGT and DM). Lipodystrophic changes are seen in ambulatory HIV-infected patients. Glucose intolerance (GI) and its associated risk factors among HIV/AIDs patients have not been extensively studied in Nigeria.
Objective: To determine the prevalence of glucose intolerance and associated risk factors in HIV/AIDs patients.
Methods: Five hundred and eighty four consecutive patients attending the HIV clinic of the infectious Diseases Unit of Jos University Teaching Hospital in Plateau State, Nigeria were recruited for the study. Demographic data, personal and family history, and clinical data and anthropometric measurements were obtained. Each patient had fasting plasma glucose (FPG), fasting plasma insulin (FPI) assayed after 8-12 hours overnight fast and glucose tolerance test (OGTT) with 75g glucose. GI was defined as follows: IFG =FPG 6.1-6.9 mmol/l, IGT = FPG< 6.1mmol and 2hrsPGL 7.8 – 11.0 mmol/l and DM= FPG≥7.0 and/or 2hr PGL ≥11.1 mmol/l. Serum Lipids, CD4 cell count and viral load were also determined.
Results: Of the 584 patients studied, 384 (130 males and 254 females) with mean age (range) of 38 (20-64)years were HAART-treated; while 200 (61males and 139 females) with mean age (range) of 33 (18-62)years were HAART-naïve.
Overall, the prevalence of GI was 40.4% (IFG 19.5%, IGT 11.5% and DM 9.4%). Prevalence rates of IFG (27.1%) and DM (11.2%) in HAART-treated patients were significantly higher than those in HAART-naïve patients (IFG 5.0%, DM 6.0%), p<0.005. Conversely, IGT was more prevalent in HAART-naïve than in HAART-treated patients (19.5% and 7.3% respectively), p<0.05. The proportions of patients with GI were higher in overweight and obese HAART-treated patients with moderate CD4 cell count, 200 – 500 ($x10^6$ cells/L); while in the HAART-naïve patients, GI was more prevalent in underweight subjects with CD4 cell count <200 ($x10^6$ cells/L). The mean FPI in HAART-treated patients (41±4.1μU/ml) was similar to that of HAART-naïve patients (39.9±3.5μU/ml), p>0.05. FPI increased in HAART-treated patients with increasing duration of treatment. The risk factors for GI included age, increasing BMI, low CD4 cell count, metabolic syndrome and HAART treatment duration. Strong independent risk factors were, low CD4 cell count and HAART treatment duration.
Conclusion: The prevalence rates of GI among these highland Nigerian patients with HIV/AIDs are high. The prevalence of DM in them is thrice higher than that recorded in the general population in the region. Treatment with HAART and low CD4 cell count are strong independent risk factors. Attention should be paid to identification of glucose intolerance in patients with HIV/AIDs, particularly those on treatment with HAART.

P-1479

3-year incidence rates of metabolic syndrome and glucose abnormalities differentially affected by typical and atypical antipsychotics in first-episode patients with schizophrenia

A. Scheen[1], V. Schreurs[2], K. Sweers[2], D. Van Eyck[2], L. Hanssens[2], M. Wampers[2], R. Van Winkel[2], J. Peuskens[2], M. De Hert[2]
[1] *CHU Sart Tilman, Division of Diabetes Nutrition and Metabolic Disorders and Unit of Clinical Pharmacology, Liège, Belgium*
[2] *University Psychiatric Center St Jozef, Katholieke Universiteit Leuven, Kortenberg, Belgium*

Aims: Second-generation antipsychotics (SGAs) are associated with an increased risk of development of metabolic syndrome (MetS) and diabetes. There are limited data on the prevalence of MetS in patients with schizophrenia at the onset of the disorder, and specifically no data on patients treated in the era when only first-generation antipsychotics (FGAs) were available. The aim of the present study was to investigate whether SGAs might more markedly affect the rate of MetS than FGAs in schizophrenic patients with first episode.
Methods: data from a historic cohort of consecutively admitted first-episode patients with schizophrenia treated with FGAs (n=148) were compared with an age and sex matched series of consecutive first-episode patients treated only with SGAs (n=148). Rates of MetS (adapted NCEP-ATP III criteria) were compared at baseline and after an average treatment exposure of 3.7 years in the SGA group (n=122) and of 3.2 years in the FGA group (n=108).
Results: the average increase in body weight was twice (p<0.0001) as high in patients started on SGAs (11.5 kg) compared to FGAs (5.2 kg). At first episode there was no difference in the prevalence of MetS between the historic (5.4%) and the current cohort (4.7%). Rates of MetS increased over time in both groups (from 5.7% to 13.1% with FGAs vs from 5.6% to 30.6% with SGAs). Patients started on SGAs had a three times higher incidence rate of MetS (odds ratio 3.6; CI 95% 1.7-7.5). The difference in MetS rate over time was mainly explained by changes in fasting plasma glucose (FPG) and triglycerides. FPG remained almost stable (from 89 to 88 mg/dl) with FGAs, whereas it increased from 84 to 89 mg/dl with SGAs (group by time interaction: p=0.001). At 3 years follow-up impaired fasting glucose was more frequent in patients on SGAs than in those on FGAs (p=0.04). In both groups, 2 patients developed diabetes, and 2 additional SGA patients were started on metformin for sustained prediabetic abnormalities. MetS was significantly more prevalent in patients treated with clozapine (58.3%) or olanzapine (47.1%), and least prevalent in patients on aripiprazole (10%) (p= 0.0092). The difference in MetS incidence rate between the FGA group and the SGA group (amisulpride, aripiprazole, risperidone, quetiapine: n=62) was no longer significant when patients started on clozapine (n=12) or olanzapine (n=34) were excluded (MetS rate at follow-up FGA 13.1% vs SGA 16.1%; NS).
Conclusion: rates of MetS at the first episode of schizophrenia today are not different from those of patients 15 to 20 years ago, arguing against a major role of lifestyle changes between the two periods to explain the currently reported high prevalence of MetS. Rates of MetS increased over time in both groups, with a threefold increased risk in SGAs compared to FGAs. Clozapine and olanzapine have a more negative impact on the incidence of MetS compared to FGAs in first episode schizophrenic patients.

P-1480

Screening for cystic-fibrosis-related diabetes and impaired glucose tolerance: systematic review and economic modelling

L. Pandit[1], P. Royle[1], N. Waugh[1]
[1] *University of Aberdeen, Public Health, Aberdeen, United Kingdom*

Background: Approximately 40% of people with cystic fibrosis (CF) develop cystic-fibrosis-related diabetes (CFRD). The risk increases with age. Survival from CF has improved greatly over recent decades and the prevalence of CFRD will continue to increase. There is uncertainty about the best methods of screening for CFRD and when to start treatment. The current gold standard screening test is the 2 hour oral glucose tolerance test (OGTT), but this has shortcomings. The OGTT can identify people with diabetes or impaired glucose tolerance (IGT), but misses those who have normal blood glucose values at 0 and 120 minutes but high values at 30, 60 and 90 minutes. This project asks two questions: 1) does screening for diabetes or IGT in people with CF improve outcomes and 2) if so, what is the best screening test or combination of tests?
Methods: A systematic review of the evidence on both screening and treatment. Exhaustive literature searches have been done of several bibliographic databases and the grey literature, with no restriction on language or study type. Experts in the area have been contacted for unpublished literature.
Economic modelling will use the software package Simul8. The model will be populated from the evidence gleaned from the systematic reviews.
Results: In terms of treatment for CFRD, the review shows a paucity of randomised controlled trials, with nearly all evidence coming from case series. Insulin remains the standard treatment and there is insufficient evidence for the use of oral agents. There is insufficient evidence on when to start insulin. Studies do not report on all outcomes including the quality of life gains from using insulin.
In terms of screening, results will include the sensitivity, specificity and cost-effectiveness of screening tests or combinations of tests including fasting plasma glucose (FPG), HbA1c, CGMS, blood glucose profiles and the OGTT. The review so far shows that neither FPG nor HbA1c are sensitive enough for screening purposes.
The best screening strategy will depend on the stage of hyperglycaemia screened, and the stage at which treatment should start needs to be considered. Further results of the reviews and of the subsequent modelling will be

presented at the World Diabetes Congress.
Conclusion: There is a shortage of high quality evidence on this important and increasing condition and we will identify research needs. Our preliminary conclusions are that screening is necessary since harm from hyperglycaemia can occur before symptoms develop.

P-1481

Metformin or sitagliptin as single treatment in glucocorticoid induced diabetes mellitus - a prospective study

E. Georgiadi[1], T. Simopoulou[1], S. Karamagkiolis[1], V. Pinakas[1], E. Markouti[1], V. Lalos[1], K. Karamitsos[1]
[1] General Hospital of Larissa, 1st Department of Internal Medicine, Larissa, Greece

Aims: Glucocorticoids are known to be the first cause of secondary-induced Diabetes Mellitus when used as long-lasting treatment for various diseases. The aim of the present study was to compare the antihyperglycemic efficiency of Metformin and Sitagliptin when used as monotherapy for Glucocorticoid-induced Diabetes Mellitus (GCDM).
Methods: Forty-two patients with newly diagnosed GCDM were enrolled for this study and were followed up for 6 months. All of them, aged 65.5±7.5, were daily receiving Prednisone 20-30 mg for at least three months. The initial levels of HbA_{1c} in our target group ranged from 8.1 to 9.0. Twenty-three patients were given Metformin as a treatment after the diagnosis (maximum dosage, 2000mg) and formed the Metformin Group (MG), while the remaining 19 were treated with Sitagliptin (maximum dosage 100mg) forming the Sitagliptin Group (SG). At the sixth month of the follow up the level of HbA_{1c} was measured in the blood and was used for the statistical evaluation of the groups. For the statistical analysis the nonparametric Mann-Whitney test and the unpaired t-test were used.
Results: Eighteen patients (78.3%) of the MG group and 10 patients (52.6%) of the SG group had HbA_{1c} equal or less than 7.0% six months after the treatment started. For the MG group, the values of HbA_{1c} were 6.861±0.227 (range, 6.5 - 7.3) with 95% Confidence Interval 6.763 to 6.959. Accordingly, for the SG group HbA_{1c} was 7.006±0.281 (range, 6.4 - 7.4) with 95% Confidence Interval 6.867 to 7.144 (p= 0.078 Mann-Whitney test, p= 0.076 unpaired t-test).
Discussion/Conclusion: When used as monotherapy in patients with newly diagnosed GCDM, Metformin and Sitagliptin showed equal capability of controlling the glucose blood level. Although treatment with Metformin seems to lead to better levels of HbA_{1C} than Sitagliptin, results of this comparison were not statistically quite significant to support that suggestion. Furthermore, weaknesses of this study, such as the small series of patients and the short time of follow up, cannot amplify our conclusions.

EDUCATION

Diabetes education in childhood and adolescence

P-1482

Camp Adam Fisher: evolution of a summer camp for children and adolescents with diabetes in South Carolina, USA

E. Todd-Heckel[1], A. Rizvi[2]
[1] Diabetes Initiative of South Carolina, University of South Carolina Site, Columbia, USA
[2] University of South Carolina School of Medicine, Department of Medicine, Columbia, USA

Background/Aims: Camp Adam Fisher is the Carolinas' largest overnight camp for children and adolescents aged 6-16 years with diabetes. Founded in 1968 by Mr. Adam Fisher in memory of his young daughter who suffered from type 1 diabetes, the camp has operated uninterruptedly for the past 40 years. Since 1984 it has been held at the Cooper 4-H Leadership Center of Clemson University in Summerton, South Carolina. Attendance has grown from 17 campers to over 200 in 2008. Initially designed and operated by volunteers of the American Diabetes Association, the camp became incorporated and achieved its not-for-profit status in 2002. It is held for one week each summer and offers a multitude of activities including ball sports, rope-climbing, wall-climbing, indoor gymnasium, horseback riding, swimming, water-sliding, and lakefront activities (canoeing, kayaking, tubing, sailing, pontoon trips, boating, fishing and jet-ski). The camp has a medical director and is staffed by volunteer physicians, nurses, dietitians, and counselors. We assessed the participants' baseline diabetes self-management skills and the impact of camp attendance on them.
Methods: 70 campers aged 12-16 years were given an 18-item self-administered questionnaire designed to measure confidence in diabetes self-management (e.g. blood glucose targets, glucose self-monitoring/meter use, insulin injections, addressing hyper- and hypoglycemia, pump skills) on the first day of camp and repeated on the last day of camp. Responses to all questions were based on a 5 point likert scale (1=not confident, 5 =very confident). Paired t-tests were used to examine differences in pre- and post-camp scores.
Results: Mean scores from both pre- and post-tests were above 3.5. For the whole group, mean scores for 17 of the 18 questions increased from pre- to post-test, 7 of them significantly ($p<0.05$). When the data were analyzed by number of years of camp attendance, a significant increase in all scores were seen among first-time campers (n=21).
Discussion: The philosophy of Camp Adam Fisher of South Carolina, USA is to provide the opportunity to youth with diabetes to grow mentally, physically and spiritually. The experience aims to help them face challenges, and develop problem-solving and leadership skills in a monitored, socially interactive, and wholesomely competitive setting. Our results show that youth older than 12 years who choose to attend camp may be a motivated group who feel secure in dealing with their disease. Reassuringly, camp attendance led to improved confidence and self-efficacy regarding diabetes self-management, especially in first-time attendees. We plan to continue to obtain periodic feedback from participants and counselors in order to enhance the camp's mission in the future.

Diabetes camps in Latin America

M.T.U. Barone[1], C. Solari[2]
[1] Associacao de Diabetes Juvenil (ADJ), and University of Sao Paulo (USP), Sao Paulo, Brazil
[2] Asociacion de Diabeticos del Uruguay (ADU), Campamentos, Montevideo, Uruguay

Introduction: It is widely known that diabetes camps have a very positive impact on children's lives It has been shown metabolic improvements, leading to delay in complications development, after participating in a diabetes camp, which seems more evident when the experience is repeated. The diabetes control gain is not only attributed to the acquisition of knowledge, but also to the psychosocial positive impact of spending days with peers who have the same condition, in a planned safe and fun environment. Sharing experiences and learning from more experienced individuals, children become motivated and realize the worth and benefits of keeping on good diabetes self-control, and that the barriers of living with diabetes are not insuperable.
Objectives: Identify the number of diabetes camps in Latin America, their location, and number of children and adolescents with diabetes who attend them yearly.
Methodology: A questionnaire in Spanish was sent to diabetes association, federations, groups and prominent people in diabetes field, in 21 countries and 2 commonwealths (Puerto Rico and Aruba).
Results: 18 have replied, 15 organize at least one camp session a year. The yearly number of camp sessions in Latin America is 56, with a mean number of sessions per country of 3±2.75SD (between 0 and 9). The total number of campers is 2,211, and the number of campers per session varies from camp to camp (between 9 and 120). Diabetes camp sessions were reported in: Argentina, 3 sessions a year; Bolivia, 1; Brazil, 6; Chile, 3; Colombia, 2; Cuba, 9; Dominican Republic, 5; Ecuador, 3; El Salvador, 1; Guatemala, 2; Mexico, 7; Paraguay, 1; Puerto Rico, 7; Uruguay, 2; Venezuela, 4. Some organizations have reported that camps are not organized in their country, or that no more than one camp session can take place yearly, because of the lack of resources.
Discussion: Although ~71% of the researched countries and commonwealths organize at least one camp session a year, it is obviously too little, and serves only a tiny fraction of all children with diabetes in this region. According to the IDF Diabetes Atlas 2003, the prevalence of type 1 diabetes among children (0-14 years) in Latin America (SACA plus Mexico) is 43,000. If camps were attended only by this age range, only ~5% of these children could attend a diabetes camp yearly.

Conclusion: Knowing the short and long-term positive impact of diabetes camps on children's life, we strongly suggest international and local communities, organizations and governments to help supporting diabetes camp initiatives, in order to enable the organization of more camps, besides improving and broadening the existing ones.

Perception of body sizes and the prevalence of overweight and obesity among Nigerian undergraduates

R.T. Ikem[1], C. Adegbenro[2], B.A. Kolawole[3]
[1] *Obafemi Awolowo University/Teaching Hospital, Department of Medicine, Ile-Ife, Nigeria*
[2] *Obafemi Awolowo University/Teaching hospital, Department of Community Medicine, Ile-Ife, Nigeria*
[3] *Obafemi Awolowo University/Teaching hospital, Department of Medicine, Ile-Ife, Nigeria*

Introduction: In medical practice, obesity has been directly linked to a lot of morbid disease conditions such as type 2 diabetes, coronary heart disease, stroke, non alcoholic fatty liver. The problem of weight and sizes has always been a subject of concern to young people in different cultures of the world. Various reasons have been adduced to different perception of people about sizes and weights. In western culture, a woman's beauty is based on how slim she is – as beauty pageants and models are chosen on their stature. Whereas, the traditional African setting perceive woman based on how well endowed she looks.

There is a paucity of literature on the prevalence of obesity in young adults in our environment. This study was carried out to:

1. Determine the prevalence of overweight and obesity among undergraduates in O.A.U. Ile-Ife.
2. Assess for mismatch the perception of body sizes and body mass index among undergraduates in O.A.U. Ile-Ife.
3. Assess the impact of life styles on weight status

Method: This is a cross sectional study carried out among undergraduates of O.A.U. Data was collected using structured self administered questionnaire. This contained 2 parts;

1. to assess their knowledge and perception of their body status
2. to measure their anthropometric parameters

Data were analysed on SPSS and the results presented as means, standard deviation and frequency and percentages.

Results: Six hundred and twenty respondents who completed the questionnaire and had their anthropometric parameters measured were analysed. The mean age of the respondents was 21.52±3.28 years. 88.4% of them were aged between 15-25 years. 43.9% were males and 56.1% females. 49 (7.9%) and 7 (1.1%) were overweight and obese respectively. Thirty-one (63.3%), of those who were overweight claimed to be of normal body size. In all 32% of our respondents had wrong perception of the body size. Two hundred and ninety-five (47.58%) of the respondent exercised out of which 142 (48.16%) exercised adequately (≥3 times a week). Twenty-two (3.5%) of the respondents were hypertensive, while 598 (96.5%) were nomotensive.

Conclusion: The prevalence of overweight and obesity were 7.9% and1.1% respectively. About a third of our respondents had wrong perception of their body size. A large majority of our respondents had inadequate knowledge of obesity and its complications which may be responsible for the high prevalence of overweight and obesity seen.

We recommend educational oriented programme targeted at this young population who are leaders of tomorrow for the prevention of health hazards associated with overweight and obesity.

P-1485

A child and parent perspective for determinants of childhood overweight or obesity in school going children in Karachi

A. Rizwan[1], J. Hatcher[1], J. Akhter[1], T. Jafar[1], A. Fahim[1]
[1] *Aga Khan University, Medicine, Karachi, Pakistan*

Aims: To analyze the risk factors for overweight or obesity in school children from both child and parent perspective.

Methods: In 2007, we surveyed four private and two public schools. Data on the childrens' sociodemographic variables, dietary habits and physical activity patterns at the school, home and elsewhere were recorded for both parent and child. Physical measurements (height, weight, waist circumference) of both parent and child were taken. Multiple logistic regression was applied to assess the significance of each risk factor for overweight or obesity. Mc Nemar was used for child and parent comparison.

Results: Of the 434 children, data was obtained for 256 parents. Subgroup analysis revealed 71% of parents of normal weight children to be overweight or obese, while 91% parents of overweight/obese children were themselves obese. (p=0.045).For both parent and child, bringing lunch from the canteen: (OR [1.72] CI 1.14,4.83) and ([OR [1.84], 95% CI 1.21,3.45); greater frequency of snacking while watching television: (OR [3.95], 95% CI 3.42,5.26) and (OR [3.32], 95%CI 3.23,4.79) and a greater frequency of fast food visits: (OR [2.83], 95%CI 1.65,12.14) and (OR [3.14], 95%CI 2.42,11.25) were associated with greater odds of overweight or obesity. Of the children, 60% stated having some form of fruit or vegetable on a daily basis, whereas only 39% parents of these children verified this ($p<0.05$). A greater proportion of children participated in more sedentary activity than what the parents were aware of ($p<0.05$). Conversely, a greater proportion of parents stated a greater frequency of fast food visits and television snacking by their child, as compared to what the child had stated ($p< 0.05$).

Discussion/conclusion: To curtail the menace of childhood obesity, a multidisciplinary approach needs to be adopted, with modification of parental behavior and the school environment. Education to the family on the provision of home food, as opposed to canteen food, may provide a healthier alternative to the child as well as a re emphasis on more fruit and vegetable consumption by the child.

P-1486

Perceptions of contributors to childhood overweight or obesity: a parent and child viewpoint through focus group discussions

A. Rizwan[1], A. Fahim[1], J. Hatcher[1], J. Akhter[1], T. Jafar[1]
[1] *Aga Khan University, Medicine, Karachi, Pakistan*

Aims: To hold focus group discussions (FGDs) with both parents and children in order to gain a richer insight into the perceptions of determinants of obesity in the context of the tradition and culture of our community.

Methods: Three groups of parents were purposively selected, each consisting of 6 individuals, from two private schools and a public school, respectively. The children of these parents were also grouped for a discussion held separate from the parents. The points of the discussion were transcribed onto Microsoft Word and divided into segments according to the emerging themes into analytic units. These meaningful segments were coded with descriptive words.

Results: Most participants voiced views equating an overweight child to a "healthy one" and a symbol of "good motherhood"; western junk food as a "status symbol" and provision of insufficient supervised physical activity at the school. Concerns were raised that activities for girls needed to be maximized at the school who, due to cultural/religious norms, may be inhibited from participating in outdoor activity. The childrens' multitasking between television and internet, this being more "convenient" than any form of additional physical exertion, has resulted in them becoming "couch potatoes". Very concerning was the belief held by certain participants that engaging in sports would deprive the child of time, energy and stamina that could be spent "studying their core subjects in this highly competitive world".

Discussion/conclusion: Themes from the FGDs revealed that the entire infrastructure and mind set of the community needs to be altered to counter the rising trend of obesity. Schools and parents are well placed to bring about a positive change in this respect. This confirmed results obtained from the questionnaire-based studies done on the subject.

Using a paediatric diabetic compendium to educate diabetic children

T.H.M. Yeung[1], K.M. Loo[1], T.T.Y. So[1], M.S.Y. Lau[1], R.Y.M. Wong[1], C.C. Chow[2]
[1] *Prince of Wales Hospital, Diabetes & Endocrine Centre Department of Medicine & Therapeutics, Shatin, Hong Kong China*
[2] *Prince of Wales Hospital, Department of Medicine & Therapeutics, Shatin, Hong Kong China*

Background: The management of pediatric diabetes is challenging. We provide a series of educational sessions on the basic management of diabetes to all newly diagnosed diabetic children during their hospitalization, followed with similar outpatient sessions. However these sessions are finite, limited in time, place and availability of expert educators. At our centre, we have put together a series of stimulating exercise tools in a Chinese compendium to enhance continuing diabetic management at home. The compendium contents provide information about diabetes in basic facts, treatment principles, ways to keep insulin and its administration, signs of hyperglycemia, hypoglycemia and hypoglycemic management through a simulative play format.
Aim: To investigate the effectiveness of this exercise tool to enhance self-education in a pediatric type 1 diabetes population.
Patients and methods: Newly diagnosed and established type 1 diabetic children aged 8 – 13 years were recruited. A pediatric diabetic compendium in Chinese was provided.
The compendium contents are: - a journal illustrating the adventures of a newly diagnosed eight year old diabetic boy character ("Tong-Tong")
- riddles relating to diabetes terminology, care providers & roles, treatment regimes and devices, etc.
- diabetic "snakes & ladders" game
- diabetic crossword puzzle

Compendium questionnaires were surveyed prior to the compendium, 1-week and 6-week after completion of the compendium. Compendium questionnaires consisted of a set of identical questions to quantify the knowledge of the recruit on various aspects of diabetes management. The overall pre- and post-compendium questionnaire scores were compared against the age of the recruit.
Discussion: We discuss our findings on the use of the compendium tool in educating our pediatric diabetic patients.

Campaign of sensitization on diabetes issues in scholar's and student's background of Burundi run by the Burundian Medical Student Association

U.B. Mfuranziza[1], U.B. Kamatari[1], U.B. Bindariye[1]
[1] *Université du Burundi, Faculty of Medicine, Bujumbura, Burundi*

Context: Diabetes is an important public health problem in the world. The World Health Organization shows that more than 200 million people are diabetic in the world and most of them are in the middle and low income countries.
The same organization predicts that in 2025, there will be 380 million diabetic in the world and 75% of them will be in the middle and low income countries. In Burundi there is no national prevalence studies done but, according to the center for combating diabetes there are diabetics in all parts of the country even if in rural areas. Their study shows also that many people are diabetic without knowing it.
There is then necessity to increase Burundian public awareness of diabetes issue especially to help them prevent it.
The Burundian Medical Students' Association in partnership with Handicap International France managed a large campaign of sensitization for students and schoolchildren of Bujumbura. This campaign took part in the week of the World Diabetes Day, meaning from the 7th to the 13rd of November.
Aim: Overall Enhance diabetes knowledge in school and academic background. Specifically:
- inform youth on physiopathology, clinic, treatment and above all prevention of diabetes;
- help students and schoolchildren adopt a favourable behaviour for prevention of the disease.

Methodology: The programme was done in four steps:
- establishment of contact with high schools' and university's authority and stundents' and schoolchildren's representatives;
- made of schedule for trainings and a questionnaire made by a team of specialists
- trainings campaign made by a team of 5 members for high school;
- organization of conference on the topic "Diabète chez l'enfant et l'adolescent" for students.

Achievement: More than 600 schoolchildren and students were sensitized on diabetes issue. The questionnaire helped us to evaluate their knowledge on diabetes; we found out that their knowledge is 20% in general.

Patient empowerment and self-management

P-1489

Knowledge, attitude and practice in diabetes management: how the community people respond in developing countries?

S. Joshi[1], R. Bhandari[2], R. Bhandari[2], R. Bhandari[2]
[1] *District Public Health, PHC, DHI, Nepal*
[2] *Community Health and Environmental Society Nepal, Health, KTM, Nepal*

Aim: Essential component of diabetes management is empowerment of patient on knowledge, attitude and practices on self-management. The purpose of this study was to assess the knowledge, attitude and practices of people with diabetes in managing their condition and daily life.
Methods: 127 subjects were randomly selected from clinical setting.
Semi structured questionnaire was used to gather the information on personal particulars, knowledge about diabetes and practices. Furthermore, weight and height were measured to assess the nutritional status of the patients.
Results: Out of 127 patients 83% and 17% were on tablets and insulin respectively. Over 65% could not explain what is diabetes, 52% did not know the risk factors for diabetes, and 10% did not know any signs or symptoms of diabetes. Patient who knew diabetes can not be cured were 47% and only 56% knew it was not infectious. While 64% and 34% did not know the causes of hypoglycaemia and hyperglycaemia, 46% and 44% did not know how to manage hypoglycaemia and hyperglycaemia. Even though majority (91%) could mention one or more complications of diabetes, 58% mention death and very few knew other complications. Even though 59% thought they had normal weight, 29% were over weight and 2% were obese, nutritional status by BMI revealed that 31% of the patients had normal weight while 31% were overweight and further 31% were obese, only 7% were underweight. Dietary advice was thought to be important for better management of diabetes by 73% of the respondents whereby, 78% have received dietary advice. Other important lifestyle factors assessed were alcohol consumption, 15%, regular exercises 61% and smoking 6%.
Conclusion: There is a need to empower people with diabetes with skills and knowledge which can help them manage the disease more effectively in developing countries like Nepal.

P-1490

Diabetes therapy with information technology: the time has come

S. Sakkal[1]
[1] *Metabolic Care Center, Endocrinology & Metabolism, Mason-Ohio, USA*

Introduction/aims: Since computing has been used to solve the most difficult challenges from cell biology to space exploration, it is almost intuitive that it should be used for diabetes therapy! Our aim in this abstract was to see how many therapeutic programs exist for direct patient use.
Methods: We ran a Medline, Cochrane Controlled Trial Register, SciSearch, EMBase search for evidence proven Diabetes therapy software1986-2009 under six different key words. We defined the following criteria for inclusion: systems with proven efficacy (Decr. HbA1C), cost effectiveness (saving 20%), safety (Decrease Hypoglycemia), and security (HIPPA compatible).
Results: Of 950 trials 56 studies were considered. Of those, 24 were therapeutic. One system was found to fulfill all criteria with improved results: Humalink, and a secod system fullfilled two criteria:Well Doc.
Humalink Has been used by more than 1700 patients since 1993 with proven efficacy (Decr. HbA1c2.3%), cost effectiveness (decr. cost by 70% compared to DCCT), safety (Decr. Hypoglycemia and Hyperglycemia 90%, with no change in

weight) and security (HiPPA compatible).It is accessible by phone and internet. In Well doc pilot study of thirty patients the intervention group received cell phone-based instructions which provided real-time feedback. The average difference in A1C was 1.6%, between intervention and control. Data regarding cost and hypoglycemia not published.
Overall, other ITs used in improving education and social support had borderline results. Few were shown to be marginally effective (HbA1c decr. by< 0.5%), or cost effective (from -5% to +30%) or safe (increased weight or decrease Hypoglycemia 5-10%)
Discussion: Improvement in diabetes outcomes1988-2006 have been dismal, with continued increased mortality in women compared to men. This is despite a time in which three major revolutions occurred simultaneously: First, improved technology of blood glucose self testing and CGM. Second, improved many new interventions like pumps, insulins, oral agents, and transplantation. Third, an explosion of knowledge and proof of the value of good glycemic control Like the DCCT/UKDS.
The only reasonable manner to improve performance is to use computing power to empower patients in such a chronic disease driven by huge data like: FBS, PPG, HbA1c, Fructosamine, Micro Albumin, LDL, HDL, TG, BUN/Cr, etc., add medications, exercise, activity, nutrition and meals, stress and other lifestyle factors influence, etc.
Conclusion: At present the evidence about the clinical benefits of ITs for managing chronic disease is limited. However two promising therapeutic systems need immediate attention for head to head large multicenter trial to compare to conventional care. Humalink has been proven to have efficacy, cost effectiveness, safety, and security with potential to improve diabetes care safely saving billions of healthcare budgets to all stakeholders.

Barriers and opportunities for delivering diabetes self-management education programs using patient empowerment in Hong Kong

J.J. Kwan[1], R. Wong[2], W. Cheng[3], E. Kan[4], M. Lau[2], M. Ng[5], A. Shiu[6]
[1] Our Lady of Maryknoll Hospital, DM Centre, Hong Kong, Hong Kong China
[2] Prince of Wales Hospital, DM Centre, Hong Kong, Hong Kong China
[3] Queen Elizabeth Hospital, DM Centre, Hong Kong, Hong Kong China
[4] Alice Ho Miu Ling Nethersole Hospital, DM Centre, Hong Kong, Hong Kong China
[5] United Christian Hospital, DM Centre, Hong Kong, Hong Kong China
[6] The Chinese University of HK, The Nethersole School of Nursing, Hong Kong, Hong Kong China

Introduction: Patient empowerment, based on the frameworks of self-determination and autonomy support, has served as the philosophical basis for diabetes self-management education in recent decades. In order to better apply the philosophy of patient empowerment, the Association of Hong Kong Diabetes Nurses (AHKDN) and Hospital Authority (HAHO) have been organizing seminars and workshops for diabetes practitioners, including nurses. Feedback from participants of these professional education activities provided invaluable insight for delivering patient empowerment programs in Hong Kong.
Purposes: This paper aims to illustrate the barriers and opportunities of delivering diabetes patient empowerment programs and suggest strategies to overcome the barriers.
Method: The barriers and opportunities were drawn from the feedback from participants of three of the most recent professional education activities organized for diabetes practitioners. A round-table discussion between one expert speaker and 30 diabetes nurses in Dec 08 focused on exploring the historical development of diabetes patient empowerment and the feasibility of its use in Hong Kong. A seminar session and a workshop, Hospital Authority Commissioned Training in Jan 09, provided a platform for over 200 diabetes practitioners to discuss their views and concerns with international and local speakers. Interactive activities were used to facilitate small group discussion. Participants' feedback was collected during the discussion and from evaluation questionnaires.
Results: The analysis of the feedback and discussion shows that time consuming is one of the major barriers for delivering empowerment programs. Participants' perceptions show a range of reasons contributing to this barrier. However, participants perceived that patient empowerment promoted better healthcare provider-patient relationship and self-management ability, thus improving patient outcomes in the long run. On behalf of AHKDN, we suggest that diabetes practitioners shall start using patient empowerment with motivated patients to develop confidence and competence.
Conclusion: The practice of patient empowerment in Hong Kong will bring diabetes education to a new level of care provision and poses both challenges and opportunities for diabetes practitioners. AHKDN will stand in the forefront to provide the best possible diabetes education to patients and continue to organize professional training programs. AHKDN will lobby for managerial support to make this possible.

P-1492

Provision of financial assistance and regular self care management sessions to the needy with diabetes is effective in reducing their HbA1c levels

P.K. Gosal[1], L.K. Chionh[1], A. Lee[1], R. Jayabalan[1], G. Tay[1], R. Tan[1]
[1] Diabetic Society of Singapore, Diabetic Society of Singapore, Singapore, Singapore

Introduction: According to the Ministry of Health, Singapore, diabetes counts as the 7th principal cause of death due to its complications. With the increasing number of those with diabetes it is important to prevent or delay the occurrence of complications to improve the quality of life and reduce the health care costs. Poor financial status and poor knowledge of diabetes has been recognised as a barrier to diabetes care. Patients can become depressed if they are both ill and in financial difficulty.
Objective: As shown by the DCCT and UKPDS results, a 1% decrease in HbA1c correlates to a 35%-60% reduction in risk for microvascular complications
The Financial Assistance (FA) program was started to provide the needy individuals with diabetes with free medical supplies and diabetes education and screening to better manage their diabetes. Through this assistance, we aim to achieve a reduction in their HbA1c levels to less than 7% over a period of 1 year.
Method: A 10 months study conducted on a total of 309 FA patients approved. They had their HbA1c test done during their initial visit followed by every 3 monthly till the end of their assistance period. During this period of assistance, a monthly assessment is required. The FA patients are required to produce their log book and glucometer every visit to monitor their improvement in BSLs. Each visit is accompanied with a counselling session on management of diabetes. The counselling sessions on management of diabetes includes:

- Diet modification
- Exercise
- Medication and Insulin Therapy
- Hypoglycaemia and Hyperglycaemia: Signs & Symptoms and Management
- Sick day management
- Self blood glucose monitoring

Diabetes complication screening such as Diabetic Retinopathy Photography, Diabetic Foot Care and Screening, Microalbuminuria and Full Lipid Profile will be rendered.
The efficiency of the FA program is assessed by the difference seen in the HbA1c level of the patient from their initial visit to the end of their financial assistance period.
Results: At the end of the 10th month period, results show that:

1. There is a 13% decrease in the number of FA patients who presented an HbA1c of >8%.
2. There is a 10% increase in the number of FA patients who presented an HbA1c of <6.9% as compared to
3. their initial visit.

Conclusion: The Financial Assistance program has proven effective in reducing the HbA1c levels of the patients and thus reducing their rate of complications. Through the regular education sessions, the patients are better equipped with knowledge in regards to diabetes management. This empowers them towards better diabetes control. With the provision of free medical supplies and regular follow up, it help these patients in reducing their financial burden and in turn motivates them towards positive self empowerment.

[2] *Universidade de São Paulo, Faculdade de Filosofia Ciências e Letras de Ribeirão Preto, Ribeirão Preto - SP, Brazil*

This descriptive cross-sectional study was accomplished at a Center for Research and University Extension located in the state of Sao Paulo, Brazil, in 2007.

Objectives: evaluate the factors related to patient adherence to drug therapy related to diabetes mellitus and associate the diabetic patient's adherence to the drug therapy with some variables: the patient, the professional-patient relationship, the therapeutic scheme and the illness.

Method: The population was constituted of 46 patients with type 1 and type 2 diabetes, who met the criteria for inclusion and exclusion. Patients were predominantly female patients, with an average age of 57 years, 8 years of study and 4.5 minimum wages. The majority of the subjects have type 2 diabetes, with a median diagnosis time of 12.5 years, and the most frequent co-morbidities were arterial hypertension and dyslipidemia. For data collection, a questionnaire and the test of Treatment Adherence Measure-TAM were used. For the analysis, the statistic software SPSS-11.5 was utilized.

Results: 89.1% of the subjects used oral antidiabetics, 26.1% used Biguanides and Biguanides in combination with Sulfonylureas, 41.3% made use of insulin therapy, and 30.4% received combined oral anti-diabetics and insulin. Concerning patient adherence to drug therapy for diabetes, 78.3% of adherence was obtained. As far as the facility and/or difficulty for adherence, 50% of the subjects obtained the drugs at the Healthcare Unit. The predominance of adherence was higher among men (85.7%) and among the elderly (82.4%); in subjects with more than 12 years of study (88.9%); with a family income higher than 5 minimum wages (90%); and who received information about the disease (84.6%) and specific information regarding the prescribed drug (86.7%). Adherence was higher among the subjects with up to 5 years of diagnosis (80%); who did not change their daily routine (81.1%); who did not mention side effects (93.8%); who did not use anti-hypertensives (84.2%) and who showed knowledge gaps (80.8%). It is worth mentioning that non-adherence prevailed among individuals with HbA1c higher than 7% (85.7%). For the majority of the factors under analysis, weak association to adherence was obtained and the differences in adherence prevalence were not statistically significant.

Conclusion: the prevalence of adherence obtained in this study was below levels recommended in literature. It becomes urgent for health professionals to acknowledge the importance of measuring patient adherence to drug treatment for diabetes control in case of bad glycemic control and supposed failure in the established therapeutic scheme.

Diabetes education programme and its effectiveness in reducing HbA1c < 7% in diabetes patients

L. Chionh[1], P.K.G. Praveen Kaur gosal[1], L.P.H. Lee Peng hoon Angie[1], R.J. Rathi Jayabalan[1]

[1] *Diabetic Society Of Singapore, South West Diabetes Education and Care Centre, Singapore, Singapore*

Introduction: In Singapore, one out of 11 people aged 18 to 69 has diabetes. That's about 10% of our population or equivalent to 300,000 people. Diabetes is the fifth most common medical condition diagnosed and one of the six top killer diseases in the country. Diabetes is a chronic disease and, if not managed well, can deteriorate steadily to cause devastating complications such as blindness, nerve damage, kidney failure, heart disease and limb amputation. Studies show that about half of patients already have diabetes-related complications at the time of diagnosis.

Objective: The purpose of this program aimed to target patients with diabetes to achieve their HbA1c below 7% after diabetes counselling sessions over a period of one year.

Method: Diabetic Society Of Singapore has worked together with Sing Health through the 'Deliver on Target' program aiming to target patients with diabetes to achieve their HbA1c below 7%.

382 patients were recruited as referred by general practitioners for this program. All of them had their HbA1c test done prior and after the 3 free counselling sessions on management of diabetes. the couselings are conducted by Diabetic Society Of Singapore. Every patient is monitored before and after the 3 free counseling sessions, within 1 year.The counseling sessions on management of diabetes include diet modification, exercise, medication and self blood glucose monitoring.

Results: 382 patients presented results of HbA1c before and after the 'Deliver on Target' program. Before the 'Deliver on Target' program, 150 patients presented HbA1c<7%. After the program, 232 patients presented HbA1c<7%. There is an increase of 54 % of patients in patients with HbA1c less than 7 %.

Conclusion: Early and proactive management of chronic diseases at primary level by diabetes education program has helped many patients with diabetes to gain better knowledge on proper management of diabetes. The 'Deliver on Target' counseling program of 3 free counselling sessions on management of diabetes has proven effective to the patients who presented their results to achieve their HbA1c below 7%. Good glycaemic management is important in prevention of complications.

Application of patient empowerment strategies in enhancing patient outcomes in a diabetes self-management education program in Hong Kong

W.M.W. Cheng[1], E.C.Y. Kan[2], M.P.H. Mok[3], T.T.Y. So[4], M.S.W. Lau[4], C.M. Wan[5], A.T.Y. Shiu[6]

[1] *Queen Elizabeth Hospital, Medicine, Hong Kong, Hong Kong China*

[3] *United Christian Hospital, Medicine, Hong Kong, Hong Kong China*

[4] *Prince of Wales Hospital, Medicine, Hong Kong, Hong Kong China*

[5] *Tung Wah Eastern Hospital, Medicine, Hong Kong, Hong Kong China*

[6] *The Chinese University of Hong Kong, The Nethersole School of Nursing, Hong Kong, Hong Kong China*

Introduction: Guided by the Michigan patient-empowerment philosophy and culturally appropriate education strategies, a structured diabetes self-management education (DSME) program for Chinese patients with type 2 diabetes was implemented and evaluated in Hong Kong. Four diabetes nurses delivered the program (three 4-weekly sessions) to groups of 10 patients in 4 diabetes centers. Program evaluation reported elsewhere showed significant improvement in participants' diabetes self-efficacy, self-management behavior and glycaemic levels.

Aim: This paper reports how the strategies were used to enhance patient learning in four selected areas of the program.

Use of strategies: A teaching kit was developed to help facilitators deliver the DSME program. It contains 180 power point slides, a logbook, a handbook and an exercise VCD. Interactive learning strategies such as peer teaching, small group discussion, story telling, games and role-playing are adopted. To facilitate participants' development of DSM ability, the patient empowerment strategies applied in the program have been identified by diabetes nurses in Hong Kong as culturally appropriate.

1. Home work on SMBG along with a diary on food and activity was introduced to participants in the first session. The aim was to capitalize on their experience on experimenting the impact of food and other factors on blood glucose levels. Peer sharing (support) and role modeling took place in every session to stimulate participants' active discussion of the experiments.
2. To learn about the principles of diabetes diet, the essence was written in rhyme, named as "10 principles of a diabetes diet". Participants rapped it together to enhance memory. Menus from popular restaurants were collected for participants to discuss and practice making choice in real eating out situations.
3. To learn about diabetic medications, multiple choice questions about drugs were designed to challenge participants to identify common misconceptions from the questions. Real life problems were set up as case studies for developing their problem solving ability. Story telling was used to increase their awareness of asymptomatic nature of diabetes.
4. To learn about physical activity, a 30-minute exercise was designed and demonstrated to guide participants to experience exercising together in groups. A VCD was to take home as a memory aide.

Conclusion: Our findings confirm that using culturally appropriate patient empowerment strategies enhance patient learning. Interactive and participative learning are well accepted by Chinese patients, and are effective in enhancing desirable patient outcomes.

Financial assistance and strength of commitment to recommended lifestyle self-management among African-Americans with type 2 diabetes

V. Zoumenou[1], M. Cecil[2], S. Lawrence[2], L. Carley[2]

[1] *Maryland Cooperative Extension, Human Ecology Department, Princess Anne, USA*

[2] *University of Maryland Eastern Shore, Human Ecology Department, Princess Anne, USA*

Aims: Describe the relationship between socio-economic status and the strength of commitment to following dietary and exercise self-management recommendations among persons with type2 diabetes in the rural Tri-County (Somerset, Wicomico, and Worcester) area of the Maryland Lower Eastern Shore.

Methods: The Commitment to Lifestyle Self-Management (CLSM) instrument was used to assess the strength of commitment to following lifestyle self-management recommendations among persons with Type 2 diabetes. Approximately 50 African-American members of type 2 diabetes support groups were surveyed. Descriptive statistics, Crosstabulation, and Chi-Square were computed.

Results: The target audience consisted of 70% females, 30% males, 32% married and 40% widowed. Approximately 35% of the participants indicated more than one source of financial assistance, 37% of the participants reported Medicare and 28% indicated private health insurance. Approximately 45% of females and 43% of males in this study received <50$/month and spent >50$/month on medical expenses. Women, especially widowed, received more financial assistance than men. Significant differences were also found between widowed and married participants. Married showed the least dedication to dietary recommendations: preferring to eat three times a day, [X^2 (4, N=50) p=0.01]; having time to buy the foods[X^2 (4, N=50) p=0.03]. Being widowed and having financial assistance for medical expenses were associated with high strength of commitment to dietary management. No significant difference was found for dedication to weight control between married and widowed. Walking was common and low exercise duration (0-3hours/week) was reported.

Discussion: Previous study conducted among Black groups in Miami, Florida and Abidjan, Côte d'Ivoire using the same instrument (CLSM) reported that ethnicity, marital status, frequency of blood glucose checking, having a schedule for meals and snacks, were significantly correlated with participant's strength of commitment. The present study not only confirmed the previous results but also indicated that being widowed and receiving financial support for medical expenses were associated with high strength of commitment to dietary self-management. Adherence to diabetes self-management is a multi-factorial phenomenon. Individualized comprehensive assessment of strength of commitment and availability of financial assistance for medical expenses should be considered before goal setting during counseling among African-Americans with limited resources in the Tri-County area of the Maryland's Lower Eastern Shore.

The creation of Beyond the Basics resources for educators and consumers

S. Zeiler[1], E. Armit[2], K. Arcudi[3], A. Garrett[4], B. Allan[5]

[1] *Canadian Diabetes Association, Research Professional Education & Government Affairs, Toronto, Canada*

[2] *Interior Health Authority, Central Okanogan Diabetes Program, Westbank, Canada*

[3] *CSSS de l'ouest de l'ile - Lakeshore General Hospital site, Lakeshore Diabetes Day Centre, Pointe-Claire, Canada*

[4] *Hotel Dieu Hospital, Diabetes Education Centre, Kingston, Canada*

[5] *Surrey Memorial Hospital, Diabetes Centre, Surrey, Canada*

Background: New medications and methods of managing diabetes have prompted changes in diabetes education. The Canadian Diabetes Association meal planning system, Good Health Eating Guide (GHEG), was reviewed. Consumers, health professionals and food manufacturers were surveyed about the use and utility of the GHEG. They indicated a need for a simpler meal planning guide, similar to those used in Quebec and the United States, which are based on 15 g of carbohydrate per serving in each of the carbohydrate containing groups (Grains & Starches, Fruits, Milk & Alternatives, Other Choices.) For more than six years, a dedicated volunteer group of health professionals representing a wide variety of expertise and geographic locations have revised the meal planning guide and created consumer resources.

Aim: To revise the meal planning system to be more in line with similar meal planning systems used in Quebec and the United States, and provide consumers with up-to-date information for managing their diabetes. Changes were made to simplify meal planning and also better reflect Canada's multicultural society and eating habits.

Method: From 2003 to 2005, the committee worked on creating food lists of the different food groups. Portions of carbohydrate foods were revised to provide 15 g of available carbohydrate gathered from data in the Canadian Nutrient File and the USDA database. The glycemic index and saturated fat content were also considered. The Beyond the Basics poster was the result of many iterations and consultations with volunteers and staff.

From 2005 to 2007, with the help of many volunteer authors and reviewers, the committee worked on writing and reviewing the chapters of the two manuals, Beyond the Basics: Meal Planning for Diabetes Prevention and Management and Beyond the Basics: Lifestyle Choices for Diabetes Prevention and Management, which include information on the food groups, ideas for meal planning, label reading, physical activity, high risk populations, and many more topics to help manage diabetes. The first manual on meal planning was launched in June 2006. The second resource on lifestyle choices was launched in June 2007.

Result: The Beyond the Basics suite of resources was created to assist both health professionals and clients to improve eating habits and aid metabolic control.

Therapeutic adhesion and other related factors in persons with diabetes mellitus type 2

M. Mendoza Trujillo[1], M. Vera Gonzalez[1]

[1] *Instituto Nacional de Endocrinologia, Psychology, Ciudad de la Habana, Cuba*

Introduction: Diabetes Mellitus is a disease that demands from patients to keep a strict discipline in following the instructions given by the health team.

Objective: To determine the therapeutic adherence of patients with diabetes mellitus type 2, as well as the linked factors that contribute to or hinder the adequate accomplishment of the prescribed treatment.

Method: 212 subjects were studied when they attended the follow-up consultation at the Center for the Attention to the Diabetic Patient from the National Institute of Endocrinology in the City of Havana, Cuba. As a tool was used the Questionnaire for the Evaluation of Therapeutic Adherence in persons with diabetes mellitus type 2.

Results: The results yielded a total therapeutic adherence in 57.0% of the studied subjects, with predominance for the female sex. 85.8% considered important to carry on the treatment for the adequate metabolic control; 88.7% can count on enough social support from family and health institutions. The factors linked to a satisfactory therapeutic adhesion were: the confidence in the treatment as beneficial; the knowledge of the disease and its complications; self-effectiveness, and the support from the family and health institutions. The imputations about the failure to comply with the treatment due to economic problems, irregularities in working timetable, and the absence of a more trustworthy, efficient method for a glycemia checks, were referred to as hampering factors for a satisfactory performance in the fulfillment of the treatment.

Conclusions: The study contributes general elements that influence on the therapeutic Adherence, thus allowing a better understanding of a complex phenomenon of a worldwide alarming magnitude.

Diabetes knowledge, attitude and practices in central India

N. Agrawal[1], O.P. Jatav[1], D. Tiwari[1]
[1] G. R. Medical College, Medicine, Gwalior, India

This unicentric, non-interventional study was conducted to assess the knowledge, attitudes and practices related to diabetes and its care in uncontrolled type 2 diabetic subjects coming for first consultation to a diabetes clinic in an underserved area of central India.
100 subjects with type 2 diabetes aged above 18 years were administered a structured questionnaire. Their mean age was 51.09 yrs with a male female ratio of 1.7:1.8. Subjects were from urban background. 15% had postgraduate education, 30% were graduates and 41% high school qualification. Duration of diabetes was < 5, 5-10 and >10 years in 57%, 22% and 21% respectively. 09 % subjects were on ayurvedic/indigenous medicines. 70 % were taking their treatment daily whereas 17% were taking it irregularly, 13 % took treatment only when they felt symptomatic. 16% did self monitoring of blood glucose once in 7-15 days, with others doing so every 1- 2 months. 26% owned glucometers but did not use them regularly. 68 % patients reported their diabetes was not controlled. 25 % patients consulted their physicians once in 2-3 months or less frequently.
Only 63% patients felt that exercise is necessary in the management of diabetes whereas 32 % felt that exercise should be done whenever there is time. 5 % felt that exercise should be done as per patient's wishes. 61% patients were of the opinion that antidiabetic drugs have to be taken life long whereas 39% reported that these have to be taken till their diabetes is controlled.
47 % of the patients reported problems in routine daily life due to diabetes. 51 % patients had fasting blood glucose > 200mg%, with only 23% reporting fasting euglycemia. 71% had postprandial values > 300 mg/dl, with 16% reporting postprandial euglycemia. Only 33 % were aware about the targets of their control.
Majority of the subjects, in spite of residing in urban area and having formal education, did not have adequate knowledge or appropriate practice about diabetes. Almost all the patients (94%) had the misconception about insulin that it is the last modality of treatment and has to be taken life long once started.
This study highlights the knowledge, attitude and practices related to diabetes in central India, and the scope for improvement in this field.

"A touch of diabetes" – self-perceived knowledge among people with type 2 diabetes

J. Leksell[1], M. Andersson[2], B.M. Carlsson[3]
[1] Science of care, School of Health and social sciences, Falun, Sweden
[2] Primary Health Care Center of Bjuv, Bjuv Primary Health care center, Bjuv, Sweden
[3] Diabetes division Skene Hospital, Skene Hospital, Skene, Sweden

Background: Type 2 diabetes is a serious and progressive disease. It is well known that individuals with good understanding of their own condition and treatment and high self-confidence in their self-management of chronic diseases perceive good health.
Aim: The aims of the following study were to describe: self-perceived knowledge regarding type 2 diabetes and experiences of diabetes related worries.
Method: On the basis of the Swedish population 3801 people were randomly selected to answer a questionnaire on if they had been diagnosed as having diabetes. The survey was carried out by telephone by SIFO research international. Out of 3801 randomly selected, 199 people reported that they had been diagnosed as having diabetes (prevalence 5%) and agreed to participate in the study. The questionnaire consists of 15 items.
Results: The age of the participants varied from 40 years to 80 years. A majority of the participants declared that they were overweight or obese. Half of the participants expressed that they had high blood pressure and one third declared that they had high cholesterol. One third of the participants did not know the value of HbA1c, and had also modest knowledge about the diabetes-related complications. Furthermore, 42% had never discussed the risks pertaining to their disease neither with the nurse nor the doctor. The patients had been told that they had a touch of diabetes, and that diabetes is nothing to worry about. Participants who expressed good knowledge had lower HbA1c and BMI compared to those with poor knowledge. The level of knowledge was associated with the educational level, i.e. those with a high educational level expressed high level of self-perceived knowledge. Half of the participants did not talk about any kind of diabetes-related worries.
Conclusion: The results showed that patients with type 2 diabetes need more knowledge and understanding about the disease and the treatment. This highlighted the fact that professionals in the health sector need to explain the seriousness of the disease to the patients in a clear manner. On the other hand, it is the patients' duty to ask for information related to the disease and its treatment. Diabetes type 2 is a serious disease and should not be labeled "a touch of diabetes".

Tips and tools for diabetes self-management education for people with vision loss

L. Baughan[1], H. Munro[2]
[1] University Health Network Toronto General Hospital, Endocrinology, Toronto, Canada
[2] Markham Stouffville Hospital, Adult Diabetes Clinic, Markham, Canada

Diabetes self-management is a challenging and often overwhelming responsibility. Vision loss can make these challenges even more daunting and for some signifies the loss of ability to maintain independence in self-management, such as blood glucose monitoring, insulin and oral medication administration.
Nurses can help people with diabetes and vision loss or blindness access the resources in their community sooner and provide diabetes education to promote independence for the individual. Timely intervention and support by nurses who are sensitive to the needs of the visually impaired and who provide diabetes education to this group are essential for positive patient outcomes. This presentation provides tips and tools for diabetes self-management education for people with vision loss.
This presentation reviews: Common terms and conditions associated with vision loss in people living with diabetes,
Components for nursing assessment of the visually impaired person,
Practical tips and tools for diabetes self-management education, including blood glucose monitoring, insulin and oral medication administration.

Factors related to self-care of people with type 2 diabetes in a hospital emergency room in Merida, Yucatan, Mexico

M.L. Zanetti[1], I.R. Baquedano[1], C.R.S. Teixeira[1], M.A. Santos[2], T.A. Martins[1], C.A.P. Landim[1], T.A.C. Becker[1], E.C.B. santos[1]
[1] Universidade de São Paulo, Escola de Enfermagem de Ribeirão Preto, Ribeirão Preto - SP, Brazil
[2] Universidade de São Paulo, Faculdade de Filosofia Ciências e Letras de Ribeirão Preto, Ribeirão Preto - SP, Brazil

Objective: This correlation study aims to analyze the factors related to self-care of type 2 Diabetes patients.
Method: Participants were 252 type 2 diabetes patients who entered the Regional Hospital of Merida in 2006. Instruments: registration form; questionnaire concerning socio-demographic, clinical and laboratory variables; self-care capacity scale; questionnaire measuring adherence to medical, dietary and physical activity treatment. The information was collected through review of clinical records and interviews. They were analyzed through SPSS version 12.0 software, univariate and bivariate descriptive statistics and correlation analysis.
Results: The population was characterized by predominantly female patients (51.8%), with an average age of 62.88±11.18 years, married (81.7%); predominantly housewives and retirees (27.9 and 25.5%), average education of 9.16±3.94 years, catholics (65.7%), with nuclear family (59%) and family support (84.8%). Average for weight was 71.39±10.59kg, height 1.51±0.07m, with an average BMI of 31.46±5.41Kg/m^2, abdominal circumference of 113±17.59cm; the systolic blood pressure was 126.95±14.26mmHg and diastolic of 83.03±9.35mmHg. The average duration of diabetes was 17.53±9.03 years, up to 6 hospitalizations with an average of 2.30±1.05. The leading causes of admission were hyperglycemia, diabetic foot and hypoglycemia. They have hypoglycemia, neuropathy and diabetic foot as major complications, with a history of diabetes and hypertension. They use oral antidiabetic agents, mainly sulfonylureas and 78% of these people have medical consultations, 48% every two months. The average blood glucose values were

197.29±52.35mg/dl, plasma glucose 209.35±119.02mg/dl; total cholesterol 333.19±69.47mg/dl, LDL 110.82±25.49mg/dl, HDL 37.55±5.53mg/dl and triglycerides 184.81±61.40mg/dl, respectively. The average score for self-care capacity was 35.72±3.69 points, with regular ability for self-care. Average for adherence to the drug treatment was 30.08±3.13 points (adherence:8.8%); for participation in dietary treatment 12.67±1.32 points (adherence:8%) and in physical activity treatment 2.73±1.53 (adherence:5.2%). A direct correlation was found between self-care ability and years of study, disease control and adherence to physical activity, and an inverse correlation between self-care ability and BMI, total cholesterol and LDL, religion, drug treatment, evolution time of the disease and risk factors.

Conclusion: it becomes urgent to implement the guidelines proposed by the Integrated Health Care Model and the Norma Oficial Mexicana for the prevention, treatment and control of diabetes, with a view to developing self-care skills for people with type 2 diabetes to manage the disease.

P-1503

The attendance to a regular diabetes health education program interferes in the treatment-management interventions

J. Dullius[1], R. Fonseca Lima[2]

[1] *University of Brasília, Physical Education College, Brasilia, Brazil*

[2] *University of Brasília, Doce Desafio Program Pharmacology School University of Brasília, Brasilia, Brazil*

Aims: The aim of this study was to correlate the disease knowledge of diabetic people who are submitted to a systematic educational process with the capacity for managing interventions during their treatment. Furthermore, this work sought to analyze the connection between the inclusion of diabetic people in a health education program and the possible alterations in their therapeutics resulting from such process.

Methods: This was a documental, evaluative and ex-post-facto research. It was analyzed both qualitative and quantitative questionnaires which was replied by 78 diabetics who attended a regular health education program which deals with Diabetes Mellitus (DM), health education and oriented physical activities. It included subjective and objective evaluations of the patients' knowledge about DM and their capacity for managing therapeutic interventions during the treatment by attending the program or even by actions resulted from the same. For the subjective questions, a scale of five values (1 - 0.5 - 0 - 0.5 - 1) was selected and, for the objective ones, it was used a percentage scale which ranged from the period before the integration into the program to the period after it. It was studied 40 men and 38 women, with the average age = 59±11, the average time of DM = 9±7 years; 94.87% (n=74) of them was type 2 DM.

Results: 100% of the diabetics who took part in the program have claimed that they increased their knowledge level both about DM and the treatment. The percentage average of the variable 'level of information on DM' before and after the inclusion in the program corresponded to 30.42% and 67.53%, respectively (the percentage change being 110.10%). Moreover, 88.46% (n=69) of the participants affirmed that their capacity for managing interventions during the treatment has increased. This increase reflected in a considerable percentage change of 101.12% when the periods before and after the program were compared taking into account the variable 'capacity/competence to take care of yourself' (average before the program = 39.70% and average after the program= 80.29%). 67 (85.89%) of the diabetics presented changes in their therapeutics during the three months which preceded the questionnaires' reply, and 85.34% of these changes, according to them, resulted from their direct or indirect participation in the program.

Conclusion: It is essential that the diabetic individuals are able to manage interventions during their treatment since the disease often presents new challenges. Therefore, it is highly important their inclusion in a regular educational process which enables them to make decisions and manage interventions during all the treatment, aiming at, above all, the management of the therapeutics.

P-1504

Successful outcome of a multidisciplinary team over an individual approach in imparting diabetes patient education

J. Kesavadev[1], J. Shamsudeen[1], A. Shankar[1], S. Jothydev[1], G. Dinkar[1]

[1] *Jothydev's Diabetes and Research Center, Diabetes, Trivandrum, India*

Introduction: Even in well developed parts of the world, more than 50 % of diabetic subjects have unacceptably high metabolic parameters. When diabetes is growing at incredible speeds crossing rural urban boundaries, the only effective tool remains to be awareness generation.Here we test efficacy of two methods of education.

Aim: Education programs for diabetes are usually conducted in groups. Conventionally a lecture is delivered by a doctor, educator or a dietician. Here we compare the efficacy in response of patients participating in a healthcare professional/paramedical individual (group A) conducted diabetes awareness program versus response from multidimensional elements incorporated diabetes education program by a team of experts (group B).

Method: The response of 51 patients each in two patient groups for a period of 2 years was compared. These patients participated in quarterly diabetes education sessions.

The patient response of two groups was captured on the basis of a Likert Scale Questionnaire.

Discussion: In this study conducted in our centre, the multidisciplinary team (group B) consisted of diabetologists, dietitians, nurses, educators, dentists, ophthalmologists etc. For group A, classes were taken either by doctor or dietitian.It has been observed that patients have learned more on self care, monitoring, life style modifications, periodic physical and lab evaluation at sessions by a team of experts rather than by an individual.

In group B, ophthalmologist and dentist participates once in a year. A dietitian talks to patients twice a year while diabetologist, nurse and diabetes educator attends all sessions. Diabetes Educator could give a clear account on use of glucometers and how to deliver insulins. Moreover a diabetes nurse could explain on medication timing, care for diabetic foot and the importance of periodic lab evaluation. Diabetologist and dietician together could educate the patient mass on importance of equilibrium to be maintained on diet, exercise and medications, time and type of exercise in accordance with carb counting and exchanges.

Results:

RESPONSE OF PATIENTS TO DIABETES EDUCATION		
Parameters in Likert Scale Questionnaire	A single	B team
Skills on monitoring of blood glucose	54%	96%
Time & type of exercise	35%	78%
Importance of carb in diet	44%	75%
Timing of oral drugs & insulin	82%	98%
Eye, Dental & Foot care	36%	87%
Periodic follow up & tests for risk evaluation	51%	93%
Awareness of pens, pumps & CGM	22%	75%

Conclusion: Conduct of repeated patient education sessions is the only way to ensure success in diabetes management. Our study underlines the importance of incorporating multiple disciplines into periodic patient education programs and customizing it, so as to suit the basic education/ethnicity of the patient population.

Physicians' empathic understanding of patients' personal representations of their type 2 diabetes: accuracy and association with health outcomes

S. Sultan[1], C. Attali[2], S. Gilberg[3], A. Hartemann[4,5,6]

[1] *Université Paris Descartes, Institut de Psychologie, Boulogne Billancourt, France*

[2] *Université Paris XII, Médecine Générale, Créteil, France*

[3] *Université Paris Descartes, Médecine Générale, Paris, France*

[4] *University Pierre et Marie Curie-Paris 6, School of Medicine, Paris, France*

[5] *Assistance Publique-Hôpitaux de Paris (AP-HP), Paris, France*

[6] *Pitié-Salpêtrière Hospital, Diabetes Department, Paris, France*

Aims: The degree of accuracy to which physicians understand the patients' views may be central for promoting self-care and adherence to treatment

and regimen in most chronic illnesses and in Type 2 diabetes in particular. The objectives of this study were to measure general practitioners' accuracy of empathic understanding of patients' views and relate it to health outcomes in Type 2 diabetes.

Methods: Participants were 14 clinicians and 78 of their non-complicated Type 2 patients included in a cross-sectional study. Predictors were empathic understanding measures of patients' views derived from the IPQ-R (Moss-Morris et al., 2002). Outcomes were clinician-rated adherence and self-reported self-care.

Results: We found that accuracy was higher when dealing with beliefs of chronicity and treatment control. Some symptoms were more easily recognized like suffering from upset stomach, fatigue, or loss of strength. In regression models controlling for clinical and personal variables, higher accuracy on reported symptoms, chronicity beliefs and controllability predicted better self-care.

Discussion: These results suggest that accuracy may impact self-care and/or adherence. They may help determine targets for intervention on communication training designed for professionals.

[1] *University of Brasília, Doce Desafio Program - Physical Education School, Brasilia, Brazil*
[2] *University of Brasília, Doce Desafio Program - Medicine School, Brasilia, Brazil*

Introduction: Education on diabetes and oriented physical activities play an important role in the therapy. Both are part of the treatment and together they can lead to a better glycemic control. A supervised program of physical exercise can be a good way to accomplish and follow the management of diabetes treatment and need a capacitated health provider in exercises. We aimed to verify the capillary glycemic variations in a regular program.

Methodology: Doce Desafio Program promotes diabetes education through an environment of classes of physical exercises. Sample: 48 adults with diabetes who attended ≥25 meetings in the semester: 42% in insulin-therapy, 90% type 2, 60% male, all in physician accompaniment. In each meeting 2 measures of capillary glycemia were made: at the beginning (IG) and end (FG) of activities (110min), including regular evaluations, oriented exercises, lectures, dynamic educative debates. Data from the 3 first meetings and from the meetings nº 23 to 25 were statistically compared (average and standard deviation). It was approved by the Research Ethical Committee.

Results: Average of initial (IG) and final glycemia (FG) in the first meetings were respectively 172±88 (41 to 550) and 134±70 (70 to 353) mg/dl, decrease of 22% in values of Initial Glycemia and reduction of extremes values in amplitude. In the last 3 meetings of 25 the mean results were IG = 158±54 (65 to 329) and Final Glycemia = 112±34 (65 to 247) mg/dl, decrease of 29% in relation to IG and a smaller amplitude of values, indicating a better correctness in the adopted procedures for each individual. A reduction of 9% on the value of IG in participants after 20 classes (<3 months) with a smaller standard deviation, especially in Final Glycemia, indicate a smaller amplitude of oscillations.

Conclusion: The attendance in the program reflected the achievement of lower glycemic levels and closer to normal, showing better control. Programs like this can be useful to achieve the glycemic aim and health and to accompany an adequate treatment.

Findings from a one-day community diabetes screening and education program by a visiting Certified Diabetes Nurse Educator in Festac Town, Nigeria

A. Akindana[1], *J. Gao*[2], *O. Olusola*[3], *A.O. Reju*[3], *V. Aroda*[1]
[1] *Medstar Research Institute, MCRC @ Capitol Hill, Washington DC, USA*
[2] *Medstar Research Institute, Statistics, Maryland, USA*
[3] *Private Practice, General Practitioner, Lagos, Nigeria*

Aims: Diabetes is a debilitating disease that, uncontrolled, can increase the risk of macrovascular and microvascular complications. These outcomes can be abated with screening, early diagnosis and self-management education. The objective of this analysis is to describe the characteristics of the participants of a screening program conducted by a visiting US CDE in a major metropolitan city of a developing country, Nigeria.

Methods: A one-day community-based diabetes screening and 2 hour diabetes education class addressing self-management, complications and ideal target values was conducted. The session was interactive and the participants had the opportunity to ask many questions. A sample of 93 adults aged 18 or higher completed a one-page demographic and history questionnaire. Individuals self reported if they had history of diabetes and/or hypertension. Random non-fasting Blood Glucose (RBG) testing, Blood Pressure (BP), height, weight, age and sex were collected. Participants were considered within goal range if non-fasting RBG was < 140 mg/dl in individuals who did not have a reported history of diabetes or <180mg/dl in individuals with reported history of diabetes. Blood pressure was considered at goal if < 140/90 for individuals without reported history of diabetes or <130/80 in individuals with reported history of diabetes. Pre-hypertension was defined as SBP 120-139 mmHg and DBP 80-89 mmHg.

Results: As a group, the age of the participants was 56.5 +/- 13.3 years (mean +/- SD), RBG 122 +/- 58.5 mg/dl, SBP 132.6 +/- 32.4 mmHg and DBP 76.9 +/- 14.9 mmHg. Only 9.7% reported history of diabetes and 10.6% reported history of hypertension. However, 14.3% of those who did not report a history of diabetes had elevated blood sugar where further screening was recommended, 38.6% of those who did not report a history of hypertension had elevated blood pressures, and 34% of individuals had unidentified pre-hypertension. Even in individuals with a known diagnosis of diabetes or hypertension, less than 1/3 were at their respective goals.

Conclusion: Results from this community-based screening highlight the high prevalence of unrecognized and inadequately treated high blood pressure and diabetes in developing countries. More efforts are needed to educate and increase self-awareness, promote screening and early diagnosis, and implement standards of care for blood glucose and blood pressure control in developing countries such as Nigeria.

Lectures, tough methods and threats in "educational" programs: strategies related to an unfavorable prognostic of diabetes

F. Moreira[1], *J. Dullius*[2], *C. Reis*[1]
[1] *Instituto Doce Desafio - UnB, Dietitian, Brasília - DF, Brazil*
[2] *Instituto Doce Desafio - UnB, Doce Desafio Program, Brasília - DF, Brazil*

Introduction: The use of inappropriate tools and strategies during the health educational process might worsen clinical conditions and raise fear among diabetics. Educational actions must be planned in consideration of the needs of a group and the partial evaluation of these actions must be used as a tool for redirecting them. Objective: Identifying through literature, the strategies related to failure in educational processes in programs for diabetics. Methodology: Review of literature in the following database: LILACS, BVS/MS, ENSP, PAHO, e MEDLINE. Articles published from 2006 to 2009 were consulted. Results and Discussion: "Educational activities" concerning only the transmission of information, mainly through lectures, and which did not improve the disease prognostic, and reported a higher number of diabetics in their meetings. General and/or tough methods restricted only to the Glycemic control that led to discouragement in the group, raising the fear for failing among patients. Specific goals, made along with the group had better effects in the metabolic control improvement, besides other aspects such as motivation to self-care. Some programmes focused on aspects related to "negative possibilities" as a significant result obtained in case of disregard of the orders from the assistance staff, who lectured about cases or made use of images of wounded

feet, amputations, patients in dialysis, transplanted patients or who have gone blind, arising discomfort in patients, who have related they took part on the programmes only for the given medical supply. Conclusion: Planning educational actions must include the participation of the diabetic to facilitate the engagement on the proposed activities. The relation educator-learner is turned into a cooperative process in which mutual experiences and lessons are exchanged. The knowledge built through this exchange of experiences is the fundamental result of educational practice.

P-1509

Coping mechanisms in geriatric patients with diabetes

S. Kalra[1], A.G. Unnikrishnan[2], B. Kalra[1], A. Sharma[1], N. Agrawal[3], A. Ahalawat[4]
[1] Bharti Hospital, Endocrinology, Karnal, India
[2] Amrita Institute of Medical Sciences, Endocrinology, Kochi, India
[3] GR Medical College, Medicine, Gwalior, India
[4] Bharti Hospital, Clinical Research, Karnal, India

This multicentric, noninterventional study was done to assess coping mechanisms utilized by geriatric patients with diabetes, and their correlation with gender, glycemic control and duration of diabetes. 36 geriatric patients aged above 65 years formed the study group while 84 young adults aged 18 to 65 years comprised the control. The Cognitive Emotion Regulation Questionnaire (CERQ), 2006 was used to quantify coping mechanisms. This questionnaire assesses 9 different coping mechanisms. Subjects were divided into two groups, one showing above average or higher degree, and the other showing average or lower degree, of utilization, for each mechanism. The percentage of subjects exhibiting above average or higher degree of each strategy was taken for analysis. Rumination was more frequent in geriatric patients than younger adults (50.00% vs 40.47%). However positive coping mechanisms such as acceptance (22.22% vs 47.61%) and putting into perspective (27.77% vs 42.85%) were less common in elderly subjects.This indicated a higher degree of negative coping mechanisms in geriatric patients, pointing towards a greater need for training in coping skills in them. Within the elderly cohort, significant gender differences were noted for catastrophizing (66.66% in female vs 33.33% in males) and other blame (22.22% in male vs 11.11% in females). No differences were noted in coping with regards to rural/urban residence, socio- economic status or duration of diabetes. This study highlights the coping mechanisms used by geriatric patients with diabetes, and highlights the need for coping skills training in them.

Labeling comprehension and performance evaluation of a new blood glucose monitoring system with integrated information management

N. Starks[1], J. Baum[2], C. Greene[2], S. Pardo[3], J. Parkes[2], H. Schachner[3], R. Cuddihy[1]
[1] International Diabetes Center, Park Nicollet, Minneapolis, USA
[2] Bayer HealthCare Diabetes Care, Clinical and Medical Affairs, Mishawaka, USA
[3] Bayer HealthCare Diabetes Care, Clinical and Medical Affairs, Tarrytown, USA

Aim: To evaluate product labeling and performance of a new blood glucose monitoring system (BGMS), determining if untrained subjects and healthcare professionals (HCPs) using fingerstick capillary blood could obtain accurate glucose measurements as compared to YellowSprings Instrument (YSI). A secondary aim assessed subjects ability to understand connecting the BGMS to a computer, review data presentations, perform meter setup, and understand the use of additional features including "AutoLog" meal marking during the 5 second test time, and use of icons and animation designed to improve ease of use. There is integrated data management through USB computer connectivity, an electronic log book display, and a Trends feature that presents pre or post-prandial results based on customizable target ranges. The system automatically detects a control solution result, so it will not be used in average calculations and other blood glucose tracking data. Memory capacity is 2,000 results. The system utilizes a rechargeable battery and full color display.
The study was IRB approved. 79 subjects were enrolled. 5 subjects were discontinued for failing inclusion/exclusion criteria. 3 test strip lots were rotated. Subjects and HCPs tested in parallel. Duplicate capillary blood glucose measurements were obtained to assess system precision. Approximately half the subjects took the system home and tested for 7 to 10 days to assess the robustness of the system. Subjects completed a questionnaire for feedback on ease of use.
Results: The coefficient of determination (R2) adjusted for sample size was 0.960 for both the lay-users and HCPs.
The percentage of combined lot results within ±15mg/dL or ±20% of the mean capillary glucose result obtained by subjects and HCPs is shown in Table 1.

Table: Results within ±15 mg/dL or ±20% of the mean laboratory (YSI) glucose value

Lay-User	98.6% (146/148)
HCP	96.6% (143/148)

Using the Parkes Error Grid, > 97% of results obtained by subjects and HCPs were clinically accurate (Zone A). < 3% were in Zone B. No values fell inside Zones C, D, or E.
Questionnaire results: >95% responded that ease of marking results with AutoLog and ease of accessing memory and blood glucose averages was very good to excellent, and close to 90% found the usefulness of the TRENDS data presentation very good or excellent.
Conclusion: This study evaluated the labeling and accuracy of a new glucose meter in the hands of lay-users and HCPs that was found to be at least 97% clinically accurate based upon Error Grid analysis. Further, the large majority of subjects found the Auto-log feature, access to data in memory and data presentation easy to use and understand.

P-1511

The relationship between home glucose monitoring and glycaemic control in an urban Nigerian population with type 2 diabetes

S. Iwuala[1], C.M. Nwaorah[1], O.A. Fasanmade[1]
[1] Lagos University Teaching Hospital, Medicine, Lagos, Nigeria

Background: Home blood glucose measurements (HBGM) are recommended components of a modern diabetes self-management. Its value though, is discussed as controversial in developed countries and its impact in resource poor settings where health care cost is often borne by the patients is yet to be documented.
Aim: To determine the relationship between HBGM and glycaemia control in type 2 DM patients of an urban Nigerian population.
Methods: Every third patient with clinic attendance over 1 year at an urban diabetes clinic recruited for the study was requested to complete a questionnaire investigating demographic data, diabetes history and home glucose monitoring practices. Glycaemia control was determined by glycated haemoglobin (HbA1C) using a point of care device.
Results: There were 100 patients studied, 62 (62%) females and 38 (38%) males. The mean age, duration of DM, BMI, FBS, 2HPP and HbA1C of the study population was 59.1 ± 10.6 years, 10.5 ± 7.3 years, 26.7 ± 4.4kg/m ^{2}, 114.8 ± 53.4mg/ml, 135.3 ± 85.7 mg/ml, 8.2 ± 2.2%. HBGM was practiced by 40 (40%) patients, 27 (67.5%) females and 13 (32.5%) males. The mean number of times HBGM was done /month was 9.2 ± 8.2 times. HBGM was practiced more by females, persons on insulin therapy, persons with higher educational level and longer duration of diabetes. The mean HbA1C in the group who practiced SMBG was lower though not statistically significant compared to the group who did not (7.97% vs 8.04%, p= 0.9).
Conclusion: There was no relationship between HBGM and glycaemic control. This may have been due to the inadequate knowledge of the value and infrequent practice of HBGM by the study participants due to the cost implication. There is thus a need for heightened awareness of the value of HBGM and for larger studies in this area to be done in the developing world.

Effects of the educational process promoted through an oriented program of physical activities to diabetic people in the self-monitoring of blood glucose

J. Dullius[1], M.C.F. Abreu[2]
[1] *University of Brasília, Doce Desafio Program Physical Education School, Brasilia, Brazil*
[2] *Instituto Doce Desafio, Doce Desafio Program Nursery, Brasilia, Brazil*

Self-monitoring of blood glucose (SMBG) is essential to the success of diabetics' treatment and support, specially in people with DM1, who are more subjected to glycemic fluctuation. This study aimed evaluating SMBG variations resultant of the participation in this diabetes education program.
Methodology: Qualitative and quantitative study. Structured questions about many aspects related to SMBG were made to 53 DM1 (78% of all type 1 people who had participated in the program until that moment, last 3,5 years) who attended at least 4 classes; the major part of them not regularly were participating. These questions related conditions before and after the attendance: age 24±13 y, time of DM 11±9 y, median of 14 attendances in classes. Qualitative data distributed in categories and statistically analyzed for pondered average.
Results: Main points: Regarding SMBG, 24,4% did not feel oriented, but after the participation this number reduced to 0%. Before the participation, 52,9% checked blood glucose daily and 30,2% $\leq$ 1 time a month; after the participation, 92,4% daily and 5,7% monthly. The SMBG made to check glycemia and to make adjustments changed from 47,9% to 87,5%. Now, 90,2% says to be well oriented regarding SMBG importance, while just 64,2% did the same statement before. 92,4% says to recognize variations which interfere in the glycemic results, against 56,6% from before. 92,5% answered to know interpreting results, against 49,1% from before. Regarding how to do adjustments after checking glycemic rates, 88,7% feels well oriented now, against 41,5% from before. Before, 36,5% always took steps of adjustment after checking glucose, 19,2% often and, 30,8% never or rarely; now 59,6% always took steps and 32,7% often. Presently, 100% considers SMBG important against 78,5% from before. The trust also increased and the discomfort regarding SMBG diminished.
Conclusion: The program was effective regarding training and making people aware about SMBG in the health education field. SMBG is an important tool of DM control, it subject is central in health education recommendations.

P-1513

Glycaemic control strategies among adult diabetics attending clinics in a metropolitan area of sub-Saharan Africa: a case study of Dar es Salaam in Tanzania

K. Leshabari[1]
[1] *Amana Municipal Hospital, Internal medicine, Dar es Salaam, Tanzania*

Aims: To assess strategies adopted for glycaemic control among adults with type 2 diabetes mellitus attending diabetes clinics in Dar es Salaam, Tanzania.
Methods: A cross-sectional survey was done in July – Sept 2007 involving adult patients with type 2 diabetes mellitus attending diabetes clinics in the city of Dar es Salaam. Data were collected using a semi-structured questionnaire and analysed using Epi-Info version 3.3.2. Statistical significance tests included the usage of X^2 test to check for the association between dependent variables and P-values <0.05 to rule out chance in findings. A verbal informed consent was sought from each respondent before interview.
Results: A total of 400 diabetes patients were surveyed out of whom 136 (34%) were males. None among the study respondents revealed to perform blood/urine sugar tests on a daily basis. Only 2% declared to have personal glucometers/urine glucose dipstick kits at home. Also, 88 (22%) respondents perceived skipping meals to be one of the options in maintaining blood sugar in a euglycaemic state. Almost one third (33.75%) of respondents declared weight gain to be acceptable once a euglycaemic state has been achieved. Significant amount (17%, P = 0.004) of respondents declared traditional medicaments to be safe and equally effective.
Conclusion: Low blood/urine glucose testing reported among study respondents acts as an indicator of poor glycaemic control. Beliefs and perceptions could be highly responsible for poor glycaemic control strategies in this study population.
Recommendations: Continuous health information on glycaemic control strategies need to be provided in these settings. Diabetes health education programmes need to be evaluated regularly in various parts of Africa. More studies on factors influencing glycaemic control strategies should be conducted.

Comparison between blood glucose checks obtained through Betachek® tape with enzymatic method

M. Gama[1], M. Muller[1], J.D. Gama[1], P.T. Freitas[1], F.C.L. Pohl[1], G.L. Biagine[1], S.L. Camacho[1], T. Halage[1], M.P. Krause[1], B.V. Souza[1], R.C. Perraro[1]
[1] *Hospital Universitário Evangélico, Endocrinology and Diabetes, Curitiba, Brazil*

Introduction: Diabetes mellitus is a chronic disease that leads to many complications as damage to small and large blood vessels, resulting in frequent hospitalization. Since the 1990s the incidence of type 2 diabetes has been dramatically increasing in childhood and teenage, before considered an exclusive disease of adult age. The goals of treatment of diabetes requires ongoing medical care as well as patient and family education both to prevent acute illness and to reduce the risk of long-term complications. The frequent control of blood glycemic levels is essential to achieve these objectives.
Objective: The aim of this study was to compare blood glucose checks obtained through instruments Betachek® tape (Tape_B), OneTouch® SureStep® glucometer (GLI) and (hexokinase/G-6-PDH – HEX) enzymatic method.
Methods and materials: One hundred (100) hospitalized patients in the Hospital Universitário Evangélico de Curitiba, were enrolled in this study between 18th Feburary 2008 and 26th of that same month. The glycemias were measured between 1 and 2 hours after lunch (postprandial blood glucose).
Results: The logistic regression analysis determinated that the proposed procedure Tape_B was responsible for 84% of the variance observed in the venous glucose procedure (HEX), being HEX=-17.216 + 1,009* (Tape_B) (p<0,001). These results indicate that the procedure Tape_B can be used as an efficient and lower cost alternative method to obtain blood glucose checks, considering that the regression equation is used in order to estimate the venous glycemia with a lower error.
Conclusion: According to the results acquired, it is advisable to implement this procedure at hospitals and mainly in the everyday monitoring performed by the patient, given them better cost-benefit relations.

Study of self reported anthropometric measures and glucose, lipid profile in type 2 diabetes

B. Azemati[1], D. Ghodsi[2], R. Heshmat[1], H. Tabibi[3], K. Derakhshani[4]
[1] *Endocrinology and Metabolism Research Center of Tehran University of Medical Sciences, Research Deputy, Tehran, Iran*
[2] *Faculty of Nutrition and Food Sciences of Shaheed Beheshti University of Medical Sciences, Clinic of Nutrition and Diet Therapy, Tehran, Iran*
[3] *Faculty of Nutrition and Food Sciences of Shaheed Beheshti University of Medical Sciences, Human Nutrition, Tehran, Iran*
[4] *National Nutrition and Food Technology Research Institute, Research Deputy, Tehran, Iran*

Background and aims: There is not enough information of accuracy of self reported anthropometry and its relationship with metabolic profile. The aim of this study, therefore, was to evaluate the relationship between self reported anthropometric measures and glucose, lipid profile in type 2 diabetic patients.
Methods: One hundred twenty (35 men, 85 women) diabetic patients (mean±SD age 53.83±9.9), were recruited from the National Institute of Nutrition & Food Sciences Clinic. Anthropometric parameters (height, weight, BMI, circumference hip, waist circumference, and waist-to-hip ratio), lipid profile, FBS, 2 hours post prandial glucose, HbA1C, Hemoglobin of all patients were measured.
Results: Mean duration of diabetes was 8.5 years. Mean and SD of BMI, FBS, TG, Total cholesterol, HbA1C was 29.94±5.2 Kg/m^2, 181.21± 65.97 mg/dl, 179.6± 85.6 mg/dl, 204.74± 40.19 mg/dl, 8.68 ± 2.25 percent, respectively. Reported waist circumference and weight were correlated with measured waist circumference and weight in men (P= 0.002, P= 0.000) and women (P=0.000). This correlation remained significant even after adjustment for age and sex. Weight deviation was decreased with age increment (P= 0.02). Weight deviation and waist deviation were not correlated with FBS,2 hours

post prandial glucose, lipid Profile (Triglyceride, Total Cholestrol, LDL-c and HDL-c), HbA1C and Hemoglobin.
Conclusion: Self reported anthropometry was well correlated with measured ones. With age increment, self image could be realistic. In our study, self image was not correlated with glucose and lipid profile.

P-1516

Acute glycemic variation observed post oriented physical activities with type 1 diabetics in a diabetes education program

G. Falcão Mendes[1], J. Dullius[2], G. Fernandes[2]
[1] *Instituto Doce Desafio - UnB, Dietitian School University of Brasília, Brasília - DF, Brazil*
[2] *Instituto Doce Desafio - UnB, Physical Education School University of Brasília, Brasília - DF, Brazil*

Introduction: Insulin theraphy, adequate nutrition, regular physical exercises, self-care, social-psychological support and education are the treatments fundamental to health with diabetes type1. The aim was to verify the acute variation of the capillary glycemia after oriented physical activities under adjustment orientation with diabetes type1 people.
Methods: Sample: 40 diabetes type1 (age 7-58 [23±12] years, diabetes type1 8±7 years duration). Capillary glycemia was collected at the beginning and end of 20 classes (duration 110min). Adjustments were individually dealt with each person according with the beginning, considering interferential variables – nutrition, insulin action, medical orientations, personal experience with the attendant. Adjustments were suggested – carbohydrates or rapid-insulin – after an evaluation of the glycemic alteration tendency as a consequence of exercise and personal aspects. Glycemic values are classified in FA (<70mg/dl), FB (71-140mg/dl), FC (141-250mg/dl) and FD (>250mg/dl).
Results: In the 800 beginning measures, we found 5%–FA, 20%–FB, 52%–FC, 23%–FD. In end measures, after evaluation, adjustment procedures oriented physical exercises and intellectual activities when necessary: 15%–FA, 42%–FB, 38%–FC, 5%–FD. There's a line of central down tendency of 183±52 to 131±45mg/dl in relation to averages of beginning and end, showing also shorter amplitudes on the glycemic values. There's been 21% of increases (reduction of hypo) and 79% of glycemic decrease after exercises (considered maintenance <15%).
Conclusion: Actions focusing education on diabetes mellitus using variables of the own treatment as a means of training (adjustments in exercises, nutrition, insulin) were efficient to improve the glycemic control, be it in its acute form (after exercises) or in the long run.

Animal models of diabetes

P-1517

A strain of Otsuka Long-Evans Tokushima Fatty (OLETF) rat with a large subcutaneous adipose tissue (SAT) is resistant to develop diabetes

Y. Han[1], S. Lee[1], M. Park[1], H. Lee[2], D. Kim[1]
[1] *Division of Endocrinology and Metabolism, Department of Internal Medicine Dong-A University College of Medicine, Busan, Korea*
[2] *Department of Pharmacology, Dong-A University College of Medicine, Busan, Korea*

Aims: OLETF rat is an animal model of type 2 diabetes. During ongoing research, we found that some of them became diabetic but others did not show diabetic feature though all OLETF rats became obese. We tried to find out the metabolic characteristics of these diabetes-resistant OLETF rats especially focusing on adipose tissue distribution, plasma adipocytokine levels as well as insulin resistance and beta cell function.
Methods: Twenty male OLETF rats have been kept in individual cages and have eaten standard rat chow and water freely. When they became thirty eight weeks old, we observed that some rats (n=10) did not develop diabetes while the others did. We measured fasting blood glucose (FBS), plasma insulin, HOMA-IR index, HOMA-beta % index, and adipocytokines from fresh blood samples and allocated blood samples which were already drawn for the ongoing research. We already had data about subcutaneous adipose tissue (SAT) and visceral adipose tissue (VAT) areas which were measured by computer tomography (CT) at twenty nine weeks old. We did urine sugar test with strip. We divided them into two groups as negative urine glucose (diabetes-resistant, DR) group and positive urine glucose (diabetes-prone, DP) group. We compared above parameters between groups at age of twenty nine weeks and thirty eight weeks.
Results: At the age of thirty eight weeks, FBS of DR group (147±23 mg/dL) was significantly lower than that of DP group (173±30 mg/dL) ($P<0.05$). Plasma insulin concentration (2.11±0.92 ng/mL vs. 1.24±0.56 ng/mL, $P<0.05$) and HOMA-beta % (125±60 vs. 65±36, $P<0.05$) of DR group were significantly higher than those of DP group. At the age of twenty nine weeks, SAT mass of DR group (18±2 cm^3) was significantly icreased than that of DP group (15±2 cm^3) ($P<0.05$), but the VAT mass did not show difference (72±2 cm^3 vs. 73±2 cm^3). The plasma insulin concentration (1.82±0.83 ng/mL vs. 2.91±1.34 ng/mL, $P<0.05$) and HOMA-IR index (16.03±6.37 vs. 26.27±11.35 $P<0.05$) of DR group were significantly decreased than those of DP group. There was no significant difference of plasma adipocytokines (leptin, adiponectin, interleukin, tumor necrosis factor a) between DR group and DP group.
Conclusion: A strain of diabetes-resistant OLETF rat showed more subcutaneous adipose tissue mass, less insulin resistance and more preserved insulin secretory function than diabetes-prone OLETF strain. We carefully suggest that a large mass of subcutaneous adipose tissue might prevent to develop diabetes independent of plasma leptin and adiponectin in a certain strain of OLETF rats.

P-1518

Diabetes abolishes the contraction-induced enhancement of GLUT4 expression in skeletal muscle participation of MEF2, GEF,TR-alpha and HIF-1a transcription factors

G. Alves de Lima[1], R.C. Mori[1], D. Guimarães-Duque[1], R. Sabino-Silva[1], H.S. Freitas[1], U.F. Machado[1]
[1] *Institute of Biomedical Sciences, Fisiologia/Biofísica, São Paulo, Brazil*

GLUT4, the main glucose transporter found in skeletal muscle, has an essential importance to the maintenance of glycemic homeostasis. It is known physical exercise enhances this gene expression, improving insulin sensitivity. Furthermore, the contractile activity has a rapid enhancer effect upon GLUT4 expression.
Objective: The present work investigates whether the contractile activity-induced stimulation of the GLUT4 expression is preserved in soleus muscle of diabetic rats, and evaluates potential transcriptional factors involved.
Material and methods: Male Wistar rats were rendered diabetic, and 14 days later they were treated with NPH insulin 6U/day (DI) or saline (DS) for 7 days. Non-diabetic rats (ND) were also studied. At the end of treatment, right and left soleus muscles were removed and incubated in Krebs Hanseleit Buffer for acute "in vitro" contraction. The right soleus was electrically stimulated (supra-maximum stimulus: 100 Hz for 10 min.), and the left soleus (non-stimulated) was used as the correspondent control sample. The GLUT4 mRNA and protein were assayed by RT-PCR and Western Blotting respectively. The binding activity of the transcriptional factors myocyte enhancer factor 2 (MEF2), GLUT4 enhancer factor (GEF), hypoxia inducible factor-1a (HIF-1a), and thyroid hormone receptor-alpha (TR-alpha) were analyzed by Eletrophoretic mobility shift assay (EMSA).
Results: As expected, diabetic rats showed hyperglycemia and increased 24-hour urinary glucose, which was reversed by insulin treatment. The "in vitro" contractile activity was efficient in increasing the GLUT4 expression in ND (mRNA 30% and protein 100%, $P<0.05$) and DI (mRNA 20%, and protein 135%; $P<0.05$) rats, but had no effect in DS group. ND and DI rats increased ($P<0.05$) binding activity of the transcriptional factors MEF2 (~63%), GEF (~120%) and TR alpha (~100%). Furthermore, in ND rats, contraction also increased the HIF-1a (35%, $P<0.05$) binding activity. On the other hand, in muscles from DS rats, the contractile activity did not alter the binding activity of the transcriptional factors.
Conclusion: Soleus muscle from normal rats responded very well to contractile stimulus, enhancing GLUT4 expression. This effect seems to involve activation of MEF2, GEF, TR-alpha and HIF-1a transcriptional factors. Diabetes abolished the contractile-induced enhancement of GLUT4 expression, as well as the activation of the transcriptional factors. The insulin treatment restored the diabetes-induced effects. These results highlight the important role of basal insulin in the control of GLUT4 gene expression. Besides, this study points

out that, in diabetic subjects, the benefit of physical exercise upon the GLUT4 expression depends on good control of the metabolic state.

Different insulinotropic effects of GLP-1 and GIP before and during an IVGTT under systemic DPP4 inhibition in Wistar rats

S. Berg[1], P. Heinke[1], E. Salzsieder[2], K. Kohnert[2], E.J. Freyse[1]
[1] *Institute of Diabetes "Gerhardt Katsch" Karlsburg, Preclinic, Karlsburg, Germany*
[2] *Institute of Diabetes "Gerhardt Katsch" Karlsburg, Telemedicin, Karlsburg, Germany*

Background: Data on insulinotropic potency of GLP-1 and GIP are controversial and systematic investigations are missing. We had performed glucose and insulin measurements in rats receiving placebo (P), 1, 2, 4 and 8 nmol/kg GIP and 4 and 8 nmol/kg b.w. GLP-1 5 min before an IVGTT. The GLP-1 dose of 4.0 nmol/kg produced an insulinotropic effect comparable to that of 2.0 nmol/kg GIP – I-$AUC_{0\text{-}25min}$: 179± 76* vs. 164±63* ng·min·ml^{-1}, insulinogenic Index (iI): 1.11±0.50* vs. 0.97±0.37* ng/mmol. The glucose efflux was less effective after GLP-1 administration. Since the generated data in the tests could be influenced by a) early insulin liberation and b) action of systemic DPP4 activity immediately after incretin injection and before IVGTT, the effects of both these components should be investigated more in detail.

Methods:

a. Catheterized Wistar rats were injected with P, 4.0 nmol/kg GLP-1 ((7-36) amide; Neo MPS; Strasbourg, France) and 2.0 nmol/kg GIP (Probiodrug AG, Halle/Saale, Germany). Incretins were dissolved in 0.1 % BSA in saline and were injected at 0 min. Arterial blood for blood glucose (BG) and plasma insulin (I) were taken (-5, 0 min and then at 1, 2, 3, 5, 7, 10, 15 and 20 min). Reactive (r) and absolute (a) G- and I- $AUC_{0\text{-}20min}$ was calculated.
b. The DPP4 inhibitor P32/98 was injected at -20 min (dose: 30 µmol/kg), the respective incretin at -5 min and the IVGTT (0.4 g glucose/kg) at ± 0 min. Blood sampling was extended to 60 min. G- and I- $AUC_{0\text{-}25min}$, iI (mg/mmol) and glucose efflux K_G (%/min) were calculated from IVGTT. To compare treatment groups with the control, the two-tailed t-test with Bonferroni-Holm correction was chosen, a *p<0.05 was considered significant.

Results:

a. Both GLP-1 and GIP induced an insulin increase under basal blood glucose –GLP-1: rI-AUC 10.6±6.0*, aI-AUC 16.9±4.1* ng·min·mL^{-1}; GIP: rI-AUC 8.8±3.4*, aI-AUC 16.5±4.7* ng·min·mL^{-1}. 33.9 % and 34.5 % of insulin increase occurred within 3 min in both the tests. rG-AUC was unchanged after GLP-1 vs. P (10.1±6.2 vs. 4.6±4.1 mmol·min·L^{-1}) but declined after GIP (-1.7±4.2 mmol·min·L^{-1}*).
b. DPP4 inhibitor declined always plasma DPP4 activity to 25-20 %. 2 nmol/kg GIP improved more efficient than 4 nmol/kg GLP-1 glucose tolerance (rG-AUC; GIP: 25±26, GLP-1: 65±30, P: 48±12; aG-AUC; GIP: 159±32.5*, GLP-1: 204±33, P: 184±17 mmol·min·$L^{-1)}$, insulin response (rI-AUC; GIP: 76±53, GLP-1: 62±19, P: 47±19; aI-AUC; GIP 140±41*, GLP-1: 71±25, P: 54±22 ng·min·mL^{-1}), iI (GIP: 0.88±0.19*; GLP-1: 0.34±0.10; P: 0.29±0.11 mg/mmol) and glucose efflux K_G (GIP: 22.0±5.5; GLP-1: 10.1±2.0*; P: 15.4±1.5 %/min).

Conclusions: Both 4 nmol/kg GLP-1 and 2 nmol/kg GIP induce an early insulin increase under basal conditions in healthy Wistar rats. Only the incretin GIP exerts a blood glucose decline. The plasma DPP4 activity on GLP-1 and GIP for a short time may not explain the different insulinotropic potency of GLP-1 and GIP in the IVGTT in rats and especially not the great difference in glucose efflux.

Liraglutide but not vildagliptin restores normoglycemia in Psammomys obesus

T.B. Bodvarsdottir[1], L. Vedtofte[2], C.F. Gotfredsen[1], A.E. Karlsen[1], L.B. Knudsen[1], R.S. Heller[2]
[1] *Novo Nordisk, Diabetes Biology, Måløv, Denmark*
[2] *Hagedorn Research Institute, Developmental Biology, Gentofte, Denmark*

Psammomys obesus, or the sand rat, is a model of human type 2 diabetes because the development of diabetes resembles what is seen in humans, i.e. initial hyperinsulinemia concomitant with obesity and later hypoinsulinemia and hyperglycemia. We studied the effects of the GLP-1 analog liraglutide and the DPP4 inhibitor vildagliptin in sand rats.

One group of animals was maintained on low energy diet and seven groups were fed high energy diet (HED) that induced diabetes over a four week period. The diabetic animals were treated for 0, 6 or 14 days with vehicle, 0.2 mg/kg liraglutide twice daily subcutaneously or 30 mg/kg vildagliptin twice daily orally. This dose was demonstrated to decrease DPP4 activity to below 50% 18 hrs after the last dosing. Beta-cell mass (BCM) and proliferation- and apoptosis frequencies were determined using stereological point counting on sections stained for insulin, Nkx6.1, ki67 and tunel activity.

Liraglutide significantly reduced blood glucose (6 day vehicle:13.9 ± 1.8 mM vs. liraglutide:3.1 ± 0.2; 14 day vehicle:16.5 ± 1.2 vs. liraglutide:9.4 ± 2.1). Blood glucose was normalized in all 13 animals treated with liraglutide for 6 days and in 11 of 17 animals after 14 days treatment compared to none in any of the two control groups (n=12 and 14, respectively). HED increased BCM and treatment with liraglutide did not change this (LE:28.3 ± 4.5 mg/kg vs. 0 day:107.5 ± 28.7). There were no significant changes in proliferation frequency after treatment with liraglutide, but there was a tendency for decreased apoptosis frequency in the normalized, liraglutide-treated animals (6 days vehicle:0.013 ± 0.004% vs. liraglutide:0.006 ± 0.003; 14 days vehicle:0.022 ± 0.008 vs. liraglutide:0.009 ± 0.003). Pancreatic insulin content at 6 and 14 days was significantly higher in the normalized animals (P<0.05). Vildagliptin was not able to reduce blood glucose (6 days vildagliptin:16.4 ± 1.8 mM; 14 days vildagliptin: 19.3 ± 1.1), did not alter the HED induced increase in BCM, nor did it increase pancreatic insulin content.

These results suggest that liraglutide improved diabetes in sand rats partly by improving the function of the remaining islets. Vildagliptin did not improve the glycemic state in sand rats.

The influence of diabetes on acetoaminophen® induced hepatotoxicity in wistar rats

K. Debri[1], M. Hamid[1], S. Bosseri[1], Z. Burkan[1]
[1] *Al-fatah Medical University, Pharmacology & Clinical Pharmacy, Tripoli, Libya*

Introduction: Uncontrolled diabetes is associated with formation of ketone bodies, which are known to cause hepatotoxicity.

The aim of this study is to investigate the effect of experimentally induced diabetes on susceptibility to acetoaminophen hepatotoxicity.

Methods: Seventy eight adult albino wistar rats of 140-180 g body weight were divided into 4 main groups. Group I; untreated (control). Group II; received acetoaminophen® in oral doses of 50, 100, 150, or 300 mg/kg. Group III (experimental diabetes); two subgroups; one Injected by alloxan 10 mg/kg, s.c, the other injected by streptozotocin 150mg/kg, i.p. Group IV. diabetic rats were injected by acetoaminophen (150 mg/kg p.o). Their blood sugar was measured at day 14 following diabetogenic agent administration. And serum (ALT) was measured a day after acetoaminophen administration.

Results: Acetoaminophen was found to produce dose-dependent increase in the serum ALT levels, untreated (10±1.68), 50mg (9.59±7.07), 100mg (19.59±1.63), 150 (23.5±2.64), 200 (24.24±1.41), 300 (52.83±83). This effect is worsened in the diabetic status (Table 1)

Table. 1: Effect of co-treatment by acetoaminophen®on sALT levels in diabetic rats

No	Treatment Design	sALT Levels	
		Mean	±SE
1	Untreated (control)	10.82	0.53
2	Acetoaminophen®	23.50	1.10
3	Alloxan (All)	27.78	1.79
4	Streptozotocin (STZ)	18.66	0.39
5	Acetoaminophen® + Alloxan	46.78	0.34
6	Acetoaminophen® + Streptozotocin	59.10	0.50

*Significant at p value < 0.05 in comparison to untreated (control) rats OR
*Acetoaminophen alone (150 mg /kg)

Discussion: The experimental chemically induced diabetes either by alloxan or by streptozotocin produced significant elevation of serum ALT levels. Treatment by acetoaminophen® to those diabetic rats resulted in significant elevation in the serum ALT to much higher levels than those produced by experimental diabetes or by acetoaminophen® alone. This elevation in the serum ALT levels represents an additive effect in case of alloxan-diabetes and a potentiate effect in case of streptozotocin-diabetes.
We conclude that careful assessment of the interaction between experimental diabetes and hepatotoxic drugs should be highly considered. As this might have clinical implications.

The effect of licorice root extract on blood sugar level in streptozotocin-induced diabetic rats

M. Shahabinejad[1], M.S. M. Rahmani[2], P.H.D. M. Khaksari Hadad[2], P.H.D. Gh. Sepehri[2], P.H.D. M. Mahmoodi[2], M.D. E. Karimghasemi[2], M.D. E. Karimghasemi[2]
[1] *Rafsanjan University of Medical science, Nursing, Rafsanjan, Iran*
[2] *Rafsanjan University of Medical science, physiology, Rafsanjan, Iran*

Background and objective: Licorice is a herbal medicine which carries a lot of traditional effects as the root of this herb is very sweet in case of reducing blood sugar or can be used in treatment or feeding diabetic patients. Present study was performed to determine whether licorice could reduce blood sugar.
Materials and methods: This experimental study was done on eight (8) groups of matured male rats weighing 200 – 250g. Diabetes were established in five groups by injection of 55 mg/kg of streptozotocin. The rats with a blood sugar of higher than 250 mg/kg were entered in the study. Three groups of diabetic animals were fed- (100, 200, 300 mg/kg) by licorice extract, respectively per day- as follows: 1) through mouth and throut tubes for 35 days. 2). One group of the diabetic rats were injected by insulin NPH at a dose of 4 units and One group of the diabetics was considered without any special treatment. The Plasma level of the blood sugar of the rats were measured on zero, 7th, 14th, 21th and 35th days, respectively.
Results: This research showed that the dosage of 100 mg/kg had not affected blood sugar but dosage of 200 mg/kg during various days of the test (7, 14, 21, 35) had significantly decreased blood sugar. The dose of 300 mg/kg only could significantly decrease blood sugar on 7th and 35th days of treatment. During all various days with various dosage of licorice reduction of blood sugar was not observed as much as zero day.
Conclusion: Results show that extract of licorice roots had no change in healthy rats blood sugar but in diabetic rats the blood sugar was reduced so it can be concluded that extract of licorice roots can be probably used as a treatment or as a dietary sweetener for diabetic patients in clinical procedures.

Liver glucagon receptor binding properties: rapid changes with exercise and post-exercise

A. Melançon[1], J. Lamanque[1], M. Cadrin[1], F. Péronnet[2], C. Lavoie[3]
[1] *Université du Québec à Trois-Rivières, Chimie-biologie, Trois-Rivières, Canada*
[2] *Université de Montréal, Kinésiologie, Montréal, Canada*
[3] *Université du Québec à Trois-Rivières, Sciences de l'activité physique, Trois-Rivières, Canada*

The purpose of this study was to describe the effects of swimming exercise and post-exercise periods on liver glucagon receptor (GR) binding properties. Rats were randomly assigned to a rest control, a swimming exercise (90- and 180-min) and post-exercise (60- and 180-min) groups. Rats were sacrificed at the end of the exercise or the post-exercise periods, blood was sampled and liver was removed rapidly. Plasma membranes were purified from liver and saturation kinetics were obtained by incubation (10 mg of proteins/150 mL) with (^{125})I-labeled glucagon at concentrations ranging from 0.15 to 3.0 nM for 30 min at 30°C.
Results: No changes were observed with blood glucose during exercise and post-exercise periods, even if hepatic glycogen concentrations were significantly depleted with both exercise and post-exercise periods. Saturating curve analysis indicated higher glucagon receptor density with exercise reaching after 180 min: Bmax = 8.19 ± 0.29 pmol/pg of proteins vs 3.09 ± 0.53 pmol/pg of proteins in liver from resting control ($P < 0.05$). The glucagon receptor density decreased in post-exercise to reach 4.46 ± 1.75 pmol/pg of proteins after 180 min of post-exercise. Moderate changes in glucagon receptor affinity were also observed in the exercise and post-exercise groups compared to the control group (Kd at 180 min exercise and post-exercise: 0.46 ± 0.05 and 0.17 ± 0.01 vs 0.33 ± 0.05 nM in the rest control group). At the pancreatic hormone levels, these binding properties changes were associated with an increase in glucagon/insulin ratio of x2.8 and x8.7 during 90 and 180 min exercise periods and x9.3 and x2.7 after 60 and 180 min post-exercise periods vs the rest control group.
In conclusion, these results suggest that exercise and post-exercise episodes induced both changes in insulin and glucagon concentrations and rapid modification in glucagon receptor binding properties. Although the exact mechanisms remain unknown, there is no doubt that the liver adapts rapidly to exercise through modulation of GR binding characteristics. Funded by Natural Sciences and Engineering Research Council of Canada.

The role of uncoupling protein 2 on secretory function of pancreatic islet a cell cultured in vitro

J. Su[1], W. Yang[1], H. Li[2], J. Xiao[1], R. Du[3], X. Shen[1]
[1] *China-Japan Friendship Hospital, Endocrinology, Beijing, China*
[2] *Boston University School of Medicine Boston USA, Endocrinology, Boston, USA*
[3] *General Hospital of the Second Artilleryman of Chinese PLA, Endocrinology, Beijing, China*

Aims: Uncoupling protein (UCP) 2 negatively regulates insulin secretion, which is related to dysfunction of ß cell induced by fatty acids. The peroxisome proliferator-activated receptor-γ coactivator-1a (PGC-1a) may participate modulate UCP2 transcription. Recent studies showed that genipin, Gardenia extract, could inhibit UCP2. But the exact role of UCP2 on a cell is still not clear. So the aims of present study were to investigate the effects of UCP2 or its mediated oxidative stress on a cell function.
Methods: (1)The a TC1-6 cells were cultured in DMEM containing 25mM glucose, with palmitate or with palmitate and genipin for 72h. To evaluate the secretory function, cells were incubated in KRB containing 25mM or 2.8mM glucose for basal or stimulated secretion. (2)After cultured for 72h, the expression of UCP2, PGC-1a and glucagon were determined by RT-PCR and western. (3)RNA Interference (RNAi) duplexes corresponding to UCP2 were transfected into cells with Lipofectamine 2000. Cells were then incubated with palmitate for 72h. In the end of culture, secretory function study was carried out as described before. (4)The effect of RNAi on UCP2, PGC-1a and glucagon expression was measured after transfection by RT-PCR and western. (5) Nitrotyrosine in supernatant of each group was detected by ELISA.
Results: (1) After 72h culture, palmitate induced glucagon secretion increased significantly, while genipin improved it and made it close to the control. (2)At the same time, palmitate increased UCP2 mRNA expression by 45.3%, and genipin decreased the elevation by 32.2%. The change of PGC-1a mRNA expression had similar tendency as UCP2 did. However, there were no differences in levels of glucagon mRNA among three groups. (3) When interfere UCP2 expression by siRNA, glucagon release decreased markedly compared to that incubated with palmitate. Western confirmed the result. (4)The siRNA targeting UCP2 reduced the palmitate induced UCP2 mRNA expression. The expression of UCP2 in palmitate and siRNA interference group was 145.3% and 64.1% of control. PGC-1a mRNA expression also had similar tendency as UCP2 did. There were also no changes in glucagon mRNA expression after siRNA interference. Western confirmed the result. (5) Nitrotyrosine in supernatant of cell cultured with palmitate elevated significantly. There was no difference when intervented with genipin, while si-UCP2 improved the elevation of nitrotyrosine.
Conclusion: Chronic exposure of fatty acid on a cell stimulated glucagon secretion, and the treatment with genipin or siRNA targeting UCP2 expression could partly improve glucagon secretion. We speculated that overexpresion of UCP2 but not oxidative stress played an important role in a cell secretory dysfunction induced by fatty acid.

The evaluation of possible roles of hormones other than insulin in the development of type 2 diabetes mellitus

O. Turhan Iyidir[1], R. Emral[2], O. Demir[2], N. Kamel[2]
[1] Ankara University, Internal Medicine, Ankara, Turkey
[2] Ankara University, Endocrinogy Department, Ankara, Turkey

Insulin resistance plays major role in etiopathogenesis of type 2 diabetes mellitus. Increasing evidence suggests that glucagon and growth hormone (GH) may play role in development and progression of type 2 diabetes. The aim of our study is to evaluate the possible roles of glucagon, growth hormone and IGF-1, to show that type 2 diabetes mellitus is not only a beta cell dysfunction but also develops as a result of failure of all endocrine pancreas and to identify what the roles of pathologic changes in growth hormone and glucagon secretion are in the development of diabetes. An oral glucose tolerance test (OGTT) was performed for all adults conducted for this study. GH, Glucagon and insulin were measured at minutes of 0, 60, 120 and basal IGF-1 was measured also. Participants divided into four groups according to the results of OGTT as diabetes, impaired fasting glucose (IFG), impaired glucose tolerance (IGT) and control group.
Insulin resistance which was calculated as HOMA-IR score was significiantly higher compared to participants with normal glucose tolerance (NGT) in those with abnormal glucose tolerance. Plasma IGF-1 levels were significantly lower (p<0,05) in participants with abnormal glucose tolerance compared to participants in control group.
Area under curve calculated for insulin was significantly higher in subjects with IFG (p<0,05). There was significant difference between subjects with IGT and NGT, there was no difference between diabetic subjects and NGT. Area under curve calculated for glucagon was significantly higher in participants with IGT, IFG and diabetes compared to participants with NGT (p<0,05). There was no difference between IGT, IFG and diabetic group. Area under curve calculated for GH was significantly higher in participants with IGT compared to participants with IFG, DM and NGT (p<0,05).
As a conclusion hyperinsulinemia is an absolute finding in subjects with prediabetes but diabetes develops as a consequence of decreased insulin secretion. In spite of the different levels of insulin in prediabetes and diabetes, hyperglucagonemia can be seen also in both diabetic and prediabetic subjects. Hyperglucagonemia may play an important role in progression to diabetes. Low plasma concentrations of IGF-1 in diabetic and prediabetic subjects may be a result of GH resistance as shown in previous studies. The significantly higher values of area under curve of GH in subjects with IFG may indicate that IFG can be an original subgroup and the hypersecretion of GH can be the cause of fasting hyperglycemia.

Comparative evaluation of the performance characteristics of adiponectin, HDL-cholesterol and triglycerides as markers of the metabolic syndrome

N. Abdella[1], A. Ben Nakhi[2], M. Al Arouj[2], O.A. Mojiminiyi[3]
[1] Kuwait University, Medicine, Kuwait, Kuwait
[2] DASMAN Center, Diabetes, Kuwait, Kuwait
[3] Faculty of Medicine Kuwait University, Pathology, Kuwait, Kuwait

First-degree relatives (FDR) of patients with type 2 diabetes (T2DM) have increased risk of developing diabetes because of aggregation of cardiometabolic risk factors. This study explores the potential use of adiponectin as a marker of the metabolic syndrome (MS) in normoglycemic FDR of T2DM patients. Fasting adiponectin, insulin, glucose, and full lipid profile were determined in 423 and 53 healthy control subjects without family history of diabetes. Clinical and anthropometric data were recorded and subjects were classified on the basis of the degree of adiposity, insulin resistance (IR) (HOMA-IR) and the number of criteria of the MS (International Diabetes Federation). Adiponectin concentration was higher in females than males (mean 9.7 vs. 6.9 ug/ml) despite similar waist circumference (WC). In both FDR and controls, adiponectin was inversely correlated with WC and HOMA-IR and positively correlated with HDL-cholesterol (HDLC). Adiponectin showed stepwise decrease with increasing number of MS criteria. Binary logistic regression showed that the odds ratio of MS as predicted by adiponectin was 0.55 [95% confidence interval 0.41-0.73; p < 0.0001]. At cut-off points of 7.5 ug/ml, the diagnostic sensitivity and specificity of adiponectin for the MS were 90% and 70% respectively compared to 42% and 95% for triglycerides and 80% and 54% for HDLC at standard cut-off points. Receiver Operating Characteristic analysis showed that adiponectin (0.859) had significantly higher area under the curve compared with HDLC (0.745) and triglycerides (0.823) for detection of MS. Adiponectin has superior diagnostic performance characteristics compared to the ubiquitously used TG and HDLC for the identification of subjects with MS.

Differential effect of metformin therapy and intensive lifestyle intervention on metabolic syndrome (MS) among young women with polycystic ovarian syndrome (PCOS)

M.R. Refaie[1], N. Sayed-Ahmed[1], W.M. Refaie[2], E.M. Refaie[3], M.H. El-Kannishy[4]
[1] Mansoura University, Internal Medicine, Mansoura, Egypt
[2] Mansoura University, Cardiology, Mansoura, Egypt
[3] Mansoura University, Obstetrics & Gynecology, Mansoura, Egypt
[4] Mansoura University, Clinical Pathology, Mansoura, Egypt

Metabolic Syndrome (MS) with polycystic ovary syndrome (PCOS) is a high risk state for DM and cardiovascular disorders. Insulin sensitizers can potentially delay the development of these complications. MS in PCOS is a potentially reversible insulin resistance endocrinopathy.
Aim: To identify the role of life-style modification and/or metformin therapy in young women with PCOS with or without features of MS.
Methods: 312 women fulfilling the Rotterdam consensus criteria (2003) of PCOS were recruited from the Gynecology and Endocrinology outpatient clinics, Mansoura University Hospital. They were grouped into group (A) without MS (n=190), and group (B) cases who fulfilled the definition criteria of MS (n=122), according to the National Cholesterol Education Program - Modified Adult Treatment Panel III (2001). All cases underwent clinical assessment and anthropometric measurements, as well as cardiovascular evaluation in the form of resting ECG, Echocardiography and Carotid intimal medial thickness (CIMT) by ultrasound doppler study, both before and 1-year after a therapeutic intervention. Each group of cases were randomly divided into 4 subgroups that were assigned to receive one of four treatment protocols after obtaining an informed consent: life-style modification (diet and physical activity), metformin therapy (500 mg tds), combined life-style modification and metformin therapy or placebo. Components of the MS as well as the cardiovascular risk data before and at the end of the therapeutic intervention were compared.
Results: The protocol of combined life-style modification and metformin therapy was the best in ameliorating the components of MS as 80% of MS cases lost their definition criteria of the syndrome after the treatment period. Life-style modification alone was effective in 51.6% of cases, while isolated Metformin therapy protocol ameliorated MS features in only 24%. In the placebo group, the definition MS progressed significantly from afflicting 38.5% to become afflicting 48.5% cases after the study period (P <0.001). Significant decrease in QT dispersion was noticeable only in the protocol of combined life-style modification and metformin therapy (P 0.031), while the interventricular septum diameter as well ad CIMT did not show significant change with any of the therapeutic protocols over the study period.
Conclusion: Therapeutic intervention with life style modification and/or metformin may be effective in prevention and amelioration of the MS as well as in halting the progression of cardiovascular risks in PCOS women. A combined intervention of both modes of therapy is far more effective than any of them alone.

Insulin secretion and insulin sensitivity in the pathogenesis of the onset and deterioration of impaired glucose regulation in Chinese subjects

H. Li[1], Y. Bao[1], J. Lu[1], W. Lu[1], W. Jia[1]
[1] *Shanghai Jiao Tong University Affiliated Sixth People's Hospital, Department of Endocrinology and Metabolism, Shanghai, China*

Aims: Impaired glucose regulation (IGR) represents an intermediate stage between normal glucose tolerance (NGT) and diabetes. However, the insulin secretion and sensitivity in the pathogenesis of the onset and deterioration of IGR remain unclear. The study was to investigate the insulin secretory dysfunction and insulin resistance in the pathogenesis of the onset and deterioration of impaired fasting glucose (I-IFG) and isolated impaired glucose tolerance (I-IGT) in Chinese subjects.

Methods We studied 4486 NGT, 91 I-IFG and 489 I-IGT subjects from 1998 to 2001 in Shanghai, which includes 75-g OGTT, insulin release test and anthropometrical measurements. We conducted a follow-up study from 2002 to 2004 in the same population. In the subgroup of the study, hyperglycemic clamp technique was performed in 32 NGT, 17 I-IFG and 15 I-IGT subjects. The study was to determine the insulin sensitivity and insulin secretion in the pathogenesis of their onset and deterioration to diabetes.

Results:

1. Compared with NGT, both I-IFG and I-IGT had significantly lower first-phase insulin release (1PH), second-phase insulin release (2PH), insulin sensitivity index calculated by Cederholm formula (ISIc) and higher HOMA-IR (P<0.01-0.05). All the parameters of insulin sensitivity and secretion except 1PH had significant differences between I-IFG and I-IGT (all P<0.05). 2PH, ISIc and HOMA-IR of I-IGT were lower than those of I-IFG. HOMA-%B of I-IFG was lower than that of NGR while that of I-IGT was not.
2. In the deterioration to diabetes, Stumvoll estimated first-phase insulin release (Stumvoll 1st), second-phase insulin release (Stumvoll 2nd) and ISIc of both I-IFG and I-IGT were significantly reduced. HOMA-IR of both I-IFG and I-IGT was significantly enhanced. Notably, the descending degrees of Stumvoll 2nd and ISIc in I-IFG were significantly larger than those of I-IGT (28.30% vs. 18.62% and 29.81% vs. 17.56%, all P<0.05). HOMA-%B of I-IFG was significantly reduced while that of I-IGT was not.

Conclusion:

1 Since first-phase insulin responses were similarly reduced in I-IFG and I-IGT, we conclude that I-IFG mainly results from impaired basal insulin secretion and hepatic insulin resistance whereas I-IGT mainly results from reduced second-phase insulin release and peripheral insulin resistance.

2 In the deterioration to diabetes, the first and second phase insulin secretion as well as the hepatic and peripheral insulin sensitivity of I-IFG and I-IGT all continue to decline. Moreover, the decreasing degrees of second-phase insulin secretion and peripheral insulin sensitivity in I-IFG are larger than I-IGT. The basal insulin secretion of I-IFG was also significantly decreased.

[2] *Cátedra de Farmacología Básica, Fac. Cs. Médicas, La Plata, Argentina*

Aim: To study the changes induced in the hepatic antioxidant system by administration of fructose-rich diet.

Materials and methods: Normal male Wistar rats were fed with commercial diet and tap water (C) or the same diet plus 10% fructose in the drinking water (F) for 21 days. Thereafter, glycemia (G) (GOD-PAP), triglyceridemia (TG) (commercial kit), insulinemia (In) (RIA), HOMA-R (insulin resistance indicator) were measured and an intraperitoneal glucose load (IGL) was performed. After liver removal, we measured: 1) content of thiobarbituric acid reactive substances (TBARS) and reduced glutathion (GSH) (spectrophotometry); 2) mRNA (qPCR), protein expression (Western blot) and enzymatic activity (spectrophotometry) of superoxide dismutase (SOD), catalase (CAT) and glutathion peroxidase (GPx); 3) hepatic microsomal susceptibility to enzymatic and non enzymatic-induced lipid peroxidation, and 4) triglyceride content (TGC).

Results: (means ± SEM; F vs. C): G 8.3 ± 0.2 vs. 7.2 ± 0.3 mM, p<0.005; TG 1.3 ± 0.1 vs. 0.8 ± 0.1 mM, p<0.001; In 4.7 ± 0.6 vs. 2.7 ± 0.5 ng/ml, p<0.02; HOMA-R 43 ± 3 vs. 26 ± 2, p<0.001; IGL (AUC) 4.31 ± 0.5 vs.1.57 ± 0.63 mM glucose/min, p < 0.01; TGC 379.7 ± 53.4 vs. 207.5 ± 12 µg TG/100 mg protein, p<0.01; GSH 3.2 ± 0.26 vs. 4.2 ± 0.28 µmol/g tissue, p<0.05; no significant changes were measured in hepatic TBARS levels. The genic expression of CAT, SOD and GPx was 43 ± 9 vs. 100 ± 5%, p<0.001; 28 ± 7 vs. 100 ± 22%, p<0.01; 51 ± 15 vs. 100 ± 4%, p<0.01, respectively. Protein levels (Western blot) of CAT, SOD and GPx were 79 ± 6 vs. 100 ± 3%, p<0.02; 70 ± 8 vs. 100 ± 2%, p<0.003, with no changes for GPx. Only CAT activity showed a significant reduction (15%, p<0.05). No significant differences were recorded in hepatic microsomal susceptibility to lipid peroxidation between C and F rats.

Conclusions: High fructose feeding induces significant hormonal and metabolic changes accompanied by a decrease in the hepatic antioxidant system; in the period studied, however, these changes did not affect the peroxidation level of liver membrane lipids.

Concomitant modulation of transcripts related to fiber type determination and energy metabolism in skeletal muscle by estradiol injection

I. Riedl[1], M. Yoshioka[1], J. St-Amand[1]
[1] *CHUQ-CHUL, Anatomy and Physiology, Québec, Canada*

Aims: In postmenopausal women, prevalence of metabolic syndrome (MS) is 40%. Aging is also associated with a decline in basal metabolic rate (BMR) and an alteration in tissue metabolism which in turn leads to MS. The skeletal muscle, an insulin-sensitive tissue, accounts for more than 30% of the BMR. Thus a loss in skeletal muscle mass by aging (sarcopenia) widely affects MS. Hormonal replacement therapy (HRT) is commonly prescribed for symptoms of menopause and can improve many components of MS in this population such as abdominal obesity, insulin resistance and blood pressure. However, the effects of HRT on sarcopenia and skeletal muscle metabolism still remain unclear.

Methods: In order to characterize the specific effects of HRT in skeletal muscle, we have analyzed the effects of estradiol (E_2) on global gene expression in skeletal muscle of ovariectomized (OVX) female mice by using the serial analysis gene expression (SAGE) method. Animals were randomly assigned to six different groups: the vehicle group (OVX), and five groups of mice in which a single physiological dose of E_2 was injected 1, 3, 6, 18 or 24 h prior to the sacrifice. Data was confirmed by Q_RT-PCR.

Results: E_2 injection modulated 177 transcripts, including 11 partially characterized transcripts and 52 potentially novel transcripts. In the early response to E_2 ($E_2$3h), most of the differentially expressed transcripts were up-regulated and were related to oxidative phosphorylation and mitochondrial ATP synthesis. On the other hand, most of the late responsive ($E_2$24h) transcripts were down-regulated, and were related to fast type skeletal muscle determination, sugar, lipid and amino acid metabolisms as well as oxidative phosphorylation and mitochondrial ATP synthesis. Specific transcripts, related to insulin sensitivity, insulin signaling and glucose transport were down-regulated at 24 h. The changes in total SAGE tag number of fast type-related transcripts coincided with changes in metabolic-related transcripts.

Conclusion: These results demonstrate that a single physiological dose of E_2 can modulate concomitantly transcripts determining skeletal muscle type, structure and growth and energy metabolism, which may in turn affect sarcopenia and MS.

Cardiovascular status and metabolic syndrome (MS) among young women with polycystic ovarian syndrome (PCOS) in a rural area In Egypt

W.M. Refaie[1], E.M. Refaie[2], M.R. Refaie[3], N. Sayed-Ahmed[3], M.H. El-Kannishy[1], S. El-Tantawy[4]

[1] *Mansoura University, Clinical Pathology, Mansoura, Egypt*
[2] *Mansoura University, Obstetrics & Gynecology, Mansoura, Egypt*
[3] *Mansoura University, Internal Medicine, Mansoura, Egypt*
[4] *Mansoura University, Radiology, Mansoura, Egypt*

Background: Women with polycystic ovarian syndrome (PCOS) have many features of metabolic syndrome where coronary heart disease may be increased. On the other hand, androgen excess is associated with premature atherosclerosis in women with PCOS with or without MS.
Objective: To evaluate the cardiovascular status and risk factors among active non smoker young PCOS women, in a rural community in Egypt, with or without features of MS.
Methods: 312 PCOS women were recruited from the Gynecology and Endocrinology Outpatient Clinics, Mansoura University Hospitals fulfilling the Rotterdam consensus criteria (2003) of PCOS. They comprised 122 women who fulfilled the definition criteria of MS according to the National Cholesterol Education Program - the Modified Adult Treatment Panel III (NCEP- ATP III panel, 2001). The remaining 187 cases did not fulfill the definition criteria (non-MS PCOS). A healthy age-matched control group of 50 women free of PCOS were also included in the study. All cases and control underwent ECG-QTc interval analysis, echocardiography for interventricular septal diameter (IVSD) and Ejection fraction (EF) estimation, and carotid intimal medial thickness (CIMT) by ultrasound Doppler study.
Results: Cardiovascular abnormalities were significantly higher among the MS PCOS cases compared to non-MS PCOS: significant prolongation of QTc interval (P 0.03) with evident QT dispersion (P 0.01), significant increase in IVSD (P 0.03), significant decrease in EF (P 0.01) and significant increase in CIMT (P 0.04) in PCOS cases with MS. On the other hand, the non-MS PCOS cases showed nonsignificant prolongation of QTc interval (P 0.07), significant increase in IVSD (P 0.01) nonsignificant decrease in EF (P 0.09) and significant increase in CIMT (P 0.02) when compared to the healthy control women.
Conclusion: Many cardiovascular risks are frequent and evidence of premature atherosclerosis is existent among young women with PCOS, being even more exaggerated if there is associated MS. Early intervention to ameliorate cardiovascular risks for these cases is an important health care demand.

Increased C-reactive protein concentration correlates with cumulative effects of metabolic syndrome components in people of the Inner Mongolia region

L. Yu[1], Y.Y. liu[2], Y.H. zhang[3], W.J. tong[3]

[1] *Soochow University School of Radiation Medicine and Public Health, Epidemiology, Suzhou, China*
[2] *Tongliao Center for Disease Control and Prevention, Epidemiology, Tongliao Inner Mongolia, China*
[3] *Soochow University School of Radiation Medicine and Public Health, Epidemiology, Suzhou, China*

Objective: To investigate the association between C-reactive protein (CRP) concentrations and individual metabolic syndrome (MetS) components and their accumulation in individuals from agricultural regions of Inner Mongolia, China
Methods: A cross-sectional survey was conducted in Tongliao City in Inner Mongolia between August 2003 and August 2004. A total of 2 536 participants, aged 20 or more, completed the survey and examination. Lifestyle risk factors were analyzed, as well as body weight, height, waistline, hipline, blood pressure, fasting plasma glucose, blood lipids, and CRP expression. MetS criteria were in accordance with the new International Diabetes Federation (IDF) definition.
Overall and gender-specific prevalence of MetS, and its individual components, were estimated, and chi-square test was used to compare categorical data. Odds ratios (95% CIs) of different CRP levels for the prevalence of individual MetS components were calculated using binomial logistic regression. And the cumulative odds ratios (95% CIs) of the various CRP levels for accumulation of number of MetS components were estimated using ordinal logistic regression analyses. The cumulative odds model was adopted for ordinal logistic regression analyses.
Results: According to the IDF criteria for MetS, the age standardized prevalence of MetS was calculated to be 16.3%. CRP levels were significantly higher in subjects with each MetS characteristic, compared to subjects lacking the corresponding MetS components both in men and women. The result of the binomial logistic regression showed that compared to the lowest CRP quartile, the adjusted ORs of 4th quartile CRP were statistically significant for all MetS components in both genders (all P-values = 0.001).
The age and smoking adjusted geometric means of CRP concentration for those with 0, 1, 2, 3, 4, and 5 components of the metabolic syndrome was 0.72, 0.79, 0.88, 0.98, 0.99, and 1.05 mg/L in men, and 0.63, 0.65, 0.75, 0.85, 0.99, and 1.08 mg/L in women respectively. There was a strong linear increase in ln CRP compared to the increasing number of MetS components (P-trend < 0.001).
Compared to the lowest CRP quartile, the age and smoking adjusted cumulative ORs values (95% CIs) of 2nd quartile CRP, 3rd quartile CRP and 4th quartile CRP were 0.96 (0.69,1.32), 2.35 (1.70,3.25), and 5.57 (3.99,7.79) in men, and 1.39 (1.07,1.82), 2.54 (1.93,3.33), and 6.11 (4.60,8.12) in women.
Conclusion: A significant and dependent association existed between increased CRP concentrations, individual MetS components, and MetS component accumulation in people from the Inner Mongolia region of China.

High-sensitive C reactive protein-to-adiponectin ratio in IFG patients with and without acanthosis nigricans

M. Timar[1], R. Timar[2], V. Serban[2], V. Feier[3], L. Diaconu[2]

[1] *Emergency County Hospital Timisoara, Dermatology Department, Timisoara, Romania*
[2] *University of Medicine and Pharmacy "Victor Babes" Timisoara, Diabetes Clinic, Timisoara, Romania*
[3] *University of Medicine and Pharmacy "Victor Babes" Timisoara, Dermatology Clinic, Timisoara, Romania*

Background and aims: Acanthosis nigricans (AN) is often associated with hyperinsulinemia and may indicate increased risk of type 2 DM.
The aims of our study were to estimate the insulin resistance, to assess plasma high-sensitive C reactive protein (hs-CRP)-to-adiponectin ratio and proinflammatory state in IFG patients with and without AN.
Material and methods: The study enrolled 142 subjects with IFG, 58 men (40.8%) and 84 women (59.2%), with the mean age 46.7 ± 7.5 years. The IFG was defined according to the WHO criteria. Five locations were examined for AN diagnosis: the neck, axilla, elbows, knuckles and knees. In these patients we assessed plasma hs-CRP-to-adiponectin ratio, interleukin 6 (IL-6), tumor necrosis factor a (TNF-a), leptin and HOMA-IR. Linear relationships between key variables were tested by Pearson's correlation coefficient.
Results: AN was present in 21 patients (14.7%) with IFG. The prevalence of AN was higher in women (16.6%) than in men (12.1%). Plasma hs-CRP-to-adiponectin ratio was significantly higher in IFG patients with AN (0.88±0.17) than in IFG patients without AN (0.35±0.09), p < 0.001. In patients with AN adiponectin was negatively correlated with body mass index (BMI), waist to hip ratio (WHR), leptin, IL-6, TNF-a and hs-CRP.

Table 1. Hs-CRP-to-adiponectin ratio, insulin resistance and proinflammatory state in IFG patients with and without AN

IFG	AN	Without AN	p
Number (M/F)	7/14	51/70	-
hs-CRP-to-adiponectin ratio	0.88±0.17	0.35±0.09	p < 0.001
Adiponectin (µg/mL)	6.4±0.6	9.5±2.1	p < 0.001
Leptin (ng/mL)	11.2±3.4	8.3±1.3	p < 0.001
TNF-a (pg/mL)	9.3±1.7	7.2±1.6	p < 0.001
IL-6 (pg/mL)	4.7±0.9	3.2±0.4	p < 0.001
hs-CRP (mg/L)	5.6±1.3	3.3±0.7	p < 0.001
HOMA-IR	5.3±0.9	3.1±0.6	p < 0.001
Data are mean ± SD. p was calculated with unpaired Student's t test.			

Conclusions: AN is independently associated with insulin resistance and therefore may be useful as an early indicator of high risk for diabetes. Increased hs-CRP-to-adiponectin ratio and plasma concentrations of acute-phase proteins are present in adult patients with IFG and AN, and may contribute to promoting

the progression of IFG to type 2 DM. Detection of AN may help clinicians more rapidly identify high-risk individuals for diabetes counseling.

Effect of antihypertensive and hypolipidemic treatment on plasma levels of leptin and adiponectin in patients with type 2 diabetes six month after the initiation of insulin therapy

N. Katsiki[1], F. Iliadis[1], T. Didangelos[1], A. Gotzamani-Psarrakou[2], J. Yovos[3], D. Karamitsos[1]

[1] Diabetes Clinic, 1st Propedeutic Department of Internal Medicine AHEPA University Hospital Thessaloniki Greece, Thessaloniki, Greece

[2] 2nd Laboratory of Nuclear Medicine, AHEPA University Hospital Thessaloniki Greece, Thessaloniki, Greece

[3] Endocrinology and Metabolism Department, AHEPA University Hospital Thessaloniki Greece, Thessaloniki, Greece

Aim: The aim of our study was to investigate the possible effect of antihypertensive and hypolipidemic drug treatment on plasma levels of leptin and adiponectin in patients with type 2 diabetes 6 months after the initiation of insulin therapy.

Patients and methods: This was an open-label prospective study of 6-month duration. A total of 45 insulin naïve type 2 diabetic patients (26 men, mean age= 64,7 ± 9,8 years, mean diabetes duration=12,2±6,9 years) from our Diabetes Outpatient Clinic were enrolled for this study and followed for 6 months after initiating insulin therapy. Blood pressure, weight, body mass index (BMI) and waist circumference were recorded for each patient. HbA_{1c} and lipid panels were measured by the standard procedures. Plasma concentrations of leptin and adiponectin were determined using commercially available radioimmunoassay kits (Linco Research).

Results:

Variables	Baseline	6 months	p
Hba1c (%)	9,98±1,7	6,9±1,5	<0,001
Weight (Kg)	72,3±16,5	76,1±17,6	<0,001
BMI (Kg/m²)	26,7±5,6	28,1±5,9	<0,001
Waist circumference (cm)	96,3±14,4	99,7±14,6	0,001
Total cholesterol (mg/dl)	205,3±43,1	192,9±51,9	0,009
Triglycerides (mg/dl)	187,5±119,6	139,9±67,7	0,001
Leptin (ng/ml)	10,44±8,57	15,92±11,75	<0,001
Adiponectin (μg/ml)	13,34±8,59	17,85±11,41	0,027

Plasma levels of leptin and adiponectin were significantly increased six months after the initiation of insulin therapy (10,44±8,57 vs. 15,92±11,75 p<0,001 and 13,34±8,59 vs. 17,85±11,41 p=0,027 respectively). However, these changes did not differ significantly between patients taking or not antihypertensive or hypolipidemic drug therapy. Furthermore, plasma levels of leptin and adiponectin did not correlate with either systolic or diastolic blood pressure at baseline and after 6 months.

On the contrary, leptin was positively correlated with BMI, weight, waist circumference, total cholesterol and HDL cholesterol, whereas adiponectin was negatively correlated with BMI, weight, waist circumference and LDL cholesterol (p<0,05 and rho>0,3 for all correlations).

Conclusion: In insulin naïve patients with type 2 diabetes, 6 months after the initiation of insulin therapy, leptin and adiponectin levels were significantly elevated.

In the present study, antihypertensive and hypolipidemic treatment did not seem to affect the observed changes in the levels of leptin and adiponectin.

Changes in body weight and plasma levels of leptin, ghrelin and neuropeptide Y in patients with type 2 diabetes six months after the initiation of insulin therapy

N. Katsiki[1], F. Iliadis[1], T. Didangelos[1], A. Gotzamani-Psarrakou[2], J. Yovos[3], D. Karamitsos[1]

[1] Diabetes Clinic, 1st Propedeutic Department of Internal Medicine AHEPA University Hospital Thessaloniki Greece, Thessaloniki, Greece

[2] 2nd Laboratory of Nuclear Medicine, AHEPA University Hospital Thessaloniki Greece, Thessaloniki, Greece

[3] Department of Endocrinology and Metabolism, AHEPA University Hospital Thessaloniki Greece, Thessaloniki, Greece

Aim: The aim of our study was to assess changes in body weight and plasma levels of leptin, ghrelin and neuropeptide Y (NPY) in patients with type 2 diabetes 6 months after the initiation of insulin therapy and to investigate possible correlations between them, in order to determine potential causes of weight gain.

Patients and methods: This was an open-label prospective study of 6-month duration. A total of 45 insulin naïve type 2 diabetic patients (26 men; mean age= 64,7 ± 9,8 years; mean diabetes duration=12,2±6,9 years) from our Diabetes Outpatient Clinic were enrolled for this study and followed for 6 months after initiating insulin therapy. Body mass index (BMI), weight, waist circumference and HbA_{1c} were recorded for each patient. The percentage of body fat was measured using bioimpendance analysis. Plasma concentrations of leptin, ghrelin and NPY were determined using commercially available radioimmunoassay kits (Linco Research and EURO RIA).

Results:

Variables	Baseline	6 months	p
HbA1c (%)	9,98±1,7	6,9±1,5	<0,001
Weight (Kg)	72,3±16,5	76,1±17,6	<0,001
BMI (Kg/m²)	26,7±5,6	28,1±5,9	<0,001
Waist circumference (cm)	96,3±14,4	99,7±14,6	0,001
Body fat (%)	35,7±9,5	37,4±11,9	ns
Leptin (ng/ml)	10,44±8,57	15,92±11,75	<0,001
Ghrelin (μg/ml)	907,39±269,58	833,88±293,48	ns
NPY (pmol/L)	170,82±64,6	89,35±30,52	<0,001

The only significant correlations observed were between changes in leptin levels and body weight, BMI and waist circumference.

Conclusion: In insulin naïve patients with type 2 diabetes, 6 months after the initiation of insulin therapy, leptin levels, body weight, BMI and waist circumference were significantly elevated, whereas NPY levels and HbA1c were significantly reduced. Our results show that although there was an increase in the levels of anorexigenic leptin in addition to a reduction in the levels of orexigenic NPY, patients' body weight increased.

MSG-induced obesity in spontaneously hypertensive rats: An animal model characterized by clustering of cardiovascular disease risk factors

N. Leguisamo[1], A. Lehnen[1], F. Azambuja[1], G. Pinto[1], U. Machado[2], M. Okamoto[2], B. Schaan[3]

[1] Instituto de Cardiologia do Rio Grande do Sul/ FUC, Serviço de Medicina Experimental, Porto Alegre, Brazil

[2] Instituto de Ciências Biomédicas (ICB)/ USP, Departamento de Fisiologia e Biofísica, São Paulo, Brazil

[3] Hospital de Clínicas de Porto Alegre / UFRGS - Instituto de Cardiologia do Rio Grande do Sul/ FUC, Serviço de Endocrinologia - Serviço de Medicina Experimental (CNPq Fapergs Fapicc), Porto Alegre, Brazil

Background: Monosodium glutamate (MSG) treatment of spontaneously hypertensive rats (SHR) in the neonatal period can generate characteristics of the metabolic syndrome, but the full animal model characterization was not studied yet.

Aims: To characterize the animal model of metabolic syndrome in MSG-treated SHR (anthropometric variables, inflammatory, metabolic and hemodynamic profile).

Methods: Male newborn SHR rats (n=48) were treated with MSG (MSG), 5mg/g subcutaneously/9 days, or saline (C). In 3-, 6- and 9-month old rats

we investigate: 1) anthopometry (body weight, length, Lee index); 2. glucose disappearance constant (kITT) during the insulin tolerance test (0.75 U/kg, EV); 2) cardiovascular evaluation (catheters were implanted into the femoral artery to measure arterial pressure (AP) and heart rate (HR) on a beat-to-beat basis in conscious animals one day later - Windaq/CODAS); 3) inflammatory markers (TNF-a; C-reactive-protein, CRP; interleukin-6, IL-6; adiponectin - ELISA) and lipid profile (total and HDL cholesterol, triglycerides). Normotensive Wistar-Kyoto rats (WKY) (n=16) were also studied, to compare cardiovascular data.

Results: As compared to C, MSG-treated rats presented higher Lee Index and insulin resistance at all ages, and hypertriglyceridemia and low HDL cholesterol at 6 and 9 ($p<0.05$) months. At 6 months, CRP (370 ± 20 vs. 201 ± 21 mg/mL), IL-6 (75 ± 11 vs. 36 ± 3 mg/mL) and TNF-a (12 ± 2 vs. 8 ± 2 pg/mL) were higher ($p<0.001$) in MSG vs C, and similar results were obtained at 9 months. Adiponectin was similar between groups, except at 9 months (0.32 ± 0.02 vs. 0.42 ± 0.02 mg/mL), when it was lower in MSG ($p<0.001$). Mean AP was higher in MSG and C (159 ± 14 mmHg and 148 ± 16 mmHg) as compared to WKY (112 ± 7 mmHg) at 3 months, p<0,001. Similar results were observed at 6 and 9 months (p<0,001).

Conclusions: The characteristics observed in the MSG-induced obesity in SHR confirms the clustering of cardiovascular risk factors in this animal model, making it useful for investigating potential treatments of the metabolic syndrome.

P-1537

Prevalence of the metabolic syndrome in patients with type 2 Diabetes: "X in T2DM"

L. Varadhan[1], S. Bradbury[1], E. Hodgson[1], A.B. Walker[1], G.I. Varughese[1]
[1] *University Hospital North Staffordshire NHS Trust, Diabetes and Endocrinology, Stoke on Trent, United Kingdom*

Introduction and aim: The increasing prevalence of type 2 diabetes (T2DM) proportionately increases the cardiovascular risk of the general population. Existence of the cluster of metabolic syndrome, with its element of insulin resistance, could significantly increase this further. The introduction of General Medical Service contract in UK has recently improved the quality of care provided to patients with diabetes in the community, especially with respect to achieving risk factor targets and increased use of statin and anti hypertensive medications. The aim of our study was to assess the presence of metabolic syndrome across our diabetic population on a cross sectional study, using the IDF criteria for establishing the diagnosis.

Methods: Data was collected on patients with T2DM from our computer database registry. Any patient who is currently under annual review, either at hospital or with the primary care physician, was included in the study. Any patient with T2DM for less than a year, or in whom the type of diabetes was debated, was excluded. Metabolic syndrome was diagnosed by using waist circumference ≥94cm for men and ≥80cm for women as essential criteria and presence of one of the following 3 (as all patients had T2DM)

- Reduced HDL cholesterol: <1.03 mmol/L in males and <1.29mmol/L in females or on specific treatment for this lipid abnormality
- Raised Triglycerides (TGL): ≥1.7mmol/L or specific treatment
- Raised BP: systolic BP ≥130 or diastolic ≥85 mm Hg or on treatment

Results: A total of 4495 patients were included in the registry. Only 3683 could be included in study based on the essential anthropometric criteria. 55% were men. The mean duration of diabetes was 7.4 years (1-57 years), average age being 64.8 years and age of onset 57.4 yrs (11-92 years). The mean HbA1c was 7.3%, BP 136/76 and total cholesterol 4.2mmol/L

92% of the patients had features of metabolic syndrome, with 67% having more than one criterion and 26.7% having all the 3 criteria. The distribution was not different between the sexes (92% men, 92.7% women). The predominant contributor was high blood pressure (prevalence 77.5%), followed by low HDL (61%) and high TGL (55.1%)

Conclusion: Although the glycaemic control appears satisfactory, the prevalence of the components of metabolic syndrome is significantly high in patients with T2DM in our study. Various cardiovascular risk factors are inadequately controlled in spite of a significant increase in use of multiple pharmacological agents. An aggressive approach is required to treat blood pressure and lipids to desired targets in this high risk population, to prevent cardiovascular events.

Effects of exogenous insulin intervention on insulin signaling pathway in the liver of diabetic mice determined by gene micro array

Q. Yu[1], M. LI[1], X. Chen[1], J.P. Weng[1]
[1] *The 3rd Affiliated Hosipital of Sun Yat-Sen University, Endocrinology, Guangzhou, China*

Background and aims: Insulin resistance in the liver is one of the main defects in type 2 diabetes. Indeed, post receptor changes in insulin signaling are at the core of insulin resistance. In the setting of insulin resistance, insulin action of metabolic (PI3K) and mitogenic (SHC/MAPK) pathways are differently affected. We explored the effects of exogenous insulin intervention on insulin signal pathway in the liver tissue, using gene micro array to investigate significant changes in hepatic gene transcription after insulin intervention.

Materials and methods: 30 5-week-old C57BL/6 mice were randomized into 3 groups: A, fed with normal diet (9.9% calorie from fat); B and C, fed with high fat diet (60% calorie from fat). After 12 weeks fed, mice in group C were injected with insulin glargine s.c. at 0.5IU. Mice in group A and B were injected with saline s.c. at 0.5ml. The intervention lasted for 4 weeks. After that, the mice were executed and the livers were frozen for mRNA extraction. The mRNA expression of 100 target genes involved in insulin signaling pathway were determined by gene micro array.

Results: If the mRNA expression in Group A was 100%, the expression of genes involved in the insulin signaling pathway of Group B and C were as follow: 1) Akt-2 26% and 63%; Akt-3 17% and 71%; Pik3r2 241% and 97%; Ptpn1 293% and 143%; 2) Cap1 38.77% and 63.60%; Cbl 34.48% and 67.85%; Crk-I 27.49 and 36.06%; 3) Shc3 526.8% and 260.6%; Sos1 203.0% and 79.29% respectively.

Disccusion: 1) Insulin resistance in diabetes was mediated by reduced PI3K as well as Cbl and CAP signaling pathway. Exogenous insulin improved PI3K signaling by up-regulation of Akt-2 and Akt-3 and down-regulation of Pik3r2 and Ptpn1. While Cbl and CAP signaling were not significantly improved because the expression of Cap1, Cbl, and Crk-I were not significantly increased by insulin intervention. 2) In the setting of insulin resistance, the SHC/MAPK pathway shifts the balance in favor of the mitogenic actions. Expression of Shc3 and Sos1 were significantly increased in high fat induced diabetic mice. It was likely that sustained activation of the MAPK pathway occurred via SHC activation. After insulin intervention, Shc3 and Sos1 were obviously down regulated suggesting exogenous insulin did not aggravate insulin action of mitogenic pathway.

Conclusion: High fat diet could impair insulin action of metabolic signaling pathway by affecting gene expression of Akt-3, Akt-2, Pik3r2, Ptpn1, Cap1, Cbl and Crk-I. After 4 weeks of insulin intervention, such defects were partially alleviated. In high fat induced diabetic mice, SHC/MAPK signaling pathway might be activated due to the up-regulated expression of Shc3 and Sos1. Insulin intervention down regulated these genes illuminating that systemic use of exogenous insulin might not aggravate the mitogenic action of insulin.

[3] *BIRDEM, Gastroenterology, Dhaka, Bangladesh*

Background: Metabolic syndrome is a strong predictor of diabetes and cardiovascular disease (CVD) and is associated with increased risk of CVD mortality. Population based data on the prevalence of metabolic syndrome is rarely available for rural Bangladesh.

Objective: We examined the prevalence of metabolic syndrome in relatively younger adults (27-50 y) in rural Matlab, Bangladesh.

Subjects and methods: We measured waist circumference (WC), blood pressure (BP), plasma glucose (fasting and 2 h after 75 g glucose challenge), fasting triglyceride (TG) and high density lipoprotein cholesterol (HDL-C) on randomly selected adult males (n=229) and females (n=288). Each metabolic syndrome variable was defined using sex and population specific cut-off values suggested by the International Diabetes Federation (IDF). Metabolic syndrome was defined as the presence of abdominal obesity (high WC) and any two of

the other four variables (high TG, low HDL, high BP, abnormal glucose).
Results: Study participants were 37 years old with average body mass index (BMI) of 20.4 kg/m^2. Females had higher BMI than males (20.8±3.4 vs 19.8±2.9; p=0.000). The overall prevalence high WC, high TG, low HDL, high BP, and abnormal glucose were present among 13.7%, 16.8%, 79.3%, 13.7%, and 19.5% of the individuals, respectively. Females had significantly higher prevalence of high WC (19.8% vs 6.1%; p=0.000), low HDL (84.7 vs 72.5%; p=0.005). Males, on the other hand, had higher prevalence of TG (21.8% vs 12.8%, p=0.007). No difference in the prevalence of high BP was observed between gender however, abnormal glucose tended to be higher in the females than males (17.5 vs 21.2; p=172). Although metabolic syndrome was prevalent among 7.4% of the participants, prevalence was higher among females than males (p=9.7% vs 4.4%; p=0.014).
Conclusions: Metabolic syndrome variables are widely prevalent among relatively younger adults in rural Matlab, Bangladesh. Higher vulnerability of females to MS than males requires further investigation. Identification of the determinants of MS is important for designing primary prevention strategy for diabetes and CVD in Bangladesh.

Prevalence of dyslipidemia in the study of metabolic syndrome in Maracaibo, Zulia State, Venezuela

S. Martínez[1], V. Bermúdez[1], Y. Luti[1], R. Canelón[1], M. Parra[1], L. Suárez[1], C. Zerpa[1], F. Quintero[1]
[1] Universidad del Zulia, Centro de Investigaciones Endocrino Metabólicas Dr. Félix Gómez, Maracaibo, Venezuela

Objetives: Dyslipidemia constitutes a risk factor for cardiovascular disease caused by atherosclerosis; for this reason, the purpose of this research was to determine the prevalence of dyslipidemia in the study of Metabolic Syndrome in Maracaibo.
Methods: Data was obtained from 1400 individuals older than 18 years and both genders (male: 634; female: 766) selected through a random number generation utility. A complete clinical history was made and glycemia, lipid profile and insulin were determined. Results were analized in the statistical program SPSS version 15.0, and were expressed as absolute frequencies and percentages taking the cutoff points suggested by the Adult Treatment Panel (ATP III) - National Institutes of Health (NIH) of EUA.
Results and discussion: 68,1% of the studied individuals had dyslipidemia, most prevalent being isolated low HDLc: 29,1% (n=408), followed by Hypertriglyceridemia with low HDLc: 13,1 % (n=183); and mixed dyslipidemia with low HDLc: 6,9% (n=97). The fourth most prevalent dyslipidemia was the Hypercholesterolemia with low HDLc: 6,2% (n=87), in fifth place the isolated Hypercholesterolemia: 5,5% (n=77), followed by the Hypertriglyceridemia: 4,5% (n=63) and finally, mixed dyslipidemia: 2,8% (n=39). The most frequent abnormality in dyslipidemic individuals was low HDLc with 55,3% (Isolated: 29,1%; Combined with other dyslipidemia: 26,2%).
Conclusion: It is well seen a high prevalence of lipid disorders in our population, which justifiy more studies to determine whether due to enviromental causes, genetic or both, specially those related to low levels of HDLc.

P-1541

Characteristics of insulin resistance and the insulin secretory capacity of young male subjects with prediabetes

S.Y. Rhee[1], J. Woo[2], S. Chon[2], S. Oh[2], K.J. Ahn[2], H.Y. Chung[2], S.W. Kim[2], J.W. Kim[2], Y.S. Kim[2]
[1] Ministry of National Defense of Korea, Dept. of Internal Medicine Service Support Group, Seoul, Korea
[2] Kyung Hee University School of Medicine, Dept. of Endocrinology and Metabolism, Seoul, Korea

Background: Prediabetes is known as an intermediate pathological state that can progress to overt diabetes mellitus. However, the pathophysiological features of prediabetes have not been fully elucidated.
Subjects and methods: This study was conducted on 392 male medical school students between 22 and 35 years of age. All study subjects had their basal anthropometry determined and a 75 g oral glucose tolerance test (OGTT). According to the OGTT results, the subjects were divided into the following four groups: normal glucose tolerance (NGT), isolated IFG, isolated IGT, and combined glucose intolerance (CGI) group. We also measured various insulin resistance indices (HOMA-IR, QUICKI, WBISI, OGIS120), insulin secretion indices (insulinogenic index [IGI], C-peptide response [CPR], HOMAb), and the disposition index (IGIxWBISI), and then compared each of the four groups.
Results: The OGTT results showed that 290 subjects had NGT, 53 subjects had isolated IFG, 28 subjects had isolated IGT, and 21 subjects had CGI. When the isolated IFG, isolated IGT and CGI groups were compared, with respect to the insulin secretory indices, IGI, CPR, and HOMAb were found to be significantly different. However, with respect to the insulin resistance indices, only OGIS120 was significantly different. Moreover, the disposition index, which is the insulin secretory index adjusted for the difference in insulin resistance, was significantly different. These results remained unchanged after adjustment for other confounders by ANCOVA.
Conclusion: There are some distinct pathophysiological and metabolic differences between young Korean male subjects with prediabetes. These findings suggest that prediabetes represents a complex pathophysiological state.

Erythrocyte glucose uptake and insulin resistance in diabetes and metabolic syndrome

Z. Shamansurova[1], A. Alieva[1], M. Akhmedova[1]
[1] Endocrinology, Diabetology, Tashkent, Uzbekistan

Background and aim: In recent study was shown increasing erythrocytes glucose uptake in patients with Diabetes Mellitus (DM), obesity (O), impaired glucose tolerance (IGT), which can be viewed as metabolic syndrome (MS). The aim of this investigation was study the relationship EGU with glycemic control degree and insulin resistance index in patients with DM2, O, IGT.
Material and methods: In 127 patients with type 2 DM, 27 with O, 21 with IGT and 18 healthy subjects (HS), fasting (FG) and postprandial (PG) blood glucose, HbA1c level, CRP, plasma insulin (PI), plasma nitrites and nitrates level (NN), erythrocytes sialidase acitity (ESA) were measured, EGU level detected by differences of glucose concentration in erythrocytes after their incubation, and HOMA index was calculated as (FG x PI):22.5.
Results: Results show significantly increased FG (27%) and PG (36%), HbA1c (33%) in patients with DM than HS. In IGT the level of PG (19%) and HbA1c (23%) was significantly increased and this indexes not changed in patients with obesity. The level of CRP, ESA, HOMA was significantly increased and NN significantly decreased in DM, O, IGT groups and suggested tissue damage and presence of insulin resistance. EGU was increased in patients with DM in 2.6 times, P<0.02, in 2.2 times, P<0.05 in IGT group, in patients with obesity in 1.9 times, P<0.05 in compare with HS. Moreover EGU had linkage with FG, ESA, CRP, had dependency of presence and severity of diabetes complications and EGU had positive correlation with HOMA in DM (r=0.62), obesity (r=0.31), IGT (r=0.46) and suggested alteration of EGU as tissue response to insulin resistance.
Conclusion: EGU increased in patients with DM, obesity, IGT and had linkage with glycemia indexes, CRP, ESA, NN, had positive correlation with HOMA and may be viewed as tissue response to insulin resistance.

HOMA-estimated insulin resistance in Nigerians with type 2 diabetes mellitus

A.O. Coker[1], O.A. Fasanmade[1], A.E. Ohwovoriole[1]
[1] Lagos University Teaching Hospital, Endocrinology and Metabolism Unit Department of Medicine, Lagos, Nigeria

Objective: To determine insulin resistance using the homeostasis model of insulin resistance (HOMA-IR) in Nigerians with type 2 diabetes mellitus.
Materials and methods: Insulin resistance was assessed using the clinical indices of waist circumference and systolic blood pressure; fasting serum insulin and the calculation of the Homeostasis Model Assessment of Insulin Resistance (HOMA-IR). Glycaemic control was also estimated using fasting plasma glucose and glycated haemoglobin (HbA_{1c})
Results: The mean waist circumference in the male subjects with diabetes of 96.4±2.2cm was higher than the mean waist circumference of 84.3 ± 3.2cm in male controls. The mean waist circumference in the female subjects with diabetes of 97.3±4.0cm was higher than the mean waist circumference of 92.2±3.0cm in female controls.

Control subjects had a mean systolic blood pressure of 120±3.2 mmHg compared with 128.5±2.5 mmHg in subjects with diabetes (p<0.05). Mean fasting serum insulin in control and study subjects was similar (5.0±0.3)µL/ml vs 4.5±0.3µL/ml).
The Homeostasis Model Assessment of Insulin Resistance (HOMA-IR) in the control subjects of 1.2±0.1 was similar to the subjects with diabetes (1.2±0.1). Regression analysis showed that waist circumference was the major contributor to HOMA-IR.
Using the waist circumference, systolic blood pressure, fasting plasma insulin and HOMA-IR, an insulin resistance score was developed. With this summation criterion, 21 (53%) of the subjects with diabetes and 5 (25%) of the controls had insulin resistance.
Conclusions: HOMA-estimated insulin resistance in Nigerians with type 2 diabetes mellitus is similar to control subjects and is related to the waist circumference.
More studies will need to be carried out to better asses the use of the HOMA index of insulin resistance as a measure of insulin sensitivity in Nigerians.

The relationship between high molecular weight adiponectin and insulin resistance in women with polycystic ovary syndrome

T. Tao[1]
[1] *Renji Hospital - Medical School of Shanghai Jiaotong University, Medicine and Endocrinology, Shanghai, China*

Objective: Women with PCOS is frequently associated with insulin resistance and a consequent increased risk of metabolic diseases. Adiponectin is an abundant serum adipokine secreted exclusively from differentiated adipocytes, among which high-molecular weight adiponectin plays an important role in regulating insulin sensitivity.The aim of the present study was to investigate the role of HMW-Adiponectin in insulin resistance in women with PCOS.
Methods: Sixty-three patients with PCOS and twenty with normal weight and forty-three with obesity, matched for age and body mass index (BMI), were enrolled in the study. Serum total-adiponectin, HMW-adiponectin, MMW-adiponectin, LMW-adiponectin, were detected in all patients by ELISA and CRP were detected by immunoturbidimetric assay, Clinical, metabolic and sex hormonal parameters), and the waist circumference, body fat rate, body mass index were measured.
Results:
1. Serum levels of total-adiponectin, HMW-adiponectin were significantly lower in patients with PCOS than in normal controls (P<0.01), but serum levels of total-adiponectin were not significantly lower in patients with PCOS with obesity than in simple obesity. Serum levels of CRP, luteinizing hormone,serum androgen, fasting insulin, HOMA-IR were significantly higher in women with PCOS than in normal controls (P<0.01).
2 The percentage of each oligomeric form of adiponectin is difference between normal controls and women with PCOS. Only the HMW-adiponectin level was significantly higher in normal women as compared with PCOS (p<0.05). (3)HMW-adiponectin level was positively correlated with HOMA-IR, FAT%, CRP and body mass index; and negatively correlated with HDL-C (P<0.05).

Conclusion: HMW-adiponectin is good marker (better than total-adiponectin) whose levels correspondingly reflect the degree of insulin resistance in patients with polycystic ovary syndrome.

Physical activity patterns and relationship with metabolic syndrome in the Maracaibo municipality, Venezuela

D. Aparicio[1], *C. Colmenares*[1], *V. Bermúdez*[1], *A. Toledo*[1], *L. Suárez*[1], *C. Pineda*[1], *R. Añez*[1], *J. Urribarrí*[1]
[1] *Endocrine-Metabolic Research Center "Dr. Félix Gómez", Faculty of Medicine University of Zulia, Maracaibo, Venezuela*

Background and objectives: It is unknown in our population the physical activity levels and its relationship with the development of metabolic syndrome (SM), so the aim of this study is to determine the relationship between the physical activity levels among the population of Maracaibo Municipality and its relationship with the Metabolic Syndrome (MS).
Materials and methods: A descriptive, transversal study was held in 1356 individuals: 741 women (54.6%) and 615 men (45.4%), selected randomly, to whom full clinical history was filled and the International Physical Activity Questionnaire applied. Statistical analysis was performed in the program SPSS 15.0 version. Pearson's Chi-square test and the ANOVA factor were used as appropriate. The diagnosis of Metabolic Syndrome was made according to the International Diabetes Federation diagnostic criteria. Results are expressed as absolute frequencies, percentages and mean ± Standard Deviation as appropriate.
Results: The categorization of physical activity levels was: Low in the 24.3% of the individuals (n = 329) Moderate in the 34.7% (n = 470), and High in the 41.1% (n = 557). There was no significant difference between the METs / min / week of a low level of physical activity with a moderate level (p>0,05), but the difference was significant between the METs / min / week of low and high physical activity (498 ± 1394 vs. 9386 ± 5357, p<0,05). There is an association between high levels of physical activity and the absence of MS (X2 = 20,863, p <0,001), hyperglycemia (X2 = 10,254, p = 0,006), high levels of triacylglycerides (X2 = 12,721, p = 0,002), but not with HDL c-low (X2 = 1901, p = 0,87) or hypertension (X2 = 0058, p = 0,033). There were significant differences (p <0.01) between waist circumference: 97 ±16 vs 92 ±14 cm, fasting glucose levels: 105 ±35 vs 98 ±27mg/dL, triacylglycerides levels: 142 ±98 vs 122 ± 95mg/dL, but not between systolic blood pressure, diastolic blood pressure and HDL-c, in Low and High physical activity levels respectively.
Conclusions: A high level of physical activity is a protective factor for the development of the metabolic syndrome, while moderate and low levels are not.

Epidemiologic behavior of metabolic syndrome according to IDF, ATP III and EGIR definitions

Y. Luti[1], *V. Bermúdez*[1], *W. Sánchez*[1], *L. Peñaranda*[1], *D. Aparicio*[1], *S. Martínez*[1], *D. Gotera*[1], *N. Ramos*[1]
[1] *Universidad del Zulia, Centro de Investigaciones Endocrino Metabólicas Dr. Félix Gómez, Maracaibo, Venezuela*

Aims: Metabolic Syndrome groups risk factors for cardiovascular disease. There are several classifications for its diagnosis, for this reason, the purpose of this research was to study the epidemiologic behavior of Metabolic Syndrome according IDF, ATP III and EGIR definitions in Maracaibo City, Zulia State, Venezuela.
Methods: It was conducted a transversal and descriptive study in 1400 adult individuals (Female: n=766; Male: n=634) selected through a random number generation utility. A complete clinic history was made and glycemia, lipid profile and insulin were determined. Results were expressed as absolute frequencies and percentages.
Results and discussion: Prevalence of Metabolic Syndrome according IDF was 52,7% (n=738; Female=389, Male=349), ATP III of NIH USA was 34,9% (n=488; Female=256, Male=232), and the EGIR was 17,7% (n=225, Female=106, Male=119); for any of the classifications the prevalence of MS was 54,6% (n=764), and by all of them was 11,5% (n=161).
Conclusion: The great divergence between the several definitions for diagnosis of MS has important influence in its prevalence. It is necesary to make risk studies to compare the different definitions to determine the capacity of prediction, sensitivity and specificity of each one of them in our population.

Point and interval contrast insulin sensitivity indexes calculated from OGTT

L. Dedik[1], *J. Chrenova*[1], *Z. Rausova*[1], *M. Durislova*[2]
[1] *Slovak University of Technology, Faculty of Mechanical Engineering, Bratislava, Slovakia*
[2] *Slovak Academy of Science, Institute of Experimental Pharmacology, Bratislava, Slovakia*

Aims: To present deterministic and statistical properties of several formulae for calculation of insulin sensitivity index (ISI), using data from frequently sampled oral glucose tolerance test (OGTT), as dimensionless, mutually comparable contrasts within a continuous scale.
Methods: Eleven formulae for ISI calculations were analyzed. The contrasts: 1) point contrasts, calculated as ratios of average ISI values, and 2) interval

contrasts, calculated as ratios of statistics T from the two-group unpaired Student's t-Test at the 0.05 significance level, were used in evaluation of data sets of 10 healthy volunteers and 20 patients, who underwent OGTT during their first visit to an endocrinology department.

Results: The subjects of both groups exhibit statistically different BMI values. The calculated ISI values, obtained using eleven formulae and measured data of both groups, were statistically different at the 0.05 significance level, according to the unpaired t-test. When presented in graphical form, the contrasts of the calculated ISI indicate significantly different properties of individual ISI values, under elimination of effects of their numerical values and dimensions. The formulae used for ISI calculation differed not only in the number of points used for the measurement of glucose and insulin concentration but also in their deterministic and statistical properties.

Discussion/conclusions: According to some authors, the use of ISI in evaluations of data from OGTT, opens the following questions: 1) which formula should be used; 2) what are dimensions of input and output quantities; 3) what are normal ISI values; 4) how to compare results obtained using different ISI formulae; 5) how to compare ISI values with parameters of OGTT model which takes into account gastric emptying rate (1). In answering these questions, based on the results obtained it could be recommended: 1) to use the formulae with the high point contrast in comparisons of data of an individual subject with the standard; 2) to select formulae with high interval contrast in comparisons of data of several subject groups.

Prevalence of metabolic syndrome (MS) among young women with polycystic ovarian syndrome (PCOS) in a rural area in Egypt: comparison of 3 different definition criteria

E.M. Refaei[1], W.M. Refaei[2], M.R. Refaei[3], N. Sayed-Ahmed[3], G.M. El-Kannishy[3], M.H. El-Kannishy[4]
[1] Mansoura University, Obstetrics & Gynecology, Mansoura, Egypt
[2] Mansoura University, Cardiology, Mansoura, Egypt
[3] Mansoura University, Internal Medicine, Mansoura, Egypt
[4] Mansoura University, Clinical Pathology, Mansoura, Egypt

Background: The prevalence of metabolic syndrome is increasing worldwide with an emerging epidemic especially in developing nations. The prevalence of metabolic syndrome in relation to PCOS has not been widely evaluated in young women in our locality.

Objective: To estimate the prevalence of metabolic syndrome among young rural Egyptian women with PCOS.

Patients & methods: 312 women fulfilling the Rotterdam consensus criteria (2003) of PCOS, were selected from the Gynecology and Endocrinology Outpatient Clinics, Mansoura University Hospitals. They were all screened for the presence of metabolic syndrome both clinically and biochemically (Blood pressure, anthropometric measurements, fasting plasma glucose, serum triglycerides, high density lipoprotein, insulin resistance, and free testosterone). Metabolic syndrome was defined in each case according to the World Health Organization criteria (WHO, 1999), the National Cholesterol Education Program - the Modified Adult Treatment Panel III (NCEP-ATP III panel, 2001) and International Diabetes Federation criteria (IDF, 2005)

Results: 125 women out of the 312 examined met the IDF (2005) criteria (40%), 122 cases met the NCEP-ATP III definition criteria (39.1%), while only 33 women (10.6%) fulfilled the WHO criteria for metabolic syndrome. The prevalence of metabolic syndrome significantly increased with age, body mass index, insulin resistance, and free testosterone. When the IDF (2005) criteria were adopted, the least representative component of metabolic syndrome was elevated fasting plasma glucose (17.2%) while the highest prevalent component of the syndrome was central obesity (77.9%).

Conclusion: Metabolic syndrome in women with PCOS is a common abnormality. The IDF (2005) definition of metabolic syndrome is comparable to that of the NCEP-ATP III (2001). Both can be utilized satisfactorily in the diagnosis of metabolic syndrome especially in young women.

P-1549

Changes in adiponectin, leptin and inflammatory markers in persons with metabolic syndrome

R. Timar[1], V. Serban[1], L. Diaconu[1], A. Vlad[1], B. Timar[1], M. Neagu[1]
[1] University of Medicine and Pharmacy "Victor Babes" Timisoara, Diabetes Clinic, Timisoara, Romania

Background and aims: The role of insulin resistance and hyperinsulinemia as etiopathogenic factors of MS is complex and is thought to be closely related to the presence of abdominal obesity and to a secretory dysfunction of adipocytes. The aims of our study were to assess plasma levels of adiponectin, leptin, proinflammatory cytokines (IL 6, TNF a), hs-CRP, fibrinogen, insulin resistance and to evaluate the prevalence of atherosclerotic cardiovascular disease in persons with and without MS.

Material and methods: The study enrolled 242 subjects with MS (IDF criteria) and 212 without MS, aged over 20 years, whose main characteristics are presented in table 1.

Table 1. Characteristics of persons with and without MS

Parameter	Without MS	With MS	p
Male/Female	98/114	109/133	NS
Age (years)*	46.32 ± 13.82	51.46 ± 12.74	<0.001
Adiponectin (µg/mL)*	13.42 ± 2.31	6.81 ± 1.54	<0.001
Leptin (ng/mL)*	6.21 ± 2.32	14.33 ± 3.82	<0.001
TNF a (pg/mL)*	5.12 ± 1.14	9.54 ± 2.41	<0.001
IL 6 (pg/mL)*	2.91 ± 0.73	5.23 ± 0.92	<0.001
hs-CRP (mg/L)*	2.14 ± 0.64	5.82 ± 1.56	<0.001
Fibrinogen (mg/dL)*	194.22 ± 28.42	386.41 ± 44.12	<0.001
HOMA-IR*	2.19 ± 0.51	5.03 ± 1.35	<0.001

*Data are means ± SD. P was calculated with unpaired Student's t test.

Results: The serum level of adiponectin, adipocytokine with anti-inflammatory and insulin sensitizing effects, was lower ($p<0.001$) in individuals with MS than in those without MS, and was negatively correlated with the waist circumference (WCF) ($r= - 0.66$, in men, and $r= - 0.64$, in women), BMI ($r= - 0.54$) and HOMA-IR ($r= - 0.58$, in men, and $r= - 0.61$, in women).

For subjects with MS, the serum levels of leptin and inflammatory markers were significantly ($p<0.001$) higher compared to those without MS and correlated positively with the BMI, WCF and HOMA-IR. We found a negative correlation between adiponectinemia and serum levels of leptin, TNF a, IL 6, hs-CRP and fibrinogen.

For subjects with MS, the cumulated prevalence of ischemic heart disease and cerebrovascular disease was 3.3 times that encountered in persons without MS.

Conclusion: Our results sustain the hypothesis that the secretory dysfunction of proinflammatory and anti-inflammatory adipocytokines represent the main link between abdominal obesity, insulin resistance and atherosclerosis.

Assessment of insulin resistance in South East Asian women with polycystic ovary syndrome (PCOS)

M. Riaz[1], A. Basit[1], A. Fawwad[2], M.Y. Ahmedani[1], A. Zafar[1], Z. Miyan[1], A. Salman[1]
[1] Baqai Institute of Diabetology & Endocrinology, Department of Medicine, Karachi, Pakistan
[2] Baqai Institute of Diabetology & Endocrinology, Department of Research, Karachi, Pakistan

Objective: To assess insulin resistance (IR) in South East Asian women with PCOS.

Methods: This cross sectional study was carried out at Baqai Institute of Diabetology and Endocrinology (BIDE) from January 2006 to December 2008. Patients fulfilling the revised 2003 Rotterdan diagnostic criteria for PCOS were included. Data of 91 patients was available for statistical analysis. Descriptive statistics were calculated using frequency and mean with standard deviation. IR was calculated using fasting blood sugar (FBS) and fasting insulin levels. Different surrogate markers of IR like Homeostatic model assessment of IR (HOMA-IR) and quantitative sensitivity check index (QUICKI) were calculated.

Results: The mean BMI of patients with PCOS was 31.85 ± 7.93. 37% of patients were infertile. Co-morbid like type 2 diabetes was seen in 12.7% patients while 15.11% patients were hypertensive. Using HOMA-IR (=2.6) 70% patients were insulin resistant while with QUICKI (=0.35) IR was seen in

88% patients. Only 43.9% of patients were having typical cystic appearance of ovaries on ultrasound.
Conclusion: Frequency of insulin resistance in patients with PCOS is quite high in South East Asian women. Further large scale studies are needed to validate the findings of this study, so that the long term sequel of IR can be prevented.

P-1551

Prevalence of metabolic syndrome in the adult population of the municipality of Maracaibo, Venezuela

C. Colmenares[1], Y. Luti[1], V. Bermúdez[1], L. Peñaranda[1], X. Guerra[1], W. Sánchez[1], C. Pineda[1], K. Vega[1], M. Chacín[1]
[1] *Endocrine-Metabolic Research Center "Dr. Félix Gómez", Faculty of Medicine University of Zulia, Maracaibo, Venezuela*

Introduction and objectives: The Metabolic Syndrome (MS) is caused by the interaction of genetic and environmental factors. The aim of this study was to determine its prevalence in individuals of the Municipality of Maracaibo, Estado Zulia.
Materials and methods: A descriptive, transversal study was held in 1400 subjects older than 18 years (female, n = 389, male n = 349), which was performed complete clinical history and determined fasting blood glucose, insulin and lipid profile. We used the criteria of the International Diabetes Federation to diagnose MS, expressing results as absolute frequencies and percentages.
Results: The prevalence of Metabolic Syndrome was 52.7% (n = 738), predominantly female (52.7%, n = 389) over male (47.3%, n = 349) and more frequently in age groups of 40-49 (26%, n = 192) and 50-59 years (23.3%, n = 172). The parish with higher prevalence of Metabolic Syndrome was Francisco Eugenio Bustamante with 19.6% (n = 145). Socioeconomic status IV showed the highest prevalence with 37.7% (n = 278). The most frequent diagnostic combination was the presence of central obesity + low HDL + fasting glycaemia ≥ 100 mg / dL (or diagnosis of DM-2) with 28.9% (n = 213) followed by central obesity + elevated triacylglycerides + fasting glycaemia ≥ 100 mg / dL (or previous diagnosis of DM-2) with 14% (n = 103).
Conclusion: The prevalence of Metabolic Syndrome in our population is higher than the ones detected in others urban areas of Latin America, which requires further studies to establish the validity of the cutoff points used for diagnosis of this syndrome in our population and its relationship with cardiovascular morbidity and mortality.

P-1552

Insulin resistance and its relationship with age in an Asian diabetic cohort

N. Deshpande[1], N. Kapoor[2], A. Syed[2], L. Dahiya[2], R. Dhareshwar[2]
[1] *Belgaum Diabetes Centre and JN Medical College, Diabetes & Obesity, Belgaum, India*
[2] *Belgaum Diabetes Centre, Diabetes & Obesity, Belgaum, India*

Background: The relationship between insulin resistance and aging is still debated. The fast transition of India and other Asian countries to western lifestyle has made the country a hub for the disease and diabetes is fast emerging as one of the most common chronic ailments to affect young adults. Obesity and inactivity have increased cases of type2 diabetes among people of younger age which was earlier prevalent only in those above 45 years of age. In this study we aimed at comparing insulin resistance and other metabolic parameters among freshly detected diabetics among those having young (<45 yrs) and old (>45yrs) onset diabetes.
Aim: To compare the insulin resistance and other metabolic parameters between type 2 diabetics having young or old onset of diabetes.
Methods: 97 freshly detected type 2 male diabetics were enrolled into the study and stratified into those having young (</=45yrs) or late onset (>45yrs) of diabetes. Several anthropometric and metabolic parameters like BMI (Body mass index), WHR (waist hip ratio), Body Fat Percentage, HsCRP, Glycemic control, Insulin resistance (HOMA-IR index), lipids, uric acid and serum transaminases were compared. The results were tabulated and statistically analyzed.

Results:
- Total number of cases: 97
- No of young onset diabetics = 44/97 (45.36%)
- No of old onset diabetics = 53/97 (54.64%).

	Young onset diabetes	Old onset diabetes	P value
N	39	58	
BMI	26.1±2.5	25.4±2.5	0.240665
Body fat	22.9±7.9	23.7±7.9	0.588181

SGPT	34.49±22.32	30.91±22.32	0.3914123

The subjects in both the groups had similar degree of Obesity (BMI and Body Fat) and Glycemic control. P values between the two groups for insulin resistance were insignificant.
Conclusion: We did not find any correlation between age and Insulin resistance among the two groups who were matched for obesity and Glycemic status, suggesting that age has no direct role to play in increasing IR in older individuals. Perhaps progressive beta cell failure contributes more towards development of diabetes in older age group. Larger studies will be needed to confirm the same.

Dual energy X-ray absorptiometry assessment of fat mass distribution in type 2 diabetic patients

A.P. Shepelkevich[1], K. Reunova[2], N.A. Vasilieva[3], O.V. Baranova[3]
[1] *Belarusian state medical university, endocrinology, Minsk, Belarus*
[2] *Minsk-city out-patient clinic ?25, endocrinology, Minsk, Belarus*
[3] *Republic medical rehabilitation and balneotreatment centre, endocrinology, Minsk, Belarus*

Background/aims: The distribution of body fat has been identified as a significant risk factor for the development of cardiovascular disease. Understanding the links between topographic features of adipose tissue and the various parameters of metabolic syndrome in type 2 diabetes mellitus (DM) is important for the prevention of macrovascular complications. The aim of the study was to assess the features of fat mass distribution in premenopausal women with type 2 DM in comparison with men and postmenopausal women. Materials and methods: 103 patients with type 2 DM (81 women, mean age 58,55 ± 7,52 yrs; 22 men, mean age 58,34 ± 7,44 yrs) and 40 (28 women, 12 men) controls matched for age, sex and body mass index were examined. The research involved anthropometry of patients (height, weight, BMI, waist circumference), general clinic examination, glycated hemoglobin test, dual energy X-ray absorptiometry (Body composition program). Fat mass distribution research was based on Total Body, Android, A/G Ratio, Trunk/Total, (Arms+Legs)/Total parameters.
Results: Fat mass distribution parameters in type 2 DM women and men were: Total Body: 38,27±7,05% vs 31,99±4,13% (p<0,01); Android: 46,80 ±6,28% vs 40,75±4,04% (p<0,01); A/G Ratio: 1,10±0,17 vs 1,41±0,24 (p<0,01); Trunk/Total: 0,58±0,07 vs 0,64±0,05 (p<0,01); (Arms+Legs)/Total:0,72±0,22 vs 0,67±0,18 (p<0,01). The android component of adipose tissue was examined in type 2 DM women depending on menopause in comparison with nondiabetic control group matched for age, body mass index and duration of menopause. It was found that android component in premenopause as well as in postmenopause is statistically higher (p<0,05) among women with type 2 DM as compared with controls (45,46 ± 6,64 vs 35,83 ± 6,57 in premenopause and 45,21 ± 6,78 vs 43,78 ± 6,98 in postmenopause). The data concerns type 2 DM there are no differences in consistence of android component in premenopause and postmenopause, unlike control group.

Conclusions: The results of study confirm the prevalence of central (android) distribution of body fat among men with type 2 DM; android component of fat mass dominates gynoid component among patients with type 2 DM. The women with type 2 DM are more likely to have significant visceral fat masses at earlier age than women without diabetes.

P-1554

Recovery of insulin sensitivity after treatment with 11ß-hydroxysteroid dehydrogenase (11ß – HSD) blocker carbenoxolone involves increased GLUT4 expression in oxidative muscle fibers

R.C. Mori[1], M.F. Marques[1], A.B. Alves-Wagner[1], U.F. Machado[1]
[1] Institute of Biomedical Sciences, Biophysics and Physiology, São Paulo, Brazil

Glucocorticoids are known to impair insulin-induced glucose uptake in peripheral tissues. GLUT4 (glucose transporter 4) protein, which is a key determinant of the glucose uptake in insulin sensitive tissues, may be regulated by the glucocorticoids, contributing to the insulin resistance observed in hypercortisolism. 11ß -hydroxysteroid dehydrogenase (11ß –HSD), the enzyme which interconverts cortisol to its inactive metabolite cortisone, has recently been recognized as a key regulator of the access of cortisol to target tissues. Carbenoxolone, which blocks the 11ß –HSD enzyme, has been shown to increase hepatic insulin sensitivity, but effects on glucose uptake in peripheral tissues are unknown.
Aim: The aim of the present study was to determine if the treatment with carbenoxolone would be able to restore the insulin sensitivity in insulin resistant obese rats and if this effect could be related to GLUT4 expression in muscle.
Methods: Monosodium glutamate-induced obese (O) rats were given carbenoxolone (Cbx, 50mg/kg/day, p.o.), for four weeks (OCbx) and compared to age-matched control rats (C). All groups were submitted to insulin tolerance tests (ITT) and GLUT4 protein analysis in soleus (oxidative fibers) and EDL (glycolytic fibers) skeletal muscles.
Results: Glycemias were similar among all groups (C: 119.4 ± 3.5mg/dl; O: 113.7± 4.4mg/dl; OCbx: 113.1± 2.8mg/dl, $p>0.05$) in spite of the hyperinsulinemia of O rats (61.36 ± 4.63µU/ml) as compared to C rats (40.13 ± 5.46µU/ml). Chronic treatment with Cbx normalized insulinemia (OCbx: 46.50 ± 4.33µU/ml) and insulin sensitivity, since the glucose decay in the insulin tolerance test (kITT) was lower in obese rats, but was restored by the Cbx treatment (O: 3.42%/min, $p<0.01$vs. C: 5.06%/min and OG: 4,68%/min). GLUT4 protein was significantly reduced in O rats in both EDL (O: 92.0 ±19.7AU, $p<0.05$ vs. C: 183.4 ±15.8AU) and soleus muscles (O: 473.9 ± 53.9AU, $p<0.05$ vs. C: 665.2 ± 40.4AU). Cbx treatment had no effect on GLUT4 protein in EDL (OCbx: 111.8 ±14.55AU, $p>0.05$ vs. O) but significantly increased its expression in soleus (OCbx: 642.6 ± 21.8, $p<0.05$ vs. O).
Conclusion: Insulin resistance of the obese rats was importantly related to reduction in GLUT4 protein expression in skeletal muscle. The Cbx drug was able to restore insulin sensitivity in MSG-obese rats and this effect probably involves enhanced glucose uptake by the oxidative fibers, as suggested by the increased GLUT4 expression in soleus muscle.

Effects of PPAR-d agonist on toll-like receptors (TLRs), NF-kB activity and expression of proinflammatory cytokines in adipocytes

H.J. Yoo[1], S.J. Yang[1], T.N. Kim[1], J.R. Park[2], Y.J. Lee[2], H.Y. Kim[2], J.A. Seo[3], S.G. Kim[2], N.H. Kim[3], S.H. Baik[1], D.S. Choi[2], K.M. Choi[1]
[1] Korea university Guro Hospital, Endocrinology, Seoul, Korea
[2] Korea university Anam Hospital, Endocrinology, Seoul, Korea
[3] Korea university Ansan Hospital, Endocrinology, Seoul, Korea

Chronic inflammatory activity in fat tissue has recently been implicated in mechanisms of insulin resistance and obesity related metabolic dysfunction. Toll-like receptors (TLRs) play a key role in innate immune responses, recent studies implicate that activation of TLRs with either lipopolysaccharide (LPS) or free fatty acid (FFA) stimulates NF-kB signalling and expression of proinflammatory cytokines, which are involved in the development of insulin resistance. It is not well known if PPAR-d and its ligand exert any effect on TLR/NF-kB signaling pathway and expression of proinflammatory cytokines in adipocytes. The aim of this study was to observe effects of PPAR-d agonist on these inflammatory pathways and proinflammatory cytokines production in cultured adipocytes.
Differentiated 3T3-L1 adipocytes were stimulated with FFA and LPS, we quantified the mRNA expression levels of TLR2, TLR4 and proinflammatory cytokine genes, such as interleukin-6 (IL-6), tumor necrosis factor-a (TNF-a), monocyte chemoattractant protein-1 (MCP-1) using quantitative real-time PCR, and NF-kB activation using electrophoretic mobility shift assay (EMSA). To investigate the effect of the PPAR-d agonist (L-165041) on FFA, LPS-induced TLRs/NF-kB signaling pathway and expression of proinflammatory cytokines, we compared the gene expression levels of TLRs and IL-6, MCP-1, TNF-a and NF-kB activity between 3T3-L1 adipocytes treated with PPAR-d agonist and non-treated control adipocytes. mRNA expression levels of TLRs and proinflammatory cytokine genes were significantly increased in 3T3-L1 adipocytes treated with LPS and FFA ($P<0.05$). PPAR-d agonist (L-165041) significantly blocked these LPS, FFA-induced expression of TLRs and IL-6, MCP-1, TNF-a ($P<0.05$). Also, LPS and FFA treatment stimulated NF-kB DNA binding activity and PPAR-d agonist (L-165041) blocked them, too ($P<0.05$).
Activation of TLRs/NF-kB signalling pathway and their target proinflammatory cytokine production were inducible in adipocytes by LPS and FFA. PPAR-d showed an anti-inflammatory effect through repressing LPS, FFA- induced TLRs/NF-kB pathway and proinflammatory cytokine production in adipocytes.

Adiponectin inhibits spontaneous lipolysis in obese, but not non-obese individuals

J. Polak[1], J. Broz[2], Z. Hnevkovska[3], V. Stich[3]
[1] 3rd Medical Faculty Charles University, Sports Medicine Department, Prague, Czech Republic
[2] Vinohrady Teaching Hospital, 2nd Internal Medicine, Prague, Czech Republic
[3] 3rd Faculty of Medicine, Sport Medicine Department, Prague, Czech Republic

Aims: Adiponectin is an adipose tissue derived cytokine increasing glucose and fatty acid metabolism in muscle and improving whole-body insulin sensitivity. The aim of this study was to investigate the role of adiponectin in the regulation of adipocyte lipolytic activity.
Methods: Adipocytes were isolated from adipose tissue obtained during selective surgical operations from 12 non-obese and 8 obese subjects. Cells were incubated for one hour without treatment and subsequently subjected to incubation with recombinant human adiponectin (20 ug/ml) or 0.5 mM AICAR - chemical activator of AMPK (adenosine monophosphate activated protein kinase). Finally, isoprenaline was added to investigate the influence on catecholamine-induced lipolysis. Glycerol concentrations were determined colorimetrically.
Results: Adiponectin suppressed spontaneous lipolysis by 21.6 % in non obese ($p=0.03$) but only by 6 % in obese subjects ($p=0.56$). Adiponectin inhibited isoprenaline-induced lipolysis by 27% ($p=0.03$) in non-obese, while no effect was observed in obese subjects. AICAR inhibited both spontaneous and isoprenaline-induced lipolysis in obese as well as non-obese subjects.
Discussion: Our results show that adiponectin in physiological concentration inhibits spontaneous as well as catecholamine-induced lipolysis in isolated human adipocytes of non-obese subjects. This regulation is lost in obesity. This mechanism might be mediated by an activation of AMPK. We suggest that inhibition of lipolytic rate in adipose tissue by adiponectin is an important factor limiting release of free fatty acids (FFA) into circulation and helps to explain how hypoadiponectinemia might contribute directly to elevated FFA levels and development of insulin resistance.

Weight misperceptions in rural Australia: recognising weight status in an environment where overweight and obesity are the norm

R. Boak[1], B. Philpot[1], J.A. Dunbar[1], A. Hernan[1], N. Davis-Lameloise[1], E.D. Janus[2]
[1] *Flinders and Deakin Universities, Greater Green Triangle University Department of Rural Health, Victoria, Australia*
[2] *University of Melbourne, Department of Medicine Western Health, Victoria, Australia*

Background: Obesity is an important modifiable risk factor for many chronic diseases. Overweight and obesity has been reported to be higher in rural Australia. The incidence of diabetes has also been reported to be higher in rural and remote areas. Failing to recognise overweight and obesity would have important public health implications in relation to chronic disease risk perception and prevention, such as diabetes prevention.
Aim: To investigate the difference between personal and clinical classifications of weight status in a rural Australian population.
Methods: Cross-sectional surveys including clinical health measures were conducted in three rural areas of South Eastern Australia in 2004–06. A stratified random sample (n=1563, response rate 48%) of men and women aged 25-74 years was drawn from the electoral roll. Participants were asked "How do you consider your weight? Too thin, a little thin, normal, a little overweight, or very overweight?" Body mass index (BMI) and waist circumference (WC) were measured by trained study nurses using the World Health Organisation (WHO) MONICA protocol and then categorised using WHO recommended standards. Since participants' weight can fluctuate daily, those who would change BMI category if their weight changed by 2kg were excluded in evaluating accuracy of self-assessed weight.
Results: Overall, 29.2% of participants were categorised as normal weight (18.5–25kg/m^2), 39.5% overweight (25–30kg/m^2), and 30.3% obese (>30kg/m^2). Among obese individuals, 3.2% reported their weight as 'normal', 56.8% reported their weight as 'a little overweight', and 40.0% reported their weight as 'very overweight'. Among overweight individuals, 24.8% reported their weight as 'normal,' and 73.9% reported their weight as 'a little overweight'.
WC cut-offs used were 94/102cm for men, and 80/88cm for women, resulting in 36.3% being normal, 24.1% overweight, and 39.6% obese based on WC. Among participants with WC in the obese range, 7.2% reported their weight as 'normal', 65.9% as 'a little overweight', and 26.8% as 'very overweight'. Among individuals in the overweight range, 33.3% reported their weight as 'normal', and 66.0% as 'a little overweight'.
Discussion/conclusion: In this rural population, 60% of people with a BMI in the clinically obese category did not consider that they were 'very overweight'. Overall levels of overweight and obesity were also high. Misperceptions of overweight and obesity may be linked to living in an environment where the majority of people are overweight or obese. Levels of overweight and obesity have been reported to be higher in rural than urban areas. These findings have important implications regarding recognition of chronic disease risk in rural populations.

P-1558

Glucocorticoids are capable of stimulating both lipolysis and adipogenesis in 3T3-L1 adipocytes

J.E. Campbell[1], T.J. Hawke[2], M.C. Riddell[1]
[1] *York University, Kinesiology and Health Science, Toronto, Canada*
[2] *McMaster, Pathology and Molecular Medicine, Hamilton, Canada*

Glucocorticoids (GCs) impact many metabolic pathways in peripheral tissues that promote insulin resistance and the development of type 2 diabetes. Although their effect on glucose metabolism is well defined in various tissues, their influence on lipid metabolism is less clear. Some studies show that GCs acutely stimulate lipolysis in adipose cells, while, paradoxically, other studies show that longer-term exposure promotes central obesity and features of the metabolic syndrome. We set out to determine the short- and long-term effects of corticosterone (CORT), the main rodent GC, on adipogenesis (formation of new fat cells), lipolysis (promotion of free fatty acid release) and lipogenesis (creation of lipid from glucose) in adipocytes. 3T3-L1 adipocytes were treated with increasing concentrations of CORT (0.01-100 uM) for 48 hrs. Lipolysis, as measured by glycerol release, was maximally increased 77±9% above control levels with 1 uM CORT ($p<0.05$). Protein expression of adipose triglyceride lipase (ATGL), a major lipolytic enzyme, was increased 193±44% ($p<0.01$) with 1uM CORT, while no change in HSL (hormone sensitive lipase) protein expression was observed. However, the basal phosphorylated states of HSL (at Ser563 and Ser660, which increase HSL activity) were increased in a concentration-dependent manner (378±68% and 165±21% with 1 uM CORT, respectively, $p<0.01$). Visualizing adipocytes with microscopy revealed that CORT treatment attenuated the increases in both lipid droplet size and overall cell size as compared to control cells. Additionally, CORT treatment had no effect on the rate of ^{14}C-glucose incorporation into cellular lipid, indicating no changes in lipogenesis. Finally, 3T3-L1 pre-adipocytes were induced to differentiate with varying concentrations of CORT for 6 days. Based on oil red O staining, cell differentiation increased in a concentration-dependent fashion with increasing CORT and was maximal with 1 uM CORT (20±4 vs. 100±2 AU; Con vs. 1 uM CORT, respectively, $p<0.01$). Taken together, these data indicate that GCs promote pre-adipocyte differentiation, and cause lipolysis but not lipogenesis in mature fat cells, thus resulting in smaller, more metabolically active adipocytes. These findings suggest that chronic exposure to GCs in vivo would promote an increase in fat cell number but these adipocytes would be more metabolically active, resulting in an overall increase in circulating free fatty acids.

Extramyocellular adipose tissue in type 2 diabetes

L. Luu[1], J. Crilly[2], B. Newcomer[3], W. Cefalu[1]
[1] *LSU-Pennington Biomedical Research Center, Nutrition and Chronic Diseases, Baton Rouge, USA*
[2] *University of Rochester, Psychiatry, Rochester, USA*
[3] *University of Alabama at Birmingham, School of Health Professionals, Birmingham, USA*

Aims: Ectopic fat depositions in skeletal muscle, i.e. intermuscular adipose tissue and intramyocellular lipids, are associated with insulin resistance and diabetes. However, extramyocellular adipose tissue (EMAT), defined as the adipose tissue (AT) between muscle fibers, has not been investigated. We sought to examine EMAT distribution in subjects with Type 2 diabetes (T2D) and evaluate possible differences as a function of gender and race. In addition, we assessed associations of EMAT with measures of adiposity, inflammation, and insulin sensitivity (IS).
Methods: EMAT was assessed by proton magnetic resonance spectroscopy in the tibialis anterior muscle ($EMAT_{TA}$, n=71), soleus ($EMAT_{Sol}$, n=70), and gastrocnemius ($EMAT_{Ga}$, n=50) in subjects with T2D [Ages 56.5±8 (mean±SD) and BMI of 31.7±5 kg/m^2]. Internal water reference was used to normalize all EMAT results. Adiposity measures were performed using DXA for total body fat (FM) and cross-sectional CT scans for visceral AT volume (VAT), deep subcutaneous AT volume (DSAT), and subcutaneous AT volume (SAT). Serum chemistries were analyzed for inflammatory markers. IS was assessed by hyperinsulinemic-euglycemic clamps. Subcutaneous abdominal biopsies were obtained and evaluated for mean fat cell size (MFCS) at the baseline of the clamp.
Results: Female subjects had increased $EMAT_{TA}$ compared to male subjects (0.0149±0.01 vs. 0.009±0.01, arbitrary scanning units (ASU), p=0.02). No other gender or race differences were noted. However, $EMAT_{TA}$ was positively associated with FM (r=0.323, p=0.02). $EMAT_{Sol}$ was directly correlated to hs-CRP (r=0.360, p=0.02), TNF-a (r=0.339, p=0.03), and IS (r= -32, p=0.05). $EMAT_{Ga}$ was associated with FM (r=0.486, p=0.001), VAT (r=0.250, p=0.08), and MFCS (r=0.459, p=0.001). In an age-FM adjusted cohort (n=51), increased $EMAT_{TA}$ in female subjects remained when compared to male subjects (0.0171±0.01 vs. 0.009±0.01, ASU, p=0.003). African-Americans showed a trend toward higher $EMAT_{Sol}$ compared to Caucasian (0.025±0.02 vs. 0.016±0.01, ASU, p=071). No other differences were observed. $EMAT_{TA}$ was positively correlated with FM (r=0.354, p=0.02) and TNFa (r=0.403, p=0.03). $EMAT_{Sol}$ showed direct association to TNFa (r=0.403, p=0.03). $EMAT_{Ga}$ showed positive correlation to FM (r=0.369, p=0.04), DSAT (r=0.396, p=0.02), and MFCS (r=0.428, p=0.01).
Discussion: We present novel observations of EMAT in Type 2 diabetes subjects. We demonstrate gender differences in $EMAT_{TA}$ distribution. A robust pattern emerged showing strong associations between $EMAT_{TA}$ and $EMAT_{Sol}$ to inflammatory markers and insulin sensitivity, while $EMAT_{Ga}$ consistently

displayed direct associations to measures of adiposity. EMAT is a novel ectopic adipose depot that may offer insights into the cross-communication network between AT and skeletal muscle.

Dietary patterns and risk of type 2 diabetes: the multi-ethnic cohort

G. Maskarinec[1], E. Erber[1], A. Grandinetti[2], S.Y. Park[1], B.N. Hopping[1], L.N. Kolonel[1]

[1] University of Hawaii, Cancer Research Center, Honolulu, USA

[2] University of Hawaii, John A. Burns School of Medicine, Honolulu, USA

Aims: It is well known that excess energy intake and overweight/obesity are risk factors for the development of type 2 diabetes. Our goal was to find out if the type and composition of the regular diet also influences diabetes risk. Using the Hawaii component of the Multiethnic Cohort (MEC), we estimated diabetes risk associated with different nutritional patterns.

Methods: After excluding subjects with other ethnicity, invalid diet, and missing values, 75,512 Caucasians, Japanese Americans, and Native Hawaiians were included in this analysis. Of these, 8,587 were incident diabetes cases which had been identified through questionnaires and linkages with the two major health plans in Hawaii. All subjects completed a validated food frequency questionnaire. Three previously identified dietary patterns, "Vegetables", "Milk and Fruits", and "Fat and Meat", and food groups were analyzed in relation to diabetes incidence using Cox proportional hazards models. We estimated hazard ratios (HR) and 95% confidence intervals (CI) while adjusting for age, ethnicity, education, body mass index (BMI), physical activity, and total energy intake.

Results: Diabetes cases were more likely to be Japanese American or Native Hawaiian than the non-cases and tended to have lower education and higher BMI. Native Hawaiians were more likely to have high scores for the "Fat and Meat" and "Vegetables" patterns, while Japanese Americans showed a stronger association with the "Vegetables" and Caucasians with the "Fruit and Milk" pattern. "Fat and Meat" was associated with a 50% higher diabetes risk among men when the highest quintile was compared to the lowest (p_{trend} <0.0001). In women, the risk was approximately 20% higher (p_{trend} = 0.01) for women in the highest quintile. The associations for the "Fat and Meat" pattern were consistent across ethnic groups. The "Vegetables" pattern was weakly protective against diabetes among men, but the trend test was only significant for Caucasians and Japanese Americans. In women, the "Vegetables" pattern did not lower diabetes risk in any of the three ethnic groups. On the other hand, the "Milk and Fruits" pattern was associated with a lower diabetes risk among women with fairly consistent risk estimates across ethnic groups, while a protective effect in men was restricted to Caucasians. When we examined individual food groups, the results were in agreement with the dietary patterns. In particular, a strong association with red meat was seen among all ethnic groups.

Conclusions: These findings within a multiethnic population indicate that food intake as described by dietary patterns is strongly associated with diabetes risk. Therefore, recommending diets low in meat and rich in vegetables and fruits may be protective against type 2 diabetes independent of weight control.

Remission of type 2 diabetes related to morbid obesity after bariatric surgery

G. Rubin[1], M. Marconetto[1], F. Moser[2], L. Obeide[2], M. Benitez R[1], M. Flores[3], P. Deshayes[3], C. Lucero[4], M. Campazzo[5], L. de Loredo[1]

[2] Hospital Privado de Cordoba, General Surgery, Cordoba, Argentina

[3] Hospital Privado de Cordoba, Psychiatry, Cordoba, Argentina

[4] Hospital Privado de Cordoba, Neurology, Cordoba, Argentina

[5] Hospital Privado de Cordoba, General Medicine, Cordoba, Argentina

Introduction: It was reported a consistent improvement of hyperglycaemia in obese patients who underwent bariatric surgery. This is considered one of the most important contributions of Bariatric Surgery taking into account the consequences of Type 2 Diabetes.

Objectives: To assess the evolution and achievement of amelioration and remission of Type 2 Diabetes (DM 2) in a group of morbid obese patients (MO) who underwent bariatric surgery.

Methods: 19 morbid obese patients who underwent bariatric surgery in Hospital Privado de Cordoba, between 2001 and 2008, with DM 2, were included. These patients had a usual treatment and frequent control after surgery.

The evolution time and medical treatment of DM 2 were considered. Blood samples for fasting blood glucose and glycated haemoglobin (HbA1c), before the surgery, at a month and at six months, were taken. Weight, height, BMI and waist circumference were measured as well.

We characterize amelioration as reducing the number and/or dose of drugs to maintain good control of DM 2. To define remission, Dixon JB et al. criteria were adopted (fasting glucose level <126 mg/dl and HbA1c value <6.2% while taking no glycaemic therapy) (JAMA 2008; 299 (3): 316- 323).

In many patients who achieved remission criteria and regular follow up, OGTT was conducted between June 2008 and March 2009, irrespective the length of post- operative.

Results: 16 patients (84 %) met the criteria for remission of DM 2.2 (11 %) achieved amelioration and 1 (5 %) remained unchanged. The evolution time of DM 2 varied between a few months and 31 years. The average reduction rate of overweight in the remission group was 55 % and the average BMI decrease of 13.3 kg/m^2. The average reduction in waist circumference was 29.5 cm.

OGTT was conducted in 13 people of the remission group; 12 of them showed normal results and 1, glucose intolerance.

Conclusion: Weight loss obtained 6 months after bariatric surgery was accompanied, in the group of studied patients, by improvements in DM 2 in almost all the cases (95 %), reaching the point of remission in most of them (84 %).

[6] Instituto Mexicano del Seguro Social, Hospital de Especialidades CMN Siglo XXI, Villahermosa Tabasco, Mexico

Evidence from several studies indicates that overweight and obesity are associated with an increased risk of diabetes. The key determinant of the association between these diseases is the insulin resistance (IR). This state is characterized as the tissues' inability to take up glucose in response to insulin. Body weight accumulation has been associated with IR in both human and animals. Some studies have shown benefit from life style changes (diet and nutrition) on reducing diabetes risk. Resistant starch supplementation from different sources has demonstrated beneficial effects on reducing body weight and improving glycemic control. The aim of this study was to investigate the effects of Native Banana Resistant Starch (NBRS) on body weight and insulin resistance in a group of obese non diabetic women. Obese non-diabetic women (BMI >30), 20-45 years aged were invited to participate if they had a Homeostatic Model Index (HOMA) values > 2.5. Selected subjects were randomly assigned to two groups of 20 subjects. One group received NBRS 30 g/d during 8 weeks and the other metformin (MF) 850 mg/d during the same period. A clinical interview and nutritional survey was performed at the beginning and every month until the end of the experiment. Anthropometric measures, arterial blood pressure and fat percentage were measured. Blood samples were obtained for routine clinical chemistry assays and insulin was determined by an enzymatic immunoassay and HOMA indexes were calculated. A significant reduction were observed in glycemia after both NBRS and MF treatment ($p < 0.05$). NBRS reduced fasting insulin (ANOVA, $p < 0.01$) through time (27.7% and 38.78 % at 4 and 8 weeks respectively). MF diminished fasting insulin through time (24.7% and 34.96% at 4 and 8 weeks respectively). There were not significant differences between NBRS and

MF effects on serum insulin. Both interventions reduced HOMA indexes along the time (ANOVA, p<0.01) and there were no significant differences between them. MF reduced cholesterol since the first month of treatment (p <0.05). No changes were observed in body weight, blood lipids, hepatic enzymes, serum magnesium and other variables after both treatments. In conclusion NBRS supplementation reduced fasting glucose and insulin levels reducing insulin resistance in a similar degree to metformin treatment.

Predicting changes in life-style and clinical outcomes in preventing diabetes

T. Laatikainen[1], E. Vartiainen[2], P. Absetz[3], N. Hankonen[3], N. Davis-Lameloise[4], B. Philpot[4], R. Sippola[1], J. Dunbar[4]

[1] *National Institute for Health and Welfare, Chronic Disease Prevention, Helsinki, Finland*

[2] *National Institute for Health and Welfare, Division of Welfare and Health Promotion, Helsinki, Finland*

[3] *National Institute for Health and Welfare, Lifestyles and participation, Helsinki, Finland*

[4] *Flinders University, GGT University Department of Rural Health, Warrnambool, Australia*

Background: Strong evidence from several studies has indicated that lifestyle changes can prevent and delay the onset of type 2 diabetes. The Diabetes Prevention Programme was carried out in Greater Green Triangle region in Australia. The programme was shown to be feasible and effective in a "real life" health care setting. The programme design was based on the Health Action Process Approach (HAPA) model.

Aim of the study: The aim of this study was to analyze how different determinants of lifestyle changes targeted in the program predict the actual changes in dietary behaviour and clinical outcome measurements.

Methods: A longitudinal pre test and post test study design was used. Out of 311 who started the intervention, 237 attended both the baseline and 12 month clinical tests and at least one group session and were thus regarded as completers. Intervention consisted of six structured 90 minute group sessions over eight months. To examine the associations between the variables, structural equation modelling (SEM) was used. We modelled the changes in determinants for lifestyle variables to the changes in dietary behaviours and clinical outcome measurements.

Results: Changes in action self-efficacy and action planning variables at three months predicted changes in fat and fiber intake through changes in coping self-efficacy and coping planning variables. Changes in fat and fiber intake predicted change in waist circumference which predicted improvement in all clinical outcome measurements.

Conclusion: The result demonstrated that changes in the lifestyle determinants predicted behavioural changes which led to reduction in waist circumference and improvement in clinical outcome measures. These results support the importance of theory based interventions.

Glucocorticoids increase adiposity and alter adipose tissue phenotype in rats, despite elevated lipolytic rates

J. Campbell[1], T.J. Hawke[2], M.C. Riddell[1]

[1] *York University, Kinesiology and Health Science, Toronto, Canada*

[2] *McMaster University, Pathology and Molecular Medicine, Hamilton, Canada*

The impact of glucocorticoids on adipose tissue metabolism is controversial. While some studies show a lipolytic role for the hormone, disease states such as Cushing's syndrome (a disease characterized by elevations in glucocorticoids) are commonly associated with increased adiposity, particularly in central regions. Our in vitro data suggests that the rodent glucocorticoid, corticosterone (CORT), stimulates lipolysis, but not lipogenesis, in 3T3-L1 adipocytes. Furthermore, CORT is vital to pre-adipocyte differentiation (adipogenesis), suggesting that CORT exposure may lead to increase in the absolute number of cells in adipose tissue. The purpose of this study was to induce basal hypercorticosteronemia in rodents and measure adipose tissue growth and metabolism in vivo. For this, male Sprague-Dawley rats were divided into three groups: sham, CORT, or pair-fed (n=5/group). CORT animals had two 150 mg CORT pellets subcutaneously implanted, whereas sham and pair-fed animals received two 150 mg wax pellets. Body weight and food intake were measured for 10 days, with pair-fed animals being given the average food consumed by CORT animals the night prior. Animals were fasted overnight on day 9, sacrificed on day 10, and their adipose tissue was isolated for primary cell culture. CORT animals had lower body mass than both sham and pair-fed after day 2 (269±7g vs. 302±5g and 310±5g, respectively, on day 10; p<0.01). CORT animals also had more epididymal adiposity than either sham or pair-fed animals (1.07±0.07g vs. 0.72±0.03g and 0.69±0.03g, respectively; p<0.01). Cell culture of the epididymal adipocytes showed a higher rate of basal lipolysis in the CORT animals compared to either sham or pair-fed (55.3±3 vs. 36.1±4 and 40.1±4 uM/g/hr glycerol release, respectively; p<0.05). Isolated epididymal adipocytes were analyzed with microscopy, showing that CORT animals had significantly smaller adipocytes than sham (7.0±0.7 vs 16.6±2.2 nL; p<0.01), but a larger number of adipocytes per mg of tissue (87.3±7.4 vs 36.2±3.5 cells/mg; p<0.01). Ten days of CORT treatment produces more adipose tissue that contains a greater number of adipocytes, but with a smaller average cellular volume. These data suggest that although CORT stimulates lipolysis, the whole tissue undergoes positive adipogenesis. The physiological consequence of this remodelling is unclear but may leave an organism more prone to central obesity and associated metabolic complications when there is a net positive energy balance.

Bariatric surgery in diabetes: A step towards cure?

A.K. Agarwal[1], R. Garg[2], A. Hartland[3]

[1] *Manor Hospital, Department of Medicine, Walsall, United Kingdom*

[2] *Queen Mary's Hospital, Diabetes Unit, London, United Kingdom*

[3] *Manor Hospital, Department of Biohemistry, Walsall, United Kingdom*

Introduction: Links between obesity and diabetes are well recognized. Bariatric surgery in people with type 2 diabetes (T2D) improves glycaemic control. Bariatric surgery results in significant weight loss that is persistent and maintained long term with improvement in metabolic control in diabetes and other co morbid conditions.

Aims: we assessed following:

1. Weight loss after bariatric surgery
2. Changes in HbA1c after bariatric surgery
3. Impact of bariatric surgery on diabetes medication use

Method: We reviewed the weight loss, diabetes control and medication use in all patients with T2D who had undergone bariatric surgery. Weight, HbA1C, fasting blood glucose and medication use was compared before and 12 months after bariatric surgery.

Results: total of 140 patients had bariatric surgery. 39 patients also had diabetes. These were included in the analysis. Table shows the weight, body mass index (BMI), fasting glucose, HbA1C, and medication use before and 1 year after bariatric surgery in patients with T2D.

	Pre	Post	p
Weight (Kg)	152.1±30	107.6±10.3	<0.0001*
BMI (Kg/sq. m)	54.6±10.3	38.6±7.4	<0.0001*
Fasting Glucose (mmol/l)	9.7±6.6	7±2.2	0.02*
HbA1C (%)	8±1.7	5.7±1.0	<0.0001*
Metformin	23	2	
Sulphonyurea	7	0	
Thiazolidinedione	13	2	
Insulin dose (mean±sd)	122 ±93 (n =11)	14.3±33 (n=2)	0.003*

* = significant

Number of people achieving fasting blood glucose levels < 6, <7 and <11 mmol/l in the pre and post surgery period changed from 10, 15, 25 to 18, 23 and 32 respectively. This indicates that more people were able to achieve euglycaemia after bariatric surgery. Number of people with HbA1C <6, 6.5 and 7% (2, 6 and 13) in the pre and 1 year post surgery were 24, 32 and 36 respectively. Thus out of 38 patients with diabetes who had bariatric surgery 36 achieved glycaemic control at 1 year. Only one patient had Hba1C of 7.4% at one year follow up post operatively.

Summary: Substantial benefits were achieved in severely obese patients with T2D who had bariatric surgery at 1 year follow up, in terms of significant weight loss (68.1%), improved glycaemic control and medication use for diabetes. 90% patients stopping oral agent, 81% stopped insulin (18% reduced insulin

dose). 94.7% patients achieved HbA1C <7% and 86.8% achieved current recommended target HbA1C <6.5% (15.7% in pre operative). Diabetes was "cured" in 86.8% patients achieving HbA1C <6% at one year follow up after bariatric surgery. Patients with higher initial HbA1C had a greater reduction. Weight loss and reduction in HbA1C was linear with time.

Conclusion: Bariatric surgery should be offered to obese people with T2D as it has the potential to cure the disease. Long term follow up is required to see whether this benefit is sustained in long term.

Serum adiponectin concentrations and cardiac autonomic nervous system modulation in obese children and adolescents

D.M.L. Prado[1], C.Y.M. Nicolau[1], M. Moreira Zanquetta[1], A.G. Silva[1], I.C. Guazzelli[1], M.S. Brasileiro[2], I.C. Trombetta[2], C.E. Negrão[2], S.M.F. Villares[1]

[1] HCFMUSP, Laboratory of Human Nutrition and Metabolic Disease LIM-25, São Paulo, Brazil

[2] HCFMUSP, Heart Institute (InCor), São Paulo, Brazil

Aims: Adiponectin is an adipocytokine and represents an important determinant of whole-body sensitivity and cardiovascular disease [i]. Previous studies have shown that variations in serum concentrations of adiponectin have close association with alterations in sympathovagal modulation. Heart rate variability (HRV) is a widely used technique for assessing the sympathovagal balance at the cardiac level. The aim of this study was to evaluate sympathovagal balance and the relationship between serum adiponectin concentrations and index of insulin resistance and secretion (including HOMA%B, HOMA%S, ISIcomp, and TAUC insulin /glucose) in obese children and adolescents (OCA).

Methods: 99 OCA (BMI =p95th) (45 boys 43,3 %, 37.5 % pubertal, aged 10.3±0.1 years, BMI 30.4±0.4 kg/m^2, Zscore BMI 2.3±0.0) were divided in terciles according to ADP: ADP1 (n=33):4.2-10.0 µg/mL, ADP2 (n=33):10.1.-15.4 µg/mL, ADP3 (n=33): 15.5-32.5µg/mL. The sympathovagal balance was assessed by power spectral analysis of heart rate variability at rest condition. All subjects were categorized in terciles of serum adiponectin concentration. Before comparison, continuous variables without normal distribution were log transformed, and arithmetic means are shown. One way ANOVA and multiple linear regression analysis were performed.

Results: Metabolic, cardiovascular and autonomic data according to adiponectin terciles are shown in Table 1.

Table 1. Baseline values after distribution in terciles of fasting plasma adiponectin concentration

	Terciles of plasma adiponectin concentration			
	ADP1	ADP2	ADP3	p- value
Glucose (mg/dL)	86.9 ± 1.7	87.7 ± 1.3	89.7 ± 1.3	0.30
Insulin (mUI/mL)	25.6 ± 2.2†*	15.9 ± 1.3	14.6 ± 1.7	0.001
TAUC insulin /glucose (mUI/mL/120 min)	165.5 ± 16.0†*	109.7 ± 8.1	119.2 ± 11.8	0.02
ISIcomp	2.6 ± 0.3†*	3.8 ± 0.3	4.2 ± 0.4	0.003
HOMA%B	215.5 ± 12.3†*	151.9 ± 8.0	130.7 ± 10.7	0.001
HOMA%S	45.4 ± 3.37†*	72.2 ± 6.5	87.7 ± 8.8	0.001
HR (beats/min)	82.2 ± 2.4	84.8 ± 2.5	79.8 ± 2.1	0.43
Total variance (ms^2)	1395.9 ± 65.2	1476.8 ± 51.6	1454.3 ± 57.0	0.49
Low- frequency power (ms^2)	323.2 ± 9.3	341.8 ± 8.8	348.6 ± 8.0	0.10
High- frequency power (ms^2)	395.8 ± 11.5*	417.4 ± 10.1	436.8 ± 10.5	0.03

TAUC, total area under curve; HR, heart rate. Values are expressed as means ± s.e. †Significant vs tercile 2;*Significant vs tercile 3.

Conclusion: Our results show that lower serum adiponectin concentrations are associated with a sympathovagal balance shift toward a progressive decrease on parasympathetic modulation in obese children and adolescents. This could be associated to earlier cardiovascular disease.

Are Albanians gaining weight - How is the situation five years after the first survey ?

G. Bejtja[1], F. Toti[2], T.H. Fureraj[2], A. Ylli[2], L. Shapo[3]

[1] Institute of Public Health, Department of Statistics, Tirana, Albania

[2] University Hospital Centre "Mother Theresa", Endocinology & Metabolic diseases, Tirana, Albania

[3] London School of Hygiene and Tropical Medicine, Health Surveys, London, United Kingdom

Background: Obesity today is one of the major burdens for health systems, being one of the primary causes of increasing diabetes, hypertension, cardiovascular disease prevalence. The developing countries, due to the shift in dietary and physical activity patterns, are at increased risk to become overweight or obese, thus fueling the worldwide endemic of Diabesity.

Aim of the study: Determine obesity prevalence in adult population, living in Tirana city (Albania capital) and comparing the results with a previous survey realized in 2001.

Methods: Self-reported weight, height, age, diabetes positive family history and educational degree of Albanian adults, during a screening program for unknown diabetes. The comparison with the data of 2001 study in a cross-sectional survey with 1172 adults aged 25 years or older. All the persons younger than 25 years, known diabetes or uncompleted data were excluded from the statistical analysis of our study.

Results: From 2640 participants, 2206 adults were included in our study (83.6%). M/F 53.7/46.3%. Mean age 50±14.02 years old. Two thirds (66%) of the participants in the study were overweight or obese. The overall obesity prevalence in men was 21.6% and 28% in women (respectively 22.8% and 30.9% in 2001). The most affected age group were middle aged women 55-65 years old with obesity prevalence of 32.1% and men 45-55 years old; 33.9% (28.8 in 2001). The prevalence of unknown diabetes has increased during these years from 2.9% (2001), to 4.07% in 2006.

Conclusions: Overweight, obesity and unknown diabetes are still major public health problems in the adult population of Tirana, and especially in middle aged persons. The same situation is observed in other cities of Albania. The increase of obesity and diabetes prevalence, urge for an immediate National Health Promotion Strategy to prevent this further increase of weight related diseases.

Obesity and type 2 diabetes increased in Dhaka City

A. Banu[1], H. Mahtab[2], P.A. Khanam[3], T. Begum[3], M.A. Sayeed[4], S. Sayeed[5], A.K. Azad Khan[3]

[1] Institute of Nutrition and Food Science, Clinical Nutrition, Dhaka, Bangladesh

[2] BIRDEM, Endocrinology, Dhaka, Bangladesh

[3] BIRDEM, Epidemiology, Dhaka, Bangladesh

[4] Ibrahim Medical College, Community Medicine, Dhaka, Bangladesh

[5] Institue of Nutrition and Food Science, Dhaka University, Dhaka, Bangladesh

Background and aims: Bangladeshis are prone to develop diabetes (T2DM), hypertension (sHTN and dHTN) and atherosclerotic heart diseases, which was observed predominantly in the urban population. The prevalence of T2DM was reported 7.9% in 1997. We have undertaken this study to determine whether there was any increase of the prevalence in recent years and also to assess the obesity status in Dhaka City.

Materials and methods: From a total of 90 City Corporation Wards (CCW) in Dhaka City we selected nine randomly. Then, we selected 100 urban households in each CCW. One member (age =25y) from each household volunteered for study. We interviewed each participant about socio-demographic information. We measured height, weight, waist, hip and blood pressure. Body mass index (BMI) and waist-to-hip ratio (WHR) were calculated. Fasting plasma glucose (FPG), total cholesterol (chol), triglycerides (TG) and high-density lipoproteins-c (HDL) were estimated.

Results: Overall, two hundred thirty nine men and 466 women participated. The mean (SD) age was 39.4 (10.9) years, BMI was 21.1 (3.7) and WHR was 0.83 (0.07).). Their mean (SD) FBG was 5.3 (1.97) mmol/l. The crude prevalence of T2DM was 11.2% (M/F = 13.6/10.0) and impaired fasting glucose (IFG) was 9.9% (M/F = 13.6/8.0). There was no significant difference of T2DM between men and women. Although general obesity (BMI =>25) was found in 18% of the participants, 40% of them had central obesity (WHR>=0.85). Compared

with the male the female participants had significantly higher BMI (20.6 v. 22.1, p<0.001); whereas, the males had significantly higher WHR (0.82 v. 0.82, p = 0.02). Interestingly, FBG did not differ between men and women. The diabetic subjects had significantly higher BMI (p<0.05), higher WHR (P<0.001) and higher TG (p<0.05) though cholesterol and HDL-c did not show any difference.
Conclusion: Compared with the previous reports the study revealed an increased prevalence of diabetes and obesity in Dhaka City. Overall, central obesity (higher WHR) was found much higher than general obesity. Compared with the non-diabetic participants, the diabetic subjects had significantly higher WHR and also higher level of TG, but not cholesterol and HDL-c. These findings suggest that central obesity and TG level are important characteristics for differentiating between subjects with and without diabetes.

Dietary factors and obesity in Japanese-Brazilians: gender differentials

M.A. Cardoso[1], M.F. Cristofoletti[1], S.G.A. Gimeno[2], L.J. Franco[3], S.R.G. Ferreira[1]
[1] *University of Sao Paulo, Department of Nutrition, Sao Paulo, Brazil*
[2] *Federal University of Sao Paulo, Department of Preventive Medicine, Sao Paulo, Brazil*
[3] *University of Sao Paulo, Department of Social Medicine, Ribeirao Preto, Brazil*

Aims: Abdominal obesity has been associated with type 2 diabetes and cardiovascular disease. Among the risk factors for abdominal obesity, diet has been considered one of the most important. The aim of this study was to examine which dietary factors are associated with the distribution of body adiposity in Japanese-Brazilians.
Methods: A total of 772 subjects (329 men and 443 women), aged 30-92 years, were evaluated in a cross-sectional population-based survey in Bauru, Brazil. Dietary intakes were assessed using a validated food-frequency questionnaire for Japanese-Brazilians. Measurements of weight, height, and waist circumference (WC, in cm) were taken using the following WHO cut-offs for Asians: overall obesity, Body Mass Index (BMI) ≥25kg/m^2; abdominal obesity, WC ≥90 cm for men and ≥80 cm for women. Logistic regression and linear models were used for comparison between the highest and the lowest tertile of intakes stratified by gender, after adjusting for socio-demographic, lifestyle, biochemical and nutritional confounders.
Results: Among men, beans fiber was inversely associated with abdominal obesity [Odds Ratio (OR) OR=0.27; 95%CI: 0.08; 0.84; $P_{for\ trend}$ = 0.015)] when compared participants in the highest to the lowest tertile. Among men, higher intakes of cholesterol and processed meats were associated with overall with abdominal obesity (OR=3.03, 95%CI: 1.21-7.60, $P_{for\ trend}$ = 0.050 and OR=2.41, IC95%: 1.40-4.15, $P_{for\ trend}$ = 0.188, respectively). Among women, higher intakes of red meats were associated to overall with abdominal obesity (OR=0.50; IC95%: 0.26; 0.98; $P_{for\ trend}$ = 0.121).
Conclusions. Different dietary factors were associated with overall, abdominal, and overall with abdominal obesity according to genders, probably related to differences in dietary patterns.

P-1570

Anthropometric conditioning of adiponectin levels' variation in obese premenopausal women after six months in a weight reduction program

J. Silva-Nunes[1], L. Veiga[2], L. Duarte[1], A. Oliveira[2], A. Melão[2], M. Brito[2], F. Malheiro[1]
[1] *Curry Cabral Hospital, Endocrinology Department, Lisboa, Portugal*
[2] *High School for the Health Technology of Lisbon, Biochemistry Department, Lisboa, Portugal*

Aims: To evaluate adiponectin levels' variation in obese premenopausal women after 6 months in a weight reduction program; to search for the degree of association between adiponectin divergence and the variation observed for the anthropometric parameters considered.
Methods: We studied 49 obese premenopausal women without a history of any active disease; they were not on any drug therapy other than oral contraceptives. Those women were characterized for BMI, waist circumference, hip circumference, waist:hip ratio (WHR) and a fasting blood sample was collected for adiponectin assessment. They entered in a weight reduction program (diet intervention and physical activity implementation, with or without anti-obesity pharmacological treatment) and all parameters were reassessed 6 months later. No other drug treatment was initiated during that period. We looked for associations of basal adiponectinemia with anthropometric parameters. We studied the percentage variation observed in adiponectin and in anthropometry and searched for eventual correlation of adiponectin variation with the variation observed in each anthropometric parameter. Statistical analysis was performed with the SPSS program, version 16.0. The established limit for statistical significance (p) was 0.05.
Results: Women were characterized by mean age=34.9 ±7.9 years, BMI=44.1±8.8 Kg/m^2, waist circumference=119.2±13.4 cm, hip circumference=134.6±13.9 cm, WHR=0.89±0.07 and adiponectin=6.61±2.9 µg/ml. Basal adiponectin levels varied inversely with waist and directly with hip circumferences, although in a non-statistically significant way. However, a significant inverse association existed between adiponectin and WHR (p<0.001; r=-0.574). After 6 months, we verified a significant increase in adiponectin levels (p=0.01) and a significant decrease in BMI (p<0.001), waist circumference (p<0.001), hip circumference (p<0.001) and WHR (p=0.02). Percentage parameters' variations were as follows: adiponectin=+21.45±41.15%, BMI=-6.87±8.73%, waist circumference=-5.13±7.12%, hip circumference=-3.73±4.96% and WHR=-1.51±4.61%. Percentage adiponectinemia variation was inversely and significantly correlated with percentage waist circumference (p=0.024; r=-0.321) and WHR (p=0.003; r=-0.416) variations.
Conclusion: More than their dependency on the total amount of fat mass, adiponectin levels are directly dependent on the pattern of fat distribution. Although they globally present a considerable decrease in excessive fat mass, we verify a broad spectrum of anthropometric parameters' variation for obese premenopausal women in weight loss programs. The decrease in fat mass is accompanied by a tremendous increase in adiponectin levels, particularly if the loss in central deposits exceeds by far losses in peripheral fat.

Impact of three different approaches on obesity prevention and management in school children including adolescents

D.K. Hazra[1], A.K. Gupta[1], S. Bansal[2], A. Kulshreshta[2], A. Agarwal[2], K.K. Vishwani[2], R. Upadhyaya[2], P.K. Gangwar[2], S.K. Kalra[2], N. Hazra[2], P. Khanna[2], P. Seth[2]
[1] *S N Medical College, Medicine, Agra, India*
[2] *Agra Diabetes Forum, Education, Agra, India*

Aim: To compare three different approaches towards obesity reduction in school children including adolescents.
Methods: In the first approach, students were invited to a Diabetes Educational Fair conducted by the Agra Diabetes Forum in which they received didactic lectures as well as were the audience for skits, monoplays, adapted popular lyrics, poems, couplets and participated in poster competitions, slogan competitions, drawing cartoons. In the second approach, the members of the forum visited schools repeatedly and in association with the teachers of the schools gave lectures and encouraged students to participate in quizzes, debates, elocution contests, tiffin competitions, slogan, cartoon and poster competitions over a 12 month period. In addition in this approach the students were submitted to measurements of height and weight, and a survey of attitudes before and after this period. In the third approach, the offspring of diabetic couples, a known high risk group were subjected to counseling after being invited to a diabetes clinic camp, under a long-term prospective intervention study, APIDS, the Agra Preventive Intervention in Diabetes Study initiated in 1997.
In each case the impact of the intervention was sought to be assessed particularly in obese children.
Results: Overall there was a definitive increase in awareness of healthy life style components in each of the three approaches.Each approach had its distinctive limitations, and also advantages. Overall about 30 % of an obese sample showed a decreased BMI one year after intervention but the limitations of simple BMI measurement were also apparent.The conflictiong demands of the book learning oriented education and competition selection system on adolescent time, as well as the impact of the joint family system as well as the westernization of life style advertisements blitz were also analysed.
Conclusions: Each of the three approaches to obesity prevention and control has distinctive advantages but the overall success rate over a short period is limited by various factors in the socioeducational milieu which need to be

addressed,particularly the demands of examinations and competitions for admission to institutions of higher learning.

TNF-alpha signaling in adipose tissue of patients with chronic obstructive pulmonary disease is modified by low BMI

D. Gasperikova[1], P. Skyba[2], B. Ukropcova[1], P. Pobeha[2], T. Kurdiova[1], P. Joppa[2], I. Tkac[3], I. Klimes[1], J. Ukropec[1], R. Tkacova[2]

[1] Institute of Experimental Endocrinology, Diabetes Laboratory, Bratislava, Slovakia

[2] Medical Faculty PJ Safarik, Department of Respirology, Kosice, Slovakia

[3] Medical Faculty PJ Safarik, Department of Internal Medicine, Kosice, Slovakia

Rationale: Low grade systemic inflammation represents one possible mechanism underlying the development of cachexia and metabolic impairment in chronic obstructive pulmonary disease (COPD). Increases in circulating tumor necrosis factor-alpha (TNFa) and decreases in whole body insulin sensitivity (IS) were observed in cachectic patients in some but not all studies. Thus, we investigated expression of proinflammatory cytokines related to TNFa signaling in subcutaneous adipose tissue (SAT), circulating levels of TNFa and IS in COPD patients with different BMI.

Methods: Thirteen patients with stable COPD and overweight (BMI 28.7±1.4 $kg.m^{-2}$, age 61.5±2.3 yrs, mean FEV_1 58.1±6.5%, SaO_2 93.7±0.6%) were compared to 7 patients with low BMI (17.9±0.2 $kg.m^{-2}$, age 61.8±2.6 yrs, mean FEV_1 24.5±1.7%, SaO_2 88.7±2.5%). Samples of SAT were obtained by percutaneous biopsy. Gene expression profile of 84 genes encoding the TNFa ligands and receptors was determined using the RT^2PCR array. Insulin sensitivity was measured by euglycemic hyperinsulinemic clamp; (1 mU/kg.per min.for 3 h) and fat mass by bioelectrical impedance (Bodystat, UK).

Results: Patients with low BMI had higher insulin sensitivity (M 4.2±0.6 vs. 7.5±0.5 mg/kg/min p <0.005) and unchanged circulating levels of TNFa when compared to patients with overweight. However, SAT of patients with low BMI had increased expression of the proinflammatory TNF soluble factor 4 (0.027±0.011 vs 0.038±0.013 a.u., p=0.056), CD40R (2.100±0.674 vs 3.687±2.175, p=0.021), TNFa receptor associated factor 2 (TRAF2) (0.864±0.306 vs 1.300±0.352, p=0.012), decoy receptor 3 (0.114±0.041 vs 0.193±0.069, p=0.005), and MAPK8 (5.655±2.114 vs 9.124±2.652, p=0.006) and reduced expression of the anti-inflammatory and anti-atherogenic RANK (0.151±0.117 vs 0.058±0.048, p=0.048) and osteoprotegerin (0.667±0.386 vs 0.256±0.237, p=0.028). In addition, circulating TNFa levels were not associated with any of the aforementioned parameters of TNFa signaling in SAT.

Conclusions: Low BMI is in patients with stable COPD associated with increased expression of several proinflammatory and atherogenic TNFa ligands and receptors, as well as with concomitant reductions in the expression of anti-inflammatory and anti-atherogenic adipokines in SAT. Interestingly, the aforementioned changes were not accompanied by increased circulating level of TNFa or with an impairment of the whole body IS. The above indicates that the severity of the lung function impairment is not yet accompanied by whole body metabolic disorder in our COPD cohort.

To evaluate waist circumference-height ratio as a measure of central obesity and its association with cardiovascular risk factors in type 2 diabetes patients

B.M. Makkar[1], N. Prasad[1], P. Sharma[1]

[1] Diabetes & Obesity Centre, Diabetes & Obesity, New Delhi, India

Aim: To evaluate Waist Circumference-Height Ratio as a measure of central obesity and its association with cardiovascular risk factors in type 2 diabetes patients.

Methods: Randomly selected 450 adults more than 20 years of age with type 2 diabetes (T2DM) were assessed for the presence of pre-existing cardiovascular risk factors including hypertension, coronary artery disease (CAD) and dyslipidemia. Measurements of anthropometric variables and blood pressure were recorded and fasting blood samples were obtained for measuring lipids. Patients on statin therapy were excluded from assessment for lipids and remaining sample of 254 patients (158 men and 96 women) was analysed for prevalence of lipid abnormalities and its correlation with waist-height ratio. Body Mass Index (BMI), waist-hip ratio (WHR), and waist circumference-height ratio (WC-HR) were calculated. Pearson's correlation coefficients (r) of WC-HR with other measures of obesity and risk factors were determined. Quartiles of WC-HR were calculated and parameters of hypertension, CAD, triglycerides, LDL- and HDL-cholesterol were plotted against each quartile to analyze the trends.

Results: After exclusion of 41 patients with incomplete data, 409 patients with type 2 diabetes were taken up for the study. Patient sample included 248/409 (60.64%) men and 161/409 (39.36%) women in the age group 23 – 83 years. A total of 373 (91.2%) patients were overweight or obese, with 88.31% men and 95.65% women being overweight (BMI>23)and 183/248 (75.81%) men and 144/161 (89.44%) women obese (BM>25). Waist circumference (WC) and WHR were increased (WC>90cm for men and >80 cm for women, WHR>0.9 for men and >0.8 for women) in 155/161 (96.67%) and 152/161 (94.41%) of women and 202/248 (81.5%) and 224/248 (90.3%) of men respectively. WC-HR more than 0.55 was present in 191/348 (77.02%) men and 149/161 (92.55%) women. WC-HR showed a strong correlation (r) with BMI (0.79) and WC (0.86). It, however, showed a weak correlation (0.28) with WHR. Correlation (r) with hypertension (0.14), CAD (-0.02), triglycerides (-0.02), LDL-C (-0.03) and HDL (0.03) was poor. Trend analysis did not show any increase in prevalence of hypertension, CAD, triglycerides, LDL-C or HDL-C with increasing WC-HR.

Discussion/conclusions: Recent studies from Asian and Indian populations have reported waist-height ratio to be a good surrogate for measuring central obesity and a strong predictor of type 2 diabetes and cardiovascular risk.

Our study shows that waist circumference-height ratio (WC-HR) is a good surrogate measure of obesity and central adiposity in patients with type 2 diabetes. However, it does not show any correlation with prevalence of cardiovascular risk factors in this subset of population.

Weight profile of newly diagnosed Indian type 2 diabetes (T2D) patients attending Primary Care Rendering Diabetes Clinic

L.K. Shankhdhar[1], K. Shankhdhar[2], U. Shankhdhar[3], S. Shankhdhar[4]

[1] L.K.Diabetes Centre, Endocrinology, Lucknow, India

[2] L.K.Diabetes Centre, Diabetology & Podiatry, Lucknow, India

[3] L.K.Diabetes Centre, Nutrition, Lucknow, India

[4] L.K.Diabetes Centre, Diabetes Education, Lucknow, India

Aims and objectives: Indian T2D patients present with several special characteristics compared to their counterparts in western countries. For instance, onset of diabetes is approximately 10 years earlier and they often present with "lean obesity," a condition when weight is normal, as per BMI, but body fat percentage is higher. The present study aimed to classify Indian T2D patients as per BMI, fat percentage and waist circumference, using commonly accepted cut off points, applicable for Indian subjects. BMI was considered normal between 18.5 to <23 kg/m^2 for both men and women, body fat percentage for men <25 and for women <30 was regarded normal and waist circumference ≤90 cm for men and ≤80 cm for women was taken as normal.

Methods: Sixty consecutive newly diagnosed T2D patients of both sexes (30 each), attending our outpatient unit, were included for the present study. Various anthropometric measurements were taken such as age, height, weight, BMI, waist circumference and body fat percentage. Their baseline characteristics were as follows:-

Observations: Analysis of data led to following categories of weight status, as shown in tables:

see table on the next page

Characteristic	Total	Female	Male
Age (yrs)	49.81± 6.05	49.73±5.72	49.90±6.46
BMI (kg/m^2)	29.30±5.82	29.58±6.10	29.03±5.61
Body Fat (%)	32.26±4.79	32.75±5.19	31.77±4.39
Waist circumference (cm)	98.26±8.44	96.08±9.21	93.89±9.58

As per BMI & Fat %	Total		Male		Female	
	N=60	%	N=30	%	N=30	%
Normal Non obese	2	3.33	1	3.33	1	3.33
Normal obese	4	6.66	3	10	1	3.33
Over Wt non obese	8	13.33	0	0	8	26.66
Over Wt obese	23	38.33	15	50	8	26.66
Class 1 obese	13	21.66	8	26.66	5	16.66
Class 1 non obese	2	3.33	0	0	2	6.66
Class 2 obese	3	5	1	3.33	2	6.66
Class 3 obese	5	8.33	2	6.66	3	10

As per BMI & Waist Circumference (WC)	Total		Male		Female	
	N=60	%	N=30	%	N=30	%
Normal Wt+ Normal WC	1	1.66	1	3.33	-	-
Over wt+ Normal WC	1	1.66	1	3.33	-	-
Obese+ Normal WC	3	5	3	6.66	-	-
Over wt+ - WC	32	53.33	14	46.66	18	60
Obese+ - WC	23	38.33	11	36.66	12	40

Results: Majority of the Indian patients (38.33%), both men and women, belonged to the category of Overweight–Obese at the time of diagnosis of T2D. This was followed by class I obese (21.66%). Class III obesity was quite rare (8.33%) in Indian patients. Observations based on waist circumference also corresponded with body fat percentage, as majority (53.33%) of the overweight T2D patients had increased waist circumference.
Conclusions: Majority of Indian T2D patients are not obese at the time of diagnosis; most being overweight only.

Does therapy with H2 receptor antagonists have an effect like gastric bypass surgery in treatment of obesity

G. Pudar[1], B. Dapcevic[2], M. Andjelic[1], P. Svorcan[2], A. Brankovic[1]
[1] *University Clinical Center Zvezdara, Department of endocrinology and diabetes, Belgrade, Serbia*
[2] *University Clinical Center Zvezdara, Department of gastroenterology, Belgrade, Serbia*

Background and aims: Many studies showed that gastric bypass surgery (GBP) has important place in therapy of obesity and in control of insulin secretion. GBP has been reported to inhibit appetite and gastric motility. Decreased plasma concentrations of ghrelin and increased concentrations of GLP 1, augmented after GBP, are the most prominent candidates for this effect. Maldigestion can be also caused by the absence of acid and pepsin secretion. The aim of this study was to examine the effects of using ranitidine hydrochloride (selective H2 receptor antagonist) in the treatment of obesity.
Materials and methods: We examined 26 healthy obese persons (BMI >30 kg/m^2), mean age 42.1 ± 10.1 years. All patients came to endocrinologist only because of their problem with obesity. Three months before this study all patients have already been on therapy with the low calories diet and physical activity, but they didn't succeed to reduce their body weight. In this study the patients continued with the same diet and physical activity and in addition they were given to take daily two tablets of 150 mg ranitidine (morning and evening) for the next eight weeks. At baseline and after 8 weeks period we determined body weight, waist circumference (WC) and BMI (kg/m^2), lipid status (total cholesterol, triglycerides, HDL cholesterol and LDL cholesterol). Also a 2 hours 75-g oral glucose tolerance test (oGTT) was done during which we followed plasma insulin concentration (by radioimmunoassay) at the beginning and after one hour of the test (60').
Results: At the end this study has shown that all patients have significantly reduced their body weight from 2 to 23 kg, mean 7.2±4.6 kg (103.1±14.1 vs 95.9±13.5 kg, p<0.01), BMI (36.8±4.9 vs 34.2±5.1 kg/ m^2, p<0.01) and WC (108.4±9.3 vs 99.6±10.2 cm, p<0.01). Also, they had better lipid status with significantly reduced triglycerides (2.2±0.9 vs 1.7±0.7mmol/l, p<0.05) and increased HDL cholesterol (1.1±0.3 vs 1.3±0.3 mmol/l, p<0.01). Fasting plasma insulin was improved (10.1±5.2 vs 10.3±4.9, NS) and insulin secretion after 60'of oGTT was significantly reduced (76.2±41.5 vs 58.1±37.6, p<0.05).
Conclusion: Potential explanation for our findings is that ranitidine has effects like gastric bypass surgery on gut hormones that control insulin secretion (GLP-1, PYY, Ghrelin). All patients also could maintain the advised dietary programme with pleasure and without being hungry, nervous or depressed.

P-1576

BMI as risk factor for type 2 diabetes and hypertension: the height and waist problem

S. Svacina[1], M. Matoulek[1], J. Lajka[2], P. Horak[3]
[1] *Charles University 1st school of Medicine, 3rd Medical Department, Prague 2, Czech Republic*
[2] *STEM/MARK Agency, Department of Statistics, Prague, Czech Republic*
[3] *General health insurance office, Directory, Prague, Czech Republic*

Aims: Obesity, defined by BMI and waist, is a risk factor for type 2 diabetes and hypertension. There are publications showing lower risk of metabolic syndrome and vascular events for high height. We have analyzed the influence of height and waist on hypertension and type 2 diabetes in the epidemiological study.
Methods: Representative sample of 2058 adults of Czech republic was examined in December 2008 - measuring of weight, waist and height and interview. χ^2 test was used to compare categories of BMI, waist and age. Correlations of BMI to weight, height and waist was calculated
Results: Mean BMI of men was 26.9, mean BMI of women 26.1 kg/m^2, mean height 178cm in men and 167 cm in women, mean waist 94 cm in men and 85 cm in women. Prevalence of diabetes in the sample was 7%, overweight 22%, obesity 34% and hypertension 21%. There is a higher relation of diabetes to obesity in women: 25% diabetics in women and only 15% diabetics in men. Both diabetes and hypertension are waist dependent and there is no difference between sexes. In men 40% prevalence of hypertension and 15% prevalence of diabetes was present in waist above 102 cm. In women 39% prevalence of hypertension and 16% prevalence of diabetes was present in waist above 88 cm.
In both sexes there is a negative relation of hypertension and diabetes prevalence to height. Hypertension prevalence 32% in men below 172 cm and 11% above 186 cm height. Hypertension prevalence 33% in women below 161 cm and 12% above 172 cm height. Diabetes 13% in men below 172 cm and 3% above 186 cm. Diabetes prevalence 11% in women below 161 cm and 3% above 172 cm.
Positive correlation (p <. 001) of BMI to weight (0.854), and waist (0.787) was found and negative correlation (p < .001) to height (-0.058) was found.
The correlations were recalculated using the survey with same methodology from the year 2000 in 1627 subjects: Positive correlation (p < .001) of BMI to weight (0.990), waist (0.262) and height (0.325) was found. The prevalence of obesity increased from 15 to 22% and of overweight from 31 to 34%.
Conclusion: Our data support the idea that BMI and waist are risk factors for hypertension and type 2 diabetes using the different waist criteria for men and women defined by IDF. The prevalence of diabetes in women is more BMI dependent. In both sexes was shown that low body height is a risk factor for diabetes and hypertension today. BMI is therefore not a good universal diabetes risk marker for men and women and for high and low body height. In last 8 years the BMI-waist positive correlation is more pronounced and a new negative BMI-height correlation occurred. This indicates that the BMI-height relation is influenced by social factors rather than by biological factors and mathematical BMI formula.

P-1577

Plasma adiponectin levels in normal weight obese, non-obese and obese Indian type 2 diabetic subjects

N. Kapoor[1], N. Deshpande[2], A. Syed[1], L. Dahiya[1]
[1] *Belgaum Diabetes Centre, Diabetes and obesity, Belgaum, India*
[2] *Belgaum Diabetes Centre and J.N.Medical College, Diabetes and obesity, Belgaum, India*

Background: Persons with a normal Body Mass Index (BMI), but a high body fat percentage (BFP),now termed normal weight obese (NWO) are very prone

to have a poor cardiac & metabolic profile.
Adiponectin is predicted to contribute to peripheral insulin resistance.
Since NWO represents high body fat composition in apparently non obese individuals & is strongly associated with a higher risk of vascular inflammation probably more so in diabetic subjects, low adiponectin levels could be the missing link between these two clinical entities.
Aim: Comparison of Plasma adiponectin levels & other metabolic parameters among NWO, Non-Obese & Obese type 2 diabetic subjects.
Methods: 70 male, well controlled, type 2 diabetic subjects with normal ECG, not on Thiazolidinediones, were enrolled. They were matched for age, duration of diabetes (DM) & glycemic control. Demographic data, anthropometry [BMI, BFP, Waist Hip Ratio (WHR)], glycemic control & Plasma adiponectin levels (ELISA, globular & full-length) were recorded. The subjects were grouped as Obese (BMI ≥25 kg/m^2)* & non-obese (BMI <25 kg/m^2)*. The non-obese group was divided as NWO (BFP ≥20%) & normal weight non obese (BFP <20%).
**Asia Pacific guidelines*
Results: Only 17% of subjects had normal BMI & BFP, whereas 46 % were frankly obese & 37% were NWO indicating a combined high prevalence (83%) of obesity.
Mean BMI in the Obese, NWO, Non-obese groups was 29.03± 2.89, 22.46±1.25, 21.19±2.04 respectively. Mean BFP in the corresponding groups was 43.60±10.01, 39.81±7.16, 15.30±2.8.
Family history of DM was significantly more in the NWO group (58%) than in the Obese group (46%). (P = 0.041)
Glycemic control (HbA1c & FPG) was best in the non-obese group, followed by NWO & then obese groups. Obese group had significantly higher FPG compared to NWO group. (P = 0.0117)
Waist circumference (WC) & WHR was maximum in obese (WC = 107.25±12.98, WHR=1.00± 0.05) subjects, followed by NWO (WC = 95.85± 7.37, WHR=0.90± 0.03) & was least in non obese (WC = 81.33±3.26, WHR=0.87± 0.04) subjects.
The prevalence of microvascular complications in the 3 groups was not significantly different, possibly due to similar glycemic control & duration of DM.
Obese group had the lowest value of adiponectin (6.43±2.47 ng/dl), followed by NWO group (10.60±2.42 ng/dl). Non-obese group had the highest value (13.72±2.99 ng/dl).
There is significant difference between adiponectin levels of NWO & Non-Obese groups (p = 0.001).
Conclusion: There is a very high prevalence of obesity (by BMI & BFP) in the Indian diabetic population.
The adiponectin levels in the NWO Group veer more towards the Obese group reflecting the importance of diagnosing & treating this subgroup of patients. Nutrition therapy in NWO diabetics has to address fat loss specifically.

P-1578

Family and childhood obesity

M. Vishnevskaya[1], A. Solnceva[1]
[1] Belarussian State Medical University, Pediatrics, Minsk, Belarus

Poor family functioning will be associated with inadequate parental monitoring and/or regulation of children's eating and activity patterns. We aimed to examine the relationship between a child's weight and a broad range of family and maternal factors.
Methods: This cross-sectional study involved 56 obese children (m/f =30/26), mean age11.05±3.50 yrs, and 56 mothers. Obesity was defined as BMI scores at or above the 97th percentile for age and gender. Psychological examination was conducted (Eidemiller test of house education) and eating attitudes test (EAT-26). All the analysis were performed with the Statistics 6.0 software, p-value < 0.05 was accepted as statistically significant. ANOVA test was used for unpaired data. BMI mother's 27.90±5.33 (19.00-41.00) kg/m^2, BMI children's 27.84±4.6 (18.20-39.60) kg/m^2, SD BMI 5.14±1.92. Results: 17.86% mothers had secondary education, 57.14%-higher education and 25%- special education. The full families were observed in 71.43%, incomplete - in 28.57% examined patients. BMI children was not correlated with BMI mothers ((r>0.1). Differences SD BMI were received depending on mothers education: high - Me 4.77 [3.24-5.44] and secondary-special - Me 5.67[4.68-7.20] (r=0.0085). The significantly differences of the following criterion of the test were determined on deflection SD BMI from Me: "forbid-requirements overweening" (r=0.1), "sanctions overweening" (r=0.015), for girls «projection male quality" (r=0.045). On the other criteria of the test differences between SD BMI were not revealed (r>0.1).By analyzing EAT-26 following data were received: gender differences breaches of the eat behavior, concerned with own body. The dissatisfaction of children's need can lead to breach of the eat behaviour in boys (r=0.7). Children's psyche can catch any uncertainty in parents correctness of the education and his place begins to occupy society (r= 0.6).On the other hand than more projection male quality on boy, that more he reveals self-verification (r=0.6). Following results were received in the female-group. The self-verification turned out to be most labile factor. We were received The negative correlations: factor hyper patronage (r=-0,5), satisfaction of requirements (r=-0.6), requirements insufficient (r=-0.61), unsteadiness of the education styles (r=-0.52).The lack of development of the parental feeling (r=0.56), overweening requirements (r=0.6), projection on child undesirable quality (r=0.6).
Conclusion: Findings indicated on increase the children BMI under using negative acceptance in household education. It was revealed that mothers had difficulties between need of the checking and granting autonomy to the child.

P-1579

Perception of obesity among adult women in Limbe urban area (Cameroon)

C. Nono[1], P. Fokumlah[1], C. Sab[2]
[1] Training School for Health Personnel, School for State Registered Nurses, Limbe, Cameroon
[2] University of Buea, Department of Health Sciences, Buea, Cameroon

Introduction and Aim: It is a fundamental need, it is a fundamental right to eat, yet it has also been observed in developing urban area that many people who are apparently obese are not aware of the problem and the factors that cause it. Many seem not to know that their eating behaviour influences their health. Between January and April 2006, women's perceptions on obesity were assessed from various household quarters in Limbe urban town.
Method: Overweight and obesity were defined according to BMI grade system of obesity lay down by the WHO. We used a questionnaire filled by 100 adult women (aged 18-65) randomly selected from middle-income household and high-income household quarters.
Result: Mean BMI per intervals of classification was 28.3. The greatest prevalences of overweight (36%) and obesity (55%) were found among women from monogamous marriages.
Housewives (32%), working women (29%) and 'buyam sellam' women (26%) recorded high prevalence of obesity. No case of obesity was recorded among farmers.
Overweight was more prevalent among the high-income households (46%) but obesity recorded the highest percentage (34%) among the middle-income households.
Most respondents (45%) related obesity to fat; 20%defined it as a result of overeating only 24% identify it as a disproportion between height and weight. Few women (27%) view lack of food intake control as an exposure factor to obesity. 95% of respondents acknowledged that fatty foods can predispose to obesity. The appearance and the taste of the food is for 35% of women a factor that triggers appetite. 37% of women always check the amount of oil in food before they eat. The provision of a fruit at each meal accounted for only 28% of the eating behavior as well as eating at scheduled times.
Among the respondents who did not view themselves as being obese, 61% was overweight and 30% was obese.
Control of diet, avoidance of sedentary life and performance of physical exercise were identified as preventing measures by 70% of respondents. 65% affirmed that a control of diet implies an intake of less fatty and sugary foods, an intake of plenty fruits and reduced quantity of starch intake.
Only 8% of women were engaged in sporting activities more than one time per week, with a significant 55% practicing sport occasionally.
Conclusion: The knowledge on behavioral factors related to overfeeding does not influence many women in developing urban area to control their weight as we had a population of 34% overweight and 32% obese regardless of occupations and households. Overweight being much perceived as a sign of well being or "peace of mind", we need a wider scale to identify the impact of risk factors of obesity on women's health to sensitize the population on dangers caused by excess weight gained.

Neck circumference as an upper body obesity index, and its relationship with cardiovascular risk factors

A.P.A.M. Sales[1], V.O. Fernandes[1], A.R.P. Quidute[1], C.M.M. Ponte[1], M.H.C. Gurgel[1], C.R.M. Rodrigues Sobrinho[1], M.V. Mota[1], P.C. Almeida[1], R.M. Montenegro Jr[1]

[1] *Federal University of Ceará, Community Health and Clinical Medicine Department, Fortaleza, Brazil*

Background and aims: This study aimed to evaluate neck circumference (NC), as an upper body obesity index, and its relationship with cardiovascular risk (CVR) factors, considering that it would be a simple and time-saving measure to identify overweight/obese, and high risk patients.
Materials and methods: We evaluated 114 Brazilian adults (27 men, 87 women), 55 with metabolic syndrome (MS) and 59 without MS (NMS) (IDF criteria). Main indicators studied included NC, waist circumference (WC), BMI, waist to hip ratio (WHR), systolic (SBP) and diastolic blood pressure (DBP), fasting serum lipoprotein, glucose, insulin, uric acid (UA), alanine aminotransferase (ALT), arginine aminotransferase (AST) levels, glucose and insulin levels 2 h after 75-g OGTT, and HOMA.
Results: NC mean was 36.2±3.3 and 34.2±2.8cm (p=0.01) in the groups MS and NMS, respectively. Among women NC was 34.7±1.9 and 33.2±2.1cm (p=0.002), and among men was 39.8±3.0 and 38.0±2.1cm (p=0.09) in the groups MS and NMS, respectively. Other measurements in MS and NMS were, respectively: WC=99.5±9.9, and 91.0±10.6cm (p=0.01); BMI=30.9±5.0 and 28.0±4.4kg/m^2 (p=0.02); WHR=0.95±0.07 and 0.88±0.06 (p<0.0001); SBP=127.6±19.8, and 115.9±11.3mmHg (p=0.04); DBP=82.9±11.2, and 77.9±7.3mmHg (p=0.16). Lab parameters in both MS and NMS groups were, respectively: UA=5.3±1.5, and 4.3±1.1mg/dL (p<00001); AST=22.1±7.4, and 19.9±5.9 U/L (p=0.08); ALT=25.3±14.0, and 22.0±18.3U/L (p=0.3); total cholesterol=198.0±51.0, and 189.0±36.0mg/dL (p=0.2); LDL-Chol=111.9±33.6, and 114.4±32.0mg/dL (p=0.6); HDL-Chol=41.8±11.0, and 50.4±10.6 mg/dL (p<0.0001); triglycerides=189.8±83.7, and 106.7±28.6mg/dL (p<0.0001); fasting glucose=106.3±24.3, and 90.9±8.8mg/dL (p<0.0001); fasting insulin=13.1±5.9, and 10.0±12.0mU/mL (p=0.09); post OGTT glucose=155.5±59.8, and 114.2±32.1mg/dL (p<0.0001); post OGTT insulin=101.4±71.6, and 74.6±74.3mU/mL (p=0.06); HOMA=3.4±1.6, and 2.2±2.5 (p=0.008). Pearson's correlation coefficients indicated a significant association between NC and: WC (MS r=0.65; NMS r=0.53; p<0.0001), BMI (MS r=0.48, p<0.0001; NMS r=0.36, p=0.008), WHR (MS r=0.59, p<0.0001; NMS r=0.41, p=0.003); UA (r=0.40 p=0.003), ALT (r=0.27 p=0.04) and HOMA (r=0.32 p=0.025) in the MS group; UA (r=0.49 p<0.0001), AST (r=0.36, p=0.005), ALT (r=0.57, p<0.0001) and HDL-Chol (r=-0.29, p=0.02) in the group NMS.
Conclusion: NC is positively correlated with main factors of the metabolic syndrome, therefore with increased risk of cardiovascular disease.

Effect of guideline choice on the prevalence of central obesity in Nigerians with type 2 diabetes

I. Sanusi[1], S.O. Iwuala[1], O.A. Fasanmade[1], A.E. Ohwovoriole[1]

[1] *Lagos University Teaching Hospital, Medicine, Lagos, Nigeria*

Background: The presence of central obesity in patients with type 2 diabetes (T2DM) impacts significantly on the management of the disease and its co morbidities. Different cut off points by various research groups have led to confusingly different prevalence data.
Aim: To compare the prevalence of central obesity using various criteria in Nigerians with T2DM.
Methods: A retrospective study of outpatients of a diabetes clinic in a tertiary health care centre was done. Data obtained from the clinic notes of the patients included the age, gender, DM duration, presence of hypertension, waist (WC) and hip circumferences. The waist hip ratio (WHR) and body mass index (BMI) were appropriately derived. Central obesity was defined according to the following: WHO (WHR > 0.90 in men, ≥0.85 in women), IDF specific values for Europids (WC ≥94 cm in men and ≥80 cm in women) and NCEP ATP III (WC ≥102 cm in men and ≥88cm in women). The results are expressed as mean (SD) and frequencies. Pearsons correlation coefficient was used to determine the relationship between the indices. The level of statistical significance was set at p value = 0.05.
Results: There were 568 persons studied, 260 (45.8%) were males and 308 (54.2%) were females. The mean ages of the male and female patients were 58.4 (9.9) and 57.3 (9.6) years respectively (p=0.14), while the mean durations of diabetes in the male and female patients were 5.8 (6.8) and 6.1 (8.7) years respectively. The frequencies of central obesity using the WHO, IDF (Europids) and NCEP ATP III criteria were 213 (81.9%), 128 (49.2%) and 56 (21.5%) in males and 263 (85.4%), 283 (91.1%) and 227 (73.7%) in females. BMI had a stronger correlation with WC in males than in females (r=0.49, p<0.00001 and r=0.35, p<0.00001). All the guidelines showed higher prevalence of central obesity in women with diabetes than men with diabetes but the difference was particularly marked using the IDF criteria.
Conclusion: The WHO criteria gave the highest prevalence rate for central obesity in the entire study population followed by the IDF (Europids specific values) and then the NCEP ATP III. There is great disparity in the prevalence rates of central obesity in the diabetic Nigerian males and females using current international guidelines. Further studies are necessary to determine which criterion is best for defining central obesity in sub-Saharan Africans especially in the female population.

The effectiveness of population health interventions for the prevention of type 2 diabetes, a systematic review

N. Sumar[1], A. Shiell[1], P. Spilchak[2], P. Hawe[1], D. Lorenzetti[3], J. Petersen[3]

[1] *University of Calgary, Population Health Intervention Research Center, Calgary, Canada*

[2] *Public Health Agency of Canada, Alberta/NWT Region, Calgary, Canada*

[3] *University of Calgary, Department of Community Health Sciences, Calgary, Canada*

Context: Tackling the burden of chronic disease requires advocacy for preventive interventions to advance the well-being of patients, communities, and populations. A summary of the effectiveness of population health interventions to prevent diabetes is valuable for decision makers seeking information on reducing the growing health burden and costs of diabetes.
Background: Diabetes is a major public health problem, in Canada and worldwide. While there is evidence on strategies for the prevention, management, and treatment of diabetes, few studies focus on universal or 'whole of community' population health interventions addressing the social determinants of health
Objective: To evaluate the effectiveness of population health interventions to prevent type 2 diabetes through a systematic review of literature.
Search strategy: Building upon a review of the evidence to 2002, eight electronic databases were searched from 2003-2006. 'Related articles' of included studies were located through PubMed.
Selection criteria: Included studies must: describe an intervention (a) designed for the primary prevention of type 2 diabetes (or related risk factors); (b) be implemented 'universally' rather than targeting those at high risk; and (c) address at least one social determinant of health (e.g. physical environment).
Data collection: Two reviewers independently screened, extracted data, and assessed study quality. Standardized tools were used for quality assessment. Discrepancies were resolved by consensus or a third reviewer.
Results: 47 population health interventions were identified in total. Eight have yet to report outcome data. Of the remaining 39 interventions, 23 took place in schools, 10 in communities and 6 in worksites. All but four studies showed significant impacts on at least one diabetes related risk factor. Studies included were diverse in terms of design, quality, target population, theory employed, and outcome measures reported. Effectiveness data was summarized in an adaptation of a harvest plot depiction.
Conclusions: Evidence suggests that population health approaches can reduce the risk of diabetes. As no pattern in the relationship between intervention setting and outcome achieved was evident, a realist review of the interventions, by setting, may provide further insight into what can be done to reduce the risk of diabetes.

Metabolic profile and adipose tissue distribution

M. Cambrea[1], G.B.C. Costa[1], V.F.D.S. Arruda[1], M.P. Tomarchio[1], A.S. Agonilha[1], L.C. Stella[1], J. Santomauro[1], A.T. Santomauro[1], F.F. Fraige[1]
[1] Beneficencia Portuguesa, Endocrinology, São Paulo, Brazil

The objective was to analyze the impact of visceral fat in patient's metabolic profile. For that, we evaluated ambulatory patients from an endocrinology clinic in Sao Paulo, Brazil. This prospective study was done during five months in 2007. It was selected non-diabetic subjects, with body mass index (BMI) = 30 Kg/m2. It was excluded those who were using metformin, anorectics or acetoacetamide-N-sulfonic acid. They were investigated about the presence of risk factors for DM2, like patients above 45 years of age, hypertension, family Type 2 Diabetes Mellitus history, prior history of fetal macrosomia and/or gestational diabetes. According to the WHR, the patients were divided in two groups: WHR > 0,9 and WHR < 0,9. These groups were compared, correlating laboratory parameters and the presence of risk factors for DM2. Fasting plasma glucose (FPG) and insulin levels, alanine aminotransferase (ALT), total cholesterol and its fractions, triglycerides and C-reactive protein were measured. Insulin resistance (IR) was evaluated by the homeostasis model assessment (HOMA)-IR. It was evaluated 101 patients, 72 female, age 35,8 ± 12,1 in the group WHR < 0,9 and age 42,6 ± 9,7 in the group WHR > 0,9. In the group WHR < 0,9, 13 patients presented three or more risk factors for DM2 and in the group WHR > 0,9, 19 patients presented this condition, without statistical significance. Alanine aminotransferase levels were higher in the group WHR >0,9 (p=0,097), as well as, FPG (p=0,088) and HOMA (p=0,075). To conclude, we could say that central fat accumulation may cause hepatocellular injuries, with increasing levels of ALT, that are correlated with an impaired IR as represented by HOMA-IR. It is important to stimulate the patients get thin, seeing that adipose tissue also has endocrine function that may cause an increased cardiovascular risk.

P-1584

Pattern of Body Mass Index (BMI) in Nigerian patients with Diabetes Mellitus

S. Iwuala[1], A. Ijasan[1], O.A. Fasanmade[2], A.E. Ohwovoriole[2]
[1] Lagos University Teaching Hospital, Medicine, Lagos, Nigeria
[2] College of Medicine, Medicine, Lagos, Nigeria

Aim: To determine the pattern of BMI in patients with confirmed diagnosis of diabetes mellitus in a tertiary health care centre in Nigeria.
Methods: Using the diabetes register of the endocrine and metabolic unit of the Lagos University Teaching Hospital, Nigeria, data extracted for this analysis included the age, gender, type of diabetes, weight, height, blood pressure status, and duration of diabetes. BMI was computed using the standard formula. BMI was classified according to the WHO criteria as follows: underweight < 18.5kg/m^2, normal BMI 18.5-24.99 kg/m^2, overweight 25-29.99 kg/ m^2, class I obesity 30-34.99 kg/ m^2, class II obesity 35-39.99 kg/ m^2, class III obesity = 40 kg/ m^2. Statistical analysis was done using descriptive methods to provide means (SD) and frequencies (%). The level of statistical significance was set as p value = 0.05.
Results: There were 1503 patients with diabetes included in the analysis, consisting of 574 (54.5%) females and 479 (45.5%) males. Thirteen (1.2%) patients had type 1 diabetes and 1040 (98.8%) patients had type 2 diabetes. 55.3% of the patients had hypertension. The mean age of the study population was 54.0 (12.7) years. The mean BMI was 26.7 (5.5) kg/m^2 and the mean duration of diabetes was 9.6 (5.7) years. The females were significantly older than the males {55.2 (12.6) vs 52.9 (12.7) years respectively, p= 0.005} while the patients with type 2 diabetes were significantly older than those with type 1 diabetes {31.5 (19.1 vs 54.2 (12.4 years, p=0.00000}. The frequencies of BMI categories in females and males were: underweight 25 (4.4%) and 17 (3.5%), normal BMI 171 (29.8%) and 215 (44.9%), overweight 197 (34.3%) and 178 (37.2%), class I obesity 130 (22.6%) and 61 (12.7%), class II obesity 54 (5.9%) and 7 (1.5%), class III obesity 17 (3.0%) and 1 (0.2%). There was a significant difference in the frequencies of the BMI in the females and the males (chi ^{2}= 56.3, df=5, p=0.0000). The frequencies of BMI categories in the type 1 and type 2 patients were as follows: underweight 2 (15.4%) and 40 (3.8), normal BMI 9 (69.2%) and 377 (36.3%), overweight 2 (15.4%) and 373 (35.9%), class I obesity 0 (0.0%) and 191 (18.9%), class II obesity 0 (0.0%) and 41 (3.9%), class III obesity 0 (0.0%) and 18 (1.7%). There was also a significant difference in the frequencies of BMI categories in the type 1 and 2 DM patients (chi ^{2}= 12.7, df=5, p=0.03).
Conclusion: Type 1 and 2 have different patterns of BMI. Almost all the type 1 patients were either underweight or had a normal BMI while type 2 patients were mostly overweight or obese as have been found in other studies. However, type 2 DM females were more frequently obese or overweight compared to the males, a pattern different from that in other parts of the world but similar to those done in Africans with diabetes.

Non-invasive method for blood glucose level estimation by saliva

N. Sharma[1], V.B. Gupta[1], M.S. Rathore[1], D.K. Sharma[1], R.P. Agrawal[2], S. Jain[2], S. Goyal[2], A. Chopra[2], N. Gupta[3]
[1] B.R.Nahta College of pharmacy, Pharmacy, Mandsaur, India
[2] Diabetes Care & Research Centre, Medicine, Bikaner, India
[3] Jaipur dental college, dental, Jaipur, India

Aims: Diagnostic devices are available in the market to measure the blood glucose level. However in all available products blood is taken as diagnostic body fluid. So necessity arises to find some non-invasive diagnostic means to measure body glucose level frequently without any discomfort to the patient. Hence, the present study aimed at estimation of blood and salivary glucose level in diabetic and non diabetic subjects.
Methods: Twenty diabetic and twenty non diabetic subjects were randomly selected for this study. A detailed history of each patient was obtained regarding the age, sex, duration of diabetes, associated risk factors, family history and any associated illness. The quantitative estimation of the blood and saliva glucose level were performed by glucose oxidase method, using enzymatic kits (GOD-DAP).
Results: A correlation was observed between fasting saliva glucose level (SGL) and fasting blood glucose level (BGL) of diabetic as well as non diabetic subjects. The correlation coefficient of non diabetic and diabetic subjects were + 0.84 and +0.34 respectively. These values of correlation coefficient proved the correlation of fasting saliva glucose and fasting blood glucose values statistically.
Conclusion: Values observed regarding blood and saliva glucose level were found distinctly difference between normal subjects and diabetic subjects suggesting that monitoring of saliva glucose level can be used as an index of diabetes mellitus. With further studies on the correlation between diabetic mellitus and SGL, it is believed that not only noninvasive BGL estimation becomes possible, but early detection of diabetes mellitus becomes a reality by the use of this procedure for screening in medical check.

Classical glucose curve x Oral Glucose Tolerance Test (OGTT)

M.F.V. Cambrea[1], V.F.D.S. Arruda[1], I.B.E. Colauto[1], G.B.C. Costa[1], M.P. Tomarchio[1], L.C. Stella[1], A.T. Santomauro[1], F.F. Fraige[1]
[1] Beneficencia Portuguesa, Endocrinology, São Paulo, Brazil

Introduction: The American Diabetes Association (ADA) created a new method for diabetes diagnosis in1997 based on the glucose curve after two hours with 75 grams of glucose, disregarding the 30', 60' and 90' marks.
Objective: To evaluate the glucose curve in a large population group with emphasis on glucose points of 30, 60 and 90 minutes.
Subjects and methods: The classic glucose curves in 1.073 individuals were randomly evaluated. According to ADA criteria, three groups of individuals were selected: 111 diabetics (D), 209 intolerants (I) and 753 normal individuals (N). The groups were analyzed based on the glucose curve incremental area, subdividing the normal individuals into those who presented one glucose peak = 200mg/dL (N1 - 51 individuals), two glucose peaks (N2 - 19 individuals) and no glucose peak (N0 - 683 individuals). Students t-test was used for the statistic analysis.
Results: The incremental area for the groups was the following: N0 - 362.56 ± 157.57 mg/dL/min (x ± SD), N1 - 663.08 ± 151.39 mg/dL, N2- 947.68 ±

214.96, I - 815.97 ± 179.07, D 1,277.35 ± 282.43. The comparison N1 x N0 and N0 x N2 showed difference with statistic meaning (p<0.001).
Conclusion: With these new ADA criteria, patients considered normal (9.29%) showed an incremental area bigger than patients considered intolerant. These results showed that ADA´s criteria for IGT must be reviewed.

P-1587

Plantar foot pressure in patients with neuropathic diabetes mellitus

H. Bahramian[1]
[1] Andamkar Technical Orthopedic Clinic, Orthotics and Prosthetics, Tehran, Iran

Aims: Diabetic patients who have neuropathy are at risk of foot pressure ulcers because of the lack of pain sensation in their feet. In this study we assessed the plantar foot pressure in neuropathic diabetic patients and compare their values with normal subjects to find points with higher pressures which are at risk of pressure ulcers. Choosing the best orthotic treatment in these patients should be after this assessment.
Methods: In this cross sectional study, 20 subjects participated. Subjects put in two groups of diabetic (5 men and 5 women) with mean age of 57 years and normal (5 men and 5 women) with mean age of 60 years. We used 2D foot scanner system to assess the foot plantar pressures in 10 different zones under the foot. We asked patients to walk at their normal speed a defined 5 meter pace.
Results: There was significant difference in foot plantar pressure in six zones in comparison between two groups which are Toe 1, Toe 2-5, Meta 1, Meta 4, Meta 5 and Midfoot. In both groups the mean foot plantar pressure was higher in forefoot.
Discussion: The higher foot plantar pressure under heads of metatarsals 3 and 4 and the overall higher foot plantar pressure under the foot of diabetic patients in comparison to normal population is in accordance with similar studies.
Conclusion: Diabetic patients had higher pressures in their forefoot and are more vulnerable to injuries in forefoot. So in orthotic treatment of these patients should choose appropriate materials in forefoot.

Latent Autoimmune Diabetes Mellitus in Adults (LADA): incidence and profile

M.F.V. Cambrea[1], V.F.D.S. Arruda[1], L.C. Stella[1], A.T. Santomauro[1], F.F. Fraige[1]
[1] Beneficencia Portuguesa, Endocrinology, São Paulo, Brazil

The adequate diagnosis of the type of diabetes in patients with determined clinical characteristics is important to program the treatment and to guide about the gravity in case of acute hyperglycemia. In case of autoimmune diabetes, the early detection of other autoimmune illnesses can even though prevent situations of risk for the patients who attend a course with auto immunity against vital glands. We use in this prospective study, 3 centers of attendance of diabetic individuals, in the period of 18 months and include patients, diagnosed as type 2 diabetes, age 30 years or older. If presence of 2 positives in 5 clinical criterias for autoimmune diabetes suspect, it was requested the levels of C-peptide and Anti-glutamic acid decarboxylase (anti-GAD). Among the 57 patients examined, 11 had confirmed the diagnosis and, therefore, we got a sensitivity of 70% for the clinical criteria. These patients then had been submitted to complete anamnesis and other examinations, in order to determine the profile of Latent Autoimmune Diabetes Mellitus in adults (LADA). The average of age at the LADA diagnosis was of 44.64 years, the majority of the diagnoses patients had been of male sex (72.73%). Most prevalent clinical criteria was the presence of acute symptoms at the diagnosis, followed by age < 50 years and BMI <25 kg/ m2.
The average for beginning insulin after the diagnosis of diabetes was 7 years, and those that had initiated insulin more precociously presented values of C-peptide smaller on the LADA diagnosis (0,36ng/ml X 2,16ng/ml); with 95% confidence interval and p=0,0016 by Student-t distribution. The anti-GAD levels were similar in the 2 groups. The most prevalent associated illness to diabetes in these patients was the dyslipidemia, and the diabetic chronic complication more found was the peripheral neuropathy. About the association with other autoimmune illnesses, the presence of thyroid illness was more prevalent, in the form of Hashimoto disease, followed by Graves's disease. We still identify cases of alopecia, vitiligo, pernicious anemia, auto immune hypogonadism, mucocutaneous candidiasis, no case of hypoparathyroidism or celiac illness was identified, and no patient of this study had criteria to Polyglandular autoimmune syndrome (PGA) type I or II.

P-1589

Short term economic benefits of improved glycemic control among commercially insured diabetes patients in the United States

W. Luo[1], M. Aagren[1]
[1] Novo Nordisk Inc, Strategic Business Development, Princeton, USA

Background: Glycemic control, measured by HbA1c, is well known to be a valid risk marker for costly long-term complications related to diabetes, e.g. blindness, amputations etc. The relationship between HbA1c and costs in the short term, however, is not known. This study aims to investigate how HbA1c is correlated to short-term diabetes-related medical expenses.
Methods: Patients from a large commercial managed care plan database with an HbA1c reading during the second and third quarters of 2007 were identified. Diabetes-related medical care utilization was obtained from the subsequent 12-month period, ending in the third quarter of 2008. Multivariate adjustment was performed using generalized linear model (GLM) regression techniques, applying a gamma model with log link, to identify the relationship between HbA1c and diabetes related medical costs.
Results: 36,306 individual patients with an HbA1c reading ≥ 6% were identified, 1,837 with type 1 diabetes and 34,469 with type 2 diabetes. Mean patient age was 55, 46% were female, 23% were treated with insulin +/- OAD, while 60% were treated with OADs only. The remaining 17% did not use any blood glucose lowering agents. The multivariate analysis showed that several characteristics significantly correlate with diabetes-related medical costs including HbA1c for both type 1 and type 2 patients. Every 1 percentage-point increase of HbA1c will, on average, be associated with a 7.3% and 3.4% increase in short-term diabetes-related medical costs for type 1 and type 2 diabetes, respectively. In monetary terms that amounts to estimated annual costs increases of $539 for type 1 patients and $194 for type 2 patients.
Conclusion: HbA1c is correlated to diabetes-related medical costs in the short-run. This supplements conventional wisdom that HbA1c affects risk of long-term complications and long-term costs. Thus, besides the clinical incentive of improving glycemic control this study shows that there are also shorter term financial incentives for managing glycemic control among patients with diabetes.

P-1590

Total health care expenditures associated with treatment modification in type 2 diabetes mellitus (T2DM) patients taking oral anti-diabetic drugs (OADs)

G. Krishnarajah[1], M. Bhosle[2], R. Chapman[2]
[1] Bristol-Myers Squibb, GMA/ Outcomes Research, Princeton, USA
[2] IMS Health, US HEOR, Falls Church, USA

Background: To provide an optimal benefit-risk profile, OADs must be appropriately titrated and are often used in combination.
Objectives: To compare health care expenditures among T2DM patients who 1) added a new OAD medication to initial therapy, 2) titrated initial OAD up to intermediate dose, and 3) up-titrated initial OAD beyond intermediate dose.
Methods: Insurance claims data were obtained from ~90 health plans for patients age ≥18 years with T2DM based on ≥2 ICD-9 claims during the period 1/1/2001-6/30/2007 and newly prescribed metformin or sulfonylurea monotherapy regimen lasting ≥90 days. Patients with type 1 or gestational diabetes, or OAD use within 180 days prior, were excluded. Patients were followed after initiation of monotherapy to identify occurrence of 1st treatment modification (addition or up-titration). Up-titration was divided into subgroup 1: titration to intermediate dose or below (=1500 mg for metformin, =4 mg glimepiride, =10 mg glipizide, = 7.5 mg glyburide), and subgroup 2: titration beyond intermediate dose. Study outcomes were analyzed during for the year following 1st treatment modification.
Results: Data for 22,917 patients were analyzed; 27% (n=6,191) had a new OAD added to their initial therapy, while 73% (n=16,726) had their initial

OAD up-titrated. Among patients who were up-titrated, 48% (n=8057) were in subgroup 1 and 52% (n=8669) were in subgroup 2. Mean [SD] total healthcare costs were lower for patients who added a new OAD to their initial therapy than for patients who were up-titrated ($8157 [$16,771] vs. $8447 [$20,281]; median = $4264 vs. $4764; p<0.0001]. Total healthcare costs were highest for subgroup 2 ($8684 [$22,182]; median = $4811) than for subgroup 1 ($8227 [$18,338]; median = $4624; p<0.0001). In a multivariable model adjusting for prior health care expenditure, demographic, and clinical variables, mean predicted costs for OAD addition remained significantly lower than initial OAD up-titration [$9568 vs. $10,027; p = 0.048]. In subgroup regression analyses, total costs of new OAD addition remained significantly lower than for both subgroups [$8542 addition vs. $8984 subgroup 1, p= 0.046; $10,425 addition vs. $11,174 subgroup 2, p= 0.042].

Discussion: Up-titration of initial OAD therapy was associated with higher subsequent total health care costs than addition of another OAD in this cohort of patients with T2DM. The difference in total costs was higher for patients who were up-titrated beyond intermediate dose than for those who were up-titrated up to intermediate dose. When appropriate, physicians should consider adding an OAD rather than up-titrating the current OAD, particularly beyond intermediate dose levels.

P-1591

Medication costs of diabetes patients in Finland in 1998-2007

P. Rissanen[1], T. Jarvala[1]
[1] University of Tampere, Tampere School of Public Health, Tampere University, Finland

Aims: Prevalence of diabetes has grown rapidly in all countries, including Finland. Especially, number of patients with type 2 diabetes is increasing. Naturally, costs of treatments of this disease have increased, including costs of medicines. We studied use and costs of medications in diabetes patients as compared to the general population.

Methods: The CoDiF study employed individually linked data from several Finnish national health registries. Persons diagnosed for diabetes were identified from the Hospital Discharge Registry, the Health Insurance (HI) Registries on reimbursement of medication, Medical Birth Registry, and Causes of Death Registry. Utilization and costs of medication was drawn from the reimbursement of medication registry of the HI in years1998-2007. All costs are in 2007 prices.

Results: The number of diabetes patients increased from 1998 to 2007 by 59%, similarly in both types. However, at the same time, the number of purchasers of diabetes medication increased by 150%. Total costs of all medication purchases of diabetes patients increased during the ten years period on average by 7.5% annually in both patient groups, while in general population the growth rate was 3.9%.

The average costs of all medications purchased by diabetes patients were € 836 per patient in 1998; € 1080 in 2007, the average annual growth being 2.3%. Accordingly, in general population, the purchases were € 180 and € 262 per person, an annual growth of 3.8%.

Conclusion: In total, in 1998-2007, the total medication costs of diabetes patients have grown faster than in general population. On the other hand, the number of diabetes patients using medicines has grown even faster, and thus, the growth of medication costs per diabetes patient has been slower than per capita growth in general population.

P-1592

Estimation of direct medical cost of severe hypoglycaemia in type 1 and type 2 diabetes patients in Switzerland

R.A. Greiner[1], M. Azoulay[2], M. Brandle[3]
[1] Consultancy Health Economics, Health Economics, Lörrach, Germany
[2] sanofi-aventis sa, Health Outcomes, Meyrin, Switzerland
[3] Kantonsspital St. Gallen, Division of Endocrinology and Diabetes, St. Gallen, Switzerland

Objectives: To assess the treatment cost of severe hypoglycemia in diabetes mellitus type 1 (T1DM) and type 2 (T2DM) in Switzerland.

Methods: Severe hypoglycemia was defined by clinical picture as not self-treatable and needed assistance from another person. Cost of severe hypoglycemia was restricted to the subdivision of cases in which medical care was required. Default values of kind and number of drugs and services as well as of the percentage of patients receiving these resources were specified from literature and locally validated by Swiss expert opinion. Resource utilization was valued with Swiss official prices, tariffs and operational costs. Drug prices were taken from the List of Specialities, outpatient services were rated with the federal medical tariff, inpatient services were valued with all patient diagnosis related groups, and operational costs of emergency were derived from personal communication with Swiss Conference of Cantonal Ministers of Public Health.

Results: The kind of services needed for the treatment of severe hypoglycemia was identical in T1DM and T2DM. By contrast, the percentage of patients utilizing a service was different in T1DM and T2DM: Ambulance transport and emergency physician rendered first aid and admitted patients to outpatient care. Glucose/glucagon was administered in 35% and 50% of all severe hypoglycemia cases in T1DM and T2DM, respectively. After 3 hours observation in day hospital 7% of T1DM and 20% of T2DM patients required inpatient care. After recovery all patients were trained in hypoglycemia awareness during a follow-up visit. Treatment cost of severe hypoglycemia amounted to CHF 1055 in T1DM and CHF 1966 in T2DM. Major cost drivers represented emergency with 50% and 38% and inpatient care with 33% and 50% of total severe hypoglycemia costs in T1DM and T2DM, respectively.

Conclusion: Cost of severe hypoglycemia was estimated first-time in Switzerland. Cost of severe hypoglycemia was found to be substantially higher in T2DM than in T1DM reflecting the higher percentage of cases requiring emergency and particularly inpatient treatment in T2DM.

P-1593

Treatment pattern and outcome changes for type 2 patients on basal therapy with insulin aspart add-on in a real-world managed care setting in the US

N. Jennings[1], W. Luo[1], M. Aagren[1]
[1] Novo Nordisk Inc, Health Economics & Outcomes Research, Princeton, USA

Background: Exogenous insulin therapy will be necessary for maintaining glycemic control for many patients with type 2 diabetes, a disease characterized by progressive beta-cell failure. Insulin aspart (IAsp) is a rapid-acting insulin analog developed for mealtime use. This study is intended to illustrate the implications of IAsp add-on in a real world setting for type 2 diabetic patients (T2DM) that are presently receiving basal therapy.

Methods: T2DM patients having the same basal insulin with add-on IAsp were identified from a large commercial US health plan database between April 1, 2007 and September 30, 2008. Patients were required to have more than 90 days on treatment pre- and post-IAsp initiation. Patients with other bolus therapy were excluded. Wilcoxon signed rank test for continuous variables, McNemar's Test for categorical variables were used to test the difference of self-comparison between before and after IAsp add on.

Results: A total of 1,739 patients with an average age of 56 years, were selected; 45% were female. After IAsp add-on, the percentage of patients using any OAD decreased from 64% pre-IAsp to 56% post-IAsp (P<0.001). In particular, Metformin decreased from 40% to 35%; TZDs decreased from 23% to 14%; Sulfonylureas decreased from 25% to 14%; Exenatide use decreased from 12% to 7%. All these percentage decreases were statistically significant. HbA1c decreased by 0.45% from 8.63%, pre-index, to 8.18%, post-index (p=0.002). With good glycemic control, total annual health care expenditures were statistically significantly lower after IAsp add-on compared to the pre-IAsp period ($44,304 vs $42,021; p=0.001).

Conclusion: With IAsp add-on to T2DM patients' basal insulin regimen, fewer patients needed OADs and better glycemic control was achieved. Furthermore, patients on average experienced reduced health care utilization after IAsp add-on, which resulted in a significant cost saving for the health care payer.

Economic costs associated to type 1 diabetes

M. Altamirano[1], J. Gil[2], V. Granados[3], G. Morales[3], A. Valderrama[2], H. Montesinos[2], C. Robles[2], R. Calzada[2], J. Garduño[4], N. Altamirano[2]
[1] *Centro Médico Nacional Siglo XXI IMSS, Unidad de Economía de la salud, Mexico DF, Mexico*
[2] *Instituto Nacional de Pediatría, Servicio de Endocrinología, Mexico DF, Mexico*
[3] *Centro Médico Nacional Siglo XXI, Unidad de Economía de la Salud, Mexico DF, Mexico*
[4] *Hospital Infantil de Mèxico, Dirección de Investigación, Mexico DF, Mexico*

Background: Type 1 diabetes mellitus is one of the most frequently encountered metabolic diseases in chronic pediatrics diseases and is associated with elevated morbimortality, and has important repercussions for health, social, and economic viewpoints because it comprises a chronic disease with a high demand of resources.
Objective: The present study was conducted to determin economic costs associated to diabetes in a patient group with type 1 diabetes.
Methods: T1 DM family direct and indirect costs were obtained from a standardized economic survey applied to parent or tutor of children with type 1 Diabetes Mellitus with no chronic severe complications, enrolled at the Diabetes Clinic at the Instituto Nacional de Pediatría in Mexico City, during 2008-2009. The data about metabolic control for each patient were obtained through the corresponding medical profile. We investigate health-related quality-of-life in all the children.
Results: 50 children with T1 DM with no chronic severe complications were identified, 46% females and 54% males, with a diabetes duration of 30 months. Metabolic control as [glucose 141 (63-450 mg/dL), HbA1c 7.29 ± 2.9 % (2.8-14.7). Mean family annual direct cost of treatment and monitoring was US $ 2,350.87/patient/year, which contains government funding given both outpatients and inpatients. With respect to costs, the highest percentage corresponds to insulin and glucose self measurement. Indirect cost were lower than direct cost US $ 567 /patient/year.
The child´s reported quality of life is related to age and gender.
Conclusions. We conclude that economic cost associated to type 1 diabetes is important and presents a notable and independent increase with hospitalizations related to diabetes, and micro and macrovascular complications.

P-1595

Cost-effectiveness of insulin glargine versus NPH insulin for the treatment of type 1 and type 2 diabetes in Switzerland

R.A. Greiner[1], M. Azoulay[2], M. Brandle[3]
[1] *Consultancy Health Economics, Health Economics, Loerrach, Germany*
[2] *sanofi-aventis sa, Health Outcomes, Meyrin, Switzerland*
[3] *Kantonsspital St. Gallen, Division of Endocrinology and Diabetes, St. Gallen, Switzerland*

Objectives: To evaluate the cost-effectiveness of insulin glargine compared to NPH insulin in patients with type 1 (T1D) and type 2 (T2D) diabetes, modeling the interaction between hypoglycemia and glycemic control (HbA_{1c}).
Methods: Two validated discrete event simulation models for T1D and T2D using evidence from Diabetes Control and Complications Trial and UK Prospective Diabetes Study, respectively, were applied to predict incidence of hypoglycemia, micro- and macrovascular events, life expectancy, quality-adjusted life years (QALYs) and direct medical costs in patients on insulin glargine or NPH insulin. Both models were populated with published Swiss patient characteristics. Baseline risks and relative risk reductions of symptomatic, nocturnal and severe hypoglycemic events as well as utility decrements of micro- and macrovascular events and the hypoglycemia fear score were derived from literature. Costs of severe hypoglycemia and of micro- and macrovascular events, applied from literature or guideline-projected resource-use estimation, were valued with Swiss official prices or tariffs and were expressed in 2006 CHF. Simulations were run with 1000 patients/cohort over a time horizon of 40 years. Costs and effects were discounted at 3.5%/year. Incremental cost effectiveness ratios (ICER) were expressed as cost per QALY and per life year gained. One-way sensitivity analyses were performed.
Results: Over 40 years, insulin glargine was associated with additional life expectancy in T1D (0.059) and T2D (0.05) as well as with an improvement in QALYs of 0.238 in T1D and of 0.098 in T2D compared to NPH insulin. In T1D, savings of CHF 1,476 turned insulin glargine into the dominant strategy. In T2D, incremental costs of CHF 2,578 resulted in an ICER of CHF 51,100 per life year gained and CHF 26,271 per QALY gained. In wide-ranging sensitivity analyses the ICER was most sensitive to changes in costs, utility decrements and relative risk reductions of hypoglycemia in T2D, while in T1D the savings were most sensitive to cost of hypoglycemia and cost of long-term events. HbA_{1c} reduction, relative risk reductions of hypoglycemic events, and utility decrements of hypoglycemia and long-term events mostly affected the QALYs in T1D.
Conclusion: Modeling the interaction between hypoglycemia and glycemic control, insulin glargine versus NPH insulin proved to be dominant in T1D and was cost effective compared to accepted ICER thresholds (less than CHF 60,000/QALY) in T2D in Switzerland.

P-1596

Cost of treating diabetes in a developing economy

A.A. Olugbodi[1], B.A. Kolawole[1], A.O. Tomi-Olugbodi[2], F. Adesina[1], R.T. Ikem[1], O.J. Adebayo[1], A.O. Oluranti[3], O.O. Aboaba[3]
[1] *Obafemi Awolo University Teaching Hospital, Medicine, Ile-Ife, Nigeria*
[2] *Obafemi Awolo University Teaching Hospital, Chemical Pathology, Ile-Ife, Nigeria*
[3] *Obafemi Awolo University Teaching Hospital, Family Medicine, Ile-Ife, Nigeria*

Aim: The study set out to determine the out-of-pocket and indirect costs of treating diabetes mellitus in Nigeria with a developing economy and little or no health insurance.
Method: The study was conducted at two tertiary health facilities that are 25 kilometers apart and operate under the same management, the Wesley Guild Hospital (WGH) and the Ife Hospital Unit (IHU) both in south western Nigeria. An interview-structured questionnaire and case note records were used to determine demographic variables, how much patients had expended on diabetes care, sources of funds for care, ability to cope with paying, number of clinic attendance and number of days spent on admission all in the preceding 12 months.
Results: There were 94 patients in all (M: F= 1:1), the average age was 62 years, 29 were retirees and 83% of the patients were in the low socioeconomic class. The average clinic attendance was 8/12 months while the average duration of hospital stay was 38 days. The total cost of insulin, oral hypoglycaemics, other drugs and laboratory test was $51,986.00. Only six patients had their own glucometer. With respect to the ability to cope with paying for care, 56 % of the patients reported that they cope with difficulty or great difficulty while a third had to depend on relations for diabetes care payment.
Conclusion: The out-of-pocket and indirect cost of diabetes care appeared intolerably high to these mostly indigent patients. An effective health insurance scheme might ameliorate this presently unacceptable situation.

P-1597

Long term cost-effectiveness of insulin detemir versus insulin glargine in type 2 diabetes patients: an analysis based on real life clinical data from a US managed care setting

M. Aagren[1]
[1] *Novo Nordisk Inc, Health Economics & Outcomes Research, Princeton, USA*

Aims: Long acting insulin analogs have been shown to be the preferred insulin for initiated insulin therapy at a point when glycemic control can no longer be adequately controlled without exogenous insulin. This study is a cost-effectiveness analysis comparing insulin detemir (IDet) versus insulin glargine (IGlarg) given to patients initiating insulin.
Methods: The analysis is based on results from real life clinical practice of type 2 diabetes in the US, i.e. data from General Electric EMR database (9/1/2004 to 4/30/2008). Insulin-naïve patients starting on IDet (N=308, age=58.8, male=53.6%) or IGlarg (N=6262, age=58.7, male=50.4%) were identified and analyzed. Overall, insulin analogs reduced blood glucose, HbA1c, by -1.4%-point (from 9.2%), which serves as the base case of the analysis. Controlling for covariates, IDet trended towards an additional HbA1c reduction of -0.216%-point, which was incorporated in the model analysis. A published, validated, peer-reviewed computer simulation model of diabetes (the CORE Diabetes Model) was used to project the difference in outcomes from the HbA1c difference in the analyzed population cohorts. Total direct medical costs (complications and treatment costs) were projected over patient lifetimes, and

future costs and clinical benefits discounted at 3% per annum.
Results: Base case scenario yields a life expectancy of 12.1±0.17 years and 7.75±0.11 quality-adjusted life years. Applying the added HbA1c reduction benefit of IDet, life expectancy and quality-adjusted life expectancy were projected to increase by 0.01±0.14 and 0.031±0.09 years, respectively. Improvements in quality of life are projected from delays of average time to onset of diabetes-related complications. Total lifetime costs/patient of were estimated to be $97,833±2.318 for IGlarg and $97,916±2,227 for IDet. These projected outcomes produce an estimated incremental cost-effectiveness of $2,658 per quality-adjusted life year gained.
Conclusion: Insulin initiation with long-acting insulin analogs effectively improves glycemic control of type 2 diabetes patients in real life clinical practice. In applying the therapeutic benefit of IDet, found in a real life electronic medical records database, to the CORE Diabetes Model, the projection of costs and outcomes suggest that IDet is a cost-effective treatment among previously insulin-naïve patients in a US managed care setting.

P-1598

Rapid-acting insulin aspart reduces cardiovascular complications and costs in type 2 diabetes when compared with human insulin

R.F. Pollock[1], W.J. Valentine[1], T.L. Thomsen[2], H. Nishimura[3]
[1] *Ossian Health Economics and Communications GmbH, HEOR Group, Basel, Switzerland*
[2] *Novo Nordisk A/S, Global Marketing, Virum, Denmark*
[3] *Osaka Saiseikai Nakatsu Hospital, Department of Endocrinology and Diabetes, Osaka, Japan*

Aims: The NICE study was a five-year, open-label, randomized controlled trial that compared cardiovascular outcomes in Japanese type 2 diabetes patients intensively treated with human insulin (HI) or insulin aspart (IAsp), a rapid-acting insulin analog. The cost-effectiveness of IAsp versus HI was evaluated from the perspective of a third-party healthcare payer over a ten-year time horizon (five years based on within-trial observation and five years based on post-trial extrapolation).
Methods: Mortality and cardiovascular event rates from the trial were used to assess within-trial cost-effectiveness and make long-term projections. Cardiovascular events/interventions captured in the Microsoft Excel®-based model included: myocardial infarction, angina pectoris, percutaneous coronary intervention, coronary artery bypass grafting, transient ischemic attack and cerebral infarction. Within-trial mortality and cardiovascular event probabilities were derived from the annual rates observed during the trial period, while post-trial outcomes were calculated using the cardiovascular event and mortality rates from the trial adjusted for increasing age based on data from UKPDS and Japanese life tables. Event costs were calculated from hospital receipt data supplied by the Japanese Medical Data Center. Annual insulin costs were obtained from the trial. Other pharmacy costs (e.g. oral antidiabetic agents and concomitant medications) were assumed to be the same in both treatment arms and were not captured in the analysis. Life expectancy, quality-adjusted life expectancy, cardiovascular event rates and costs were evaluated over a ten-year time horizon. All costs were expressed in 2008 Japanese Yen (JPY) and future costs and clinical benefits were discounted at 3% annually. Sensitivity analyses were performed.
Results: Compared with HI, IAsp was dominant (life- and cost-saving) over a ten-year time horizon. IAsp was associated with an improvement in discounted life expectancy of 0.056 years (9.224 versus 9.168 years) and an improvement in quality-adjusted life expectancy of 0.085 quality-adjusted life years (QALYs) (7.481 versus 7.396 QALYs) versus HI. Patients in the IAsp arm also incurred lower costs (JPY 942,835 versus 1,233,553, difference -290,719) compared with HI. The reduction in cost resulted from the decreased incidence of cardiovascular events with IAsp. Breakdown of costs indicated that drug costs were higher with IAsp (JPY 625,360 versus 495,952), but these costs were more than offset by the reduced costs associated with cardiovascular complications over ten years of treatment.
Conclusion: In a Japanese type 2 diabetes population, prescribing rapid-acting insulin aspart significantly reduced cardiovascular complications, resulting in increased quality of life and decreased costs compared with human insulin

P-1599

Equivalence between capillary, venous whole blood and venous plasma glucose concentrations in non diabetic individuals and type 2 diabetic patients

A. Onana[1], E. Sobngwi[2], K.M. Azabji[3], J. Mbanya[2]
[1] *Faculty of Medicine and Biomedical Sciences, Medicine, Yaounde, Cameroon*
[2] *Faculty of Medicine and Biomedical Sciences, Internal Medicine, Yaounde, Cameroon*
[3] *Faculty of Medicine and Biomedical Sciences, Physiology and Biochemistry, Yaounde, Cameroon*

The diagnosis of diabetes is based on the quantification of glucose in venous plasma, but in most limited-resource settings capillary whole blood is used as an alternative, although not recommended. WHO suggested a +11% capillary whole blood to plasma conversion factor, assuming linearity in equivalence, based on studies involving a limited range of blood glucose concentrations. Whether this applies to a wider range of glucose concentrations is questionable. To verify the equivalence between glucose concentrations measured in plasma, capillary and venous whole blood, we developed a protocol involving an insulin injection followed by graded glucose infusion to induce glucose concentrations variations from 50 to 400mg/dl. We studied 12 adult healthy volunteers in whom we collected simultaneous samples at specific capillary glucose targets (80-120mg/dl, 180-220mg/dl, 280-320mg/dl, 380-420mg/dl). In addition, we recruited 32 diabetic outpatients presenting spontaneously with capillary blood glucose at the similar desired targets, in whom we measured glucose concentration in simultaneously drawn venous and capillary blood samples. For venous whole blood and capillary measurements, we used Hemocue 201, and for plasma, we used a standard glucose oxidase method.
We found no statistical difference between capillary whole blood glucose and venous plasma glucose concentrations at all target glucose concentration levels (ANOVA F = 2.16, P=0.144 for non diabetic participants; ANOVA F =0.09, P=0.766 for the diabetic patients). No statistical difference was found comparing venous whole blood glucose to venous plasma glucose concentrations (ANOVA F =0.19, P=0.661 for non diabetic participants; ANOVA F =0.18, P=0.671 for the diabetic patients). Glucose concentrations on plasma and on whole blood were strongly correlated (r_s=0.953, p<0.01 for plasma versus capillary whole blood and r_s=0.873, p<0.01 for plasma versus venous whole blood). However, overall methods agreement analysis using Bland and Altman plots showed a bias of -7.1mg/dl (95% confidence interval -60.5 to 46.3mg/dl) with capillary whole blood glucose, and -10.5mg/dl (95% CI -69.0 to 48.1) for venous whole blood glucose. In 37% and 15% of measurements in non diabetic individuals and diabetic patients respectively, the difference between adjusted capillary whole blood versus venous plasma glucose concentrations were greater than recommended 20% limit. Fifty-three percent and 30% were greater than the 20% variation from the reference method for non diabetic individuals and diabetic patients respectively when comparing plasma to venous whole blood. These were above the acceptable 20% variation from plasma glucose measurements provided by the ISO.
In conclusion our results showed a good correlation but poor agreement between plasma and whole blood glucose concentrations. Diagnosis of diabetes using non plasma samples should therefore be extremely cautious.

P-1600

Prevalence of type 2 diabetes and related factors in the Cameroon Defence Forces

A. Nkondjock[1], E. Bizome Bigombe[1], M. Mbida[1], J.M. Atah Mgba[1], J.M. Ekoé[2]
[1] *Military Health Department, Research Center for Military Health, Yaounde, Cameroon*
[2] *CHUM Hotel-Dieu, Centre de recherche, Montreal, Canada*

Background: Although type 2 diabetes (T2D) is increasing in the general population in Cameroon, little is known about the prevalence of T2D and its associated risk factors in the Defence Forces.
Aim: To estimate the prevalence of T2D and its related risk factors in the Army population ≥ 21 years, in Yaounde, Cameroon, according to the new diagnostic criteria.
Methods: A cross-sectional study was carried out in Yaounde, Cameroon in November 2008, with 664 soldiers ≥21 years who filled out a lifestyle questionnaire to gather information on physical activity and lifestyle risk factors

and a food frequency questionnaire to ascertain dietary intake. Measurement of glycaemia, arterial pressure, weight, height, waist circumference, and other risk factors for T2D was assessed. The log-binary regression was used for the identification of factors associated with T2D, with the estimate of Odds ratios (ORs) and its corresponding 95% confidence intervals (CIs).
Results and discussion: Age varied from 21 and 59 years (mean age was 37.2 ± 9.6 years). The T2D prevalence was 10.4% (95%CI: 7.1% - 13.8%), and it was higher among officers (13.9%) than warrant officers (10.6%) or enlisted men (7%). After adjustment for physical activity, fibre and total energy intake, the following factors remained independently associated with T2D: family history of T2D (OR=2.22; 95% CI:1.18 - 4,19, p=0.014); rank (OR=2.92; 95% CI:1.28 - 6.62, p=0.01); body mass index (OR=3.32; 95% CI:1.60 - 6.86, p=0.002); waist circumference (OR=2.51; 95% CI: 1.39-4.51, p=0.002) and arterial pressure (OR=2.10; 95% CI:1.21-3.65, p=0.009).
The prevalence rate found in this study is approximately 20-fold higher than that found in a similar U.S Army population and 1.5-fold greater than the general population in Cameroon. The associated risk factors for T2D can be compared with those of other populations.
Conclusion: These findings suggest the need to control obesity and arterial pressure, especially among officers in order to reduce the prevalence of T2D.

P-1601

How does developing diabetes care influence observed incidence of type 2 diabetes?

S. Koski[1], P. Ilanne-Parikka[1], T. Jarvala[2], I. Keskimäki[3], T. Klaukka[4], O. Nylander[3], A. Reunanen[3], R. Sund[3], K. Winell[3]
[1] Finnish Diabetes Association, FinDM II study group, Tampere, Finland
[2] Finnish Diabetes Association / University of Tampere, FinDM II study group, Tampere, Finland
[3] The National Institute for Health and Welfare, FinDM II study group, Helsinki, Finland
[4] The Social Insurance Institution of Finland, FinDM II study group, Helsinki, Finland

Aims: To explore the trends of newly diagnosed cases of persons with type 2 diabetes in relation to activities to develop diabetes care in Finland in 1995-2007. The population of Finland was 5 116 826 in 1995 and 5 300 484 in 2007.
Methods: The FinDM II - study uses individually linked data from several Finnish national administrative registers. All persons diagnosed with diabetes were identified from five sources: the Hospital Discharge Register (1969-2007), the Health Insurance Registers on reimbursement of antidiabetic medication (1994 – 2007) and on entitlements to elevated reimbursement of the medication (1964-2007), Medical Birth Register (1987-2007) and Register of Causes of Death (1988-2006). The linked data was used to identify newly diagnosed cases of type 2 diabetes in 1995 – 2007.
Results: In the late 1990s the Finnish Diabetes association worked actively on developing the prevention and care of diabetes. In 2000, work resulted in the launch of the Development Programme for the Prevention and Care of Diabetes (DEHKO 2000 – 2010). In 2003, the programme was further intensified by starting The Programme for the Prevention of Type 2 Diabetes and its implementation project FIN-D2D. In 2007, the Finnish Medical Society Duodecim launched Diabetes Current Care Guidelines underlining effective diagnosis and medical treatment of type 2 diabetes.
The number of new cases of type 2 diabetes has closely followed the actions to develop diabetes care. In the late 1990s the annual number of new cases of type 2 diabetes remained relatively stable varying between 15 000 and 16 000 in 1995 – 2000. Since then the number has rapidly increased. In the launching year 2003 of the prevention programme, the number of new cases exceeded 18 000 and by the year 2007 when the guidelines were published the number was nearly 29 000.
Conclusion: The observed incidence of type 2 diabetes based on register data on newly diagnosed cases has almost doubled during follow-up (1995 to 2007) in Finland. Besides the lifestyle and personal causes, the growing number of newly diagnosed persons with type 2 diabetes must be seen in context of age-class distribution of the population and health care actions. The adopted active and early screening and identification of persons with type 2 diabetes leads the expectation of decreasing trends in complications of type 2 diabetes in the future.

P-1602

How access to healthcare affects the detection of diabetes: a comparison of the border regions of the U.S. and Mexico

X. Zhang[1], G.L. Beckles[1], K.M. Bullard[1], G. Imperatore[1], X.Z. Zhang[1], E.W. Gregg[1]
[1] Centers for Disease Control and Prevention, Division of Diabetes Translation, Atlanta, USA

Aims: The population of the 10 contiguous states of the US-Mexico Border Region is vulnerable to high risk of diabetes (DM) and limited access to health care. This study assesses the association between healthcare access and detection of DM and explores whether the relationship varies by country.
Methods: Using data from the U.S.-Mexico Border Study, a population-based cross-sectional survey, we identified 127 adult persons (18-64 years) with undetected DM, 218 persons with self-reported diagnosed DM, and 1775 persons without DM residing on the Mexico side of the border region; and 78 persons with undetected DM, 263 persons with self-reported diagnosed DM, and 1559 persons without DM residing on the U.S. side. Those who reported no DM but had fasting glucose = or > 126 mg/dL were classified as undetected, and the others were classified as having no DM. Healthcare access was measured by current healthcare insurance coverage, number of times receiving healthcare over the past year, and routine patterns of healthcare utilization. Stratifying by country of residence, we used logistic regression and predictive margins to estimate the association between undetected diabetes and each of the three healthcare access variables, controlling for age, sex, marital status, education, occupation, body mass index, and perceived health status.
Results: Among persons with DM residing on the U.S. side of the border, the multivariate adjusted percentage of undetected DM was higher among the uninsured (33.2% [SE:9.8%]) than among the insured (12.5% [3.2%]) ($p<0.05$). Among persons with DM in Mexico, the percentage of undetected DM was similar between insured (34.3% [7.6%]) and uninsured (39.2% [5.1%]) ($p=0.5$). Among persons with DM in the U.S., those who received healthcare 0 or 1-3 times over the past year were more likely to have undetected DM (41.2% [13.3%] and 23.5% [6.3%], respectively) than those who received healthcare 4+ times (9.1% [3.7%]) (all $p<0.05$). In Mexico, the percentage of persons with undetected DM did not vary among those receiving healthcare 0 or 1-3 times or 4+ times (39.2% [7.1%], 39.6% [6.5%], and 37.1% [6.7%], respectively). The percentage of undetected DM among those reporting use of urgent care for healthcare was higher than that of those reporting use of private care in both the U.S. (33.7% [12.9%] vs. 10.6% [2.7%], $p<0.05$) and Mexico (59.0% [8.9%] vs. 38.2% [6.9%], $p<0.05$).
Conclusion: On the U.S. side of the border, limited healthcare access was significantly associated with undetected DM. On the Mexico side, healthcare access was less strongly associated with undetected DM, and the percentages of undetected DM among both insured and uninsured on the Mexico side were similar to that of the uninsured on the U.S. side. Efforts to increase detection of DM are urgently needed, especially in Mexico. In the U.S., these efforts should focus on healthcare access.

P-1603

The impact of rural to urban migration on glucose- and diabetes-related risk factors: PERU MIGRANT Study

J.J. Miranda[1], R.H. Gilman[2], L. Smeeth[3]
[1] Universidad Peruana Cayetano Heredia, School of Medicine, Lima, Peru
[2] Johns Hopkins Bloomberg School of Public Health, Department of International Health, Baltimore MD, USA
[3] London School of Hygiene and Tropical Medicine, Department of Epidemiology and Population Health, London, United Kingdom

Objectives: To describe differences in glucose- and diabetes-related risk factors amongst migrants from Ayacucho, a rural area, to Lima, an urban area, and those who did not migrate.
Methods: Cross-sectional study, three groups: 1) always lived in Ayacucho (n=289); 2) migrated from Ayacucho to Lima (n=589); and, 3) always lived in Lima (n=199). Age- and sex-adjusted standardised mean differences (SMD) for continuous variables were calculated with rural group as baseline with linear regression.
Results: Rural people had fasting glucose geometric mean (GM) of 79.9 mg/dL (95% CI 77-83) and insulin GM 2.7 μIU/mL (2.3-3.2). Migrant and urban people had greater glucose (9% (5-12) and 13% (8-17)), greater insulin (193% (135-266) and 251% (167-362)) and greater HOMA insulin resistance

(202% (156-257) and 245% (181-324)) than rural group, respectively. Diabetes (glucose ≥126 mg/dL) and impaired fasting glucose plus diabetes (IFG, fasting glucose ≥110 mg/dL) prevalences doubled from rural to migrant to urban groups: 0.5%, 2.2% and 5% for diabetes and 1.5%, 4% and 7% for IFG plus diabetes, respectively.
Compared to rural people, the size of differences observed were markedly high, with a difference of more than 1 SD unit, for insulin and insulin resistance. Glucose also had an important size of difference, of 0.5 SD for migrants and nearly 1 SD unit for urban people. HbA_{1c} was only higher in the urban group but no difference was observed in migrants.
Migrants' median age at first migration and years lived in an urban environment were 14.4 years (IQR 10-17) and 32 years (IQR 25-39), respectively. Within the migrant group, compared to those who migrated aged 12yo or less, a tendency towards increased chances of diabetes (OR 7.5 (1-58.7)) and IFG or diabetes (OR 6.6 (1.5-28.6)) was observed in those who migrated >12yo. No clear pattern was observed when classified by lifetime exposure to urban environment or number of years in urban environment.
Conclusions: The findings of this study suggest the impact of migration on glucose- and diabetes-related factors is more complex than previously described. Diabetes and IFG prevalences double from rural to migrant to urban groups. Within migrants, the impact of migration appears to differ by age at first migration but not length of exposure to urban environment.

An open source statistical engine for the automatic production of standardized diabetes indicators within and across regions: results of the BIRO project

F. Carinci[1], L. Rossi[1], M. Massi Benedetti[2], BIRO Consortium (3)
[1] Serectrix, Health Systems Research, Pescara, Italy
[2] University of Perugia, Internal Medicine, Perugia, Italy
[3] European Project Consortium, European Commission, Brussels, Belgium

Aim: The EU DG-SANCO co-funded BIRO project aims at building a shared information system through the application of two consecutive data processing steps, locally and centrally. A participating region maintains a Postgres database of resident data exported with common criteria. A statistical engine is required to deliver a standardized report for each region, including all diabetes indicators agreed by a literature review, and to derive aggregate tables that are sent to a central server to produce a global report based upon the same structure.
Methods: R software has been adopted as a development platform for the statistical engine, connected to the database through drivers publicly available. The concept of "statistical object" has been introduced to create aggregate tables from local data that can be sent over the network as encrypted comma delimited files. A taxonomy has been specified to provide details of all objects implemented. Graphical R functions and Latex have been used to produce individual centre and overall reports in .html and .pdf format, at agreed intervals of 6 months.
Results: The statistical engine has been successfully developed and tested on both MS Vista and Fedora Linux. Average hardware allowed completing all steps from a test sample of 17,0000 patients and over 90,000 episodes in about 20 minutes. Installation of the software is identical regardless of hardware, requiring R>1.8, Latex (Miktex), Java 6.0 and PostgreSQL. All software is released under the GPL license.
Conclusion: The statistical engine provides a platform for accurate benchmarking that currently does not exist at the point of health care provision. It may serve multiple users, from the EU/NGOs, to provide updated benchmarking of key indicators on a routine basis, to the local physician, to monitor the status of patients in a modern standardized procedure. The system may improve, through a shared infrastructure, the validity and completeness of information available. Users, once inducted to using the software, can apply it independently and build up indicators of higher quality and comparability, to be exchanged safeguarding privacy at the highest level of protection, as a result of the application of rigorous rules set in BIRO by the privacy impact assessment. The application of the statistical engine in regional and individual clinical units can help evaluating clinical practice more rapidly and efficiently. Adoption of open source technology may spread the adoption of the engine at no cost, making it available in deprived areas and worldwide to organizations e.g. the IDF. At the same time, it would allow refining statistical procedures, improving the capacity of current registers to translate data into action.

P-1605

Prevalence and risk factors for diabetes mellitus in a suburban population of Northeastern Nigeria

B.M. Mubi[1], S.J. Yahaya[2], I.D. Gezawa[1], I. Halliru[1], B. Bakki[1], B.O. Omotara[2]
[1] University of Maiduguri Teaching Hospital, Medicine, Maiduguri, Nigeria
[2] University of Maiduguri Teaching Hospital, Community Medicine, Maiduguri, Nigeria

Objectives: To determine the prevalence of diabetes mellitus (DM) and its associated risk factors in a suburban population of Northeastern Nigeria.
Methods: This was a cross-sectional study of consenting adults aged 17 years and above resident in Gwoza, a suburban community near Maiduguri, the state capital of Borno, Northeastern Nigeria. A questionnaire on sociodemography, personal and family history of DM and hypertension was administered. Height, weight, waist and hip circumference were measured and the body mass index (BMI), waist-to-hip ratio and waist-to-height ratio (WHtR) were calculated from the values obtained. Blood pressure (BP) was measured on the right arm with the subject sitting quietly after 5 minutes of rest. The average of two readings 1 minute apart was used. Casual plasma glucose (CPG) levels were determined using a glucometer (Liberty® Blood Glucose Monitoring System). DM was defined as CPG ≥ 11.1 mmol/L. Hypertension was deemed present if BP > 140/90mmHg. Two tailed students t-test was used to compare means. Pearson's correlation was used to determined the relationship between the risk factors. Multiple logistic regression analysis was employed to estimate the odds ratio (OR) of the risk factors for the development of DM. In all cases p-values < 0.05 were considered significant.
Results: A total of 1140 subjects made of 792 (69.5%) males and 348 (30.5%) females were studied. The mean age of the subjects was 42.9 (12.8) years [39.9 (12.7) among females and 44.3 (12.6) among males, $p < 0.05$]. Overall the crude prevalence of DM was 4.6%. the prevalence was 4.8% in males and 4.0% in females (M:F = 1.2: 1), being higher in males than in females, $p = 0.04$. Majority of the identified diabetics were ≥ 30 years of age, while only 3.8% were younger than 30 years of age. The risk factors for DM identified were increasing age, BMI, WC, WHR, WHtR and presence of hypertension. Family history of DM was not found to be a risk factor in this study. Of all the risk factors only BMI was found to be an independent risk factor for DM [OR = 3.29 (95% CI 1.229- 8.836), $p = 0.018$].
Conclusions: The prevalence of 4.6% found in this community is higher than previously reported in similar populations across Nigeria. The finding of increased BMI as an indepedent risk factor for DM in this study, underscores the need for concerted efforts to control the scourge of obesity through intense campaign on the importance of lifestyle modification. This will go a long way in reducing the rising trend of DM in our environment.

Regional prevalences of diabetes mellitus and intermediate hyperglycemia in Kisantu, Bas-Congo, D.R. Congo: comparison of ADA 2003 and WHO/IDF 2006 criteria

M.T. Muyer[1], F. Buntinx[2], M.A. Mapatano[1], I. Bieleli[3], J.R. Makulo[3], W.K.D. Kaimbo[3], M. Mvitu[3], W. Kimenyembo[3], B.A. Mandja[1], W. Okitolonda[1], P. Kimbondo[4], E. Muls[5]
[1] University of Kinshasa, School of Public Health, Kinshasa, Democratic Republic of Congo
[2] Catholic University of Leuven, General Practice, Leuven, Belgium
[3] University of Kinshasa, University Hospital, Kinshasa, Democratic Republic of Congo
[4] St-Luc Hospital, Internal Medicine, Kisantu, Democratic Republic of Congo
[5] Catholic University of Leuven, Endocrinology, Leuven, Belgium

Aim: Prevalences of diabetes mellitus (DM) and intermediate hyperglycemia (IH) have not been evaluated previously in D.R.Congo. Data for DRC (DM 3.1%; IGT 7.4%) in the IDF Diabetes Atlas (3rd edition 2006) were extrapolated from studies in populations with a different ethnic background (Tanzania: MacLarty 1989; Aspray 2000). We have therefore evaluated regional prevalences of DM and IH in Kisantu, a semirural area in Bas-Congo province, DRC, using both ADA 2003 and WHO/IDF 2006 criteria.
Methods: The 2007 study was carried out in Congolese residents of Kisantu aged ≥ 20 years.

A representative sample (n=2025) of the population was selected. Fasting capillary glucose (FCG) was measured on day 1 using a Glucocard X-Meter. On day 2 FCG was repeated in subjects with FCG 126-199 mg/dl on day 1, and 2-h 75 g glucose was measured in those with FCG 100-125 mg/dl on day 1. WHO/IDF 2006 criteria were used for DM and IH. These results were compared with ADA 2003 criteria.

Results: Participation rate was 93% (1898/2025). Data for analysis were available in 1866 subjects (92%) (65% female; 51.5±16 years; BMI 22±5 kg/m^2). Regional prevalence of DM was 4.7% (3.2% known cases; 1.5% newly diagnosed cases). IH prevalence was 4.8% or 13.7% according to 2006 WHO/IDF or 2003 ADA criteria, respectively.

	WHO/IDF 2006		ADA 2003	
	n	%	n	%
Diabetes mellitus	88	4.7	88	4.7
Impaired Glucose Tolerance	27	1.5	41	2.2
Impaired Fasting Glucose				
100-125 mg/dl			215	11.5
110-125 mg/dl	62	3.3		
Normal	1689	90.5	1522	81.6

Age of DM subjects was higher than in non-diabetic subjects (p=0.03). BMI was elevated in both DM and IH subjects (P<0.01):

		Normal	DM	IH
Gender	M n (%)	596 (90.4)	36 (5.5)	27 (4.1)
	F n (%)	1093 (90.6)	52 (4.3)	62 (5.1)
Age (years)		51 ± 17	56 ± 15	52 ± 18
BMI (kg/m^2)		22 ± 5	23 ± 5	23 ± 5

Conclusion: DM regional prevalence of 4.7% in Kisantu, Bas-Congo, is higher than previously reported for DR.Congo (IDF Diabetes Atlas 2006). Regional IH prevalence varies widely depending on the choice of diagnostic criteria: 4.8% versus 13.7% according to 2006 WDF/IDF or 2006 ADA criteria, respectively.

P-1607

Mean values of cardiovascular risk factors in Spanish workers with impaired fasting glucose, type 1 and type 2 diabetes. ICARIA-DM study

M. Cabrera[1], E. Calvo[1], J. Román[1], C. Fernández-Labandera[1], M.A. Sánchez[1], F. Gutiérrez[1], A. Goday[2], J. Reviriego[3], E. Caveda[3], M.I. Hernández[4], M.I. Núñez[4], R.B. Rabanal[1]

[1] *Ibermutuamur, Sanitary Projects, Madrid, Spain*

[2] *Hospital del Mar, Department of Endocrinology and Nutrition, Barcelona, Spain*

[3] *Lilly S.A., Department of Clinical Research, Madrid, Spain*

[4] *Ibermutuamur Health Surveillance Society, Occupational Medicine, Madrid, Spain*

Background and aims: To know the mean values of cardiovascular risk factors among subjects with normal and abnormal glycemic profile [impaired fasting glucose (IFG), type 1 DM (T1DM) and type 2 DM (T2DM)] and to compare the different groups, within a nationwide Spanish working population.

Material and methods: This was a cross-sectional study of 375,607 workers, 72.3% male (M), with a mean age (SEM) of 36.87 (0.02) yr. All subjects underwent a routine medical check up from January 2007 to December 2007 at Ibermutuamur. A structured questionnaire, physical examination and standard serum biochemical analysis were performed. IFG was defined as fasting glucose levels between 100-125 mg/dl (without T1DM or T2DM diagnosis)[1]; T1DM (previous diagnosis of T1DM); T2DM (previous T2DM diagnosis, oral antidiabetic agents or insulin treatment or fasting glucose levels ≥ 126 mg/dl)[1]. Bivariated analyses were conducted comparing cardiovascular risk factors between altered glucose metabolism groups and non altered subjects.

Results: Anthropometric/biochemical parameters of subjects with normal glucose metabolism, IFG, T2DM and T1DM are presented in Table 1. The mean prevalence for T1DM, T2DM and IFG was: 0.3 % (95% CI, 0.00 - 0.62), 2.39% (95% CI, 2.07 - 2.71) and 10.39% (95% CI, 10.09 - 10.69), respectively.

	Normal population (n=326448)	IFG (n=39007)	T2D (n=8978)	T1D (n=1138)
Age (years)	35.7 ± 0.0	*43.4 ± 0.1	*50.2 ± 0.1	*38.1 ± 0.4
Weight (kg)	74.6 ± 0.0	*81.7 ± 0,1	*85.3 ± 0.2	*76.5 ± 0.4
Abd. Per (cm)	87.0 ± 0.0	*95.1 ± 0.1	*101.2 ± 0.2	*89.6 ± 0.6
SBP (mmHg)	124.6 ± 0.0	*134.6 ± 0.1	*142.2 ± 0.2	*131.0 ± 0.6
DBP (mmHg)	75.2 ± 0.0	*81.1 ± 0.1	*84.4 ± 0.1	*77.4 ± 0.4
BMI (kg/m2)	25.6 ± 0.0	*28.0 ± 0.0	*29.8 ± 0.1	*26.2 ± 0.1
Glycemia (mg/dl)	83.5 ± 0.0	*106.4 ± 0.0	*163.3 ± 0.6	*174.6 ± 2.5
Total cholesterol (mg/dl)	194.7 ± 0.1	*212.8 ± 0.2	*215.2 ± 0.5	194.2 ± 1.3
LDL- chol (mg/dl)	116.9 ± 0.1	*129.5 ± 0.2	*127.2 ± 0.4	*113.5 ± 1.0
HDL- chol /mg/dl)	58.0 ± 0.0	*57.2 ± 0.1	*53.8 ± 0.1	58.7 ± 0.5
Triglycerides (mg/dl)	103.1 ± 0.1	*138.3 ± 0.6	*189.6 ± 1.9	*118.4 ± 3.7
Uric acid (mg/dl)	4.9 ± 0.0	*5.5 ± 0.0	*5.3 ± 0.0	*4.2 ± 0.0
Creatinine (mg/dl)	1.0 ± 0.0	*1.0 ± 0.0	*1.0 ± 0.0	*1.0 ± 0.0
EGFR** (ml/min/1,73m^2)	88.9 ± 0.0	*86.7 ± 0.1	*88.1 ± 0.2	*91.20 ±0.5

Table 1. Anthropometric/biochemical parameters. Mean values ± SE. *p < 0.001 versus normal population. **Estimated Glomerular Filtration Rate (Abbreviated Modification of Diet in Renal Disease Study –MDRD-4- Equation).

Conclusion: In a nationwide Spanish working population, glycemic profile alterations coexist with a pathological pattern in other cardiovascular risk parameters. This data stress the need to promote and reinforce lifestyle intervention programs within working population.

Development of the Nova Scotia Diabetes Repository: A project of the Nova Scotia Diabetes Repository Advisory Committee

Z. Karlovic[1], P. Dunbar[1], P. Talbot[1]

[1] *Diabetes Care Program of Nova Scotia, NS Department of Health, Halifax, Canada*

Background: The Diabetes Care Program of Nova Scotia (DCPNS) maintains a comprehensive registry of clinically confirmed diabetes (DM) cases; however, only Diabetes Centre attendees are represented (about 70% of DM population in NS). The Nova Scotia Atlee Perinatal Database (NSAPD) and Nova Scotia Seniors' Pharmacare Database (NSSPD) also contain gold standard DM cases, but for a limited population. The National Diabetes Surveillance System (NDSS) derives nationally comparable DM statistics using administrative data; however, these cases are estimated not clinically confirmed. Combining data from various Programme Databases with routinely collected administrative data could greatly enhance DM case ascertainment. In Nova Scotia, all of these data sources are readily linkable, making the province an ideal sentinel surveillance site for DM in Canada.

Aims: To determine the technical and organizational requirements for combining data from disparate sources into an ongoing Nova Scotia Diabetes Repository (NSDR)

Methods: An advisory group with one or more representatives from each partner as well as expert consultants and several working groups identified organization and technical requirements for constructing a sustainable NSDR. These issues were addressed and a provisional NSDR was constructed using data from the DCPNS Registry, NSAPD, NSSPD, and NDSS. The repository was tested using 7 preapproved requests.

Results: Each partner has a specific mandate to collect personal information about the population it serves. Sharing these data across programmes required a Privacy Impact Assessment. Some ethical and jurisdictional issues were also clarified. To streamline access, a single Application for Access to Provisional NSDR Data was developed to replace several Programme-specific applications. Programme-specific case definitions were used to extract 107,643 unique DM cases from 1996/97 to 2005/06 for the provisional NSDR. Of the 81,447 cases for 2005/06, 33% were found in 1 source, 48% in 2 sources, and 19% in 3 sources. No single case appeared in all 4 sources.

Discussion: Many fully engaged partners collaborated successfully to develop the provisional NSDR. This work will in turn attract more partners, further enhancing the NSDR. A third of DM cases were contributed by a single partner, highlighting the importance of collaboration to DM surveillance. Merging disparate data sources identified several data quality issues, resulting in improved data quality for both the NSDR and the contributing partners.

Defining the best architecture for secure data exchange of diabetes information in Europe: privacy impact assessment in the BIRO project

C. Di Iorio[1], F. Carinci[1], J. Azzopardi[2], P. Beck[3], S. Cunningham[4], S. Skeie[5], G. Olympios[6], S. Pruna[7], M. Massi Benedetti[8], BIRO Consortium (9)
[1] *Serectrix, Pescara, Italy*
[2] *University of Malta, Malta,*
[3] *Joanneum Research, Austria,*
[4] *University of Dundee, Scotland, United Kingdom*
[5] *NOKLUS, Norway,*
[6] *Cyprus Ministry of Health, Cyprus,*
[7] *Telemedica Consulting, Romania,*
[8] *University of Perugia, Internal Medicine, Perugia, Italy*
[9] *European Project Consortium, European Commission, Brussels, Belgium*

Aims: The BIRO project involves the use of sensitive-medical data collected through diabetes registries, standardized, exchanged and further processed to support the routine publication of diabetes reports across Europe. Privacy impact assessment is a systematic process allowing to optimise the system based upon the study of its impact upon privacy. Aim of a specific project work package is to provide a definitive description of privacy risks, applicable privacy legislation and mitigation strategies adopted in the implementation and management of the BIRO system.
Methods: Four steps have been carried out: preliminary assessment, data flow analysis, privacy analysis and final report. Preliminary assessment was conducted by a multidisciplinary team carrying out a systematic review of the privacy literature and a general discussion on the data flow focused on alternatives identified in the first step. A Delphi consensus procedure was used to define the best alternative through the use of data flow tables, an information flow questionnaire and an overall consensus table. Privacy analysis covered any privacy issue arising in the transfer of data from the local centres to the central database. Potential privacy risks have been explicitly listed to indicate mitigation strategies to be implemented. The final report compiled all results according to a structured format.
Results: Preliminary analysis identified three candidate architectures, with differing levels of data sharing: "individual patient data, de-identified through a pseudonym"; "aggregation by group of patients, with Centre's identifiers available in de-identified form, securely encrypted"; and "Aggregation by Region". The second has been identified as best solution in terms of privacy protection, information content, scientific soundness and feasibility. Privacy analysis performed a detailed assessment of the various aspects involved in the adoption of the final BIRO architecture.
Conclusion: Privacy is a fundamental right of diabetic patients that must be carefully taken into account in the construction of information systems promoted by the IDF. According to Recital 26 of the EU Data Protection Directive and other relevant legislation, transborder data flow and data processing envisaged in BIRO is legally viable. Privacy impact assessment shows that the selected architecture flexibly affords the best privacy protection in the construction of an efficient model for the continuous production of European diabetes reports.

Lifestyle and environmental risk factors associated with progression of diabetes in British Columbia, Canada

K. Atwood[1], K. Reimer[1], P. McCrea[1], B. Fisk[1], K. McDonald[1], R. Smith[1], R. Mercer[1], M. DesMeules[2], W. Luo[2], M.P. Dressler[2], L. Gibbons[2]
[1] *BC Ministry of Healthy Living and Sport, Population and Public Health, Victoria, Canada*
[2] *Public Health Agency of Canada, Health Promotion and Chronic Disease Prevention Branch, Ottawa, Canada*

Aim: The purpose of this research was to use a unique data linkage study, using both self-report and administrative data, employing the case definition of diabetes used in the Canadian National Diabetes and Chronic Disease Surveillance System (NDCSS), to study the relationship between these factors and diabetes progression.
Methods: Residents of British Columbia were classified as having diabetes according to a previously validated case definition based on physician and hospital claims from administrative health records. Degree of diabetes progression (including pre- and post-diagnosis and a hierarchy of severity that distinguished between diagnoses early in the progression of diabetes and those at a more advanced stage) was determined by accumulated evidence from administrative data of physician services, hospitalizations, and prescription usage, in terms of presence of comorbidities and duration of diabetes case definition. Self-reported data from the Canadian Community health Survey (CCHS) Cycles 2.1 and 3.1 for BC residents was linked to administrative data for consenting respondents. Logistic regression models were used to determine whether there were any significant differences between persons without diabetes and those with early, medium, or advanced stage diabetes at the time of diagnosis.
Results: A total of 1,737 persons with diabetes were identified. Of these, 343 were surveyed prior to a confirming diagnosis of diabetes. 646 were at a mild stage of disease, 746 experienced a moderate stage, and 345 experienced an advanced stage of diabetes.
Persons with advanced stage diabetes were more frequently former drinkers and smokers, ate more fruits and vegetables, were least active, reported higher levels of stress and a weaker sense of belonging, were more often exposed to second hand smoke, were more likely to be at an increased weight, more frequently perceived their health to be poor, reported an unmet health care, and experienced greater mortality in comparison to those with mild or moderate stage diabetes, as well as in comparison to persons without diabetes.
Discussion/conclusion: Results from our unique data linkage study suggest substantial differences in lifestyle and environmental factors associated with more advanced stages of diabetes, and poorer overall outcomes. In some cases it appears that respondents with advanced stage diabetes have adapted some lifestyle factors to address diabetes. However, decreased physical activity levels among those with advanced stage diabetes may contribute to increased weight. Environmental factors, such as a sense of belonging to the community, second hand smoke exposure, and perceived unmet health care needs may also contribute to progression of diabetes and complications.

Prevalence of metabolic syndrome and acanthosis nigricans in students from 6 to 12 years who present overweight and at risk of obesity in elementary school, Hidalgo, Mexico

Z. Calderon[1], M. Velazquez Bautista[2], A. Atitlan Gil[3], M.A. Morales de Teresa[4], J. Rodriguez Saldaña[5], A. Omaña Covarrubias[2], A. Peña Irecta[1], G. Betanzos Cabrera[1]
[1] *Universidad Autonoma del Estado de Hidalgo, Area Academica de Nutricion, Pachuca, Mexico*
[2] *Universidad Autonoma del Estado de Hidalgo, Student of Licenciatura en Nutricion, Pachuca, Mexico*
[3] *Universidad Autonoma del Estado de Hidalgo, Area Academica de Odontologia, Pachuca, Mexico*
[4] *Resultados Medicos Desarrollo e Investigacion, Research Director, Pachuca, Mexico*
[5] *Resultados Medicos Desarrollo e Investigacion, General Director, Pachuca, Mexico*

Overweight and obesity are increasing among children, there the early development of chronic diseases has increased, when it appears as common

precedent of metabolic syndrome, however the overweight is linking with acanthosis nigricans. Acanthosis nigricans is a clinical sign that associated hyperinsulinemia and type 2 diabetes. Nowadays, Mexico is the number one in the statistics with obese children.

Aims: Establishing the prevalence and the association between the metabolic syndrome and acanthosis nigricans in school-children who present overweight and risk of obesity. Before we will relate it with diet, exercise and physical activity in students of the elementary school on March 18 students, Pachuca, Hidalgo.

Methods: Study observational, transversal and descriptive. They included 215 students between 6 to 12 years, we applied a survey which include clinical interview, frequency of consumption, physical exploration [weight, height, Body Mass Index (BMI), abdominal perimeter, arterial tension], and blood tests [cholesterol HDL, triglycerides and fasting glucose]. The metabolic syndrome diagnosis was performed according to the International Diabetes Federation. The presence of acanthosis nigricans was assessed in children with BMI ≥ percentile 85°, AN was located on the neck, knee, elbow, palm of the hands and sole of the feet.

Results: According to BMI 45% had normal weight, 21% overweight and 34% had risk of obesity. The prevalence of metabolic syndrome was 9%, 23% had high risk of developing it and 68% didn't present it. The prevalence of acanthosis nigricans was 35%, the neck was the most frequent area. In the analysis in the association of variables the prevalence of metabolic syndrome was linked by acanthosis nigricans specially in those that presented risk of obesity ($Xi^2 = 53.455$, $p < 0.05$), sedentary activity ($Xi^2 = 42.119$ $p < 0.05$), who does < 150 min of exercise a week ($Xi^2 = 48.473$, $p < 0.05$), hypercaloric diet ($Xi^2 = 11.833$), rich in carbohydrates ($Xi^2 = 27.725$) and fats ($Xi^2 = 37.730$ $p = 0.05$).

Discussion/conclusion: The students with overweight and risk of obesity had more predisposition of development metabolic syndrome and acanthosis nigricans, because they presented abdominal obesity which is the most significant criteria to diagnosis in the IDF definition to metabolic syndrome. While the acanthosis nigricans is a sign of alert in children who are obese, though all of these had been a consequence of unhealthy habits and sedentary activity.

P-1612

Monotonic increase in type 2 diabetes risk with lower education in women, concentrated risk increase among least educated men

K. Dasgupta[1], S. Khan[2], N. Ross[3]
[1] *McGill University, Department of Medicine, Montreal, Canada*
[2] *Statistics Canada, Health Information and Research Division, Ottawa, Canada*
[3] *McGill University, Department of Geography, Ottawa, Canada*

Aims: We sought to assess type 2 diabetes (T2D) risk by income and by education among Canadian men and women.

Methods: Data were obtained from the first wave of the Canadian Community Health Survey (2000/2001), a national cross-sectional population-based survey designed to collect information on the health status and health care use of Canadians. Using logistic regression (SAS version 9.1.3), we assessed (separately in men and women) for associations of T2D with educational level (less than high school, high school without post secondary, some post secondary). The highest education category (some post secondary) was the reference group. Associations were assessed separately in men and women through unadjusted models, age-adjusted models, and multivariate models models (ethnocultural group, immigrant status, urban vs. rural residence, weight status, physical inactivity, smoking status, other chronic conditions, regular physician).

Results: Among the 131,535 individuals surveyed, 87,309 fulfilled eligibility criteria (41,814 men and 45,495 women). In age-adjusted models, women with less than a high school education were more than twice as likely to have T2D (OR 2.16, 95% CI 1.85 to 2.54) while women with high school education only were 33% more likely compared to women with some post secondary education (OR 1.33, 95% CI 1.12 to 1.58). Further adjustment for other demographic and clinical variables somewhat attenuated these associations such that women with less than a high school education were 70% more likely to have T2D (OR 1.72, 95% 1.46 to 2.03) and women with high school education only were 26% more likely to have T2D compared to women with some post secondary education (OR 1.26, 95% CI 1.06 to 1.50) In age-adjusted models, men with less than a high school education were 36% more likely to have T2D compared to men with some post secondary education (OR 1.36, 95% CI 1.17 to 1.58). Further adjustment for other demographic and clinical variables slightly attenuated the risk increase observed in the least educated men to 26% (OR 1.26, 95% CI 1.08 to 1.48). There were no differences between men with high school education only and men with some post secondary education in either age-adjusted (OR 0.95, 95% CI 0.80 to 1.14) or fully adjusted models (OR 0.93, 95% CI 0.78 to 1.12).

Discussion: The least educated Canadian women and men are at highest risk for T2D. Further, we have detected a monotonic risk increase with lower levels of education in women but no such gradient in men. Higher levels of education appear to offer a sort of "inoculation" against T2D, particularly in women.

Prevalence of type 1 diabetes in north India: a physician and chemist-based district level assessment

S. Kalra[1], B. Kalra[2], A. Sharma[2], A. Ahalawat[3]
[1] *Bharti Hospital, Endocrinology, Karnal, India*
[2] *Bharti Hospital, Diabetology, Karnal, India*
[3] *Bharti Hospital, Clinical Research, Karnal, India*

Little work has been done on the prevalence of type 1 diabetes in North India. This paper reports the prevalence of type 1 diabetes in Karnal District of Haryana state, India as assessed by a hospital-based registry and by inputs from chemists and other physicians. Data of all type 1 diabetes patients attending the only endocrine OPD in the region was analysed, and screened for patients living in the district. All chemists in insulin business were contacted through wholesalers of the drug and requested about details of children purchasing insulin. Similarly all 18 paediatricians and 22 internists working at other urban centres within the district were requested for details of patients being treated by them. All names and addresses were cross checked to avoid duplication. Population data was taken from the 2001 national census.The survey revealed 79 male and 51 females with type 1 diabetes in the district. Of these 54 men and 36 women were from urban areas, while 25 men and 15 women were from a rural background.The overall prevalence of type 1 diabetes in Karnal district was 10.20/100,000 population (130/1274183), with a higher prevalence in urban areas: 26.6/100,000 (90/337842) as compared to rural areas: 4.27/100,000 (40/936341).Karnal City, with a population of 222017, showed a high prevalence of type 1 diabetes 31.9/100,000 (total 71 patients). The prevalence in men was much higher (11.56/100,000 or 79/683368) than in women (8.6/100,000 or 51/590815).Prevalence was 21.2/100,000 (3/14119) and 18.2/100,000 (2/10931) in boys and girls, aged 0 to 6 years respectively, yielding a total of 19.9/100,000 (5/25090). This work highlights the relatively high incidence of type 1 diabetes in North India, with a high male:female gender ratio, and high urban:rural gradient, using a simple, economical methodology. This methodology may be appropriate for assessing the prevalence of diabetes in many developing nations.

Up-date on the epidemiology of childhood type 1 diabetes mellitus in Romania: ONROCAD Study Group

V. Serban[1], A. Vlad[1], A. Trailescu[2], V. Botea[2]
[1] *University of Medicine and Pharmacy "Victor Babes", Diabetes Clinic, Timisoara, Romania*
[2] *Districtual Hospital, Diabetes Clinic, Timisoara, Romania*

Aims: Starting year 1996, Romanian National Organization for the Protection of Children and Adolescents with Diabetes (having the acronym ONROCAD) gathered, centralized and worked up data regarding epidemiology of type 1 diabetes mellitus (T1DM) in Romanian children (aged 0-14 years) and issued the National Diabetes Registry for Children, updated every year. The aim of this work was to evaluate the evolution of the incidence of childhood T1DM over the last 10 years and to reveal some characteristics according to gender and age group.

Methods: The information regarding new cases of T1DM in children was obtained from 3 sources: 1. The National Diabetes Registry for Children; 2. Medical records from Clinical Center "Cristian Serban" Buzias; 3. Medical records from the 41 regional diabetes centers. The databases from these sources were merged, in order to obtain as accurate information as possible. Demographic data were retrieved from the National Institute of Statistics.

Results: The yearly incidence of T1DM in children, according to gender and age group, for the last 10 years, is presented in the table.
Table. Incidence (no. of cases/100,000) of T1DM in Romanian children between years 1999 and 2008

Incidence	1999	2000	2001	2002	2003	2004	2005	2006	2007	2008
0-14 years	5.14	5.25	5.52	5.61	5.91	6.27	6.80	7.35	8.81	7.71
0-5 years	2.96	2.53	2.20	2.37	3.25	3.01	3.89	3.78	5.48	4.34
5-10 years	4.65	5.25	5.67	6.67	6.76	8.38	7.57	8.37	9.64	8.19
10-14 years	7.41	7.49	8.25	7.51	7.59	7.33	9.09	10.19	11.57	10.93

A constant increase in the incidence of T1DM was noted, for both genders, with a peak in year 2007. This was determined by 2 factors: 1. Increase in number of new cases of T1DM in children – 199 (year 1999), 197 (2000), 202 (2001), 195 (2002), 198 (2003), 203 (2004), 213 (2005), 228 (2006), 273 (2007) and 239 (2008); 2. Decrease of the number of inhabitants aged 0-14 years during the 10 years interval. There was no rule regarding the dominance of a gender. The highest incidence was noted in age group 10-14 years.
Conclusion: The incidence of T1DM in Romanian children had an ascending trend in the last 10 years, as a consequence of the higher number of new cases and a decrease in population in this age-group. The most affected age group is 10-14 years.

The metabolic syndrome in Bolivian adolescents: does residence at altitude protect against the metabolic syndrome ?

A. Baya[1,2], A. Perez-Cueto[3], P. Monllor-Vasquez[4,5], P. Kolsteren[1,2]
[1] *Prince Leopold Institute of Tropical Medicine, Department of Public Health, Antwerp, Belgium*
[2] *Ghent University, Department of Food Safety and Food Quality, Ghent, Belgium*
[3] *Ghent University, Department of Agricultural Economics, Ghent, Belgium*
[4] *Universidade de Campinas, Faculdade de Engenharia dos Alimentos, Universidade de Campinas*
[5] *Universidad del Valle, Facultad de Ingenieria de Alimentos, Cochabamba, Bolivia*

Objective: To describe the prevalence of risks factors and Metabolic Syndrome (MetS) in Bolivian adolescents, focusing on the role of altitude of residence.
Design: Nationally representative cross-sectional survey.
Subjects: Sample of 2578, age 12-18, (45% males, 55% females) adolescents from the Metabolic Syndrome in Adolescents Study.
Methods: MetS International Diabetes Federation (IDF) criterion components data and altitude of residence were evaluated by standard procedures.
Results: The overall prevalence of MetS was 7.7% (girls 8.1%, boys 7.1%) showing a gradient variation of lower prevalence at higher altitude: 11.1% <1500m vs 6.5% ≥1500m, p<0.0001. MetS was found in 47.6% of obese, in 19.8% of overweight, in 4.0% healthy weight and absent in thin adolescents. Healthy weight girls presented higher prevalence of MetS (p=.012) than healthy weight boys (5.0% vs 2.8%). Prevalence among obese boys was higher (p=.011) than in obese girls (59.7% vs 38.3%). Risk factors (1 or more) were present in 86.5% of the adolescents, rising from 75.5% at age 12 to 91.1% at age 18. The prevalent abnormality was low HDL-c level, (79.3%), followed by hypertriglyceridemia (16%), abdominal obesity (15%), high blood glucose (12.7%) and high blood pressure (5.6%). Multivariate binary logistic regression model adjusted by gender, nutritional category and altitude revealed that living at high altitude decreased the odds-ratio of hypertriglyceridemia by a factor of 0.5, while abdominal obesity increased it by 2.1, hypertension by 1.6, and hyperglycemia by 2.2 times. Overall prevalence of MetS as well as HDL-c levels showed no differences by altitude when gender and category of BMI-per age were controlled.
Discussion: Altitude can be protective against some MetS risk factors and detrimental to other, although overall prevalence is lower at high altitude. The interactions of MetS risk factors at altitude remain to be investigated to explain lower frequencies of cardiovascular mortality reported at high altitude.

Type 2 diabetes in younger people is becoming more common in Bangladesh

S. Khan[1], M.A. Sayeed[2], R. Amin[3], T. Begum[4], P.A. Khanam[4], Fahad.B.M (1), B. Mashroor[1], S.A. Khan[4]
[1] *North South University, Pharmacy, Dhaka, Bangladesh*
[2] *Ibrahim Medical College, Community Medicine, Dhaka, Bangladesh*
[3] *BIRDEM, Department of Gynecology and Obstetrics, Dhaka, Bangladesh*
[4] *BIRDEM, Research Division, Dhaka, Bangladesh*

Background and Aims: Diabetes registry at Bangladesh Institute of research and rehabilitation of Endocrine and Metabolic disorders (BIRDEM), a referral center in Dhaka, has exceeded 300000 by December 2008. The registry showed an increasing proportion of younger diabetic patients. Some studies also reported that despite overwhelming malnutrition in the population, obesity in the young is on the increase. This study addressed whether there was an early onset of diabetes affecting younger people and whether obesity in the young is related to early onset.
Subjects and Methods: This retrospective study was conducted on the registered subjects at BIRDEM. It maintains the registry with relevant socio-demographic, clinical and biochemical information. From the registry, we took age, height, weight, systolic and diastolic blood pressure (SBP & DBP) including 2-samples oral glucose tolerance test (OGTT). Body mass index was calculated (BMI= weight in kg / height in m^2). We compared diabetic subjects registered in 1988 with those registered 10 years later in 1998.
Results: Overall, 18087 registered files (6263 of the year 1988 and 11824 of 1998) were retrieved. The number of registry was almost double in 10 years. In 1988, the men were 66.4% and women 33.6%. In 1998, the proportion women increased to 40%. Compared with the rural and suburb the registry from urban dwellers increased from 60% in 1988 to 65% in 1998. Regarding age distribution, 47 and 55 years were on the 50th and 75th percentile in 1988, whereas in 1998, these were 44 and 51 years, respectively, indicating an early onset. Moreover, the comparison between the two subsets (1988 v. 1998) showed that mean (SD) age was significantly lower in 1998 than in 1988 (p<0.001). In contrast, despite lower age these subjects had significantly higher BMI, higher SBP and higher post-load plasma glucose (for all, p<0.001).
Conclusions: We conclude that diabetes starts affecting younger people more than that observed 10 years back. Obesity onset was also found more in the younger age than that observed 10 years back. These findings suggest that an educational intervention or translation of the study results should be made available to the younger people at risk

Feto-maternal outcomes in pregnancy with and without diabetes in a referral hospital: BIRDEM experience

P. Khanam[1], M.A. Sayeed[2], T. Begum[1], H. Mahtab[1], A. Khan[1]
[1] *BIRDEM, Epidemiology and Biostatistics, Dhaka, Bangladesh*

Background and aims: Most of the diabetes related pregnancies are referred to Bangladesh Institute of research and rehabilitation of Endocrine and Metabolic disorders (BIRDEM) for follow up and subsequent deliveries. The subjects with normal pregnancy are also referred. Although many pregnancy cases admitted for perinatal care, there are few studies on pregnancy outcomes with and without hyperglycemia. This study described the characteristics of pregnancies and outcomes at BIRDEM.
Subjects and Methods: This retrospective study was conducted on the admitted pregnancy cases in BIRDEM-inpatient for delivery. The Obstetrics and Gynecology department of BIRDEM followed up 375 diagnosed cases of gestational diabetes and conducted 1451 deliveries of various categories. We investigated obstetric history (pre-, intra- and post-natal information). We also took the history of diabetes and other systemic illnesses including complications occurred during pregnancy. Detailed history of intranatal and post-natal events was noted.
Results: A total of 1105 deliveries were investigated. Of them, 1082 had singleton and 23 were twins. The proportion of pregnancy with normo-glycemia, diabetes and gestational diabetes were 33.8, 37.6 and 28.7%, respectively. The mean (SD) age of the pregnant mothers of both hyperglycemic categories was significantly higher than the non-hyperglycemic mothers (p<0.001). There was no significant difference of gestational age between mothers with and without hyperglycemia. Intrauterine and neonatal death was found in 2.3%.

The pregnancy related complications among mothers were premature rupture of membrane (4.4%), oligohydromnia (4.4%), pregnancy induced hypertension (3.9%) and pre-eclampsia (3.1%). Of the 25 neonatal deaths according to birth-weight, 20 were found in the first quartile (less than 2.5kg), none in the second (2.5 – 2.9kg), one in the third (2.9 – 3.2kg) and 4 deaths in the fourth quartile (over 3.2kg) – indicating a "U" shaped curve.

Conclusions: The study described the types of pregnancy admitted in a referral hospital of a developing country. It revealed that despite follow up and delivery conducted in a referral hospital the mortality still remained high. Some common but important pregnancy related complications have been observed. Another interesting finding is the neonatal death according to birth-weight, which showed a "U" shaped curve – more death at the extremes of the birth-weight. More study is needed to confirm our study findings.

Trends of diabetes prevalence in Bangladesh: a silent epidemic

S. Talukder[1], S. Khan[2], S. Haque[3], D. Farhana[2], G. Rabbani[2]
[1] Eminence, CEO, Dhaka, Bangladesh
[2] Eminence, Assistant Coordinator, Dhaka, Bangladesh
[3] Eminence, Associate Coordinator, Dhaka, Bangladesh

Context: Very few population-based studies conducted in Bangladesh at different times have revealed an increasing trend of diabetes prevalence in rural and urban populations. The studies conducted to observe the increased prevalence of type 2 diabetes in Bangladesh were largely based on unplanned coincidental investigations. As a consequence, these studies generally suffer from valid comparisons as they were performed at different times in different populations with varied sample sizes and applied different procedures for both blood glucose estimation and other biophysical measures.

Aims: The purpose of this study was, therefore, to observe the temporal changes in the prevalence of diabetes in both rural and urban population of Bangladesh.

Methods: This study was purely based on literature review. Authors of this study have reviewed in total of 11 full articles and 22 abstracts and related articles were reviewed to prepare this paper. The articles were reviewed from "Diabetes Medicine", "Diabetes Care", "Diabetes Research and Clinical Practice" and "PUBMED". The key word of searching the articles was "Diabetes in Bangladesh", "Diabetes + Bangladesh" and "Diabetes & Bangladesh". The articles, abstracts and related articles were reviewed chronologically by year and the starting year was 1956 and the end was at 2007.

Results: As in 1974 the total population of Bangladesh was 78,479,000 and if we calculate the percentage of diabetes patients depending on that data then the percentage of identified diabetes patients in 1974 was 0.0033%. In another study it was found that total 50,000 patients were registered with BIRDEM since its inception on 1956 till 1980's. In this manner it can be said that the number of patients rose drastically from 1970's to 1980's. In 1994 the prevalence of NIDDM in rural Bangladesh was 2.1% and IGT prevalence rate was 13.3%. The crude prevalence of NIDDM was 2.1% (men 3.1%, women 1.3%) and IGT was 13.3% (men 14.4%, women 12.4%) and age-adjusted (30-64 years of age) prevalence was 2.23% for NIDDM and 15.67% for IGT in 1995. In another study conducted in the same (1997) year followed by WHO criteria the crude prevalence of IGT was 7.5% and NIDDM was 4.1%. After that in 2006 a nationally representative study reveled that the prevalence of diabetes among urban population has become almost 21%. The presence of this disease in slum population is also very high.

Sociodemographic, clinical and lifestyle factors associated with psychiatric illness among patients with diabetes

M.N.A. Jadoon[1], M.A. Shehzad[1], W. Munir[1], I. Bashir[1]
[1] Nishtar Medical College, Medicine Unit 3, Multan, Pakistan

Aim: The aim of this study was to determine the association of metabolic control, sociodemographic and lifestyle factors with the presence of psychiatric illness in diabetic patients after controlling for potentially confounding variables.

Methods: The study was carried out on a sample of 150 individuals with diabetes. The Patient Health Questionnaire and Aga Khan University Anxiety and Depression Scale were used for psychiatric evaluation. Sociodemographic, clinical and lifestyle data was collected from patients after taking consent. Logistic regression was used for determining the association.

Results: The age of patients was 50.48 ± 12.02 years and the duration of diabetes was 5.85 ± 5.36 years. 55% of the patients were female and 89% had type 2 diabetes. Independent factors found to be significantly associated with depression included younger age, female sex, being unmarried, being from urban locality, low income, unemployment, higher fasting and random blood sugar values, higher HbA_{1c} values, non-smoking and being physically inactive.

Conclusion: The study shows that many factors adversely affect the psychological health of diabetic patients. There should be routine screening of diabetic patients especially targeting individuals with low socioeconomic status and deteriorating glycemic control.

P-1620

Risk factors for arterial disease (RFAD) evolution at a city of the province of Córdoba - a 13 year follow up: Study Deán Funes 2

S. de Loredo[1], L. de Loredo[2], H. Luquez[3], R. Madoery[3], K. Fuentes[2], D. Carri[4], M. Paganini[3], M. Ruiz[3], L. Jamier[1]
[1] Hospital Privado Centro Medico De Cordoba S.a., Internal Medicine, Córdoba, Argentina
[2] Hospital Privado Centro Medico De Cordoba S.a., Diabetes And Nutrition, Córdoba, Argentina
[3] Hospital Privado Centro Medico De Cordoba S.a., Cardiology, Córdoba, Argentina
[4] Hospital Privado Centro Medico De Cordoba S.a., Stadistics, Córdoba, Argentina

Introduction: The internationally known RFAD: dyslipemia, obesity, diabetes, hypertension and smoking habits are growing in the western world. It is important for us to know the prevalence of RFAD, and the evolution that has had in the last years. We decided to follow up a demographic sample that had already been studied and evaluated in 1994 (Study Deán Funes 1, 20-70 years population).

Objectives:

1. To evaluate the current prevalence of the RFAD: dyslipemia, obesity, diabetes, hypertension and smoking habits in the Dean Funes population.
2. To compare the current prevalence with the ones found in 1994 (Study Deán Funes 1).

Materials and methods: 336 persons (women and men) between 33 to 83 years old, 33% men and 67% women. Anamnesis about risk factors, physical examination with anthropometric measures (weight, height, abdominal circumference), blood pressure (BP) and lab: Cholesterol, HDL, LDL, insulinemia, glycemia and triglycerides. Criteria: Diabetes diagnosis: Previous diagnosis of diabetes or fasting glycemia ≥126 mg/dl or OGTT ≥ 200 mg/dl 2 hours later. Overweight BMI ≥ 25 and < 29,9, obesity BMI ≥ 30. Hypertension: Systolic BP ≥ 140 mm hg or diastolic BP ≥ 90 mm hg. Dyslipemia: High cholesterol ≥ 200 mg/dl; high LDL ≥ 130 mg/dl and low HDL < 40 mg/dl in men and < 50 mg/dl in women, high triglycerides ≥ 150 mg/dl.

Results: The prevalence of diabetes in Deán Funes 1 was 6.9% and in Deán Funes 2 was 8.5%; The BMI increased from 27.66% to 29.09%, the waist increased from 86.9 cm to 96.9 cm; the overweight decreased from 43.1% in 1994 to 38.8% in 2007, but the cases of obesity increased from 25.1% to 38.9%. The hypercholesterolemia in men increased 49.1% to 53.6%, and in women 32.1% to 56.3%, with a global average of 209.62 mg%; the triglycerides increased from 150.34 mg% to 167.49 mg%; HDL 45.98 mg% to 59.86 mg%. The hypertension in men increased from 39.3% to 40.2%, and in women from 33.5% to 50.9%, with a global prevalence of 45.6%. The obesity among hypertensive people was 39,8% vs 17,05% non hypertensive people. The smoking habits had a favorable evolution, people that quit smoking were 37.5% of men and the 33.8% of women.

Conclusions: Even though the demographic sample is 13 years older, the increase of the prevalence of the different RFAD was very significant from 1994 to 2007, coinciding with many demographical studies such as NHANES. This prevalence increase shows us that there is a need for more prevention programs.

No conflict of interest

P-1621

Diabetes and impaired fasting glycemia in a rural population

R. Bhandari[1], S. Bhattarai[1]
[1] NMC teaching Hospital, Com. Medicine, KTM, Nepal

Aim: To determine the prevalence of type 2 diabetes and impaired fasting glycemia (IFG) in a rural population.
Methods: A cluster sampling of 254 subjects >/=20 years old in a rural community were investigated. Fasting plasma glucose, blood pressure, height, weight, and girth of waist and hip were measured. BMI and waist-to-hip ratio (WHR) were calculated. Total cholesterol, triglycerides, and HDL cholesterol were also estimated. We used the 1997 American Diabetes Association diagnostic criteria.
Results: The crude prevalence of type 2 diabetes was 4.3% and IFG was 12.4%. The age-standardized prevalence of type 2 diabetes (95% CI) was 3.8% (3.12-4.49) and IFG was 13.0% (11.76-14.16). The subjects with higher family income had significantly higher prevalence of type 2 diabetes (5.9 vs. 3.5%, P < 0.001) and IFG (15.6 vs. 10.8%, P < 0.001) than those with lower income. Employing logistic regression in different models, we found that wealthy class, family history of diabetes, reduced physical exercise, and increased age, BMI, and WHR were the important predictors of diabetes. Total cholesterol, triglycerides, and HDL cholesterol showed no association with diabetes and IFG.
Conclusions: The prevalence of diabetes and IFG in the rural population was found to be on the increase compared with the previous reports and other Asian studies. Older age, higher obesity, higher income, family history of diabetes, and reduced physical activity were proved significant risk factors for diabetes and IFG, whereas plasma lipids showed no association with diabetes and IFG.

Impact of depression on body composition and cardiometabolic risk factors in Korean elderly women

H.S. Kim[1], J.A. Seo[1], H.J. Cho[1], N.H. Kim[2], H.Y. Kim[2], S.G. Kim[2], D.S. Choi[2], K.M. Choi[3], S.H. Baik[3], M.H. Park[4], C.S. Han[5], N.H. Kim[1]
[1] Korea University Ansan Hospital, endocrinology and metabolism, Ansan, Korea
[2] Korea University Anam Hospital, endocrinology and metabolism, Seoul, Korea
[3] Korea University Guro Hospital, endocrinology and metabolism, Seoul, Korea
[4] Korea University Ansan Hospital, neurology, Ansan, Korea
[5] Korea University Ansan Hospital, psychiatry, Ansan, Korea

Depression has been associated with abdominal obesity through the accumulation of visceral fat and subsequently has been found to predict diabetes, cardiovascular disease, and cardiac mortality. Although Korea is a rapidly aging society and depression is one of the most common mental disorders in old population, the effect of depression on visceral fat accumulation and cardiometabolic risk factors in Korean elderly women has not been studied yet. This study aimed to investigate the relationship between depression and indices of body composition, including body mass index (BMI), abdominal visceral (VFA) and subcutaneous fat area (SFA), and appendicular skeletal muscle mass (ASM), and cardiometabolic risk factors in elderly Korean women. A total of 311 women aged over 60 years and without a history of diabetes mellitus, were chosen in a cross-sectional study from an ongoing, prospective, population-based study in Ansan city, South Korea. Depressive symptoms were evaluated using the 30-item Geriatric Depression Scale (GDS 30) Korean version, with a cut-off point of 16. ASM was estimated by dual energy X-ray absorptiometry and VFA and SFA were measured by single slice abdominal CT scanning. Body mass index (BMI), blood pressure, glucose, insulin, lipid profile, high sensitive CRP (hsCRP), brachial-ankle pulse wave velocity (baPWV), carotid intimal medial thickness (IMT) were measured.
About twenty percent of the participants had depression. Subjects with depression had lower BMI, waist circumference, ASM, SFA, but had higher diastolic BP than those without (mean ±SD; BMI, 25.0±3.2 vs. 23.9±2.9 kg/m^2, p=0.01; waist, 88.5±8.0 vs. 85.4±8.0 cm, p=0.007; ASM, 12.6±1.4 vs. 13.3±1.7 kg, p=0.003; SFA, 240.4±69.5 vs. 216.8±66.5 cm^2, p=0.019; diastolic BP, 74.6±7.5 vs. 77.1±9.4 mmHg in subjects without vs. with depression). The other cardiometabolic risk factors were not different according to the presence or absence of depression. After adjusting for age, BMI, glucose, hypertension, smoking, alcohol, physical activity, education and socioeconomic status, ASM was lower and diastolic BP was higher in the subjects with depression than those without (mean ±SE; ASM, 13.5±0.1 vs. 13.0±0.2 kg, p=0.039; diastolic BP, 74.5±0.5 vs. 77.6±1.0 mmHg in subjects without vs. with depression). In multiple logistic regression analysis, the prevalence of depression in the bottom tertile of ASM was about 2.7-fold higher than those with the top (odds=2.7, 95% CI 1.1-6.4) after adjusting for confounders mentioned above.
In contrast with the previous findings, depressed Korean elderly women were leaner and had less muscle mass than those without. There may be a possibility that reduced muscle mass rather than fat mass is responsible for depressive symptoms, and vice versa.

Self reported diabetes and estimate of undiagnosed diabetes in Quebec

E. Rahme[1], K. Dasgupta[1], M. Dawes[1], I.S.Q. The Institut de la Statistique du Quebec Survey Team[2], J.L. Chiasson[3]
[1] McGill University, Department of Medicine, Montreal, Canada
[2] Institut de la Statistique du Quebec, Montreal, Canada
[3] Université de Montréal, Department of Medicine, Montreal, Canada

Background: Diabetes is increasingly affecting people at a younger age and the prevalence of the disease continues to rise worldwide. Diagnosing people at an early stage is important to prevent or delay diabetes complications.
Method: We conducted a telephone survey of 6,500 persons selected at random from the Quebec population to assess the self reported prevalence of diabetes and estimate the prevalence of undiagnosed diabetes. Responders were encouraged to provide a blood sample consisting of depositing two drops of blood on a blotting paper prepared by the laboratory of the Centre Hospitalier de l'Université de Montréal. The blood sample was then mailed to the lab for analysis. We report the results of the first round of the survey including 750 persons randomly selected from that population.
Results: Among the 340 individuals who agreed to participate in the study, 55% were women. 42% had a family history of diabetes, 49% had a blood test done less than a year ago, 19% reported smoking at the present time and 26 (8.4%) reported having been previously diagnosed with diabetes. Among the 134 blood samples analysed, 18 tested positive for diabetes (glucose level > 7 mmol/L) and reported not having been diagnosed previously, and 36 had a glucose level > 6,1 mmol/L and also reported not having been diagnosed previously.
Conclusion: The prevalence of undiagnosed diabetes in Quebec is high and almost equal to that of diagnosed diabetes. The prevalence of pre-diabetes is also concerning. The diagnostic test we used was easy to implement and was well accepted by the population and may constitute an affordable method to screen the population for diabetes.

P-1624

Prevalence of metabolic syndrome in the city of Celaya, Mexico

J. Rosas-Saucedo[1], S. San Roman-Torres[2], A. Eguia[3], J. Rosas-Guzman[1]
[1] Instituto de Diabetes A.C., Diabetes, Celaya, Mexico
[2] Facultad de Medicina, Universidad de Guanajuato, Celaya, Mexico
[3] Colegio Medico de Celaya, Colegio Medico de Celaya, Celaya, Mexico

Metabolic Syndrome (MS), includes the entities which are the main cause of morbidity and mortality in many cities and countries in the world. This is why we designed the present randomized, prospective transverse trial to determine the prevalence of MS and each of its components in the urban area of an average city of central Mexico.
A total of 608 surveys were made house-visiting random-selected addresses, in order to determine the presence of the components of MS, alimentary habits, physical activity, tobacco users, weight, height, body mass index (BMI), waist circumference and blood pressure. In a random subgroup of 102 persons, glucose, total cholesterol, HDL-cholesterol, LDL-cholesterol, VLDL-cholesterol and triglycerides were quantified in a central laboratory with a fasting time of 8-12 hours.
Among our findings, the prevalence estimates of the entities of MS by themselves were: type 2 diabetes mellitus 8.8%, of those, 11.1% newly diagnosed, fasting glucose intolerance 29.4%, overweight 40%, obesity 24.1%, hypercholesterolemia 34.3%, hypertriglyceridemia 45.0%, low HDL-c 42% and 53% in men and women respectively, and elevated blood pressure

31%. The prevalence of MS by International Diabetes Federation (IDF) criteria was 48.5%, and by Adult Treatment Panel III (ATP-III) 41.5%. Dividing men and women into 2 groups each, from 18 to 40 and 41 to 60 years of age, we observed that men tend to present MS earlier, having 50% of the cases in the first group. Women, in contrast, develop MS more avidly after 40 years of age.
Analyzing BMI and its correlation with MS, we found that people with lower risk of MS are those with BMI < 24 and < 26 in men and women respectively. Waist circumference < 89 cm is also associated with a lower risk for MS in both men and women.
Thus, we are able to conclude that Metabolic Syndrome and each one of its entities have an elevated prevalence, especially in the group of age < 40, reaching up to 50% in men.
The clinical elements that confer a greater risk for MS are BMI ≥ 24 and ≥ 26 in men and women respectively, and waist circumference ≥ 89 cm in people over 18 years of age. Half of the inhabitants 18 years or older, have MS because of the increasing prevalence of each one of the elements of MS, especially overweight and obesity.

P-1625

Characteristics and prevalence of metabolic syndrome among three ethnic groups in Cameroon

D. Mandob Enyegue[1]
[1] *University, Biochemistry, Yaounde, Cameroon*

Aims: To compare the characteristics and prevalence of the metabolic syndrome (MetS) in three Cameroonian population: Beti, Bamiléké, Sawa.
Methods: The study was based on four cross-sectional studies conducted between 2006 and 2008. Among the participants received during the study, originate from three ethnic groups living in the urban city of Yaounde were selected and underwent anthropometric measurement and biochemical test. The MetS was identified among participants according to the National Cholesterol Education Program (NCEP) definition.
Results: The age-standardized prevalence of the MetS varied by ethnic group, ranging from as high as 16.8 % among Bamiléké women to as low as 2.7% among Beti men. Compared with MetS components overall prevalence in Cameroon, Sawa had a worse metabolic profile, while Bamiléké had a better metabolic profile except for a high rate of abdominal obesity.
Conclusions: The results indicate that the MetS is prevalent in diverse ethnic groups in Cameroon but varies in the pattern of phenotypic expression. Preventives measurements must take into account these ethnics variations for the efficient reduction of metabolic syndrome frequency in Cameroonian population.

[2] *Haute-Saône Hospital, Internal Medicine, Vesoul, France*

Studies describing the quality of care of type 1 diabetic patients in a population-based setting are scarce. This work aims to describe, on a specific French health area, the care of patients with type 1 diabetes selected from the French medical insurance system (covering 75% of the population).
Methods: The selection of patients was done from diabetic patients who were reimbursed from at least one delivery of insulin during the first 2007 trimester. Were first considered as having a type 1 diabetes, those with a diagnosis of diabetes before the age of 45 years and an early definitive treatment with insulin less than 2 years after diagnosis. This list has been refined by local diabetologists and then by the administration of a questionnaire by telephone or mail to patients or physicians. Biological data were collected from laboratories. All medical reimbursements and hospital data were extracted for 2 years.
Results: At last, 227 patients with type 1 diabetes were selected including 174 with questionnaires. Sex: 57% male, mean age: 40 yrs (9% <18 yrs), mean diabetes duration: 21 yrs. Based on patient reports, obesity was seen in 13%, and overweight in 24%; 21% smoked. After optimisation based on the different sources, the highest range value was 69% for ≥ 3 HbA1c tests/yr, 79% for = 1 creatininemia/yr, 77% for = 1 urine albumin/yr. During the previous 2 yrs, at least 30% did not see any ophthalmologist and 18% any diabetologist (24% based on patient reports). 26% reported having a retinopathy and 17% had an ophthalmologic laser treatment. Based on laboratory reports, 12% had a creatinine clearance < 60ml/min and 21% had micro or macro-albuminuria; 2.4% were on dialysis or with a kidney transplant; 1.1% had a major lower limb amputation. HbA1c was < 7.5% in 30% and >9% in 25%. A basal-bolus "state of the art" treatment with human analog insulin was used by 74% with 21% with an insulin pump.
Conclusion: This study evaluating the quality of care in a representative and specific population of French type 1 diabetic patients highlights that severe microangiopathic complications are frequent and that about one quarter of these patients do not receive adequate care in terms of recommended monitoring, metabolic status and insulin treatment.

Relation between nutritional risk and metabolic syndrome in the elderly

H. Kim[1], *S. Han*[1], *D. Kim*[1], *K. Lee*[1], *K. Lee*[2], *J. Eom*[3], *K. Lim*[4], *C. Hong*[4]
[1] *Ajou University School of Medicine, Endocrinology and Metabolism, Suwon, Korea*
[2] *Yonsei University School of Medicine, Psychiatry, Seoul, Korea*
[3] *Chungbuk National University, Psychology, Cheongju, Korea*
[4] *Ajou University School of Medicine, Psychiatry, Suwon, Korea*

Aims: Nutrition is regarded as a major factor in the development of metabolic syndrome. Undernutrition or nutritional imbalance, rather than overnutrition, can be associated with metabolic syndrome. We evaluated the relationship between nutritional risk and metabolic syndrome in the elderly.
Methods: We analyzed 2,284 Koreans aged over 60 years (689 men and 1,595 women, mean age 72.0 ± 6.7 years) from baseline data of a large prospective study called the Gwangju Dementia and Mild Cognitive Impairment Study (GDEMCIS). Metabolic syndrome was determined according to the National Cholesterol Education Program Adult Treatment Panel-III, and nutritional risk was evaluated using the Nutrition Screening Initiative (NSI) checklist.
Results: Among 2,284 subjects, 1,219 (53.4%) had metabolic syndrome. NSI score was higher in subjects with metabolic syndrome than in those without metabolic syndrome (2.46±1.89 vs. 2.18±1.87, $p<0.05$). The risks of abdominal obesity, elevated blood pressure, elevated glucose, and metabolic syndrome were higher in subjects with moderate or high nutritional risk compared to subjects in a good nutritional state. Nutritional risk was independently associated with metabolic syndrome for subjects in their 60s, but not in their 70s or 80s and above.
Conclusion: High nutritional risk is associated with increased risk of metabolic syndrome in the elderly. Measurement of nutritional status in the elderly may serve as a marker for metabolic syndrome, and the identification and adjustment of nutritional risk can be beneficial for the prevention of metabolic syndrome, especially for the younger elderly.

[3] *Hospital Privado Centro Medico De Cordoba S.a., Cardiology, Córdoba, Argentina*
[4] *Hospital Privado Centro Medico De Cordoba S.a., Stadistics, Córdoba, Argentina*

Introduction: It has been proved that the Metabolic Syndrome (MS), high risk entity for cardiovascular disease, is widely prevalent in populations of the Western world, and has been related to cardiovascular disease and also with global mortality rate in several population groups. It is known that its

prevalence is increasing together with an increasing obesity and a sedentary life style.

Objectives:

1. To evaluate the current prevalence condition of the MS in a population and its comparison to the same population in 1994.
2. Prevalence condition of MS in the mortality of this population.

Materials and methods: 336 persons (women and men) between 33 and 83 years old, 33% men and 67% women. Physical examination with anthropometric measures (weight, height, abdominal circumference), blood pressure, blood tests: total cholesterol, HDL, LDL, insulinemia, glycemia and triglycerides.

The criteria for the MS was according to ATP III and IDF with Asian- American waist.

Results: According to the criteria of the ATP III, the metabolic syndrome increased from 23.6% in 1994 to 33.3% in 2007 and according to the criteria of the IDF from a 36.9% to 45.8%.

From the total deaths (64) between 1994 and 2007, 36.9% had MS according to ATPIII and 53.2% according to IDF.

Conclusions: as we expected and in accordance with other Latin American studies, the prevalence condition of MS has increased during the last few years, being clearly higher than in the general population. It was involved in more than half of the deaths according to IDF criteria.

P-1629

Gender and age related differences in body composition and prevalence of obesity in a semi urban Asian-Indian population

N. Deshpande[1], N. Kapoor[2], A. Syed[2], L. Dahiya[2], R. Parmaj[2], P. Deshmukh[2]

[1] Belgaum Diabetes Centre and JN Medical College, Diabetes & Obesity, Belgaum, India

[2] Belgaum Diabetes Centre, Diabetes & Obesity, Belgaum, India

Background: Growing urbanization, reduced physical activity and an increase in fat-laden foods are responsible for an explosive growth in life style diseases in formerly lean Asians. However by conventional standards (BMI) Asians who are apparently lean are still prone to the ill effects of obesity. Although WHO has lowered the definition of overweight for Asians, prevalence of obesity is still greatly underestimated.

Aim: To ascertain gender & age differences in prevalence of obesity measured by different parameters.

Methods: 525 randomly selected subjects were enrolled & evaluated for anthropometric measurements: Waist circumference (WC), Body Mass Index (BMI) & body composition including Body Fat Percentage (BFP). Prevalence of obesity was studied using above parameters. The subjects were stratified as obese on the basis of BFP (men ≥ 25 Body fat % & women ≥ 30 Body fat %); BMI (≥ 25)*; WC [men ≥ 90 & women ≥ 80]*. The body composition was determined by BIA (Bioelectric Impedance Analysis)-Inbody230. The prevalence of obesity was compared across various age groups in both the sexes.

. *Asia pacific guidelines

Results: · n = 525

- Men: Women = 250:275
- Prevalence of obesity:

Parameter studied	Total population n=525 (%)	Male n=250 (%)	Female n=275 (%)
BFP	334 (63.6%)	123 (49.2%)	211 (76.7%)
WC	239 (45.5%)	89 (35.6%)	150 (54.5%)
BMI	215 (41%)	91 (36.4%)	124 (45.1%)

- 91/525 (17.33%) of the population was found to be overweight (BMI = 23 -24.9)
- Age wise mean BMI in females was 21.1±4.1 (< 30 yrs); 24.1±4.5 (30-49 yrs); 26.0±3.9 (> 50 yrs). There is a clinically significant rise in mean BMI, both from young (<30 yrs) to middle age (30 to 49 yrs)[p=0.003] & from middle age to old (> 50 yrs) [p=0.034] individuals.
- Age wise mean BMI in males was 21.5±3.8 (< 30 yrs); 24.7± 3.8 (30-49 yrs); 24.6±4.0 (> 50 yrs).However there is no significant change in the mean BMI from the middle aged men to the older group. [p=0.820]
- Age wise mean BFP in females was 31.1±8.9 (< 30 yrs); 37.6±13.5 (30 to 49 yrs); 39.7±8.7 (> 50 yrs). There is a clinically significant rise in mean BFP from young (<30 yrs) to middle age (30 to 49 yrs) [p=0.008]
- Age wise mean BFP in males was 19.8±8.1 (< 30 yrs); 25.4±7.7 (30 to 49 yrs); 26.5±9.4 (> 50 yrs). There is a clinically significant rise in mean BFP from young (<30 yrs) to middle age (30 to 49 yrs) [p=0.006] However there is no significant rise in the mean BFP from the middle aged men to the older group. [p=0.43]

Conclusion:

- Prevalence of obesity is highest when BFP is used as a measure of obesity followed by WC and then BMI. This suggests a far greater role for measuring BFP routinely alongside WC & BMI.
- There is a drastic increase in the prevalence of obesity (BMI) among females as they grow older reflecting their sedentary life style.
- In our population only 41.66% were of normal weight (BMI). More prevalence of obesity is seen in females.

Age of onset of type 2 diabetes mellitus in Nigerians: is it decreasing?

A.E. Edo[1], A. Eregie[1], O. Ogbera[2], O.S. Adediran[3], A.O. Adesanya[4], O.S. Ogedengbe[4]

[1] University of Benin Teaching Hospital, Department of Medicine, Ugbowo Benin City, Nigeria

[2] Lagos State University Teaching Hospital, Department of Medicine, Lagos, Nigeria

[3] Benue State University Teaching Hospital, Department of Medicine, Makurdi, Nigeria

[4] University of Benin Teaching Hospital, Department of Medicine, Benin City, Nigeria

Background/Objective: The prevalence of diabetes mellitus is increasing worldwide. The age of onset of type 2 diabetes mellitus is reportedly decreasing. We investigated the age of onset of type2 diabetes in a Nigerian population.

Patients and Methods: Hospital records of patients with diabetes mellitus seen between July 2006 and July 2008 at the Diabetes Clinic of Faith Medical Centre, Benin City were retrieved. Data extracted included the age of the patients, the year of diagnosis of DM, parity of female patients, family history of DM, presence of hypertension, height and weight for body mass index, waist and hip circumferences for waist:hip ratio. The data was analyzed with SPSS. Significant level was set at $p < 0.05$.

Result: Two hundred and ninety six (110 males, 182 females) patients with diabetes mellitus were reviewed. The mean age of onset of DM was 52 ± 11.1 years (52.4 ± 10.2 vs 51.3 ± 12.5, p = 0.015, for females and males respectively).

Females were more obese than males (BMI 29.2 ± 5.3 vs 26.7 ± 4.3 p = 0.108).Obesity and overweight were present in 31.8% and 35.5% of the patients respectively. There was hypertension in 34.8% of them. Hypertension was commoner in females. Family history of diabetes mellitus in first degree relatives was documented in 22.3% of the patients.

More females had early onset type 2 diabetes (onset before the age of 50 years) than the males (23.6% vs 16.9%) and late onset DM (37.8% vs 19.2%). Parity, presence of hypertension, a family history of diabetes mellitus in a first degree relative, did not significantly affect the age of onset of diabetes mellitus among Nigerians. The mean age of onset of DM for each year over the last 10 years ranged from 47.7 ± 9.7 to 59.7 ±13.8 years.

Conclusion: The age of onset of type 2 diabetes mellitus in Nigerians appears to have remained relatively constant despite the increases in the number of patients presenting for treatment.

Location of diabetes 'hotspots' in Melbourne: prevalence in multicultural groups

A. Hernan[1], J.A. Dunbar[1], N. Davis-Lameloise[1], R. Boak[1], M. Coates[1], P. Reddy[1]

[1] Flinders and Deakin Universities, Greater Green Triangle University Department of Rural Health, Warrnambool, Australia

Background: Diabetes is one of the most concerning health issues worldwide, and in Australia it will be the leading contributor to the overall burden of disease within the next 20 years. The risk of developing type 2 diabetes is suggested to be two to three times higher for certain culturally and linguistically diverse (CALD) populations than the Australian born on average. However, the actual prevalence rates for specific CALD populations are lacking or not readily available. Victoria is one of the most multicultural states in Australia, with

Melbourne being the fastest growing capital city. Since 44% of the Victorian population is born overseas or have at least one parent who was born overseas (over 200 different countries), a review of current demographic data for CALD populations' location and diabetes prevalence in Melbourne, is needed to better target population health resources for these high risk communities.

Aim: To collate demographic data and type 2 diabetes prevalence data for culturally and linguistically diverse populations in Melbourne.

Methods: Information on diabetes prevalence and demographic data for CALD populations living within the local government areas (LGAs) was investigated from a variety of government documents/databases and the published literature.

Results: Demographic data from the Australian Bureau of Statistics 2006 Census identified the LGAs of Melbourne that contained high numbers of CALD populations (as categorised by country of birth). Specific data on prevalence rates for type 2 diabetes by country of birth has not been recorded to date.

Discussion: In order to reduce health disparities for CALD populations, the identification and location of these at risk communities has been acquired. The findings outline specific areas within the LGA where high proportions of CALD populations reside. This study highlighted the lack of data directly linking diabetes prevalence with location of specific CALD populations in Melbourne. The methodology used in local, state and national health surveys should be revised to include prevalence of diabetes for CALD populations. A possible mechanism for displaying this data collection could be through the use of geographical information system (GIS) spatial mapping tools to identify areas of high prevalence for diabetes and high CALD population densities, also known as diabetes 'hotspots'.

Conclusion: To better target diabetes prevention and management resources for CALD populations in Melbourne, data collection regarding their location and prevalence need to be improved and utilised more efficiently. Accurate identification could assist in reducing health disparities for these communities at high risk for diabetes.

Waist circumference measurement and its correlation with bioelectrical impedance parameters in the metabolic syndrome prevalence study in Maracaibo Municipality, Venezuela.

E. Rojas[1], V. Bermúdez[1], D. Carrillo[1], J. Montes[1], M. Pirela[1], G. Ruiz[1], D. Vilchez[1], L. Peñaranda[1], A. Pérez[1], A. Urdaneta[1]

[1] Centro de Investigaciones Endocrino-Metabólicas "Dr. Félix Gómez", Endocrine-Metabolic Diseases, Maracaibo, Venezuela

Introduction: Waist Circumference (WC) above the normal values is an essential criterion for Metabolic Syndrome diagnosis according to IDF and ATPIII definitions, and widely recognized to increase cardiovascular diseases incidence. The aim of our research was to determine reference values for WC in our population and to relate them with body composition parameters.

Materials and methods: A descriptive and transversal study was carried out in 979 healthy adult individuals randomly chosen (533 women and 446 men), for whom a complete clinical history was made. Body composition parameters were measured by using TANITA Body Composition Analyzer Model TBF300A. WC was measured having as reference a medium spot between anterior and superior iliac eminence and the last rib. Statistical analysis was made through the program SPSSver.15 for Windows. Results are expressed as median, percentiles were used to establish normal ranges and correlations were made by means the Pearson coefficient.

Results: WC values had a positive lineal correlation with the weight, basal metabolism, fatty mass and percentage of body fat, a non lineal correlation with lean mass and total water was seen ($p < 0,05$). Fatty mass percentiles for women and men were: p10: 5kg and 7kg, p25: 9kg and 12kg, p50: 18kg and 19kg, p75: 29kg and 28kg, and p90: 38kg and 38kg, respectively. WC percentiles were: p10: 73cm and 79cm, percentile p25: 80cm and 89cm, p50: 89cm and 100cm, p75: 99cm and 100cm and p90: 108cm and 120cm, for men and women respectively.

Conclusions: These results expose normality ranges adapted to our population, which is genetically and environmentally different. Significant correlations were found among WC and bioelectrical impedance measurements demonstrating the utility of the WC to sharply predict higher risk for acute coronary events and endocrine-metabolic disorders.

P-1633

Association of overweight and obesity with diabetes: Differential impact of adiposity between women and men according to rural or urban setting

C. Boissonnet[1], J. Krauss[2], P. Hernandez Moran[3]

[1] CEMIC, Cardiology, Buenos Aires, Argentina

[2] Hospital Italiano, Cardiology, Buenos Aires, Argentina

[3] Sanofi-aventis, Medical Department, Buenos Aires, Argentina

Background: It is well-known that a strong association exists between obesity and diabetes in both sexes; however, scarce data are available about this relationship in rural populations.

Material and Methods: IDEA (International Day for the Evaluation of Abdominal Obesity) was an international cross–sectional study that recruited 168,159 consecutive patients aged 18 to 80 years who attended the offices of randomly chosen primary care physicians on two pre-specified half days in 2005. IDEA included consecutive patients from rural and urban general practitioners in all geographic areas of all 63 participating countries, giving a representative sample of the patients attending primary care consultations. The present analysis compares the association of overweight and obesity with prevalent diabetes in rural and urban women and men in the 2965 patients (rural 1469, urban 1496) included in the IDEA study in Argentina.

Results: Rural and urban populations were similar in age and proportion of males (mean age 53.6 ± 16.0 years vs 53.9 ± 16.7 years; male sex 37.1% and 37.0%, respectively; p=ns). Prevalences of obesity and overweight were higher in rural than in urban women (28.5% and 36.3% vs 26.2% and 32.1%, p=0.017) but not different in rural and urban men (33.2% and 44.0% vs 30.4% and 45.8%, p=ns). Prevalences of diabetes were similar in rural versus urban women (8.1% vs 8.6%, p=ns) and in rural versus urban men (11.4% vs 11.2%, p=ns). In women, there was a strong, graded association between overweight-obesity and diabetes: OR (CI 95%) of obesity versus BMI < 25 kg/m² in rural women 14.0 (4.9-54.6), in urban women 4.7 (2.4-9.7); in rural men no association was found (OR: 1.5, CI 95% 0.7-3.4) but in urban men there was a moderate association (OR 3.1, CI 95% 1.3-8.1).

Conclusions: There was a differential cross-sectional association of overweight-obesity and diabetes according to gender and setting. In women, this association was stronger than in men and more apparent in rural women (albeit not statistically different from urban women); in contrast, no association was found in rural men. This data suggests that additional efforts should be directed to effectively reduce overweight and obesity, particularly in women (both urban and rural) if diabetes is to be prevented.

P-1634

Prevalence of diabetes among the subjects diagnosed with hypothyroidism: experience from a Thyroid Clinic in a specialized hospital in Bangladesh

A. S.M. Ashrafuzzaman[1], A.B.U. Abu Nesar Taib[1], Z. Prof. Zafar A. Latif[1]

[1] Ibrahim Medical College & BIRDEM, Endocrinology, Dhaka, Bangladesh

Aims: Type 2 diabetes is a major public health problem affecting approximately 4.8 percent of the Bangladeshi (BD) population, with probably more than an equal number of cases being undiagnosed. On the other hand, symptoms of thyroid disease may be nonspecific or attributed to other diseases, which makes diagnosis more difficult. Incidence rates of autoimmune hypothyroidism varied between 2/100000/year to 498/100000/year. Thyroid disease had a higher incidence in women. The prevalence of diabetes in hypothyroidism is not well studied. Literature showed association of autoimmune thyroid diseases with type 1 diabetes. So, the study was designed to see the prevalence of type 2 diabetes in hypothyroid patients of any etiology.

Methods: All diagnosed hypothyroid subjects (subclinical or overt) reported in one year (July 2007- June 2008), not known to be diabetic previously, underwent standard OGTT (FPG and 2-hour post 75 gram glucose) before initiation of thyroid hormone replacement. The diagnosis of glucose intolerance was done according to W.H.O. criteria of 1997.

Results: 442 subjects with hypothyroidism were studied. (N=442).Mean age ranging 31.7±3.5 years. Male144 (30.69 %) and Female 298 (69.31 %). BMI 23.3 ± 2.3 kg/m. Among the study subjects 56 (12.66%) has Impaired Glucose Tolerance (IGT). Thirtyone subjects was detected as diabetic 31/442 (7.01%). Total glucose intolerance was detected 87/442 (19.68 %). All of

these according to W.H.O. criteria adopted in 1997. The prevalence of diabetes in Bangladesh is 4.8% [8] and IGT 8.6 % according to study in 2006[8]. Newly detected diabetes among the subjects diagnosed with hypothyroidism is significantly higher 4.8 % vs. 7.01 % ($p<0.01$) and the prevalence of pre-diabetic state Impaired Glucose Tolerance (IGT) is also higher (11% vs. 12.6 %). Pure IFG (FPG ≥ 6.1 mmol/l but <7.0 mmol/l, and 2-PG < 7.8 mmol/l) was found in 5.2 % according to WHO criteria and the prevalence is higher (6.8%) with ADA criteria (considering normal FBG <5.6mmol/l).

Conclusion: In this study, the prevalence of diabetes (particularly type 2 diabetes) is found higher among the hypothyroid subjects. The prevalence of pre-diabetic state, Impaired Glucose Tolerance (IGT) is also found higher than the epidemiological data of the country Bangladesh published in 2006. The present study indicates that all patients presenting with hypothyroidism should be screened for diabetes also. As in this study, sample size is small, further study with larger population as RCT (Randomized Control Trial) also needed to explore and to confirm the results. Another possibility is that, the prevalence of diabetes in the country is rapidly increasing; measures should be taken urgently to prevent the rapid progression of the disease (Type 2 diabetes).

Prevalence of vitamin D deficiency and associated factors in Taiwan

C.J. Chang[1], Y.C. Yang[1], J.S. Wu[1], F.H. Lu[1]

[1] National Cheng Kung University College of Medicine, Department of Family Medicine, Tainan, Taiwan

Aims: Vitamin D deficiency (VDD) is common in elderly people in northwestern European countries, especially in institutionalized people. VDD is particularly prevalent in patients with hip fractures, and a causal relationship between osteomalacia and hip fractures had been demonstrated. The aim of this study was to determine the prevalence of VDD in the people who were aged over 30 years living in Tainan city, and also to investigate possible risk factors associated with VDD.

Methods: A total of 2412 subjects were eligible and 1596 subjects (66.2%) participated in the study (1034 men; 562 women). The dietary calcium and vitamin D intake was estimated by using a food frequency questionnaire. In all subjects, a fasting blood sample was drawn for measuring by radioimmunoassay and VDD was defined as serum 25 (OH) vitamin D level <20 ng/mL.

Results: The prevalence of VDD was 9.9% (10.0% men and 9.9% women). Elderly subjects had higher levels of systolic blood pressure, fasting plasma glucose, HbA1c, total cholesterol and triglyceride but lower vitamin 25 (OH) D level and smoking habit than younger subjects. Elderly subjects also had a higher prevalence of VDD than younger subjects. The significant factors associated with VDD were old age and alcoholic drinking habit in women. However, there were no significant associated factors with VDD in men.

Discussion/conclusions: The prevalence of VDD was 9.9% and elderly subjects had a higher prevalence of VDD than younger subjects. The significant factors associated with VDD were old age and alcoholic drinking habit in women, but not in men.

P-1636

Acute hyperglycaemia in patients with thyroid orbitopathy treated with steroid pulses – based on own materials

B. Bandurska-Stankiewicz[1], E. Kuglarz[1], D. Wiatr-Bykowska[1], K. Myszka-Podgorska[1]

[1] General District Hospital, Diabetology Department, Olsztyn, Poland

The aim of the work was to estimate the prevalence of acute hyperglycaemia during systemic steroid therapy in patients with thyroid orbitopathy in the course of Graves-Basedov's disease during euthyreosis with previously non-recognised carbohydrate metabolism disorders (pre-diabetic condition, diabetes) and normally functioning kidneys and liver.

Material and Methods: The study comprised 35 patients, 25 women and 10 men aged 52.74 +/-7.8 yrs. In all patients without previously recognised diabetes prior to steroid therapy, oral glucose tolerance tests were carried out and HbA1c, transaminase activity and creatinine level were determined. During steroid therapy (average Sol-Medrol dose 6+/-2 g) an 8-point daily glycaemic profile was run.

Results: Based on oral glucose tolerance test (OGTT) carbohydrate metabolism disorders were recognised in 15 patients (diabetes in 2, IGF in 8 and IGT in 5). All patients during steroid therapy had postprandial hyperglycaemia (140 to 330 mg/dl). Patients with hyperglycaemia over 140mg% were administered insulin therapy in the form of short-acting insulin boluses before each main meal in the daily dose 8+/-2 units (22 patients) or metformin (4 patients). In these patients after steroid therapy completion glycaemic level lowered to 120+-5 mg%. Following steroid therapy in 7 patients with continuing glycaemia (diabetes recognition criteria with HbA1c 5.74 +/-0.48) hypoglycaemic treatment was carried on.

Conclusions:

1. Before deciding on systemic steroid therapy patients with thyroid orbitopathy should be given oral glucose tolerance tests.
2. A daily glycaemic profile should be run during therapy with steroid pulses.
3. Acute hyperglycaemia occurring during systemic steroid therapy should be treated with boluses of short-acting insulin /or analogues before each main meal.
4. In patients meeting diabetes recognition criteria (acc. to WHO) both after completing and during continuations of oral steroid therapy there should be applied hypoglycaemic treatment like in diabetes type 2.

Prevalence of diabetes mellitus in a town of the Argentine Mesopotamia (Gobernador Virasoro, Corrientes, Argentina)

S. Lapertosa[1], J. Benitez[1], M. Cespedes[1], C., Bordon[1], M. Villagra[2], L. Lecuna[2], L. De Loredo[3], S. Santoro[4], C. Gonzalez[5], M. Sereday[6]

[1] Medical School, U.N.N.E., Corrientes, Argentina

[2] Hospital J.R.Vidal, M.S.P., Corrientes, Argentina

[3] Hospital Privado, Medicine, Cordoba, Argentina

[4] Hospital Ramos Mejias, M.S.P., Ciudad Autonoma Buenos Aires, Argentina

[5] Catedra Farmacologia, U. B.A, Ciudad Autonoma Buenos Aires, Argentina

[6] Comite Epidemiologia, S.A.D., Ciudad Autonoma Buenos Aires, Argentina

Background and aims: Our aim was to estimate the prevalence of Diabetes Mellitus (DM) in a town of the interior of the Corrientes province, Argentina and to evaluate (later on) the association of diabetes with independent covariates such as obesity, hypertension and dyslipidemia.

Methods: Out of a population of 26.018 inhabitants, almost entirely Caucasians, we selected a representative sample of 657 individuals with a multietapic probabilistic aleatoric procedure and with a precision of 4 %.

The demographic and clinical data was registered in a validated questionnaire. We used colorimetric enzymatic procedures for the biological variables and we applied the WHO and the JNC 7 diagnostic criteria for diabetes and obesity, hypertension and dyslipidemia respectively.

The confidence interval was calculated by the exact binomial method and the rates were standardized by age. The association between DM and several covariates was studied both by univariate (Chi 2, t test, Mann-Whitney) and multivariate (multiple logistic regression) techniques.

Results: The sample included 657 individuals, (52.6 % women) between 20 and 79 years of age with a mean of 56.5 +/- 12.3 years. There were 31.37 % of unknown cases of diabetes.

The crude prevalence rate for DM was 7.76 % (95 % CI 5.64 - 9.89 %), for obesity 26.00 %, for hypertension 44.59 % and for dyslipidemia 27.85 %.

The adjusted rate by age for each pathology and sex was:

- Men Women
- DM % (95% CI) 7.48 (4.42 - 10.54) 7.93 (4.99 - 10.87)
- Obesity % (95% CI) 23.69 (18.22 - 29.17) 28.00 (22.43 - 33.58)
- Hypertension % (95% CI) 50.13 (42.16 - 58.10) 39.75 (33.09 - 46.40)
- Dyslipidemia % (95% CI) 29.45 (23.39 - 35.50) 26.45 (21.04 - 31.86)

In the univariate analysis there was a significant statistical association ($p <.001$) of DM and age, BMI, SBP, DBP, total cholesterol and triglyceridemia. In the multivariate analysis, DM adjusted by BP and cholesterol was significantly associated with age (p .00001), triglyceridemia (p .0001) and log BMI (p .0161)

Conclusion: The prevalence of DM in Gdor. Virasoro was 7.76 %, in concordance with others studies in the country. Its presence was significantly associated with age, BMI and triglyceridemia.

Registry of people with diabetes with young age at the onset

T. Kaur[1], B. Shah[1]

[1] Indian Council Of Medical Research, Division Of Non Communicable Diseases, Delhi, India

The Task Force Project entitled," Registry of People with Diabetes in India with Young Age at the Onset," was started with the aim to understand (i) the magnitude of problem; (ii) disease pattern or types including the geographic variation and (iii) incidence and prevalence rate of complications. All the cases of diabetes reported after January 1st, 2000 with the age equal to or less than 25 years age with fasting plasma glucose >126 mg/dl and/or 2 hr post load plasma glucose >200mg/dl, referred/non-referred, treated/untreated residing within the assigned geographical area are included. The cases on steroids and those having short term increase in blood sugar are excluded. The tertiary hospital based registry is set up with the recruitment of all subjects in the age group equal to or less than 25 years. One Collaborating center each in the north, south, east, west and northeast regions of the country are included. Each centre has obtained information from the interacting diabetes centers/ clinics. The core or broad proforma is being followed by all the centers during the data entry. The proforma includes the demographic and clinical information of the subjects along with the family history. The data entry is done with the help of manually filled in proforma. The centres having facilities are encouraged to use the screen-based proformas provided by the Coordinating Unit. In these centers, the data entry would follow a web-based approach but the hard copies of proforma would also be kept for the record. At Northern Indian; 75.7% subjects were Type 1 diabetes and 24.3% were Type 2 diabetes. The prevalence and complications of the reported case were as follows: Neuropathy: 4.17%; Retinopathy: 6.94%; Nephropathy: 4.17%; CAD: 1.4%; Tuberculosis: 6.94%. At Southern India, 44.2% were reported with Type 1 Diabetes, while type 2 is 25.6% and MODY is 19.2%. At Eastern India, 94% subjects were presented with Type 1 Dabetes Mellitus. At a North Eastern centre of country, 20% are reported with Retinopathy and 10% with Nephropathy. The workshops are conducted by each Collaborating Centre for interaction with other Reporting Centres. (which are usuall more than 50 centres per region) for data entry and filling up of the proforma. The study is into its third year and blood samples are being stored for future molecular and genetic analysis and shall help in creating the Biobank.

[4] Burhan Nalbantoglu Hospital, Primary Health Care Department, Lefkosa-Kuzey Kibris- Mersin-10, Turkey

[5] Cypru Social and Economic Research Centre, Medical Research Department, Lefkosa-Kuzey Kibris- Mersin-10, Turkey

[6] University of Istanbul Cerrahpasa Medical Faculty, Department of Endocrinology, Istanbul, Turkey

The aim of this study is to determine the prevalence of diabetes and IGT among Turkish Cypriot people.

The study group was chosen among adults between 20-80 years by random sampling method, taking their age, gender and place of residence into consideration. 1,780 people were invited to take part in the study. Between 24-28 November 2008 the participants were invited to 21 health centres according to a schedule and a questionnaire form was filled in order to obtain personal information, family history and lifestyle. Following this, anthropometric measurements were taken and an OGTT was performed.

Diagnosis of diabetes was based on capillary blood glucose levels using the 2006 diagnostic criteria recommended by the WHO and IDF. Those participants who had diabetes history, only their fasting blood sugar and anthropometric measurements were taken and the questionnaire was filled. All other participants who did not have diabetes history and had a fasting blood sugar level of ≥ 125 were given an OGTT. Those with a fasting blood sugar level of ≥ 126 were asked to come back the following day to have their fasting blood sugar level evaluated again. The subjects with a blood sugar level of ≥ 126 were diagnosed to have diabetes and were not given an OGTT. Those whose blood sugar level was found to be ≤ 125 in the second measurement were given an OGTT and the results were evaluated according to WHO/IDF 2006 criteria.

5.4% of the study group was found to have a history of diabetes by questionnaire. Following the OGTT the total diabetes and IGT prevalences were found respectively 11% and 18%. Obesity and overweight prevalences according to BMI among Turkish Cypriot Community were found to be 31.6% and 35.4% respectively. In men with waist circumference ≥ 94 cm and <94 cm diabetes prevalences were found 18.6% and 5.8% respectively ($p<0.05$). In women with waist circumferences ≥ 80 and < 80 cm diabetes prevalences were found 15.8% and 3.8 % respectively ($p<0.05$).

In the first study on the prevalence of diabetes among the Turkish Cypriot Community, which was carried out in 1996, diabetes prevalence was 11.3% and IGT prevalence was 13.5%.

According to the results of screening carried out among the Turkish Cypriot Community, it can be said that diabetes continues to be a major health problem and that the increase in the IGT prevalence is an indicator that diabetes prevalence will further increase in the future. In addition to raising public awareness in the efforts to prevent diabetes, we believe that it would be beneficial to identify people with IGT and put them under treatment and observation. Therefore, we are continuing with our efforts to closely follow and treat the patients identified as a result of this study, or those who did not take part in the study but are in diabetes risk group.

Smoking history in the study of metabolic syndrome in a sample of Maracaibo municipality: Profiles of risk

G. Ruiz Acosta[1], L. Acosta[1], S. Martinez[1], M. Pirela[1], V. Bermudez[1], V. Lijuzu[1], F. Quintero[1], D. Vilchez[1], E. Rojas[1], J. Montes[1]

[1] Endocrine-Metabolic Research Center "Dr. Féliz Gómez", Faculty of Medicine University of Zulia, Maracaibo, Venezuela

Introduction and objectives: Smoking is a risk factor for cardiovascular disease, cancer and others disease. The objective of this research is to study the prevalence of smoking and its relationship with anthropometric and laboratory parameters in a sample of Maracaibo Municipality.

Materials and methods: A descriptive cross-sectional study in 1400 inhabitants of the Municipality of Maracaibo, selected randomly, who had a complete clinical history, determination of lipid profile, insulin and fasting glucose by venepuncture of 8-12 hours. Statistical analysis was performed using the SPSS program for Windows ver.15. Results were expressed as arithmetic mean ± standard deviation and absolute frequencies and percentages as appropriate. Comparisons were made with one factor ANOVA test and Post Hoc Tukey test considering significant a $P<0.05$.

Results: 16.7% of the sample studied consisted of active smokers, 69.1% non-smokers and 14% smoked in the past. Among the variables with statistically significant differences between the group of smokers, non smokers and former smokers are: basal blood glucose 99.49 ± 27.96 mg / dL, 97.56 ± 22.76 mg / dL and 104.63 ± 30.54 mg / dL ($p<0.01$), total cholesterol 191.47 ± 47.36 mg / dL, 185.86 ± 41.55 mg / dL and 201.58 ± 42.7 mg / dL ($p<0 01$); Triglycerides 154.95 ± 106.05 mg / dL, 116.34 ± 77.22 mg / dL and 148.50 ± 103.18 mg / dL ($p<0.01$), LDL-c 117.73 ± 40 01mg/dL, 116.79 ± 37.25 mg / dL and 128.04 ± 42.58 mg / dL ($p<0.01$); SBP 118.66 ± 13.90 mmHg, 118.66 ± 16.23 mmHg and 123 26 ± 16.30 mmHg ($P = 0001$) and DBP 76.62 ± 10.50 mmHg, 76.65 ± 10.74 mmHg and 79.84 ± 10.56 mmHg ($p<0.01$) only in females abdominal circumference of 94.21 ± 16.42 cm, 88.62 ± 14.15 cm and 96.39 ± 12.95 cm ($p<0.01$), respectively, statistically significant differences.

Conclusions: Individuals with positive history of smoking were found elevated levels of basal glycemia, Triglycerides, LDL-c, SBP, DBP, and female only, abdominal circumference, which suggested that this habit might contribute significantly with the incidence of diseases such as acute coronary events and cancer.

Prevalence of diabetes mellitus type 2 in adult population of Maracaibo, Zulia State, Venezuela

S. Martínez[1], V. Bérmudez[1], F. Moreno[1], C. Colmenares[1], L. Vega[1], J. González[1], J. Urribarri[1], G. Ruíz[1], D. Gotera[1], A. Urdaneta[1]

[1] Universidad del Zulia, Centro de Investigaciones Endocrino Metabólicas Dr. Félix Gómez, Maracaibo, Venezuela

Aims: Today, Diabetes Mellitus type 2 is an important cause for discapacity and death in all countries, practically, and constitutes a real epidemic in the world. The prevalence of diabetes has increased impressively during the last two decades. In our locality is not well known yet, for this reason, the purpose of this research was to determine the prevalence of this pathology in Maracaibo, Zulia State, Venezuela.

Methods: It was used a sample of 1400 individuals older than 18 years (male: 45,3%; female: 54,7%), selected through a random number generation utility. A complete clinical history and quantification of glucose, lipid profile and insulin was made. Also, it was realized the statistical analysis in the SPSS program version 15.0. It was used the chi^2 test to prove the association between variables, and the results were expressed in absolute frequency and percentage.

Results: The prevalence of Diabetes Mellitus type 2 in this population was 9,4% (n=131), being higher in females (56,2%; n=73) than males (43,8%; n=57). Related to age groups, the percentage of prevalence were: younger than 20 (5,6%; n=8); 21 to 30 years: (6,3%; n=8); 31 to 40 years: (14,1%; n=18); 41 to 50 years: (30,8%, n=40); 51 to 60 years: (23,4%; n=30); 61 to 70 years (16,4%; n=21); 71 years and more: (4,6%; n=6). Also, it was found an association between the presence of personal history of diabetes and personal history of hypertension (34,6%; n=45), family history of Diabetes Mellitus (64,6%; n=84), and smoking (78,5%; n=99).

Conclusion: It is well seen a significant prevalence (9,4%) of diabetic individuals in Maracaibo's population, being higher in females (56,2%) and age groups older than 40 years (70,6%), justifying more studies to determine the prevalence of this pathology in other population and its prevention on time.

Thyroid diseases in adult diabetic patients

B. Bandurska-Stankiewicz[1], U. Tarasiewicz[1], D. Wiatr-Bykowska[1], K. Myszka-Podgórska[1], E. Kuglarz[1]

[1] General District Hospital, Diabetology Department, Olsztyn, Poland

Aim: Estimation of thyroid diseases incidence in adult diabetic patients.

Material and methods: Among diabetic patients with diabetes mellitus type 1 (DM1) and type 2 (DM2) diagnosed according to the WHO criteria, there has been isolated a group of patients with thyroid diseases diagnosed based on interviews, physical examinations, imaging examinations and in some cases on thin-needle biopsy, thyroid hormone level (FT4, FT3), thyrotropic hormone, antithyroid antibodies (aTG, aTPO) and TSH-1. The obtained results were statistically handled.

Results: The study comprised of 276 patients (in this 87% women, 107 with DM1 and 169 with DM2). Autoimmune thyroid disease was recognised in 136 patients (80 with DM1), Hashimoto disease in 101 patients, Grave's disease in 35 patients, nodular goitre in 27 patients with DM1 and 113 with DM2, thyroid cancer in 2.8 % (14% with DM2).

Conclusions:

1. Autoimmune thyroid diseases are the most common endocrinopathy related to DM1.
2. Thyroid cancer in patients with nodular goitre and DM2 occurs significantly more frequently than in general population.

P-1643

Prevalence of glucose metabolism abnormalities among population of the European part of Russia

I. Misnikova[1], A. Dreval[1], I. Barsukov[1]

[1] Moscow Region Research Clinical Institute, Endocrinology department, Moscow, Russia

Background: Registered prevalence of T2DM in Russia makes about 2.0%, and the prevalence of the early glucose metabolism abnormalities (IFG, IGT) is investigated insufficiently.

Aim: to study the prevalence of T2DM and the early glucose metabolism abnormalities (GMA) among the adult population of the European part of Russia by the organization of screening the population of the two areas of Moscow County.

Materials and methods: Population-based screening for GMA among 2508 individuals of Moscow County was conducted in 2006. FPG was measured in all the participants. The standard 2-h 75g OGTT was performed using HemoCue analyzers in the subjects previously undiagnosed with diabetes. T2DM, IFG and IGT were diagnosed according to the 1999/2006 WHO criteria.

Results: The prevalence of T2DM and the early glucose metabolism abnormalities depending on gender and age (%) is submitted in the table:

Age, years	men		women		Significance of gender difference		In total	
	T2DM, %*	prediabetes %*	T2DM%*	prediabetes %*	p (T2DM)	p (prediabetes)	T2DM%*	prediabetes %*
18-30	0.98	5.88	0.92	4.59	>0.05	>0.05	0.94	5.00
31-40	0	4.00	2.19	9.84	<0.05	<0.05	1.55	8.14
41-50	0	15.97	4.01	17.19	<0.05	>0.05	2.99	16.88
51-60	11.49	18.39	10.25	15.48	>0.05	>0.05	10.58	16.26
61-70	9.34	24.18	11.14	23.14	>0.05	>0.05	10.53	23.50
Over 70	12.96	28.70	12.43	39.64	>0.05	<0.05	12.64	35.38
In total, %**	6.84	17.76	7.38	17.74	>0.05	>0.05	7.22	17.75
In total, %	24.61		25.13		>0.05		24.97	

* % of an age group among men and women;

** % of a group among men and women.

Conclusions:

1. The prevalence of T2DM among the surveyed population has made 9.4 %, including the first time diagnosed T2DM - 7.2 % that exceeds the given official statistics in 4.3 times.
2. The prevalence of IFG and IGT exceeded the prevalence of the first time diagnosed T2DM in 2.5 times.
3. The persons over 70 years had the maximal prevalence of GMA and it achieved 54.9 %, including T2DM-19.5 %, and IFG and IGT - 35.4 %.
4. The significant gender differences in the total prevalence of the T2DM and the prediabetes were not revealed.

P-1644

Diabetes care in a Turkish population at one center

G. Oruk[1], D. Kurt[2], S. Isli[2], N. Ozen[2]

[1] Ataturk Training and Research Hospital, Endocrinology and Metabolism, Izmir, Turkey

[2] Ataturk Training and Research Hospital, Endocrinology and Metabolism Diabetes Registered Nurse, Izmir, Turkey

The aim of this study was to examine the characteristics of our diabetic patients who were hospitalized in our hospital for several reasons. The group consisted of 1777 patients. 977 of them were female (55%), 800 of them were male (45%). 185 of them were Type 1 diabetic (10.4%), 1592 (89.6%) were Type 2 diabetic. When they were questioned for their home address, 1046 (58.9%) of them were living in local area, 731 (41.9%) were referred to our hospital from other hospitals which were out of town. The educational level of these patients was also investigated. 430 (24.2%) were illiterate, 1001 (56.3%) had elementary school, 282 (15.9%) had high school, 62 (3.5%) had university education. These patients were also researched for diabetes education. Only 177 (10%) of them had received diabetes education before. Treatment modalities were as follows: 47 (2.6%) of them were receiving only medical

nutrition therapy, 334 (18.8%) oral antidiabetic treatment, 1379 (77.6%) insülin therapy, 17 (1.0%) insülin and oral antidiabetic treatment. 999 (56.2%) of the patients who were receiving insulin treatment were able to accomplish the insulin injections by themselves, but 412 (23.2 %) of them had needed help from a member of the family. As a result it can be concluded that our center is one of the biggest referral centers for diabetic patients in Aegean region. The educational level investigated in this inpatient group is low. Also only small part of these patients have been educated before for diabetes. Mostly the patients are treated by insulin when they are hospitalized at our hospital. All of these patients are given diabetes education and insulin injection education by registered diabetes nurses. But even with education some patients are unable to apply insulin by themselves.

P-1645

One year change in metabolic control in a cohort of type 2 diabetic subjects at the American University of Beirut in Lebanon

M. Barake[1], T. Haddad[1], R. Bou Khalil[1], H. Salti[2], I. Salti[1], N. Taleb[1], M. Nasrallah[1], A. Kobeissy[1]

[1] American University of Beirut, Internal Medicine, Beirut, Lebanon

[2] American University of Beirut, Ophthalmology, Beirut, Lebanon

Aim: To describe the change in metabolic control over one year among a cohort of diabetic patients in a tertiary care center in Lebanon.

Methods: Out of 313 subjects initially recruited, a total of 228 with Type 2 Diabetes completed their first year and came back for a second year follow-up. Subjects were first recruited in a cross-sectional manner during their usual diabetic care at the American University of Beirut and their initial metabolic control and presence of complications were described previously[1]. We compare, in this observational cohort study, the changes in metabolic control (HbA1C, lipid profile, urine microalbumin) as well as in anthropometric measures (weight, blood pressure) upon one year follow-up. Paired sample t-test was used for comparison.

Results: Over 1 year, there was a significant decrease in total cholesterol and LDL-C levels by 7.5 mg/dl (p=0.012) and 5.77 mg/dl (p=0.03), respectively. Systolic blood pressure significantly decreased as well by 5.48 mmHg (p=0.000) with a similar trend in diastolic blood pressure (drop by 2.77 mmHg, p=0.003). There was, however, a concomitant drop in HDL-C by 2.16 mg/dl (p=0.001). No significant change was detected in triglyceride level, body weight, urine microalbumin or HbA1c (table). The proportion of subjects with controlled glycemia (HbA1C < 7%) and no microalbuminuria (urine albumin-to-creatinine ratio < 30 mg/gram) did not change significantly from year one to year two.

Variable (unit)	Year1 Mean ± SD	Year 2 Mean ± SD	P value	% change
HbA1C (%)	8.41 ± 2.3	8.36 ± 2.6	0.77	-0.6
Total Cholesterol (mg/dL)	193.0 ± 46.8	185.5 ± 41.7	0.012	-3.9
LDL-C (mg/dL)	116.5 ± 40.5	110.7 ± 36.6	0.033	-4.9
HDL-C (mg/dL)	47.3 ± 14.8	45.1 ± 12.6	0.001	-4.6
Triglyceride (mg/dL)	186.1 ± 122.9	176.5 ± 123.1	0.236	-5.2
Microalbumin/creatinine (mg/gram)	178.6 ± 394.5	209.0 ± 546.3	0.395	+14.6
Weight (Kg)	78.3 ± 16.4	78.8 ± 17.2	0.161	+0.6
SBP (mmHg)	131.9 ± 18.9	126.5 ± 15.8	0.000	-4.1
DBP (mmHg)	78.4 ± 9.9	75.6 ± 9.5	0.003	-3.5

Discussion/conclusions: This study showed improvement in LDL-C and blood pressure which might reflect adequate patients' adherence with prescribed medications. The lack of change in all other metabolic markers and the negative change in HDL-C might be the result of inadequate lifestyle modification, as reflected by the absence of weight loss. We can thus conclude that 1) poor metabolic control remains high in this population of diabetic subjects attending a tertiary care center in Beirut, Lebanon and 2) measures targeting effective lifestyle modification should be implemented aggressively.

Epidemiological aspect of prediabetes visiting non-diabetes specialists at University Medical Hospital in Japan

S. Yamaguchi[1], A. Inoue[1], T. Origuchi[1], N. Abiru[2], Y. Kazaura[3], N. Matsuo[3]

[1] Nagasaki University, Deapartment Of Nursing Graduate School Of Biomedical Sciences, Nagasaki, Japan

[2] Nagasaki University, Deapartment Of Endocrinology And Metabolism Unit Of Translational Medicine, Nagasaki, Japan

[3] Nagasaki University, Hospital Of Medicine And Dentistry, Nagasaki, Japan

In 2002, the Japanese Ministry of Health, Labour and Welfare estimated that there were 10.62 million diabetes mellitus (DM) patients in Japan, including 7.4 million DM patients diagnosed and 3.22 million suspected cases. In 2007, this number rose to 22.10 million (8.9 million DM patients and 13.20 million suspected cases, called 'Prediabetes'). Once DM progresses, it damages small blood vessels and leads to severe complications including renal and peripheral vascular disease. This affects an individual's quality of life (QOL), and has a negative impact on the national health economy. With regards to DM, the role of a hospital is to primarily control the blood glucose level and treat severe complications within their specialized DM Department. Patients visiting other departments within the hospital might be overlooked. Since early detection of potential DM patients and intervention is critical, the goal of this study is to develop a program which provides primary prevention and intervention to patients at high risk for developing DM or who are in the early stages of the disease. To this end, we conducted an epidemiological study of potential DM patients who visited non-diabetes specialists at the Nagasaki University Medical Hospital between 2007 to 2008. 3,734 potential DM patients were enrolled in the study including both elderly patients over 65 years of age and young patients below 60 years of age. Our results showed that the percentage of Prediabetes in our study is higher than its statistic data of the Japanese Ministry of Health, Labour and Welfare estimated in 2007, and that patients who are taking steroids are at particularly high risk for developing DM. Early detection of potential DM patients and timely intervention is crucial in preventing the development of DM and protecting the QOL of these patients.

Diabetes mortality and complication in two Cuban provinces, in the period 1990-2002

O. Diaz-Diaz[1], A.I. Conesa[1], J.R. Conesa[2], E. Dominguez[3]

[1] National Institute of Endocrinology, Diabetes Care Center, Ciudad de la Habana, Cuba

[2] Sancti Spiritus Hospital, Epidemiology, Sancti Spiritus, Cuba

[3] National Institute of Endocrinology, Epidemiology, Ciudad de La Habana, Cuba

Objective: To know mortality and direct cause of death in diabetic persons in Havana City (HC) and Sancti Spíritus (SS) province.

Method: It was a cross-sectional study carried out on data from the registry of death certified in both Provincial Statistic Departments from 1990-2002.

Results: During this period the diabetes mortality as basic cause rate trend to decrease in both provinces (mortality rate: HC: 24.2 x 100 000 in 1990 to 11.3 x 100 000 in 2002, in SS: 16.4 in 1990 to 8.3 in 2002), by other hands the specific diabetes complications as cause of death decrease, except for renal complication in both provinces (Adjusted rate: in HC: 2.9 to 4.1, and in SS: 3.2 to 3.8), and peripheral vascular complications in Sancti Spíritus. In general, the basic adjusted rates of death for diabetes in the whole period where higher in Havana than Sancti Spíritus. Cardiovascular and stroke conditions were the major complications of diabetes in both provinces (HC: 38.1% & SS 35.7% from total of direct cause of death). The adjusted rate of ketoacidosis and coma, as cause of death, decrease from 2.3 to 1.1 in HC, and from 1.8 to 0.2 in SS. The number of ill-defined cause of the death at the final of period, were several times reduced. (HC from 451 in 1990 to 40 deaths in 2002, and SS from 55 to 5 death in 2002) The major figures were found in females and over 65 years old. We found important differences between above provinces mentioned.

Conclusions: It was confirmed the decrease in mortality in these provinces, as well as, was in the rest of the country, which could be due to the efficiency of the diabetes care program, the decrease of metabolic complications and ill-defined cause of death remark it. It was found that the mortality and the lethal complication of diabetes, in the country, are still heterogeneous in different regions.

Establishing abdominal diameter cut-offs and association to conventional indices of obesity among Arab children and adolescents

N. Al-Daghri[1], M. Alokail[1], O. Al-Attas[1], K. Al-Rubeaan[1], K. Al-Rubeaan[2], S. Kumar[3]
[1] King Saud University, Biochemistry, Riyadh, Saudi Arabia
[2] King Saud University, University Diabetes Center, Riyadh, Saudi Arabia
[3] King Saud University, University of Warwick, Warwick, United Kingdom

Aims: This is the first study to document the association of sagittal abdominal diameter (SDI) to measures of obesity among Arab children and adolescents. It aims to identify associations of SDI to indices of obesity among Saudi youth and to establish cut-offs among Arab youth.
Methods: 964 Saudi children aged 5-17 years [365 pre-pubertal (146 boys & 219 girls); 249 pubertal (125 boys & 124 girls); and 350 post-pubertal (198 boys & 152 girls)] were included in this cross-sectional study. Holtain Khan abdominal caliper by Holtain Ltd. (Crymych, UK) was used to measure sagittal abdominal diameter. Other anthropometric measures of interest were measured routinely.
Results: SDI was significantly correlated to indices of obesity regardless of gender, strongest among pubertal boys. For pre-pubertal, the cut-off is 14cm (equivalent to 50th percentile among girls and 60th percentile among boys); for pubertal, 15cm for girls (30th percentile) and 16cm for boys (50th percentile); and for post pubertal, 21.5cm for girls (70th percentile) and 22cm for boys (80th percentile).
Conclusion: SDI is a reliable indicator of visceral obesity among Arab children and adolescents in particular. Further studies should be done to compare its association to components of metabolic syndrome and indices of insulin resistance.

The metabolic syndrome and associated risk factors in the Johannesburg Metro District

N. Moodley[1]
[1] University of the Witwatersrand, Community Health, Johannesburg, South Africa

Background: The metabolic syndrome (MS) cluster represents the most critical risk factors for the development of a myocardial infarction. Estimates suggest that 20 – 25% of the world's adult population have the metabolic syndrome. The chronic metabolic diseases are a growing cause of death and disability in South Africa. While MS is a poorly recognized clinical entity in this country, the individual components of the MS have become more prevalent. Diabetes prevalence rates are higher than the African average at 4-6%. The prevalence of hypertension and hyperlipidaemia in 2007 was 5.5% and 3% respectively. In 2002, despite South Africa's growing concerns of under-nutrition, poverty and infectious diseases, more than 29% of males and 56% of females were classified as obese or overweight. Paucity of South African MS data limits the planning of effective preventative strategies for individual components of MS.
Aim: The study aims to determine the MS prevalence and the risk factors associated with its development in the Johannesburg Metro District, Gauteng Province in South Africa, with a view to reducing the burden of disease in terms of long term management and the development of complications.
Methodology: Study design: Stepwise approach with review of routinely collected District Health Information System (DHIS) data followed by community based survey.
Setting: Johannesburg Metro District the largest metropolitan area in South Africa. The community survey will be conducted in Chiawelo, a homogeneous suburb in Soweto representing all black ethnic groups in South Africa.
Sampling: Routinely collected DHIS data for the entire district was analysed. The community survey will use a stratified randomised cluster sampling technique (sample size=288). Inclusion criteria for the community survey would be residents of Chiawelo who are over 18 years old and have lived in the area for more than five years.
Variables: Analysis of socio-demographic, socio-economic, risk factor, clinical and biochemical parameters would isolate the key determinants of disease development in this community.
Study period: The study will run from January 2009 – February 2010.
Results: (a) Analysis of DHIS data from the Health District showed diabetes and hypertension prevalence at 120 and 200 per 100,000 population (over 45 years). Information regarding hyperlipidaemia and obesity is not routinely collected. Chiawelo Clinic ranked 2nd in the Johannesburg Metro District for the number of diabetics managed from April 07 to March 08.
(b) Community survey results will be available at the time of presentation.
Conclusion: Initial data analysis showed increased prevalence of some components of MS despite scarcity of information. The second phase of this project will provide important information.

Epidemiologic evaluation and glycemic control of a population with type 2 diabetes, part of a family health program in Curitiba, Brazil

F. Reis Gomes[1], S.A.O. Leite[2], L. Picolo Furlan[3], A. Bittencourt Guimarães[4], F. Marques[1], P. Albizu Piaskiwy[1], R. Fadel Friedlander[1], L. Welter Neto[1], L. Pikissius[1], M. Pires Ramos[5]
[1] Positivo University, Medical Student, Curitiba, Brazil
[2] Positivo University, Endocrinology, Curitiba, Brazil
[3] Positivo University, Family Health, Curitiba, Brazil
[4] Positivo University, statistics, Curitiba, Brazil
[5] Positivo University, Infectology, Curitiba, Brazil

Aims: To assess glycemic control through the measurement of glycated hemoglobin (A1c) and the main factors that might be associated with it in a population based on a sample of patients with type 2 diabetes in a primary care setting.
Methods: During patient's home visit, a questionnaire was administered asking about lifestyle, oral antihyperglycemic agents and/or insulin treatment compliance; anthropometric data and blood sample were collected for A1c levels. The variables exercise frequencies, diet orientation, medication type, program adherence were correlated with different A1c levels categories through multivariate analysis of correspondence.
Results: One primary care site with a total of 170 patients with type 2 diabetes included in the family health program was selected, 39 patients dropped out, 131 patients were included in this sample, 101 women, 30 men, age ranged from 23 to 84y/o, BMI= 29±6kg/m^2, abdominal circumference 101±12cm, 69% of this population have not completed high school and 87% have family profits under U$500/month. 42% of patients had A1c < 7 and 58% A1c > 7.0%. Among sedentary patients 64% presented A1c > 7, whereas 56% of patients exercising regularly three or more times a week had A1c < 7. The majority of patients (63%) who received diet education have A1c >7, beside 41% of patients who follow dietitian orientation have A1c < 7. Only 39% of patients participating in diabetes education group have A1c < 7, while 61% have A1c > 7.
Patients taking oral agents combination and insulin have had the higher risk with A1c>9%. The best correlation with a good glycemic control (A1c<7) was found in patients taking monotherapy and exercising at least three times a week.
Conclusions: This study was conducted evaluating health family program for diabetes care. Low social economic and education level make difficult patients' compliance for insulin therapy and oral medicine combination, reflecting poor glycemic control in patients with higher treatment complexity. Changes in life style with regular physical activity demands few resources and results in significant improvement of glycemic control in primary care setting.

Effects of low socioeconomic status on diabetes mellitus: the case of Itapirapua Paulista, Vale do Dibeira, Sao Paulo State, Brazil

R.E.T. Navarrete[1], A.C. Santomauro Jr[1], A.T.M.G. Santomauro[1], F.F. Fraige[1]
[1] Faculty of Medicine ABC, Department of Endocrinology, Santo Andre, Brazil

Objectives: Our goal was to establish the relationship between socioeconomic status and the prevalence of overweight and type 2 diabetes mellitus among people of Itapirapua Paulista, city situated in Vale do Ribeira, which is the poorest region of Sao Paulo State, Brazil. The hypothesis was that prevalence of type 2 diabetes would be inversely related to socioeconomic status.
Material and methods: A cross-sectional study was performed by using data from the 2002-2008 Family Health Program conducted by the Brazilian System of Registration and Accompaniment of Hypertensive and Diabetic Patients

(www.hiperdia.datasus.gov.br) in the municipality of Itapirapua Paulista. The evaluated factors were physician-diagnosed diabetes mellitus, hypertension and overweight. Analysis was conducted according to age, gender, race, income level and education level.

Results: A total of 81 diabetic patients including 50 women (61,70%) and 31 women were studied, of whom 65.4 percent are of mixed race and 44.4 % overweight. Other cardiovascular risk factors were essential hypertension (56,8%) and tobacco use (37%). The increased prevalence of diabetes in the most deprived areas was accounted for by increased prevalence of type 2 diabetes in the age band 50-74 years (54%). Only 22% finished the basic education level. There was no association between the prevalence of type 1 diabetes and socioeconomic status.

Conclusion: For certain conditions identified as education level or occupational status, our data confirm an inverse association between socioeconomic status and the prevalence of type 2 diabetes in the middle years of life. Economic resources should be addressed in efforts to explain and reverse the increasing prevalence of diabetes among communities with low human development index.

Models of care delivery

P-1652

Saving families time and money: a new model using telemedicine for follow-up care for children with type 1 diabetes

D. Pacaud[1], G. Currie[1], S. Crawford[2], T. Schweitzer[2], M. Chiasson[3]
[1] University of Calgary, Pediatrics, Calgary Ab, Canada
[2] Alberta Children's Hospital, Pediatrics, Calgary Ab, Canada
[3] Lancaster University, Dept of Management Science, Lancaster, United Kingdom

Regular medical contact is important for optimizing diabetes control. However, it can be time consuming and costly for families.

Aim: The objective of this analysis was to compare time involvement and direct costs for families between conventional face to face clinic visits and phone contact visits.

Methods: As part of a randomized control trial looking at an alternative model care that replaced some face to face visits with a phone visit, information on time involvement and costs to families was collected. Both groups had regular multidisciplinary visits at 0, 6 and 12 months. The conventional group had a physician-only visit at 3 and 9 months while the intervention group had a phone follow-up visit with a diabetes nurse educator preceded by communication of information by fax or internet followed by a phone call.

Results: 82 subjects (39 boys and 43 girls, average age 11.5 ± 3.6 years were randomized to conventional treatment (n=40) or intervention (n=42). At baseline, no significant differences emerged between the two groups for gender, age at entry into the study, age at diagnosis, time since diagnosis, insulin regimen or A1C at first visit in the study. Further, there was no significant difference in traveling distances and time, mode of transport, parking costs, time away from work for parents, or from school for children, between the two groups. However, when a face to face visit is replaced by a phone visit, group differences were found in hours missed from work for mothers (controls 3.4 ± 2.6 hours vs intervention 0.8 ± 0.6 hours, F (1,63)=31.7, p<.001), for fathers (controls 3.3 ± 2.1 hours vs intervention 0.5 ± 0.2 hours, F (1,10)=6.70, p=.027); and for children's time spent away from school for visit (controls 2.3 ± 2.0 hours vs intervention 0.2 ± 0.8 hours, F (1,66)=30.38, p<.001). Traveling time and costs remained the same for the conventional group but decreased to zero for the intervention group.

Discussion/conclusion: Replacing some face to face medical visits with phone visits results in better outcomes for families in terms of decreased time away from regular activities and costs. If found to result in similar medical outcomes in terms of A1C and acute complications and in similar health care providers time involvement, this may be an efficient option for organizing follow-up care for children with diabetes.

Staged Diabetes Management: improving clinical outcomes in Russia

R. Mazze[1], E. Strock[1], M. Idrogo[2], R. Cuddihy[2], A. Ametov[3]
[1] International Diabetes Center, Academic Research, Minneapolis, USA
[2] University of Minnesota Medical School, Family and Community Medicine, Minneapolis, USA
[3] Institute for Advanced Studies, Endocrinology, Moscow, Russia

Aims: The overall aim was to implement Staged Diabetes Management (SDM), a systematic evidence based approach to the management of type 2 diabetes, and measure its impact on glycemic control in five sites located in Russia.

Methods: Prior to training in SDM, medical centers in Moscow, Krasnodar, Perm, Stavropol and Rostov agreed to undertake a pilot project to measure clinical outcomes in a randomly selected sample of patients. Eleven endocrinologists agreed to randomly select 220 patients with type 2 diabetes and to treat these patients in accordance with SDM clinical pathways (treat-to-target $HbA_{1c} \leq 7\%$) immediately following SDM training. Each site followed the subjects for three months.

Results: Baseline and follow-up data were available for 161 subjects (73%). There were no significant differences in baseline demographic or physiologic measures between patients who completed the study and those who did not return to the clinic for follow-up. At the first clinic visit all patients were measured for glycosylated hemoglobin using a common assay. At that time it was determined that 65% of the patients were treated with sulfonylurea and/or Metformin, 2% with thiazolidinedione and 31% with insulin (pre-mixed); additionally, 97% of the patients used SMBG, averaging 2 tests/day and 98% received education and nutrition counseling. Based on HbA_{1c}, 6% of the patients were at target ($HbA_{1c} \leq 7\%$) and required no further change in treatment. Current treatment was reviewed for all patients exceeding the target. It was discovered that of the 12 patients meeting the criteria for insulin treatment ($HbA_{1c} > 10.9\%$), two were currently prescribed insulin. It was also noted that patients who exceeded target tested less frequently (2 tests/day) than those at target (3 tests/day). Based on these data, treatment was altered by dose or by drug classification in accordance with the Master DecisionPath customized by the endocrinologists during SDM training. Alterations in the current regimen's dose plus initiation of insulin in some patients led to 50% of the patients (81) achieving the target glycosylated hemoglobin within 3 months. Overall, there was a significant ($p<0.0001$) reduction in HbA_{1c} (9±1.6% versus 7.3±1.2%) between baseline and three months at each site and for all sites when data were pooled.

Conclusions: Staged Diabetes Management, a systematic evidence-based approach to diabetes, can be effectively implemented in multiple sites within Russia to produce improvements in glycemic control.

P-1655

Coaching by a dietician: a cost-effective alternative to diabetes management?

P. Perron[1], M. Labonté[1], F. Jean-Denis[1], G. Houde[1], J. Menard[1], J.L. Ardilouze[1]
[1] CHUS, Endocrinology department, Sherbrooke, Canada

World prevalence of diabetes and associated burden of care and complications are rising. Cost-effective management alternatives are badly needed. Cardiovascular risk (CVR) management by dieticians is one alternative worth assessing over a long term. This 2-year randomized trial aimed to show that dietician-led therapy management with an endocrinologist, for purposes of annual follow-up and advice as needed, enables recommended diabetes outcomes and is less costly than regular care.

Diabetic subjects (n=101, $HbA_{1c} > 7\%$) were randomized to a Dietician-Coached Group (DCG) or a Conventional Group (CG) with follow-up as usual by endocrinologists ± general practitioners. DCG met with coach every 3 months (physical and biochemical measures, exercise, diet and smoking, hypoglycaemia recording, capillary glucose monitoring and motivation), had monthly follow-up phone calls with coach and a yearly endocrinologist follow-up. Variables were taken every 3 months for DCG vs. yearly for CG.

At baseline, groups (DCG n=51/CG n=50) were similar in age (60±10/60±11 yrs), duration of diabetes (16±9/16±10 yrs), systolic and diastolic blood

pressure (sBP: 131±15/131±24; dBP: 74±9/77±10 mmHg), fasting plasma glucose (FPG: 8.8±3.2/8.4 ±3.3 mM), HbA_{1c} (8.1±0.9/8.1±1.1%), triglycerides (1.88±1.28/1.78±1.23 mM), LDL (1.94±0.70/2.03±0.64 mM) and total cholesterol/HDL (3.39±1.16/3.50±1.27 mM). DCG subjects were heavier (BMI: 34±8/31±5 kg/m^2; p=0.03, waist circumference: 113±18/106±12 cm; p=0.03).
At 1 year (DCG n=36/CG n=39), repeated measure ANCOVA showed groups differed for HbA_{1c} (8.0±0.8/7.2±0.8% vs. 8.0±1.2/8.0±1.4%; p<0.001) and waist circumference (113±18/112±19 vs. 105±13/107±13 cm; p=0.03). Moreover, a trend was noted for sBP (130±14/130±26 vs. 121±16/130±14 mmHg; p=0.06), dBP (74±8/69±10 vs. 77±10/77±13 mmHg; p=0.06), microalbuminuria (15±41/8±16 vs. 3±5/9±27%; p=0.06) and fasting plasma glucose (8.8±3.2/7.1±2.6 vs. 8.2±3.1/8.6±5.7 mM; p=0.052).
Dietician coaching seems to be superior to regular care at improving diabetes outcomes and CVR factors. Cost analyses are ongoing.

Effectiveness of a structured diabetes care program with limited resources

J. Rodriguez-Saldana[1], M.A. Morales de Teresa[1], R.S. Mazze[2], E. Strock[2], C.M. Clark[2], J.D. Piette[3]
[1] *Resultados Medicos Desarrollo e Investigacion SC, General Direction, Pachuca de Soto, Mexico*
[2] *International Diabetes Center, General Direction, Minneapolis MN, USA*
[3] *University of Michigan, VA/UM Program on Quality Improvement for Complex Chronic Conditions, Minneapolis MN, USA*

Rationale: Despite scientific evidence confirming the efficacy of metabolic control in the reduction of the incidence of chronic diabetes complications, worldwide deficiencies in diabetes management are still prevalent. Contributing factors include lack of coverage or limited access to public/private services, scarcity of diabetes educators, organizational deficiencies, scarce economic resources, and shared lack of effective interventions by current systems of care, providers of diabetes health care and their patients.
Objective: Investigate the effectiveness of a structured program on the quality of outpatient diabetes care at the primary level and with very limited economic resources in Mexico.
Patients and methods: A prospective study was conducted in diabetes patients treated at outpatient diabetes clinics established in 2001-2007 as the state diabetes program in Hidalgo Mexico, one of the poorest states in the country, with a mostly rural population. Baseline and follow up consultation was provided by multidisciplinary teams including general physicians and nurses as a minimum. Goals of treatment were clearly explained and negotiated with each patient. Organizational arrangements were made to reduce waiting times, avoid rotation of doctors and nurses, and provide adequate time for baseline and follow-up visits. Each follow-up visit included measuring process and outcomes indicators of quality of diabetes care, including: 1) body mass index; 2) blood pressure; 3) fasting or casual blood glucose 4) lipoprotein measurement; 5) hemoglobin A1c (HbA1c); and 6) foot examination.
Results: Analysis of 4,393 patients who attended five visits showed the following increases in the percent of recorded process indicators of quality of diabetes care from baseline: 1) body mass index, 85.0 vs. 95.9%; 2) blood pressure measurement, 73.29 vs. 95.6%; 3) HbA1c 12.5 vs. 17.7%; 4) total cholesterol, 18.2 vs. 55.9%; 5); 6) foot examination, 19.0 vs. 95.0%. Outcome measures that showed non-statistically significant differences were body mass index (27.79±4.9 vs. 27.82±4.76), systolic blood pressure (124.7±21.36 vs. 123.54±19.27 mmHg), total cholesterol (193.50±47.94 vs. 208.41±54.02 mg/dl) and triglycerides (258.2±231.5 vs. 244.7±181.6 mg/dl). Significant improvements in glycemic control were documented by a decrease in fasting blood glucose (185.75±79.01 vs. 162.89±72.53 mg/dl, P <0.001), and a 3.6percentage point decrease in HbA1c (12.05%±4.47 vs. 8.45±1.89, P 0.001).
Conclusions: The results confirm that it is possible to improve the quality of diabetes care at the primary care level without additional economic resources, through the implementation of a program that integrates changes in the structure and in the process of care, customized clinical guidelines, and a standardized system of information that enables measuring clinical results in settings with limited resources.

Treating 4000 diabetic patients in Cambodia, a high prevalence but resource limited setting: five year program outcomes

P. Isaakidis[1], M.-E. Raguenaud[1], T. Reid[2], L. Keuky[3], C. Say[4], G. Arellano[4], W. Van Damme[5]
[1] *Medecins Sans Frontieres, Medical, Phnom Penh, Cambodia*
[2] *Medecins Sans Frontieres, Medical, Brussels, Belgium*
[3] *Cambodia Diabetes Association, Medical, Phnom Penh, Cambodia*
[4] *Médecins Sans Frontières, Medical, Siem Reap, Cambodia*
[5] *Institute of Tropical Medicine, Public Health, Antwerp, Belgium*

Background: Despite the worldwide increasing burden of diabetes, there is no corresponding scale up of treatment interventions in developing countries and there is limited documentation on program effectiveness. In 2002 Médecins Sans Frontières in collaboration with the Ministry of Health of Cambodia initiated a program to provide subsidized diabetic care on an out-patient basis in two hospital-based chronic disease clinics. The objective of this study was to describe program outcomes of patients enrolled in care.
Methods: This was a descriptive study of outcomes of 4000 diabetic patients treated over five years. Diagnosis and treatment were standardized. Blood glucose, blood pressure, and BMI were measured at each quarterly visit. Random blood sugar (RBS) was used for monitoring from 2002 to 2007, when HbA1C was begun. We calculated the proportion of patients who met the recommended treatment targets for RBS, HbA1c, blood pressure, and BMI and examined the evolution of these parameters over time. We used t-test to compare baseline and subsequent paired values.
Results: Of 4404 patients enrolled, 2872 (65%) were still in care, 24 (0.5%) died and 1508 (34%) were lost to follow up (LFU). The mean age was 53 years, 66% were female and 99% had type 2 diabetes. Median follow-up period was 20 months. Nearly 50% (740/1544) of patients had an RBS<145 mg/dl after one and a half years and 24% (51/213) had HbA1c<7% by 18 months of treatment. Forty-five per cent (377/836) and 76% (88/116) of patients with systolic and diastolic hypertension at baseline respectively, reached the treatment goals of ≤130/80mmHg within one year. There was a significant drop in mean RBS [106 mg/dl (SD:136) P<0.001], mean HbA1c [-2.6 (SD:3.1) P<0.001], and mean blood pressure [SBP −13.5mmHg (SD20.7) and DBP −11.7mmHg (SD12.1) P<0.001] between baseline and six months, but not in BMI. Factors associated with LFU were male sex, age >60 years, living outside the province, normal BMI on admission, high RBS on last visit, and coming late for the last consultation.
Conclusions: Significant and clinically important improvements in glycaemia and blood pressure were observed in this programmatic setting in rural Cambodia, but a relatively low proportion of diabetic patients reached the recommended treatment targets. These results and the high defaulter rate highlight the challenges of delivering diabetic care in resource limited settings.

P-1658

Improving diabetes care in Nova Scotia through a Provincial Program Model

M. Dunbar[1], E. Cummings[1], L. Harrigan[1], Z. Karlovic[1], B. Harpell[1], B. Cook[1]
[1] *Diabetes Care Program of Nova Scotia, NS Department of Health, Halifax, Canada*

Background: Established in 1991, the Diabetes Care Program of Nova Scotia (DCPNS) is a Provincial Program funded by the Nova Scotia (NS) Department of Health (DoH). Guided by an Advisory Council and a number of committees, the DCPNS advises on service delivery models; establishes and monitors adherence to DM guidelines; provides support, services, and resources to DM healthcare providers; and collects, analyzes, and distributes DM data for NS. Program priorities have evolved over the years to reflect provider and health system needs.
Aims: To improve, through leadership and partnerships, the health of Nova Scotians living with, affected by, or at risk of developing DM.
Methods: The DCPNS works closely with the province's 9 District Health Authorities (DHAs), 39 Diabetes Centres (DCs), and DM care providers to influence practice. Program staff and dedicated fiscal resources, as well as a number of groups with membership reflective of both urban and rural practice (Pregnancy, Pediatrics, Best Practice, and Long Term Care) ensure the interests of the DoH, DHAs, and special populations. A provincial registry, built and supported by the DCPNS, gathers population & clinical data from DCs to

inform policy and provincial initiatives. DCPNS initiatives (grants, workshops, newsletters, practice tools, and annotated bibliographies) support networking, knowledge transfer, sharing of lessons learned, and the uptake of guidelines.
Results: Standardized documentation forms (including referral, assessment, and flow sheets for adult, pediatric, and pregnant populations) as well as data collection tools have been in use since 1992. Guidelines for special populations (pregnancy, pediatrics, frail elderly), specific complications/comorbidities (HTN, dyslipidemia, and foot problems), and care protocols (insulin dose adjustment) have been implemented. The DCPNS Registry contains over 70,000 cases of DM/prediabetes, and provides data for local use to support quality improvement. Improvement in clinical measures has been documented, e.g., for DC follow-up attendees, 50% now have BPs within target (<130/80). Insulin initiation by DCs' staffs has also increased over 300% since 1992. Since 2005, 20 DC grants have been funded leading to practice innovations and efficiencies.
Discussion: The DCPNS ensures that Nova Scotians have local access to quality DM programs and services. DCs, regardless of location, are measured by the same standard. DC staffs are supported and have ready access to new knowledge. Over 70% of estimated NS DM cases are found in the DCPNS Registry. The availability and use of local data has resulted in program change, targeted interventions, and improved clinical measures.

Application of Disease Management for diabetes: a patient centered approach

N. Musacchio[1], A. Giancaterini[1], A. Lovagnini-Scher[1], L. Pessina[1], G. Salis[1], F. Schivalocchi[1], G. Errichelli[2], C. Montaperto[3], A. Bonaldi[3], G. Genduso[4]
[1] *A.O.Istituti Clinici Perfezionamento, Diabetic Care Unit, Cusano M. Milan, Italy*
[2] *A.O. Istituti Clinici di Perfezionamento, Diabetic Care Unit, Cusano M. Milan, Italy*
[3] *A.O.Istituti Clinici Perfezionamento, Direzione Sanitaria, Milan, Italy*
[4] *A.O. Lecco, Direzione Sanitaria, Lecco, Italy*

The protocols of the integrated care (IC) applied up to now foresee a strong integration between a specialistic structure and a General Practitioner (GP), but still with insufficient participation of the patient. The hypothesis proposed is that the centrality of the person is the essential element for the success of the entire treatment process
Aim: To implement a model that foresees various possibilities of contact of the patient with the team; to present the relevant data to the results obtained from 2002 to 2008 by applying this model of Disease Care strongly centered on the patient.
Methods: Our Unit has a team (3 Diabetologists, 2 nurses, 1 diet expert) that has reorganized diversifying all the activities in distinct pathways:
Clinical Pathway: the objective is the optimization of the metabolic parameters and the prevention of the complications (by doctors and by the paramedic staff). Activity: visit, advising to the MMG for acute problems, particular therapies, and podologic outpatients' center.
Welfare Pathway: the objective is the self-management of the patient.
Activity: dietology, devices, course of Therapeutic Education, individual education.
The two processes are autonomously performed but can entwine to optimize resources and intervention.
Telemedicine Pathway: the objective is the control and the quick recovery of the patient. At every meeting the self-control and the tests performed are checked. In this way the patient learns and verifies his ability of self-management and is thus protected from criticalities and/or urgencies that he is unable to recognize and face alone. In fact the operator that meets him can at any time reintroduce the patient in the medical process. At any moment either the patient or the MMG can be connected using the telemedicine pathways as consulting channels or re-insertion in the control system.
Results: Of the 2586 active patients in our structure, 1422 are in IC in accordance to «our model». All the indicators of clinical effectiveness at the end of the period of observation are overlapped to the incoming data and they have shown to be in line with the standards proposed by the American Diabetes Association (ADA). The average values of the group in GI: HbA1c= 6,98%, FBG=134 mg/dl; PPBG=129 mg/dl; LDL=108 mg/dl (standard ADA demands <7%; <130 mg/dl; <180 mg/dl; <100 mg/dl respectively). The time analysis of the data of the patients with a longer follow up, has permitted to evidence that the worsening of the differential indicators is clinically irrelevant. The adhesion to the proposed model is excellent (2,5 % drop out).
Saving 51,1% of the medical time allowed us to slow down the saturation point of the entire system achieving nevertheless a good effectiveness (a constant trend of acquisition of about 300 new patients/year; 4040 access in 2006 versus 4903 in 2008).

Joint Asia Diabetes Evaluation (JADE) Program – a web-based program to translate evidence to clinical practice in type 2 diabetes

J. Chan[1], W. So[1], G. Ko[2], P. Tong[1], A. Kong[1], R. Ma[1], R. Wong[1], F. Le Coguiec[3], B. Tamesis[3], G. Lyubomirsky[3], T. Wolthers[3]
[1] *The Chinese University of Hong Kong, Department of Medicine and Therapeutics, Hong Kong, China*
[2] *Hong Kong Institute of Diabetes and Obesity, and Asia Diabetes Foundation, Hong Kong, China*
[3] *Merck Sharp & Dohme (MSD), a subsidiary of Merck & Co. Inc., NJ, USA*

Aims: The Joint Asia Diabetes Evaluation (JADE) Program is the first web-based program incorporating a comprehensive risk engine, care protocols, clinical decision and self management support to improve ambulatory diabetes care. We validated the risk stratification system of the JADE Program using a large prospective cohort.
Methods: The JADE interactive risk engine stratifies patients into different risk levels using results from an annual comprehensive assessment of complications and risk factors. The risk engine makes use of the following 4 clinical entities to derive the levels: cardiovascular-renal complications, conventional risk factors for diabetic complications, estimated glomerular filtration rate and the Hong Kong Diabetes Registry risk scores to predict complications. We used a prospective registry consisting of 7534 type 2 diabetic patients [45.6% men, median (range) age: 57 (13-92 years)] to perform internal validation of the risk engine.
Results: The JADE Risk Engine categorized patients into 4 risk levels (from low to high): Level 1, n=4520 (6%); Level 2, n=1468 (19.5%); Level 3, n=4476 (59.4%) and Level 4, n=1138 (15.1%). After a median follow-up period of 5.50 years (mean ± SD: 5.42 ± 2.81 years), 763 (10.1%) died, 1129 (14.9%) developed cardiovascular disease (CVD), 282 (3.7%) developed end-stage renal disease (ESRD) and 1400 (18.6%) had at least one of these events. Compared to risk level 1, levels 2, 3, 4 were associated with 2.8, 4.7 and 8.6 fold increased risk of clinical endpoints. Risk levels 3 and 4 were respectively associated with 2.2 and 3.9 fold increased risk for all-cause death and 4.8 and 12.1 fold increased CVD risks. The respective 5-year absolute risks of death or cardiovascular-renal events were 2.5%, 8%, 21.5% and 60%.
Conclusion: Based on results from a comprehensive assessment, the JADE Risk Engine successfully categories patients into different risk levels to guide clinical management.

Can an inpatient blood glucose management team impact post-discharge glucose control

R. Gianchandani[1], S. Kling-Colson[2]
[1] *University of Michigan, Int medicine/endocrinology, Ann Arbor Michigan, USA*
[2] *University of Michigan, Int medicine/Endocrinology, ANN ARBOR MICHIGAN, USA*

Blood glucose (BG) control is well known to improve outcomes in elective surgical inpatients and has become standard of care in cardiothoracic surgery, although BG goals remain controversial. Following a major procedure the patient is a captive audience to standard glucose management practices. This allows an inpatient blood glucose management team to reinforce and reeducate a patient on diabetes care issues. The impact of such a team on the maintenance of glycemic control after discharge has not been examined or analyzed
Aim: The Hospital Insulin Program (HIP) at a large academic center recently set up an outpatient clinic to manage BG in post-discharge cardiothoracic and vascular surgery patients. Our aim is to study the impact of inpatient glucose management and education on patient's ability to obtain better glycemic control with a more intense regimen upon discharge.

Methods: We performed a retrospective analysis of post-surgical patients with diabetes mellitus seen by the HIIP clinic in 2008. A chi-squared test was performed using SPSS.
Results: Mean patient age was 61.8 ± 7.8 years and 69% were male. Average hemoglobin was 11 ± 1.7 g/dl. Time between pre-operative HbA1c to last clinic HbA1c ranged from 2 weeks to 6 months and 30% of patients had 2 or more clinic appointments.

Table 1

	Number of patients	Mean pre-operative HbA1c	Mean post-operative HbA1c	Difference in HbA1c from pre-operative level	p-value
Whole group	39	7.91%	6.65%	1.26	<0.01
Subgroup-follow-up >2.5 months	14	7.56%	6.58%	0.98	0.02

We found a statistically significant reduction in average post-operative HbA1c level of the group as a whole. This decrease was maintained in the subgroup that had a >2.5 month follow-up (Table 1). HbA1c reduction was greatest in patients with the highest pre-operative HbA1c. Sixty-one percent of patients were controlled with diet or oral hypoglycemic agents before surgery. Post-operatively, 97% had adopted a regimen of basal insulin with an oral agent or bolus meal insulin.
An intensive inpatient insulin regimen can lead to a reduction in post-operative HbA1c which partly reflects their tight BG control in the hospital. For the subgroup of patients with follow-up after 2.5 months, the sustained decrease indicates good outpatient BG control. Post-discharge, most patients remained compliant with diabetes regimens of much greater intensity than their preoperative ones. For patients with diabetes mellitus the inpatient admission provides a unique opportunity to refocus on their BG management practices, therapy and goals. Larger studies with prolonged post-operative follow-up are needed to demonstrate ability of the inpatient encounter to improve post hospital diabetes management.

[4] patients association, diabetes, Navoi, Uzbekistan
[5] association, diabetes, Bukhara, Uzbekistan
[6] Diabetes center, association, Tashkent, Uzbekistan
[7] patients association, diabetes, Tashkent, Uzbekistan

Aims: Adequate insulin therapy and self-monitoring permit good glycemic control, reduce diabetes complications and prolong active life of people with Diabetes Mellitus (DM). Since 2004 Diabetes task force teams "Insulin for Life" (IFL) and "Life for a Child" (LFC) provided insulin aid and supply for patients with DM especially to children and adolescents. This observation aims was evaluation of the glycemic control of people with DM, who were accepted on IFL and LFC programs.
Methods: In 258 adults, 62 children with DM, fasting (FG) and 2 hour after meal blood glucose (2HG), HbA1c levels were measured and self-monitoring test score were observed at start and after 6 month. Control group presents from 12 healthy subjects (HS). All people were treated with insulin and controlled blood glucose level by test strips and/or meters from IFL and LFC, all patients were educated at the regional diabetes centres where they were tested according to questionnaire in the start and end of observation. Observation was done in 4 regions, where insulin and supply was distributed.
Results: The level of FG, 2HG, HbA1c obtained on start of observation were significantly increased on 36%, on 32%, and 27% subsequently in compare with HS and indicated poor glycemic control in DM patients, average self-monitoring score was 2. Patients re-observation after 6 month shown significantly decreasing the level of FG on 1.57 times, 2HG on 1.7 times and HbA1c on 1.4 times, whereas self-monitoring score was increased till to 8. Through anamnesis at the start of observation were detected that 26% children had frequent ketoacidosis, and 38% patients had frequent hypoglycemia episodes, and after 6 months observation no one had ketoacidosis and hypoglycemia were dropped till to 4%. In start of observation only in 54% of people with DM treated intensively and during the program all patients was on intensive insulin therapy and daily insulin doses increased to 37%. During this time patients-doctors cooperation, and number of new regional associations increased.
Conclusion: In people with DM accepted to IFL and LFC program after 6 month intensive insulin therapy and self-monitoring significantly decreased the levels of FG, 2HG, HbA1c and increased the self-monitoring test score records to 4 times. Adequate long term insulin therapy and insulin supply with patient education are important factors in achieving of best glycemic control. Moreover, insulin aid and supply which provide by IFL and LFC help to rise patient-doctors cooperation and facilitate the patients to unite in associations.

P-1663

A computer-based monitoring tool for a large scale diabetes care program in Cambodia

P. Isaakidis[1], S. Khem[1], M.E. Raguenaud[1], C. Khim[2], S. Chy[3], T. Reid[4]
[1] Medecins Sans Frontieres, Medical, Phnom Penh, Cambodia
[2] Medecins Sans Frontieres, Medical, Takeo, Cambodia
[3] Medecins Sans Frontieres, Medical, Siem Reap, Cambodia
[4] Medecins Sans Frontieres, Medical, Brussels, Belgium

Aim: Cambodia is a resource-constrained country with a high prevalence of diabetes and limited access to care for the great majority of diabetic patients. In 2002 Médecins Sans Frontières, in collaboration with the Ministry of Health of Cambodia, initiated a program to provide subsidized care for diabetic patients in two hospital-based chronic disease clinics. A computer software tool was developed to facilitate data collection and analyses at the patient and programmatic level, to monitor the diabetes program.
Methods/software features: Microsoft Visual Basic® for Application (VBA) was the underlying programming language and Microsoft Access® 2003 was the core of the program. The main technique used was splitting database into a front-end application and a back-end database. Specifications were written to ensure an "open" product that could be adapted to work in other database environments (such as Microsoft SQL Server®, etc.) without substantial modifications.
The software was designed to allow for modifications of all major parameters by the user (drug lists, laboratory results, screening tests etc) in order to be adaptable to different contexts. Standardized patient files were created for use in the clinics (admission forms and follow-up forms) and for entry into the database. Reports were standardized and included: patient summary, outcome reports (proportion of patients reaching treatment targets) and main outcomes including deaths, complications, loss-to-follow-up and transfer-outs. The software was planned to be available free, providing open-access to the Ministry of Health, non-governmental organizations and other actors involved in care of patients with diabetes.
Results: The software has been used for over six years in two clinics delivering care to over 4000 patients with diabetes. Clinicians and programme managers were able to access the database easily and analyze data on a monthly, three-monthly and annual basis, for the assessment of individual patient progress as well as for the evaluation of program performance. The software was user-friendly and did not require special computer skills for the data entry and analysis. However, the high patient load and high frequency of follow-up consultations (on quarterly basis) required that data entry of new admission and follow-up visits be performed by full-time data clerks on a daily basis.
Conclusions: A simple, user-friendly, computer software tool for diabetes patients was developed in a programmatic setting in Cambodia. The monitoring tool was field-tested for several years and is free-ware and open-access. Nevertheless, it requires additional human resources for data entry and database maintenance if it is to be used by large scale programs or for monitoring of large cohorts of patients.

P-1664

Targeting diabetes prevention in an interactive, innovative and patient focused multidisciplinary metabolic syndrome program

S. Burns[1], M. Naruki - van Velzen[1], K. McQueen[1], C. Kam[1], S. Chan[1], A. Graham[1], A. Ignaszewski[1], G. Bondy[1], G. Frohlich[1]
[1] St. Pauls Hospital Providence Health Care, Cardiology, Vancouver, Canada

Aim: Successful self-management of cardiovascular and diabetes risk factors requires risk assessment, identification and diverse self-management strategies for effective risk reduction. Best practice for diabetes prevention interventions is unknown. We developed and implemented the first metabolic syndrome program in Canada targeting intensive risk reduction through self-management support.
Method: Participant referral may be from physicians, allied health professionals or self-referral. This multidisciplinary, nurse-managed physician supported program includes a clinical nurse specialist, patient educator, dietitian, exercise specialist, occupational therapist, physicians and psychology support. Behaviour change strategies target physical activity, nutrition, weight management, psychosocial risk factors, and self-management. This program is 18 months in duration and includes a minimum of 17 visits. Interactive group sessions are enhanced with prescheduled individual follow-up visits at baseline, 6, 12 and 18 months with the multidisciplinary team members.
Results: FBG at baseline 5.9 (5.5, 6.5), N = 228, at 12 months 5.9 (5.4, 6.4) N = 147, p = 0.10. Weight (kg) at baseline 98.0 (84.3,115.9); at 12 months 92.3 (79.5,106.4) N = 144, p=0.002. Waist circumference (cm) at baseline 112 (102,124,), at 12 months 106.0 (96.0,115.0), N = 133, p <0.0001. TC at baseline 5.5 (4.8, 6.3), at 12 months 5.2 (4.3, 5.8), N = 147, p =<0.001. LDL at baseline 3.3 (2.7, 3.9), at 12 months 3.1 (2.3, 3.6) N = 145, p = 0.008. HDL at baseline 1.2 (1.0, 1.4), at 12 months 3.1 (1.2 (1.1, 1.5), N = 147, p = 0.03. TG at baseline 2.0 (1.5, 2.8), at 12 months 1.7 (1.2, 2.5), N = 147 p =<0.0001. SBP at baseline 130 (0.7), at 12 months 121 (1.1), N = 140, p <0.0001 and DBP at baseline 80.5 (0.4), at 12 months 75.9 (0.7), N = 140, p <0.001.
Conclusion: This new innovative model incorporates key multifactorial strategies for diabetes prevention. We conclude that this comprehensive multidisciplinary program meets the needs of both participants and communities for effective chronic disease prevention. Further evaluation of long term program outcomes and community based partnerships need to be explored.

Local outpatient educational units creation: interest in gestational diabetes mellitus management

S. Clavel[1], A. Desserprix[2], H. Agopian[1], C. Denizot[2], M.A. Desbas[1], L. Labbé[1]
[1] Foundation Hotel Dieu, Dept of Diabetology, Le Creusot, France
[2] Foundation Hotel Dieu, Prérédiab network, Le Creusot, France

Aims: Improve GDM diagnosis and access to appropriate care pathway management and delivery with local outpatient educational units creation through a coordinated network.
Methods: Through a coordinated network commited to provide a high quality care across the local health organisation that is diabetic centred and responsive to local need, our goal was to promote early diagnosis and to improve treatment and outcomes for women with GDM: -collaboratively work with public and private partners (4 hospitals, 4 towns), medical doctors (general practitioners, obstetricians and diabetologists), nurses, dietitians and midwives to develop and to implement recommendations –building on any links with them in their local areas –proximity educational units (n=4) creation, organised on a non hierarchical basis around common concerns with structured education programs.
Results: Since 4 years: 418 women with GDM were detected and followed, mean age 31,1±5,3 years. Among them, 39% had family history of diabetes, 60% were multiparous with pre-existing GDM (26%) and macrosomia (15%). At conception there weight had more 6,3 kg than form weight, BMI: 28±8 among them 49,7% with BMI <25. Before delivery: weight gain: 12±6,3 kg and 33% had insulin treatment. At delivery: 30% caesarean sections, postnatal maternal complications 4%, 12 days before predicted term. The offspring: birth weight: 3,27±0,50 kg, 7,6% macrosomia, 10% postnatal complications (2,3% link with DG), 2,5% malformations. At 10 weeks post partum 70% women were screened by a 75 g OGTT: 7% remained diabetic and 29% had impaired glucose tolerance.
Discussion/conclusion: This health organisation allowed the involvement of medical professionals and patients, promoting early diagnosis of GDM, followed by structured education and self management program. With a diabetes network, the creation of local outpatient educational units permitted the GDM diagnosis and to manage and deliver individually appropriate care pathway.

An innovative and targeted approach to chronic disease prevention and management – Alberta Health Services initiative

S. Davachi[1], S. Delon[1]
[1] Alberta Health Services, Chronic Disease Management, Calgary, Canada

Background: Canada is ethnically, culturally and socially diverse country. Although diverse, one characteristic shared by specific populations in Canada is their increased risk for developing diabetes and cardiovascular disease. Individuals of South Asian, Hispanic, African and Aboriginal ancestry and those experiencing poverty and homelessness in particular are disproportionately afflicted by diabetes and other chronic conditions, a grossly under-estimated reality which has not been adequately addressed in health care surveillance, planning and provision in Canada and worldwide. There is a serious lack of targeted and coordinated chronic disease programs addressing the unique needs of diverse and medically under-served populations. This hinders health care system's efforts in combating the emerging epidemic of diabetes and other chronic conditions. Since 2002, the Alberta Health Services, Calgary area, has developed an innovative and targeted chronic disease prevention and management program for diverse populations.
Program aim: The aim of the program is to ensure that diverse populations with diabetes and other chronic conditions do not experience barriers accessing mainstream services. The specific objectives are to: strengthen the role of the community and patients in service development and delivery; enhance patient's self-management capacity; improve health outcomes and access to appropriate and socio-culturally competent chronic disease services; and decrease the rising burden of chronic diseases on the health care system.
Methodology: The program has adopted Chronic Care Model developed by the MacColl Institute for Healthcare Innovation as its framework. The model has been modified to meet the unique needs of the ethnically, culturally and socially diverse populations. The key components of the program include nurse case management, self-management support, community-based education, and specialty clinic expertise. The program objectives are achieved through delivery of socio-culturally competent and coordinated services delivered by multi-disciplinary and multi-lingual teams in accessible community-based settings such as temples, mosques, homeless shelters, cultural and community centres. Currently, services are offered to the South-Asian, Chinese, Filipino, Vietnamese and homeless populations.
Results: The evaluation results show significant improvements in access, clinical outcomes, service utilization in terms of decreased in-patient and emergency department admissions and patient-provider satisfaction.
Conclusions: This innovative, targeted approach which focuses on the determinants of the health, is effective in optimization of services, increased access and improved health outcomes. Strong community partnerships are instrumental in the success, acceptability and accessibility of the program.

P-1667

Glycaemic outcome and acceptance of knowledge-based decision support in diabetes care is strongly related to HbA1c at baseline

E. Salzsieder[1], K.-D. Kohnert[2], P. Heinke[3], V. Heuzeroth[4], L. Vogt[5], P. Augstein[6]
[1] Institute of Diabetes Karlsburg, Director, Karlsburg, Germany
[2] Institute of Diabetes Karlsburg, Clinical studies, Karlsburg, Germany
[3] Institute of Diabetes Karlsburg, Statisticts, Karlsburg, Germany
[4] BKK TAUNUS, Health insurance, Frankfurt, Germany
[5] Diabetes Service Center Karlsburg, Health care support, Karlsburg, Germany
[6] Institute of Diabetes Karlsburg, Research and Development, Karlsburg, Germany

Background and aim: The Diabetiva® program launched 2006 by the German insurance company BBK TAUNUS offers continuous glucose monitoring (CGM) and decision support generated by the Karlsburg diabetes management system KADIS® to their insured diabetics. Diabetiva® is open for diabetics with

cardiovascular risk and focuses on improvement of routine out-patient diabetes care according to the guidelines of the German Diabetes Association. We addressed the question, whether acceptance of decision support and metabolic outcome differs between general practitioners (GP) and diabetes specialists (DSP) involved in the Diabetiva® program.

Materials and methods: The Diabetiva® timeline includes an annual CGM followed by decision support for therapy optimization and quarterly medical check-up including HbA_{1c} detection. Patients with two CGM readings (n=150) were retrospective analyzed for acceptance of the KADIS®-based decision support by the GP/DSP using a questionnaire and the outcome of the Diabetiva® program, with HbA_{1c} as primary outcome parameter.

Results: After running Diabetiva® for 20 months 538 insured diabetics (95.9 % Type 2 diabetes) were enrolled and had received 727 CGMs. Patients were cared for by 276 GPs and 40 DSPs. Approximately 67 % of physicians accepted KADIS® as patient-focused support to optimize diabetes therapies; 36 % used the therapeutic regimes without changes and 31 % used slight modifications. Thirty percent did not accept KADIS®-based decision support. Logistic regression revealed that KADIS® acceptance was dependent on HbA1c at baseline ($p<0.05$). GP or DSP type of therapy had no significant influence whether on acceptance or on outcome parameters. Multiple regression analysis revealed that HbA1c and secondary outcome parameters 20 months after enrolment into Diabetiva® depend only on acceptance of KADIS® and on HbA1c at baseline ($p<0.001$). Again, GP or DSP type of therapy, age, onset of diabetes, BMI, and gender had no significant influence on the outcome parameters. If KADIS® was accepted for routine diabetes care HbA1c could be decreased (HbA1c at baseline < 6.5: -0.11 ± 0.05 %, p=0.04; 6.5 – 7.5: -0.47 ± 0.09 %, p< 0.001; > 7.5%: -0.97 ± 0.13 %, p< 0.001), whereas if KADIS® was declined the impact of Diabetiva® was diminished (HbA1c at baseline < 6.5: +0.40 ± 0.01%, p<0.001 %; 6.5 – 7.5:+ 0.17 ± 0.10 %, n.s.; > 7.5%: -0.29 ± 0.40 %, n.s.).

Conclusion: Decision support is accepted by GPs and DSPs especially for diabetics with elevated HbA1c. KADIS® in combination with continuous glucose monitoring and telemedicine-based communication can be a useful tool for providing effective management of diabetes.

[3] *Muhimbili National Hospital, Paediatrics And Child Health, Dar Es Salaam, Tanzania*

[4] *Muhimbili National Hospital, Internal Medicine, Dar Es Salaam, Tanzania*

[5] *Tanzania Diabetes Association, Operational, Dar Es Salaam, Tanzania*

Type 1 Diabetes Mellitus (T1DM) is a growing concern worldwide. While there has been a great development in the management of this condition in the developed world, there has been little or no improvement in sub-Saharan Africa. The burden of this disease is not known, but there is an obvious difference in the outcome. Tanzania is currently experiencing a rise in childhood diabetes as the rest of the world.

The major challenge lies in glycaemic control, and the rate at which new cases of diabetes are emerging poses an additional burden. The impact of T1DM in children is bound to continue if nothing is done. Activities to raise public awareness including World Diabetes Day, media events, other national campaigns, etc and have helped a lot in improving the management to be exact at least early diagnosis of children with Diabetes. Tanzania was among the countries which were given support in an IDF child sponsorship program.

Methods: We did an audit of the clinical data of children and adolescents with T1DM attending Muhimbili National Hospital diabetes clinic, under the sponsorship of IDF from 2005 to date. The clinical data of 126 children and adolescents aged 10 months to 23 years, attending the clinic were assessed. We looked at the prevalence of DKA at the time of diagnosis and after the initiation of insulin. We then looked at the age of diagnosis of the new patients and the glycaemic control. We then compared the data of 2005 (at the beginning of the programme) and after.

Results: Data of 126 children was assessed. Among these 61 (48.2%) were females and 65 (51.5%) were males. Mean age was 12.3±3.7 years. There were 27 new patients diagnosed between Dec 2005-december 2008. Among the 27 patients, 9 (33.3%), presented in DKA at the time of diagnosis compared to 74 (75%) patients before 2005. DKA after the initiation of insulin reduced to 42 (33.3%) from 89 (89.9%) in 2005. Age at diagnosis was 8.8±3.8 compared to 13±3.5 years in 2005. The mean HbA1c was 12.1±2.4%, compared to 12.3% in 2005. Only 3 (2.3%) patients died due to DKA during this period from 2005-2008.

Conclusion: Diabetes care in developing countries needs to address the specific background of the patient population, their needs, medical problems and social constraints. Active participation of patients, families, the community, media, governmental and non-governmental organizations, and health workers can overcome some of the difficulties. In a setting where the Diabetes is still superseded by infectious diseases, public awareness will lead to early diagnosis, less complications and improvement in life expectancy.

Finally the provision of insulin, will not give these children the good glycaemic control as soon as we wish, but at least, it reduce the acute complications we were seeing before.

A novel initiative to "Bridge the Gap" in reducing patient wait times for diabetes assessment

K. Hurst[1], J. Chen[1], S. Williams[1], C. Peng[1], J. Tarini[1], A. Hall[1], J. Mason[1], T. Richardson[1]

[1] *St. Michael's Hospital, Diabetes Comprehensive Care Centre, Toronto, Canada*

Valentine (2000) notes that Diabetes Educators play an important role in assessing and educating people about diabetes, however, they are often underutilized. Diabetes educators may improve wait times for people awaiting consultation by an Endocrinologist by facilitating early assessment and education. The Diabetes Care Centre at St. Michael's Hospital has restructured current programming in an effort to address current wait times for patients newly referred to an Endocrinologist. Typically, the average wait times for a new non-urgent referral range from 2-6 months. The Diabetes Care Center (DCC) team has implemented a new intake assessment program where patients newly referred to an Endocrinologist are pre-screened by both a Registered Nurse and Dietitian. This intake program has afforded the DCC staff the opportunity to identify patients' who need to be seen urgently, address patient educational needs prior to physician appointments, and, to implement a standardized process to ensure that patients are triaged into appropriate diabetes education support services in the interim while they await their appointment with the Endocrinologist. As a result of this new program, current wait times to be assessed by a health care professional in the DCC are now 2-3 weeks versus 2-6 months to see an Endocrinologist without any prior diabetes assessment or education. This novel program has improved patient services and ensures that all patients referred to the DCC receive early assessment and education. A triage tool has been created by the DCC team to standardize approaches to referring patients to DCC programming, and to determine those patients requiring urgent endocrine assessment.

Community based prevention and management of diabetic foot complications in the Philippines

D. Christodoulou[1]

[1] *Handicap International, Rehabilitation, Davao City, Philippines*

Introduction: Undetected and neglected diabetic foot complications are one of the leading causes of disability and amputation in Davao City, Philippines (1). Handicap International in collaboration with relevant partners and the City Health Office is conducting a pilot project on diabetes management and awareness in Davao City.

To better address the diabetic foot issue, the assumption of the project was that the community health workers (CHW) could be enabled to do basic foot risk assessment to categorize risk levels and refer for further medical treatment if needed, and basic patient foot care eduation, and be taught to make simple pressure relieving foot orthosis in a pre ulcerative foot.

Objective: To pilot test the implementation of a community based strategy for prevention, identification and management of early stages of diabetic foot complications in the 10 pilot communities in Davao City in the Philippines.

Methods: 84 community health workers have attended the Training workshops and in-community follow up training with regular monitoring of the practices of skills gained from the training.
The use of a one day intensive theory and practical workshop for knowledge transfer established the core information needed for the foot care and foot risk assessment training. This was followed by in-community training workshops.
The simple pressure relief orthosis were made from readily available innersole material from local shops.
The CHW were also encouraged to use a referral system to refer any more serious cases to health care professionals and a local partner trained in orthotics and prosthetics production.
Results: The training effectiveness and impact has been assessed by means of a checklist and frequent monitoring in the community.
The results of the assessments have been collected from post training activities. The results have demonstrated an increased awareness and knowledge in diabetic foot care practices, with an increase in the number of tasks completed on the checklist that is used to assess the diabetic foot.
This has resulted in two cases whereby foot ulcers have been prevented from progressing, and through frequent monitoring by the CHW they have closed and healed.
Conclusions: Community health workers can play a key role in the prevention and management of diabetic foot and its related complications.
With appropriate training, CHW are able to provide an affordable and early intervention by use of simple innersoles to help prevent further foot complications.
The training further empowers the CHW to provide patient education to create greater awareness of the serious nature of diabetic foot complications and their consequences in the community.

Patients with diabetes mellitus (DM) undergoing elective surgery – management in primary care

J. Kaczynski[1], J. May[2], I. Pogoda[3], G. Caldwell[2]
[1] *ABM University NHS Trust, Department of Trauma and Orthopaedics, Swansea, United Kingdom*
[2] *Worthing and Southlands Hospitals NHS Trust, Department of Diabetes, Worthing, United Kingdom*
[3] *Lime Tree Surgery, General Practice, Worthing, United Kingdom*

Introduction: Patients should have stable DM at least 3 months before surgery. Maintaining acceptable glycaemic control in patients with DM can be challenging especially when there is a short period of time and no clear pathway to follow.
Aim: Assess management of patients with DM in primary care referred and scheduled for elective surgery.
Methods: Retrospective study undertaken in one of the General Practices in the West Sussex, United Kingdom. All patients (90) with DM who underwent operations under general anaesthetic between January and October 2007.We looked for relevant blood work-up and way of optimising patients for surgery within period of time from the referral to surgery.
Results: Sixty six percent of patients had type 2 DM and remaining 34% had type 1 DM. Median age was 68 (range 37-90), with M:F ratio 2:1.Patients who underwent operations were scheduled for Day Surgery in 53 %, major operation in 38% and urgent 2-week cancer referrals in 9%.
Waiting time for the operation was in 36 cases longer then 6 months. Thirty one patients waited for the operation less then 6 months. In nine cases waiting time was 2 weeks. Most common registered complications related to DM were hypertension (66%), retinopathy (24%), ischaemic heart disease (24%), nephropathy (15%), peripheral vascular disease (11%) and neuropathy (4%).
Forty-nine patients had Hb1AC performed within time from the referral to surgery as a part of the routine review of DM in the practice. Among them 33 had Hb1AC<8% and in 16 cases Hb1AC was >8%. Thirty three patients had Hb1AC performed before the date of the referral and in 8 cases there was no record of Hb1AC at all.
Other investigations if performed were done as part of routine review of DM in following number of cases: eGFR 31%, U&E 53%, Creatinine 59%, Liver Function Tests 53%, Blood Pressure 58%, random blood glucose 7%, LDL 11%, TC 50%, HDL 12%, TC/HDL 7%.
There was one telephone review and extra appointment was given in 11 cases and 7 of those patients had Hb1AC> 8%.
Conclusions: Pre operative management of patients with DM in the selected GP surgery appears to be inadequate, which can potentially lead to increase in post-operative complications.
In a view of this, we are working currently to develop a system where such patients would be highlighted at the time of surgical referral so that the practice could address diabetes control and complications whilst the referral passes through the surgeon.
This will require a new way of multidisciplinary teamwork involving primary and secondary care.

Report on the International Workshop on Integrated Treatment for Lymphatic Filarias, Leprosy and Diabetes

D. Janisse[1]
[1] *Medical College at Wisconsin, Physical Medicine and Rehabilitation, Milwaukee, USA*

In June 2008, three American certified pedorthists – Mary Jo Geyer, Ray Burdett and Dennis Janisse – traveled to Bamako, Mali (West Africa) to present a week-long workshop for healthcare workers from 13 countries who treat patients with diabetes, leprosy and lymphatic filariasis (LF). The goal was to increase and enhance the treatment that these healthcare workers are able to provide to their patients with diabetes, LF, and leprosy.
The program was part of an initiative by the World Health Organization to promote integration in the treatment of diseases by healthcare workers in developing countries. Diabetes is an emerging epidemic in many developing countries and few are well-prepared to deal with the complications of diabetes. LF is a leading cause of permanent disability and therefore, a major obstacle on the road to socioeconomic development. While leprosy is no longer highly prevalent - even in developing countries - it is estimated that between one and two million people are permanently disabled from past or present leprosy. Like diabetes, the peripheral neuropathy associated with leprosy causes severe foot complications and must be addressed in a similar manner.
The faculty was presented with the challenge of designing a universal sandal that could be fabricated with local materials, using simple tools and with minimal training. The design also had to be very low cost, durable, and adaptable to a variety of therapeutic interventions. Participants in the course were asked to bring shoe-making materials with them that were native to their areas or readily available to them. To complicate matters, the fabrication had to be taught in such a way as to transcend multicultural language barriers. Lectures, as well as practical workshops, were used throughout to ensure that after the program participants could return to their native countries and establish and monitor footwear programs.
As health care professionals in westernized countries, we are constantly concerned with insurance, reimbursement and other financial issues. While these issues are important to our everyday practices, it is important to remember that there are innumerable people in our vast world who need pedorthic and orthotic services who do not even know what money is; much less health insurance. These people need help just the same.

The important role of the health care provider during a human factors trial when developing a new remote monitoring device for Self- Management of Diabetes

D. Guattery[1], C. Pegus[1], S. Eslava[1], D. Winfield[2]
[1] *SymCare Personalized Health Solutions, Clincal, West Chester, USA*
[2] *SymCare Personalized Health Solutions, Research and Development, West Chester, USA*

Background and aims: The world of technology in healthcare provides patients and their healthcare providers (HCPs) new cost-effective methods of managing diabetes A wireless monitoring device was developed to allow patients to automatically transmit their blood glucose (BG) data and other important diabetes healthcare related information to a secure web site utilizing Bluetooth technology. On the website, data is displayed in several simple graphs for patient review. A study was developed to demonstrate that the system was simple to use, easy to understand and provided value to the end users.

Materials and methods: A prospective human factors study was conducted at two specialty endocrinology clinics. A total of (15) participants diagnosed Diabetes were recruited along with (6) HCPs. Each patient participant was provided with a blood glucose meter, a wireless device, cell phone and an account to the secure website. Participants followed their physician's prescribed BG testing schedule during the 7-day study period. Participants, for a total of 3 visits uploaded their BG information and health related data to the secure website. The participants could then view BG in relation to their meals, insulin and activity, as well as have access to a large library of Diabetes health related articles. Patients had the ability to personalize their website by setting personal goals. The participant and HCP had opportunity to review information together. At the end of the 7 days (±3) participants and HCPs completed a comprehension questionnaire, human factors testing ability of the system and a satisfaction survey.
Results: HCPs rated the system as being beneficial and effective in management of patients. Importantly, 100% of the HCPs rated the system as one that could help them to provide effective care by improving communication to their patients. HCPs noted tools that were helpful were a library of educational articles that could be assigned, and seeing BG readings in relation to meals, insulin and activity. 100% of study participants who completed all 3 visits thought the system would improve their diabetes care and communication with their HCPs. Among patient participants, ease of use was demonstrated by all patients being able to use the mobile phone application, personalization of the website during first use, and familiarity of site navigation. An ease of use score was reported by patients as a minimum of 92.8% and a maximum of 100%.

A multidisciplinary approach to increase access to primary, community-based diabetes care in low-resource settings

I. Boyose-Nolasco[1], J.L. Hernandez[1], J. Villafuerte[2], C. Vasseur[3], O. Fabre[3], E. Pasquier[4]
[1] *Handicap International Philippines Program, The Diabetes Project, Davao City, The Philippines*
[2] *City Government of Davao, City Health Office, Davao City, The Philippines*
[3] *Handicap International, Philippines Program, Manila, The Philippines*
[4] *Handicap International, Domaine Soins Santé et Réadaptation, Lyon, France*

Introduction: Multidisciplinary, patient-centered diabetes care has been proven successful in encouraging diabetes self-management resulting in improved quality of life. This approach has mostly been possible in high-resource settings. In developing countries, team approach is not only hindered by the lack of manpower and limited technical capability. Challenges also include physical and financial access to medicines and biochemical analysis, community responsiveness and governmental support. The participation of other sectors of society is necessary to answer to needs that are beyond the scope of health care professionals – an alternative approach known as multidisciplinary Primary Health Care (PHC). Handicap International (HI) in its pilot Diabetes Project in the Philippines is working with communities to make essential health care accessible by adhering to PHC's three pillars: participation, intersectoral collaboration and equity.
Aim: To increase access to essential diabetes care in low-resource settings by capacity building of various community stakeholders as members of an interdisciplinary, integrated diabetes management team at the primary care level.
Methods: Major stakeholders were organized to form the Diabetes Task Force, the extended diabetes management team emphasizing the importance of each partner's active involvement. Vital partners are the local government unit, primary health care team (health care professionals and community health workers) and persons with diabetes. The subsequent needs assessment led to the formulation of the community action plan where each stakeholder identified their roles and responsibilities. HI provided technical and logistics support to allow each stakeholder to carry out their part. Parallel to these activities simple, culturally appropriate tools including IEC materials, algorithms, registries, forms, and a referral and monitoring system were developed to provide continuous care, feedback and evaluation.
Results: Within two years of project implementation essential diabetes care including affordable medicines, diabetes screening and management are available in seven out of ten pilot communities.
Conclusions: Involving other sectors in the diabetes management team is an effective opening approach for HI's Diabetes Project. The resulting sense of ownership and responsibility is the foundation for a community managed diabetes project. With essential diabetes care in place, stakeholders can now focus on sustainability, quality, and access to psychosocial support. Communities can then be on their way to self reliance.

Patients without service; establishing a new multidisciplinary diabetic foot clinic in Sharki, Egypt (prevention and management)

M. Soliman[1,2], M.R. El-Kaseer[2], E. El-Shorbagy[2], E. Salim[2], A.F. Arafa[2], G.S. Soliman[2], S.M. Rajbhandari[1]
[1] *Lancashire Teaching Hospitals, Medicine, Chorley, United Kingdom*
[2] *Zagazig University, Medicine, Zagazig, Egypt*

Introduction: In order to detect the foot problems and subsequent complications, a multidisciplinary service is introduced in Zagazig Uni. hospitals, with a team working together in a dedicated diabetic foot clinic.
Steps: The goals of this clinic are divided into direct and remote.
Goals: Direct goals were screening of foot problems, prevention and management of pre-ulcerative, ulcerative, complicated states. This service is under IWGDF guidelines. Regarding the remote goals the clinic tried to achieve better glycaemic control, survey of other diabetic complication, strict follow up and education of patients, staff and assistant personnel training and continuous education. Those needs emerged from the fact that there was no diabetic foot service in our local community.
Epidemiology and importance: The new foot clinic is implemented inside a population of about 5.3 m. citizens in a highly condensed rural (52%) governorate called Sharkia. The diabetes is a major, emerging clinical and public health problem in Egypt. Diabetes (diagnosed and undiagnosed) affects about 9.3% of Egyptian population. Our centre will potentially serve an underprivileged locality with surrounding 6 neighbouring governorates with no foot clinics. In other words 2 known centres of diabetic foot is known all over our country: Mansoura and Alexandria.
Method: Zagazig multidisciplinary diabetic foot clinic is established in a medical facility in Zagazig university (Outpatient clinics of internal medicine department, diabetes & endocrinology unit).
Domestic approach: studying the clinic outcome in the first 100 days is designed as follows: Design; admission, registration, health education, (vascular, diabetes, rehabilitation) consultation, podiatry service, dietary education, offloading and orthotists. Individual files for each patient contain his referral to the pathway data, follow-up and discharge summary, with digital pictures evidence.
International approach: The clinic project was accepted in the first round of IDF-BRIDGES GRANT and team leader attended their workshop proposing our project "Diabetic foot clinic in Zagazig University hospitals, Sharkia, Egypt". Moreover, a team member is now spending two years grant in multidisciplinary diabetic foot ulcer clinic in Lancashire teaching hospitals, UK.
Results: Mean age of diabetic patients with foot problems are 55.8 +/- 9.8 years, while the duration of diabetes was 13.1 +/- 7.8 years. Regarding diabetic foot problem, 24 among 199 diabetic patients have active foot disease (12.06%), two patients with chronic Charcot`s neuroarthropathy, notably among them 17 female (70.8%). 13 patients have hypertension (54.1%), there were no records regarding hyperlipidemia, eye screening, regular feet check, 3 patients with previous minor amputations and one patient with major amputations. Unconfirmed cases with OM were about 4 (16.6%).

International collaboration in Guyana to reduce amputations in persons with diabetes

R.G. Sibbald[1], K. Woo[1], M.G. Rambaran[2], B. Ostrow[3]
[1] *University of Toronto, Women's College Hospital, Toronto, Canada*
[2] *Georgetown Public Hospital Corporation, Medical and Professional Services, Georgetown, Guyana*
[3] *University of Toronto, Office of International Surgery, Toronto, Canada*

Aim: This project created an interprofessional, patient-centered clinic in Guyana, South America to prevent and treat diabetic foot ulcers and reduce amputations.
Methods: A multi-faceted, longitudinal, evidence-informed educational intervention, was linked to professional practice change and improved patient outcomes. The educational program was designed to:

1. apply effective primary and secondary educational strategies to translate knowledge into practice,
2. adapt the highly rated evidence-based guidelines from the Registered Nurses Association of Ontario and the Best Practice recommendations of the Canadian Association of Wound Care in a resource-poor setting and
3. identify and empower key opinion leaders with a collaborative practice model.

Results: The interprofessional Diabetic Foot Centre was opened at the Georgetown Public Hospital Corporation in July 2008. Four teams of doctors, nurses and rehabilitation specialists were trained and mentored by an expert Canadian team modeling interprofessional collaboration. Thirty participants were taught in two training visits (20 trainees attended both). Trainees rotated through the clinic, working with context-specific enablers that acted as quick reference guides to translate new knowledge into practice. The new knowledge was reinforced with practice reflection through daily seminars. To empower four key opinion leaders with a greater theoretical framework for education methodology, wound care practices and health care systems, they and the project coordinator were enrolled in the International Interprofessional Wound Care Course from the University of Toronto. This course consists of two 4 day residential weekends of interprofessional education separated by 8 months of self study modules and a selective that relates course material to day to day practice.

Discussion/conclusions: Diabetic foot ulcers are a major and growing public health problem in Guyana and elsewhere. They represent the single largest (30%) reason for admission to the surgical wards. The development of sustainable local capacity in low-income countries requires more than one time training sessions. This international collaboration developed local capacity by modeling and adapting Best Practices using primary and secondary (enabling and reinforcing) educational strategies in a longitudinal format with key opinion leader training. This multiple intervention model has facilitated interprofessional collaboration along with knowledge, skills and attitude change to improve diabetic foot care patient outcomes.

P-1677

Comparing the performance of a joint psychiatry/ endocrinology clinic to a community endocrinology clinic for management of weight gain, impaired glucose tolerance and type 2 diabetes in patients with schizophrenia

S. Robertson[1], M. Silverman[2], C. Antonello[1], C. Cotaras[1], L. Murata[1], C. Robertson[1], O. Kelly[3]
[1] Royal Ottawa Mental Health Centre, Schizophrenia Program, Ottawa, Canada
[2] Royal Ottawa Mental Health Centre, Endocrinology Clinic, Ottawa, Canada
[3] Royal Ottawa Mental Health Centre, Institute of Mental Health Research, Ottawa, Canada

In 2001, the Canadian Diabetes Association recognized schizophrenia as a risk factor for the development of type 2 diabetes (DM2). Schizophrenia spectrum disorders are associated with increased rates of impaired glucose tolerance (IGT), DM2, metabolic syndrome and cardiovascular disease. To improve management of weight gain, IGT and DM2 in tertiary care psychiatric patients, we compared a joint psychiatry/endocrinology clinic located in the Royal Ottawa Mental Health Centre to a community based endocrine clinic. Outcome data from these two service delivery models are presented below. There were 16 subjects in each group with a majority of non-smokers. The majority of patients had schizophrenia spectrum illness (14/16 (Royal Ottawa) and 12/16 (Community)) and were Caucasian (15/16 (Royal Ottawa) and 13/16 (Community)). Mean duration of mental illness was 15 years for the Royal Ottawa group and 18 years for the Community group. All individuals were on psychotropic medications. The Royal Ottawa group had stronger family histories of DM2 (25%) and cardiovascular disease (31%). Attendance rates at the Royal Ottawa and Community clinics were 82% and 48% respectively. Attendance rates for the dietician and Healthy Lifestyle group only available at the Royal Ottawa were 90% and 58% respectively. Caloric intake decreased, knowledge scores from the Healthy Lifestyle group improved and psychiatric symptom rating scales remained stable. Over 12 months, the BMI for the Royal Ottawa and Community groups remained at 34 and 41 respectively. Waist circumference at the Royal Ottawa decreased slightly in males and females but remained over 100 cm. For the Community group, waist circumference increased in males and decreased in females but remained over 100 cm. In the Royal Ottawa group, no patients progressed to IGT or DM2 and 2/4 with IGT normalized. In the Community group, there was no progression to DM2, 1 progression to IGT and 4/4 with IGT normalized. Despite trends toward improvement, triglycerides remained elevated and HDL low. There was no change in blood pressure. In conclusion, patients in the Royal Ottawa group were more likely to attend clinic and receive more comprehensive care than the Community group. Healthy lifestyle knowledge and food choices improved. However, metabolic syndrome risk factors remained unchanged or minimally changed in both groups. Aggressive pharmacological management of elevated glucose and lipids should be started together with comprehensive on-site lifestyle changes at initial diagnosis in this high-risk group of patients.

Building connections: the Maestro Project. The evolution of a systems navigator model for transition from pediatric to adult care for young adults with type 1 diabetes

C.A. MacDonald[1], H.J. Dean[2]
[1] Winnipeg Regional Health Authority, Pediatrics and Child Health, Winnipeg, Canada
[2] University of Manitoba, Pediatrics and Child Health, Winnipeg, Canada

Building connections: The Maestro Project uses a systems navigator model to maintain contact with young adults with type 1 diabetes, age 18-25 years, after transfer to adult diabetes services in Manitoba, Canada. The objective of this quality improvement project is to increase their rate of medical and educational follow-up and thus reduce morbidity and mortality from complications of diabetes.

A central database was initiated in 2002 for two cohorts of participants in the Maestro Project: 1) those referred to the program at age 18 years directly after graduation from the regional pediatric program (younger group, n=84) and 2) those age 19-25 years who had graduated from pediatric care prior to the start of the program (older group, n=164). Evaluation was completed Sept-Dec 2004. The feasibility and responsiveness to the program for this age group as well as medical outcomes and effectiveness in improving surveillance has been published (Diabetes 2008; 57 (1):A495). In the first 2 years of the project there was significant improvement in medical surveillance, but no evidence of improved short term medical outcomes for young adults. This may be due to specific characteristics of the young adult cohort, specific characteristics of service delivery in the adult care system, inadequate project development or insufficient time of observation for this model.

As of February 2009, 791 young adults were enrolled in the project. 229 were >25 yrs of age (63 not participating, 166 still participating). 462 were between the ages of 16-25 yrs and 93.5% (432/462) participating. There have been 406 referrals made to connect 183 young adults with services (27.3% Endocrinologist, 49.2% Diabetes Education, 11.3% Family Physician, 8.6% Optometrist, 3.4% Advocacy).

This project has been successful in receiving program status and permanent funding through the Winnipeg Regional Health Authority and has served as the catalyst for implementing a young adult specific evening clinic with dedicated medical and educator staff in a community diabetes center. The systems navigator model is a successful stimulus for systems change, for improving services and for reducing rates of those lost to medical follow up within the first few years of transfer.

Highlighting multidisciplinary team work in the area of diabetes management

H. Genik[1], C. Schmaltz[1], J. Chorney[1], B. Deschamps[2], C. Torgerson[2], B. Fagnou[3], T. Sorestad[3], J. Ferguson[3], J. Senecal[3], G. Stewart[1]
[1] KTHR, Diabetes and Heart Health Centre, Nipawin Saskatchewan, Canada;
[2] KTHR, Diabetes and Heart Health Centre, Tisdale Saskatchewan, Canada;
[3] KTHR, Diabetes and Heart Health Centre, Melfort Saskatchewan, Canada

The Kelsey Trail Health Region is located in North Eastern Saskatchewan; it covers 47,400 km and has a population of 43,204 people. The Diabetes & Heart Health Centre (DHHC) within the Kelsey Trail Health Region provides assistance to people managing health conditions including diabetes, heart disease, weight management, cholesterol problems, and any other nutrition-related concerns. The DHHC teams consist of nurses, dietitians, and an exercise therapist as well as support from other health professionals as much as possible. There are three primary bases for the DHHC teams (Nipawin, Tisdale, and Melfort) as well as satellite clinics in a number of surrounding communities.

The objective of the Diabetes and Heart Health centre is to provide clients with opportunities for secondary prevention through a client centered multidisciplinary approach. Specific programming includes self-management skills, promotion of exercise, nutrition counseling and lifestyle support.
We will highlight examples of effective teamwork, locally and provincially, which enhances the diabetes care for the clients and families we work with.
Examples of this team work include:

- Foot assessment clinics with diabetes nurse and home care nurses team. The team visit involves assessment of sensation and circulation plus it provides a perfect opportunity to engage clients in learning how to best care for their feet. Referrals and follow-up is directed based on client specific needs.
- Local community pharmacies have partnered with the DHHC educators to provide on site consultations with clients. Often the location is more accessible for clients and it provides a different venue for collaboration and client-centered care.
- Teaming up for Diabetes clinics involving the physician, dietitian, diabetes nurse, and exercise therapist. Four clients are invited to attend a morning session involving a conversation map discussion, goal setting and then fifteen minute visits with each health care provider. Clients get to re-energize while experiencing teamwork at its best!
- Acute Care/Diabetes team collaboration in policy development and inpatient client education
- Health Clinic collaboration/ nurse practitioner and diabetes team
- Provincial diabetes resources developed
- Best practice in hypertension treatment
- Glucose meter clinics provide the opportunity for clients to have their blood glucose meters checked for accuracy against the lab standard.
- The Nipawin team travels to the northern community of Cumberland House every two weeks to offer services locally. Optimal diabetes care involves the cooperation of the diabetes nurse, the dietitian, local nurse practitioner, clinic nurses, physicians, support staff, pharmacists, and many key community members.
- Supervised walking program in two communites

Exploring the educational needs of health care workers in primary health care services and the challenges they face in implementing evidence-based diabetes health care

M. Hausken[1], G. Holmefjord[2], M. Graue[2]
[1] *Stavanger University Hospital, Department of Enodocrinologi, Stavanger, Norway*
[2] *Bergen University College, Department of Healt and Social Sciences, Bergen, Norway*

Background: A large number of people with diabetes are elderly who receive treatment and follow-up care from primary health care services. Good quality health care is important for metabolic control, ensuring quality of life and for slowing or preventing the development of diabetes-related complications. In order to provide good quality health care there is a need to improve the organization of health care services, and to enhance collaboration within and between primary and specialist health care services.
Aim: The aim of this project was to explore the educational needs of health care workers in primary health care services and to describe the challenges they face in implementing evidence-based diabetes health care.
Sample and method: Focus group interviews were conducted among 16 primary health care workers (12 nurses and 4 nurses aids) age 32-59 years in a primary health care setting that includes nursing homes (n= 10) and a district nursing service (n=6).
Results: Preliminary findings show that the participants experience a lack of knowledge concerning diabetes and of evidence-based standards and guidelines for diabetes treatment and follow-up care. Further, the findings show that the participants often feel alone in their follow-up care of persons with diabetes, and that they lack the professional support of those with expertise in diabetes treatment and care.
Conclusion: There appears to be a need to develop a model that enhances the competence of diabetes health care workers in primary health care and facilitates systematic support in the clinical setting.

The model of care and unique service delivery for black women and women of colour living with diabetes from African, Caribbean, Latin American and South Asian communities in Greater Toronto Area, Canada

S. Khoo[1], V. McCalla[1], C. Tsai[1]
[1] *Women's Health in Women's Hands Community Health Centre, Diabetes Education Program Clinic, Toronto, Canada*

Women's Health in Women's Hands Community Health Centre's Diabetes Education Program will present the model of care for diabetes care and support for women of colour from the African, Caribbean, Latin American and South Asian communities in Toronto, Canada. This initiative was realized from the recognition that black women and women of colour from these communities are believed to be at higher risk of developing diabetes and it is imperative that health services delivery be culturally sensitive and competent to the community. The presentation will explore how the program and model of care has impacted the overall health and quality of life of women who are marginalized and are of low socioeconomic status living in the urban and rural Greater Toronto Area. Women's Health in Women's Hands Community Health Centre is a feminist, pro-choice, anti-racist and multilingual health centre for women. The centre is committed to working with women from diverse backgrounds, particularly immigrant and refugee black women and women of colour, young women, women with (dis)abilities and women over the age of 16 from the above-mentioned communities. The service delivery of diabetes care and support is framed within an anti-oppression framework, which recognizes the multiple intersecting dimensions of oppression women face in Canada. We will expand discussion of this topic during the presentation. Our goal is to disseminate knowledge on our model of care within this framework for women living with Diabetes and also women at risk for developing Diabetes.
Briefly, the program is designed to create a safe inclusive environment where women who have developed or at risk of developing diabetes can be supported and encouraged to make their health a priority. The program provides a culturally appropriate health promotion and prevention services given the diaspora of client population living in Canada. The presentation will also explore five areas of specialization regarding education and awareness around a diabetes diagnosis. The areas are resource development, prevention education and outreach care and support of women with diabetes, training and skills development and partnership advocacy activities.
The program is structured to encourage women to self-manage diabetes, address existing stigma around living with diabetes and empower women to take charge of their health care with the knowledge of the most current evidence in regards to diabetes self-care.

Medication discussion and consultation participation between nurse prescribers and people with diabetes in the UK

S. Latter[1], A. Sibley[1], T.C. Skinner[2], S. Cradock[3]
[1] *University of Southampton, School of Health Sciences, Southampton, United Kingdom*
[2] *Combined Universities Centre for Rural Health, Combined Universities Centre for Rural Health, Geraldton, Australia*
[3] *Portsmouth NHS Hospitals Trust, Consultant Nurse Diabetes Medicine, Portsmouth, United Kingdom*

Background: In the UK, there are now over 15,000 nurse independent prescribers with virtually the same prescribing rights as doctors. Prescribing nurses therefore represent an increasingly common model of care delivery for people with diabetes. Medication adherence often falls short of what is required for effective symptom control ad optimum long tem health outcomes. Recent national guidance on medicines adherence recommends improving communication, increasing patient involvement, understanding the patient's perspective and providing information (NICE 2009). Nurse prescribers have an important opportunity to improve patient medicine-taking behaviour through their consultations with patients. However, little is known about the characteristics of their medication discussions with diabetes patients in practice.
Aim: This paper will provide an analysis of the frequency, nature and extent of medication discussions between nurse prescribers and people with diabetes in the UK. The findings are taken from a larger study evaluating the impact of an educational intervention for nurse prescribers, funded by Diabetes UK (Latter, Sibley et al, in progress).

Methods: A cross-sectional sample of 59 consultations from 20 nurse prescribers were analysed using MEDICODE (Richard & Lussier 2006), a validated tool for assessing medication discussion. MEDICODE enables assessment of (a) the nature and extent of health professionals' communication across up to 40 medication discussion topics, and (b) levels of consultation participation using two measures: Preponderance of Initiative and Dialogue Ratio.
Results: A mean of 4.4 medications per consultation were discussed, with 6.46 themes per medication. Across all themes, frequently raised discussion themes included: issues of medication usage (68.4% of the time) and dosage instructions (51.1%). Rarely raised discussed themes included: reasons for the medication (8.7%) and concerns about the medication (3.1%). Common concerns discussed included fear of dependency and concerns about starting insulin. Across all themes, the preponderance of initiative was skewed towards the nurse prescriber, and consultations were largely conducted as a dialogue – as opposed to nurse and patient conversing in monologues. These participation indices applied at the individual medication theme level showed a similar overall pattern.
Discussion/conclusion: The extent of nurse prescribers' medication discussion is limited, and comparable to that of doctors. Some important medication themes predictive of adherence were infrequently discussed. However, the dialogic pattern, and the preponderance of initiative findings are more consistent with national recommendations on best practice for medication adherence.

P-1683

Care of diabetes foot ulcers

J. Menang[1], *E. Ngwa*[1]
[1] *Divine Providence Low Cost Clinic (DIPROLOCC), Diabetes Clinic, Molyko Buea, Cameroon*

Background: If an amputation is performed every 30 seconds for diabetes related causes when it is proven that 85% of the amputation is preventable, then there is an urgent need for strategies to salvage many more limbs left. In rural Cameroon, survey was done at the local DIPROLOCC clinic, finding out the efficiency of various wound products and availability.
Method: Each of the ulcerated cases, especially the diabetics ulcers were closely followed since January 2008, wound sizes measured routinely with measuring tape, normal saline used for thorough cleansing and liquid honey (unprocessed) applied generously and then applying gauze.
Results: The locally produced honey by wild bees with the scientific name Apis mellifera was found to be more tolerable, rapid in healing, and affordable as is product of the indigenes, cheap and magical in nature of healing.Many ulcers ranging from venous, tropical, diabetics as well as burns were greatly relieved and cured with pure honey.
Conclusion: Though more effort to understand detailed mechanism of action of honey on ulcers, and its chemical composition, the safety of the product has not been guaranteed and mechanism of action not yet fully understood as well as the safety on diabetes ulcers, coupled with the fact that most people here are poor and medical supplies are very expensive, frequently out of stock; it is seemingly clear that, many ailments from ulcers especially diabetes ulcers, will be relieved and many limbs possibly salvaged with the product.

Diabetes Low Vision Support Clinic

D. Brewer[1], *A. Malmheden*[2]
[1] *Heart of England NHS Foundation Trust, Diabetes Centre, Birmingham, United Kingdom*
[2] *Heart of England NHS Foundation Trust, Ophthalmology, Birmingham, United Kingdom*

With an increase in the incidence of diabetes, the associated complications are becoming all the more common.
The more obvious complications, such as obesity, diabetic neuropathy, heart disease, diabetic nephropathy and retinopathy, are all more screened for on an annual basis.
Some areas have proved difficult for people with diabetes and the associated visual problems to continue with self management. Therefore the Low Vision Clinic has been set up to address the specific needs for these people. It was established as a tool to promote independence and self management for patients with visual problems of varying degrees.
The clinic is jointly run by an orthoptist and a diabetes specialist nurse, to review the patients current equipement to administer medication, monitor blood glucose levels, and the optical aides that they use.
The clinic was initially set up in 2002, at Heartlands Hospital, but the demand and success of the clinic has led to the service being expanded to now being held at Solihull Hospital as well. This denotes a 100% increase in consultations across the two sites.
The clinic has established links with outside agencies, such as Birmingham Focus, R.N.I.B and R.N.I.D.
All new patients referred into the clinic have a full 1 hour assessment, followed by 1/2 hour reviews 3-6 months later. They are then reviewed on an annual basis, or can call for an urgent review if required. All patients are given direct emergency access to the service should they have any urgent concerns.
The clinic adopts a multi-disciplinary approch, empowering the patients to stay independent and motivated.

Health economics and social engineering in diabetes care – an Indian experience

R. Karmegam[1], *G. Kamath*[1], *S. Srikanta*[1]
[1] *Jnana Sanjeevini Medical Centre, Operations, Bangalore, India*

Introduction: The current health care scenario in India is compounded by increasing incidences of infectious, nutritional and lifestyle related disorders along with low health insurance penetration (about 2 %) as well as absence of 'out of hospital' insurance. India has the world's largest diabetic population with over 32 million people affected. This is expected to more than double by 2025.
Objectives: To implement a financially self-sustaining, affordable, comprehensive, integrated and continued preventive health and medical care project to address the gigantic Indian public health problem of diabetes and related disorders (ie. co morbidities – hypertension, dyslipidemia, cardiovascular diseases etc).
Methods: In 2003 "JNANA SANJEEVINI" project was started with an initial investment of 200,000 $, from Samatvam Trust (non-profit charity organisation). This was to provide "health care of highest possible quality to highest possible quantity".
The cost cross-subsidy service delivery model adopted is as below:

Services	Charity	Low	Middle	Upper
Health education	free	free	market	premium
Consultations	free	highly subsidised	market	premium
Diagnostics	free	subsidised	market	market
Medicines	free	subsidised	market	market

Consultations include endocrinologists, ophthalmologist, surgeons, gynecologists, etc.
Diagnostics includes T.M.T, X-ray, pathology, biochemistry, etc.
Revenue Generation is as follows:
1. Above 90% from patients constituting about 75% of the total patients served.
2. Less than 10% from public charity.

The revenue generated from the upper 2 socioeconomic classes helps to support and cross subsidize the expenses related to the lower classes, thus fostering the financial viability of the project.
Results: Since 2003 Jnana sanjeevani has served nearly 12,000 patients with Diabetes, 25% being charity patients. The project has attained financial sustainability in its 5th year of operations and is currently striving to grow in terms of its reach / patients serviced.
Conclusion: Cost cross-subsidy is a financially viable model of service delivery that can be adopted in societies with a mixed socio-economic status.

P-1686

Diabetes care centre: providing an innovative and comprehensive care approach for diabetes patients in Mauritius

M. Chagny[1], *V. La Hausse de la Louvière*[1]
[1] *Association pour la Promotion de la Santé, Curepipe, Mauritius*

Aims: The 'Association pour la Promotion de la Santé' is Mauritian based NGO, involved in diabetes prevention and education since 1994. Concerned with the alarming prevalence of diabetes in Mauritius, the association decided to

build the first Diabetes Care Centre in the Indian Ocean. The centre will be established as a model in comprehensive care for the patient with diabetes. This holistic, multi-specialist centre will provide a unified team approach to the management of diabetes: diabetes specialists and educators, dieticians, podiatrists, clinical psychologists, and bio exercise therapists will work together around each patient. Healthcare professionals will be trained in order to provide a coordinated standard of care. A fully equipped gym as well as a health bar and shop will be available. The centre will be operational as from December 2009.

Methods: The building has been specifically designed to allow the patient to have easy access to various consultation and medical facilities. A minimum care protocol will be provided including a minimum of 2 annual visits with the doctor, the diabetes nurse educator, and the health educators, and one annual visit with the nutritionist, the podiatrist and the ophthalmologist, and only when required, with the exercise therapist and the clinical psychologist. Laboratory tests such as HbA1c, Lipogram, FBC, U&E and Microalbuminuria will also be performed to monitor diabetes and patient's results. This protocol will be known as the Diabetes Management Programme and will be implemented to effectively improve glycaemic control, reduce hospitalization and progression of both micro vascular and macro vascular diseases. All patient databases will be monitored and patients' progress will be collected and entered in a database on a daily basis to assess and report outcomes. In this way real-time information on all patients will be available for analysis at any time through a centralised web database.

Results: In the first year 500 to 1,000 people will be included in the Diabetes Management Programme. This number will increase to 2,000 in the second year and more in subsequent years. By reducing the patients modifiable risk factors and HbA1c, the Diabetes Management Programme aims to reduce diabetes related deaths by 42 to 63%, Fatal and non-fatal MI by 28 to 42%, Fatal and non-fatal Stroke by 24 to 36%, Cataract extraction by 38 to 57%, Heart Failure by 32 to 48%, Micro vascular endpoints by 60 to 90% and amputation or death due to PVD by 86 to 95%.

Discussion: The expected results bring a discussion about the necessity of implementing a diabetes clinic in Mauritius that will provide a patient centred care in one location. This approach will enable the patient to be closely monitored and therefore reduce diabetes related hospitalization.

Views on the involvement of pharmacy service in screening for diabetes and hypertension: the collaboration between community pharmacies and National Health Insurance, Thailand

P. Sookaneknun[1], A. Leelathanalerk[1], P. Assawathanabodi[2], J. Kanjanasilp[3], W. Sawangsri[2], P. Tapaneeyakorn[4], T. Seesin[5], R. Senanok[6], A. Kamwat[7]

[1] *Faculty of Pharmacy Mahasarakham University, Primary Care Practice Research Unit, Maha Sarakham, Thailand*

[2] *Mahasarakham Hospital, Social Community Group, Maha Sarakham, Thailand*

[3] *Faculty of Pharmacy Mahasarakham University, Clinical pharmacy and research group, Maha Sarakham, Thailand*

[4] *Mahasarakham Public Health Office, Administration Board, Maha Sarakham, Thailand*

[5] *Faculty of Pharmacy Mahasarakham University, Clinical pharmacy and reseach group, Maha Sarakham, Thailand*

[6] *Mahasarakham Hospital Community Clinic, Administration Board, Maha Sarakham, Thailand*

[7] *Burapa Community Medical Center, Administration Board, Maha Sarakham, Thailand*

The general coverage of screening for diabetes and hypertension was still below target. The role of community pharmacy in prevention and promotion activities is developing to do screening for diabetes and hypertension with the National Health Insurance as an alternative outlet for people to access. Although a few areas have started the collaboration between community pharmacies and the government primary care units, the level of involvement of community pharmacy in local health insurance overall is still limited.

Objectives: To learn more about the opinions from health policy makers, health care providers and customers who are involved in the screening project for high risk population for diabetes and hypertension by community pharmacies with the collaboration of primary care units in Maha Sarakham Province.

Methods: In-depth interview using open questions was conducted in six local policy makers, nine health care providers and nine customers who had experience with community pharmacy service. The participants were asked about their opinion, attitudes, expectations and barriers towards the screening program by community pharmacy. Thematic analysis of the audio-taped transcripts was conducted.

Results: The findings revealed three themes towards the collaborative screening project: (1) perception of the contribution of the screening project, (2) the desired role of collaborative development, (3) barriers. The results showed that policy makers, health care providers and customers supported the themes with different contexts.

Conclusions: Participants realized the importance of working together as a network in local area to do screening for diabetes and hypertension as part of the national health insurance. It appears that the collaborative screening program is a good model to strengthen Thai health care system that still needs more development.

An interprofessional diabetes health promotion clinic at an academic urban family health team – an innovative way to improve access to diabetes care

A. Langer[1], V. Phokeo[1]

[1] *St. Josephs Health Centre, Urban Family Health Team, Toronto, Canada*

Aims: Over 1.8 million Canadians have diabetes, and this number is projected to grow due to an aging populations and increased immigration. Specialized diabetes clinics bring together the personnel and resources necessary to meet patient needs.

The goal of the program is to optimize the primary care of patients with diabetes by improving community access to a team of interprofessional practitioners. The program incorporates the training of family MD residents and other professional interns. Another objective is to increase the consistent adherence to clinical guidelines.

Methods: The Interprofessional Diabetes Health Promotion clinic was initiated 2 years ago. Each clinic is a 2-hour process whereby mostly complex, type 2 diabetic patients rotate between a pharmacist, dietitian, nurse, physician, and patient education specialist. Each provider conducts detailed, specialized assessments on the patient. Each clinic concludes with an interprofessional patient-centered discussion. Documented team recommendations for each patient are sent to each patient's primary care physician for appropriate follow-up.

Results: A significant increase in patients prescribed cardiovascular protective medications was reported post-clinic. A significant improvement in TC:HDL was seen in most patients post-clinic.

An average downward trend in blood pressure was seen post-clinic.

Patients reported better understanding of overall diabetes care, and self-efficacy post-clinic. It was reported that 67% of patients had a healthier diet post clinic, and 50% reported an increase in physical activity post clinic.

All of these results plus more will be explored further as more data becomes available.

Discussion/conclusion: The clinic involves care delivered by five team members, and one clinic is equivalent to five patient visits for assessment and counselling with each health care professional. This format is patient centered, improves access to diabetes care, and provides efficient service. A visit to our clinic also replaces a patient's quarterly diabetes appointment with their primary care provider.

Preliminary results show promising trends in both objective and subjective measures. We continue to collect data to evaluate our program.

Our interprofessional clinic serves as primary care model that saves time for both the patients and health practitioners and incorporates medical and healthcare professional training while delivering optimal patient-centred care and improving access to healthcare for the community.

Diabetes related admissions to the emergency room of a district hospital in South Africa

L. Nkombua[1]

[1] *Middelburg Hospital, Family Medicine, Witbank, South Africa*

Background: The global threat of diabetes is immense. The prevalence of diabetes is increasing and is hitting lower income countries and communities hardest. Africa will not escape the impact of diabetes. Already it is caught in a double burden of infectious diseases and emerging chronic diseases.

Undetected, untreated or poorly controlled diabetes can result in devastating complications.
The author wished to evaluate the reasons for diabetic patients visiting the emergency room of a district hospital in a semi rural area of South Africa. The findings will go a long way to alert the practitioners in this and similar areas about the complications seen in diabetic patients at this underserved emergency room, so that improvement in the management of diabetic patients can be implemented to avoid unnecessary admissions to the hospital.
Method: Data from the emergency room register were retrospectively collected for the period of twelve months, from 01 January 2008 to 31 December 2008 for patients seen with the diagnosis of diabetes or diabetes related complications.
The diagnosis of diabetes or diabetes related complications was based on the findings by the doctor on duty as recorded in the emergency room register.
Other variables included diagnoses not related to diabetes in diabetic patients, or a co-morbidity diagnosed by the treating doctor.
Results: The study found that diabetic patients were admitted to the emergency room for various different reasons with hyperglycemia, cataract, new diagnosis of diabetes, hypoglycemia, diabetic ketoacidosis and hypertension, respectively as the main diagnoses made on admission.
The study also found that type 2 diabetes was the predominant type of diabetes seen in the emergency room and hypertension the most common clinically associated condition in most diabetics.
Conclusions: The survey established that patients suffering from diabetes mellitus do consult the emergency room for diabetes related complications and also for non-diabetes related problems. The diabetes complications constitute the bulk of the diagnoses made by the casualty doctor. These complications might have been prevented if patients were adequately counseled about lifestyle changes and appropriate management instituted by the treating clinicians. Therefore, the author recommends that tight control of diabetes in the patients attending the practices have to be prioritised in all diabetics. Treatment of hypertension in diabetic patients should not be unnecessarily delayed.
Appropriate and up to date management guidelines on treatment of complications of diabetes to be available in the emergency room at all times. The establishment of diabetes clinics in the community is to be encouraged and supported.

Contribution of nurse's consultation in diabetology - experiment in a French country area

J.P. Ory[1], S. Barbat[1], L. Perrin[1], C. Bourgogne[1]
[1] CHI Haute-Saône, Dept of Internal Medicine, Vesoul, France

Introduction: In France, increase of diabetic patients number, requires actualization of strategy in screening and in care for diabetes. As a matter of fact, diabetologists number is more and more insufficient.
Study: The experiment has been lasting since three years in non university hospital, in rural zone, in the French north-east quarter. The followed patients are 2 500. Two doctors are involved in consultation (about 1 000 a year), planned hospitalisations (during five days) for education and actualisation of treatment, diabetology out-patients facilities for annual or bi-annual check up, conventional hospitalisation for cardiovascular complications, mal perforant etc…). Two nurses have been trained. They effect 400 out-patient consultations a year, with an object of therapeutic education. Of course, medical supervision is permanent. The nurse's function is specifically educational; about dietetics and treatment's control (insulinization, oral anti-diabetic drugs) giving glycemia targets and means to reach them. The visit lasts half an hour. The patient comes back every month so long as the target is not reached.
Results: The improvement of HbA1C is 1.5 %.
Conclusion: The investment is middle-term and long-terms. Nurse's contribution makes up partially for shortage of specialists.

Psychological process and psychometric study of diabetic and non-diabetic men who will undergo penile prosthesis surgery for erectile sexual dysfunction

C. Garcia Alvarez[1], B. Fabré[1], R. Fragas[1]
[1] Instituto Nacional de Endocrinologia, Psychology, Ciudad de la Habana, Cuba

Introduction: This study come to the results from the 100 diabetic and non-diabetic men studied since 2006 to 2008 to penile prosthesis surgery by erectile sexual dysfunction, under study national project in Havana Cuba.
This study was as the main objectives of research: to know efficacy, safety, side effects, and satisfaction from men and partner whit the penis prosthesis surgery.
In addition as a different approach this study showed the results from the psychological and psychometrics approach of whole group of patients.
Objectives: To know body representations, anxiety, depression, and the characteristics of psychological process, particularly satisfaction with the surgery results and to know these psychological process involved to own body and partner body.
Methodology: In depth interview to men and a sample of partners, and Psychometric Test like as: Anxiety Test of Catell, MMPI Test of Hathaway y Mac Kinley, Somatic Test –Body Symbolism of Wilfred A. Cassell (Cuban version C.T.García) and Case Study.
Results: 25 % of men were Diabetic person. The majority of them are normal results from the psychometrics test. Nevertheless 40% of them have psychological conflicts with body symbolism particularly with vagina representation. Some of them showed psychological repression and in front the card of the vagina they show answers like that: "this is a butterfly", "it´s an insect", it's a flower", "this is a dark and dangerous place".....In addition a sub-group of wife showed partner conflicts after penis husband surgery and dissatisfaction with this surgery.
Conclusions: Studies from psychological and partner relationship and psychological counselling were very helpful to improve penis prosthesis surgery satisfaction by erectile sexual dysfunction and men and partner well being.

Quality assurance in diabetes care

P-1692

Multi-national study examining the association between diabetes therapy and glycaemic control in patients with type 2 diabetes

E. Strock[1], R.S. Mazze[1], R. Cuddihy[1], M. Idrogo[2], D. Wesley[1], B. Morgan[1], SDM Global Study Group[1]
[1] International Diabetes Center, International Diabetes Center, Minneapolis, USA
[2] University of Minnesota, Medical School, Minneapolis, USA

Aims: In preparation for an international intervention aimed at improving quality of care using Staged Diabetes Management (SDM), baseline data on current status of diabetes care were collected in a sample of patients with type 2 diabetes in India, China, Brazil, Mexico and Russia. The aim of this study was to determine in this sample whether treatment modality was associated with metabolic outcome.
Methods: Prior to the training in SDM (a systematic, evidence-based approach incorporating national diabetes guidelines and local resources), each participating physician collected baseline data on approximately 20 patients with either type 1 or type 2 diabetes randomly selected from their practice using a standardized data collection tool. Data were entered into an electronic database for analysis.
Results: 323 physicians (India 157, Brazil 71, Mexico 59, China 25, Russia 11) were included in the analysis. After removing duplicates and erroneous data, and limiting the analysis to only adult patients with type 2 diabetes, there were 2920 (63%) evaluable cases (India 1377, Brazil 509, Mexico 542, China 292, Russia 200). Mean age was 55±19 years (55% male) with diabetes duration 10±8 years. Diabetes therapies were divided accordingly: 11% insulin alone, 36% insulin with oral agents (OA), 33% combination OA, 16% OA monotherapy (half of whom were treated with metformin) and 4% treated by diet alone. There was a significant ($R=0.24, p<0.0001$) relationship between treatment type and glycemic control when data from the countries were pooled. Patients treated by insulin alone had the highest HbA1c (8.7±1.9%).

Patients using metformin in combination with TZD (n=52) or metformin alone (n=257) had the lowest HbA1c (7.28±1.1%, 7.5±1.5% respectively). Separate analysis showed that in all countries with the exception of Russia (p=0.18), treatment was correlated with metabolic outcome. In China the relationship between HbA1c and treatment was strongest (R=0.36, p<0.0001). Patients treated with insulin alone averaged 9.3% HbA1c, while those treated with metformin alone averaged 6.7% HbA1c.

Conclusions: This data can be utilized to understand the relationship between treatment and clinical outcomes in order to target interventions towards improving glycemic control in countries with high prevalence of diabetes. Because SDM systematically advances therapies and maximizes insulin-based strategies it can be employed to ameliorate glucose control in a rapid and safe fashion.

P-1693

Comparative effectiveness of high quality versus usual diabetes care

J. Rodriguez-Saldana[1], M.A. Morales de Teresa[1], L.I. Vazquez-Rodriguez[1], C.B. Rangel-Leon[1], J.D. Piette[2], R.S. Mazze[3], E. Strock[3], C.M. Clark[4]

[1] *Resultados Medicos Desarrollo e Investigacion SC, General Direction, Pachuca de Soto, Mexico*

[2] *University of Michigan, VA/UM Program on Quality Improvement for Complex Chronic Conditions, Pachuca de Soto, Mexico*

[3] *International Diabetes Center, General Direction, Minneapolis MN, USA*

[4] *Indiana University, Continuing Medical Education, Indianapolis IN, USA*

Aims: To compare the effectiveness and quality of diabetes care delivered through a comprehensive program including all the components of quality of care (structure, process, performance and outcomes), versus usual diabetes care delivered by a tertiary care hospital in Mexico.

Methods: A case-control study was made to compare demographic data, clinical characteristics, and clinical outcomes in patients treated at Diabetes Center in Pachuca, a research and development institution devoted to improve the quality of diabetes and chronic disease care, with results recently published from a diabetes clinic in a tertiary care hospital in Mexico city. By comparison to usual diabetes care, with long waiting times, rotation of doctors and brief visits with a vertical, doctor-centered and prescriptive approach, Diabetes Center in Pachuca has introduced improvements in the delivery of patient-centered and evidence-based healthcare to increase patient adherence, reduce clinical inertia, and enforcement of a multidisciplinary approach. Diabetes self-care education is an essential component of the program, with goals of treatment clearly explained and negotiated with patients.

Results: General characteristics and outcomes of patients with Type 2 Diabetes receiving usual care (CUC) by specialists, or structured diabetes care (SDC) by multidisciplinary groups of primary care providers are shown in the following table:

Variable	CUC	SDC
Number of patients	468	428
Mean A1c	10.2%	7.77%
Patients with A1c <7.0%	12.9%	44.4%
Patients with blood pressure <140/80 mm Hg	82.2%	67.4%
Patients with LDL cholesterol <100 mg/dl	45.1%	55.3%
Patients with Triglycerides <150 mg/dl	75.8%	40.9%

Conclusions: The results of this analysis shows that structured diabetes care delivered by multidisciplinary teams of primary care providers achieves better glycemic control than usual non structured care delivered by specialists. Factors to consider are organizational arrangements to reduce waiting times, rotation of doctors, adequate time for baseline and follow-up examinations, a patient-centered approach and prompt delivery of self care diabetes education. By comparison, control of cardiovascular risk factors, including blood pressure and triglycerides is superior in patients treated at a tertiary care facility. Taking into account that most of the patients with diabetes receive lifetime treatment from general practitioners, the results of this analysis reinforce observations from structured primary diabetes care programs published in developed countries.

Consumers drive collaboration with health professionals, academia and industry to inform quality improvement through the development of A Statement of Issues affecting Australians with Type 1 Diabetes

K. Gilbert[1], M. Kamp[2], A. Robinson[3], C. Shankley[4], K. Marsh[5], M. Seed[6], S. Greenbank[7], M. Leadston[8]

[1] *The Type 1 Diabetes Network, Brisbane, Australia*

[2] *Queensland Health, Centre for Healthcare Improvement, Brisbane, Australia*

[3] *The Townsville Hospital, Department of Endocrinology and Diabetes, Townsville, Australia*

[4] *Concord General Repatriation Hospital, Sydney, Australia*

[5] *Northside Nutrition & Dietetics, Sydney, Australia*

[6] *The Type 1 Diabetes Network, Sydney, Australia*

[7] *The Type 1 Diabetes Network, Brisbane, Australia*

[8] *General Practitioner, Melbourne, Australia*

Background: Type 1 Diabetes represents 15% of diabetes in Australia yet 42% of the cost. Evidence-based clinical targets, essential monitoring and management of risk factors are achieved by less than 20% of Australians with Type 1 Diabetes, and health outcomes remain poor[1]. Government policy and service delivery have focused on Type 2 Diabetes, and Type 1 Diabetes has fallen behind in priority and action.

The Type 1 Diabetes Network, a consumer organisation, formed the Type 1 Diabetes Opinion Leaders Group in 2008 with health professional bodies, academia and industry represented alongside 15 people affected by Type 1 Diabetes. Private endocrinology, psychology, adolescent services, tertiary hospitals, health promotion and general practice were also represented.

Methods: Online communication tools were used by 33 members of The Type 1 Diabetes Opinion Leaders Group to collaborate over five months through a four-stage process: broad scoping of issues; exploring issues in themes aligned with Wagner's Chronic Care Model; identifying key issues within themes and reviewing a draft statement. 78 public submissions were also received and considered.

Results: Ten key issues were identified and published as A Statement of Issues affecting Australians with Type 1 Diabetes, including:

1. Access to specialist medical advice is very limited, especially in rural and regional areas
2. Complexity of Type 1 Diabetes is neither well understood nor managed
3. Coping with long-term complications is left to the individual with very limited support
4. Hospital admissions, planned and emergency, are managed poorly when a diabetes team is not involved
5. System for the essential long-term monitoring is inefficient and highly ineffective

Over 100 solutions to the issues were also collected and published.

The Statement has been provided to government, peak bodies and health service managers nationally.

Conclusion: The challenge is finding a cost-effective means of supporting people with Type 1 Diabetes to achieve optimal control of blood glucose levels and other risk factors to improve outcomes.

Healthcare quality improvement is informed by economic, clinical and consumer values of quality. Consumer values are generally complex and expensive to ascertain and difficult to align with other values. The Statement, and its resource-efficient method of development, exemplifies an effective method of capturing and contributing consumer values of healthcare quality.

The Statement provides a framework for health policy and planning to support improvement of health outcomes for Australians with Type 1 Diabetes, against which future policy and planning could be evaluated from the patient perspective.

A wide difference of quality of diabetes care in the secondary/tertiary healthcare centers in Korea; Korea national diabetes program survey 2008

S. Chon[1], Y. Lee[1], M.C. Choi[1], Y. Hwang[1], S. Oh[1], K. Ahn[1], H. Chung[1], J. Woo[1], S. Kim[1], J. Kim[1], Y. Kim[1], K.N.D.P. Korea National Diabetes Program[2]

[1] Kyung Hee University School of Medicine, Endocrinology and Metabolism, Seoul, Korea

[2] Authorized by Ministry of Health & Welfare, Endocrinology and Metabolism, Seoul, Korea

Aim: This study investigated the status of diabetes control in secondary/tertiary care centers in which diabetic patients are treated by diabetologists.

Methods: It was conducted at 12 university hospitals (all were collaborative centers for Korea National Diabetes Program) from July to September 2008. Total of 1500 (721 men) type 2 diabetes mellitus (T2DM) patients who had been followed-up for more than 3 months at each center were surveyed. Five patients were consecutively recruited daily among the patients who visited their clinics. Data were collected by reviewing their medical records and conducting interviews.

Results: The mean duration of diabetes was 9.1 ± 7.3 years, and mean age was 58.5 ± 11.3 years. Among them, 75.4% of patients were overweight or obese. The proportion of those with a history of macrovascular complication was 20.3%. By history, patients with diabetic retinopathy was 19%, neuropathy 23.6% and nephropathy 7.0%. But in terms of nephropathy by medical record, microalbuminuria was 12.1%, overt proteinuria 9.6%, and renal insufficiency with GFR less than 60 ml/min was 21.8%. The proportion of patients with diabetic education, test for diabetic complication, and self monitoring of blood glucose was 70%, 85% and 75.5%, respectively. The prevalence of severe hypoglycaemia (within the last one-year period) was 4.5%. Mean HbA1c was 7.5 ± 1.5%, fasting blood glucose 138.8 ± 48.2 mg/dL, and postprandial 2 hour glucose 203.7 ± 91.0 mg/dL. The proportion of good glycemic control (HbA1C <7%, ≤ 6.5%) was 41.7% and 27.1%, respectively. The proportion of poor glycemic control (HbA1c ≥ 8%) was 28.4%. Patients treated with oral antidiabetic drug was 85% and insulin therapy 15%. Patients achieving optimal control of blood pressure (<130/80) and lipid (LDL-cholesterol <100 mg/dL) was 40.9% and 29.6%, respectively. The proportion with antiplatelet therapy was 51.5%. There were significant differences in status of glycemic control, quality of care between participating centers (p=0.000).

Conclusion: This data revealed that even for specially treated type 2 diabetes in secondary/tertiary care center, it was very difficult to achieve optimal glycemic control and risk management for overall type 2 diabetic patients. For the overall improvement of quality of care, constructive national intervention program for optimal diabetes care should be performed.

P-1696

Quality of care and outcomes of diabetic foot ulcer patients managed by a diabetes extremity care team at the Philippine General Hospital

M. Cardino[1], I. Isip-Tan[1], C. Josol[1]

[1] Philippine General Hospital, Endocrinology, Manila, The Philippines

Background: The diabetes extremity care team (DECT), multi-specialty team of the Philippine General Hospital composed of internists, endocrinologist, orthopedic and vascular surgeons, infectious disease specialist and rehabilitation physician, was created to decrease mortality and amputation rates.

Objective: To compare the quality of care and outcomes of patients managed before and after the DECT was established.

Research design and methods: Retrospective study done on all diabetics admitted with foot ulcers managed by the DECT from 2004 to present. There were 550 charts retrieved, however 58 charts were excluded because of missing pages; 492 were eligible for review. Ulcer severity was graded with University of Texas. Demographic data, outcomes and quality of care indicators were expressed as means and percentages. The differences between 2 means were tested for significance by t- test and differences between two proportions by z test.

Outcomes: Using the Structure-Process-Outcome model, the following were analyzed: factors affecting the structure: protocol, response rates; process: adequacy of foot examination and antibiotic use; outcome: mortality and amputation rates.

Results: There was no significant differences in age, 56± 10.7 (versus 55±11 years, pre-DECT, p0.27), duration of diabetes 7±7.2 years (versus 7.4±6.8 years), BMI, 24±6.6 (versus 24±3.6 kg/m^2), without treatment, 82 out of 492 (versus 25 out of 204, p0.14), with neuropathies 371 out of 492 (versus137 out of 204, p0.49). There were more males (308 out of 492 versus102 out of 204, p<0.01), arterial occlusion (146 out of 492 versus 40 out of 204, p<0.01), University of Texas 3D ulcers (318 out of 492 versus 97 out of 204, p<0.01).

Quality of care: Seventy five percent (372 out of 492) were seen on day of admission. All were seen by the internist on the first day followed by orthopedic surgeons (402 out of 492). Number of patients with adequate foot examination was 40% (197 out of 492), with culture guided antibiotic use was 76% (377 out of 492), compliance was poor (258 out of 492 had missed doses of <25%), and mean time antibiotic was started in 9.8±1.4hours (versus.15.1±3.9 pre-DECT).

Outcome: Mortality rates decreased from 13.8% (28 out of 204) to 5.8% (29 out of 492), amputation rates decreased 70% (143 out of 204) to 47% (233 out of 492).

Conclusion: This study shows the effectiveness of a team management. Using the above model, further improvements can still be done at the level of the structure and process.

No conflict of interest

P-1697

Assessing the degree of success for American Diabetes Association clinical goals among diabetic subjects in a teaching hospital setting in Nigeria

O. Alebiosu[1], O. Mrs Obi[2], O. Odusan[1], A.E.A. Jaiyesimi[1]

[1] Olabisi Onabanjo University Teaching Hospital, Medicine, Sagamu, Nigeria

[2] General Hospital, Pharmacy Unit, Asaba, Nigeria

Background: The American Diabetes Association (ADA) published treatment goals for physicians managing patients with diabetes mellitus in an attempt to improve control of diabetes and prevent complications. The success with which physicians are able to meet the clinical goals is unknown in Nigeria.

Objective: The study aim to assess the success with which physicians are able to meet the set ADA clinical goals in Nigeria.

Methods: Hospital records of sub-samples of consecutive patients with type 2 diabetes seen between September 1999 and August 2001 were reviewed to assess the attainment of the six ADA treatment goals and the frequency of receiving the four ADA-recommended health services.

Results: The mean number of ADA goals attained was 4.4 +1.2. No patient had attained all 10 goals. A total of 118 (54.1%) and 123 (56.4%) patients had attained the ADA goals of diabetes daily use of aspirin and HDL level respectively; most patients had attained ADA goals for triglycerides 189 (86.7%), LDL level 168 (77.1%) and diastolic blood pressure control 175 (80.3). Most patients had not received annual eye examination 210 (96.3%) nor attained systolic blood pressure control 133 (61%). Although most of the patients had urinary microalbumin screening as part of another study protocol using the same sample population, routine microalbuminuria screening is not presently done and should be incorporated into the management protocols of our diabetics.

Conclusion: ADA treatment goals may be quite difficult to attain in the developing health care setting. Physicians and patients should make efforts to attain the ADA treatment goals so as to prevent diabetic complications.

Key words:

- Quality assurance in diabetes care
- Guidelines, clinical care

Self-evaluation of lipid-lowering drug prescriptions in type 2 diabetic patients in a diabetes department

D. Simon[1], F. Bosquet[1], C. Sachon[1], M. Halbron[1], A. Heurtier[1], S. Jacqueminet[1], N. Chastang[1], P. Radetich[1], M. Charles[2], L. Vesco[1], A. Grimaldi[1]

[1] Hôpital de la Pitié, Diabétologie, Paris, France

[2] INSERM, U-780, Villejuif, France

Aims: Type 2 diabetic (T2D) patients are at high cardiovascular (CV) risk, and multifactorial intervention is needed to reduce hyperglycaemia, hypertension, dyslipidemia [mainly LDL-cholesterol (LDL-C)] and tobacco consumption. To decrease LDL-C level is rather easy, using lipid-lowering (LL) drugs, mainly

statins, in addition to diet, and it provides the most effective prevention for CV diseases. In France, the Health Authorities published in 2007 recommendations concerning the LDL-C objectives in T2D patients with regards to their CV risk. From 2004 the law makes it mandatory for all practitioners to evaluate their own practice, in order to improve patient care. We evaluated how the recommendations concerning lipids were applied in our Diabetes Department by a cross-sectional study.

Methods: From February 2008 to April 2008, 11 diabetologists were asked to include 20 consecutive T2D patients consulting in our Department. They filled in a short questionnaire providing information on the level of CV risk (personal and family history of CV events, CV risk factors, retinopathy, nephropathy, HbA1c and lipid levels), current LL treatment and compliance, then modification of LL treatment if any. Statistical analysis calculated means and percentages, and compared observed and expected LDL-C.

Results: 199 T2D patients were examined, aged 63±12 yrs (m±sd); 54% men; 81% treated by metformin, 54% sulfonyureas, 40% insulin, 18% thiazolidinediones; HbA1c=7.5±1.2%; hypertension in 74%; 10% current smokers; personal history of coronary event in 16%, stroke 5%, nephropathy 27%, laser treatment 10%; LL drugs were used in 68% of patients (statin 64%, fibrate 13%, ezetimibe 8%). Lipid levels within the 3 last months: LDL-C=0.93±0.31g/l, HDL-C=0.50±0.15g/l, triglycerides=1.34±0.79g/l. In secondary prevention and high-risk CV patients, LDL-C=0.83±0.29g/l (objective<1.00g/l) and in T2D patients with a single CV risk factor, LDL-C=0.97±0.32g/l (objective<1.60g/l). Recommendations for LDL-C were fulfilled in 89% cases. Statin had been interrupted in 6% because of side-effects. Compliance was excellent: 3% acknowledged not to take the prescribed LL drug and 4% forgot LL drug once a week. LL treatment was increased in 12% of the patients at the end of consultation.

Discussion/conclusion: Recommendations concerning LDL-C objectives and LL treatment in T2D patients are well applied in our Department. TO practice self-evaluation has probably contributed to improve diabetes care: the two consultants whose patients had the highest LDL-C levels were the two who increased most LL prescription at the consultation. In addition, each consultant having received the statistical analysis of his own data should be able to improve his diabetes care practice for lipid control.

How does sex differentiate the situation of diabetic patients

A. Abramczyk[1]
[1] *Medical University, Sciences about the Health, Wroclaw, Poland*

Aim: This study characterizes the situation of patients with diabetes in relation to sex-determined differences.

Materials and methods: The research for this study was carried out among 1986 patients with diabetes and1366 families, originating from the randomly chosen 61 units of the national primary health care. This study was carried out within the scope of SCSR grant no 6P05D02320.

The study used: nurse interviews, assessment of patients' fitness and independence, questionnaires for patients and their families and analysis of medical data.

Results: Co-existence and over-lapping of factors (lack of preparation to self-care, improper results of biochemical tests, excessive body mass, arterial hypertension, additional diseases, addictions, ailments and disturbances of psychosomatic health, difficulties in respecting recommendations, deficiency in social functioning, deficiency in caring efficiency of the family, unfavourable socio-economical situation), which determine high and very high need for care were more frequently found for women (66.4%) then men (33.6%, p=0.00002).

The unfavourable situation of diabetic patients expressed by their expectancies towards care of family nurse (p=0.01576) and a social worker (p=0.03281), are more frequently expressed by women then men.

The analysis of the family situation of the tested person showed that the families of diabetic women are most frequently characterized by a lack of preparation to give support for a patient (63%, p=0.02038), as well as by a deficiency in satisfaction from the results of treatment (67.9%, p=0.03105).

Conclusion: Lack of adjustment of care to the patients' expectations and needs is confirmed by their expectations towards the care of a family nurse and a social worker. The expectations towards the care of a family nurse and a social worker may also result from a feeling of helplessness and lack of competence determined by the lack of preparation, lack of fitness and a difficult socio-economical situation of the patients as well as by the lack of possibility of obtaining help from the family.

The research confirmed existence of inequalities in health and functioning of diabetic patients and the necessity to intensify medical and social care for women. The knowledge of the factors differentiating situation of women in comparison to men allows to adjust the care to the existing needs and counteract the negative consequences of diabetes. The increase of involvement of family nurses and social workers in the care of diabetic patients can be a way to optimize the results of treatment, especially in the population of poor patients and women.

Insulin glargine and quality of life of type 2 diabetes patients in Bangladesh

M.F. Pathan[1], *K. Pervin*[1], *R.F. Khan*[1], *A. Zaman*[1], *F. Amin*[1]
[1] *BIRDEM, Endocrine Medicine, Dhaka, Bangladesh*

Background: Quality of life is an important health outcome besides achieving the therapeutic target in patients with type 2 diabetes mellitus. The ADA/EASD consensus statement recommends early addition of basal insulin therapy for intensifying treatment to achieve therapeutic targets. Due to fear and concerns about quality of life, both physicians and patients are often reluctant to initiate insulin therapy. Once daily basal insulin glargine has proven better glycaemic control and improved quality of life in several clinical studies. We conducted the survey to observe effects of insulin glargine on quality of life in Bangladesh.

Methods: Type 2 diabetes patients poorly controlled with previous oral anti-diabetic agents and reluctant to insulin therapy, currently on insulin glargine for at least 3 months, completed a questionnaire related to quality of life. The questionnaire was designed for patient satisfaction about knowledge on diabetes, diet, exercise and current treatment.

Results: A total of 50 patients completed the questionnaire. Of them 56% were moderately satisfied, 22% moderately dissatisfied and 10% very dissatisfied with their knowledge on diabetes and its management. To 46% of patients unplanned dietary habit was believed to be a barrier for controlling diabetes. However, 40% expressed dissatisfaction to the changes of usual diet. Regular physical exercise was performed by 30% of patients and 12 % never had exercise as suggested by physicians. To control diabetes, profession was neither considered a barrier to 86% of cases, nor limits the career to 64% of cases. However, 18% of the patients had a worry about missing work due to diabetes. For being a diabetic, 36% of the patients did not usually feel physically ill but 16% had a feeling of not being well most often. A bad night sleep was reported by 30% of the patient because of diabetes. To control blood glucose, 86% of patients were satisfied with current treatment of insulin glargine. Administration of insulin was convenient and flexible to 70% of cases. About 90% of the patients reported that insulin glargine neither interrupted food intake nor was troublesome to daily activities.

Conclusion: Early basal therapy with insulin glargine improves the quality of life in diabetes. To enhance the quality of life in patients, strategies on diabetes education, lifestyle interventions and supports to be adopted as well.

P-1701

Risk factor control in patients with known and newly diagnosed type 2 diabetes mellitus

S. Eckert[1], *W. Quester*[2], *D. Horstkotte*[1]
[1] *Heart and Diabetes Center North Rhine-Westphalia Ruhr University Bochum, Department of Cardiology, Bad Oeynhausen, Germany*
[2] *Heart and Diabetes Center North Rhine-Westphalia Ruhr University Bochum, Department of Diabetology, Bad Oeynhausen, Germany*

Aims: The prevalence of type 2 diabetes mellitus is underestimated. In many cases diabetes mellitus is only diagnosed in connection with an acute myocardial infarction. We examined the control of cardiovascular risk factors in high-risk patients.

Methods: In 192 patients with type 2 diabetes mellitus admitted for preliminary invasive diagnostics in conjunction with suspected coronary artery disease, we determined the following classic risk factors: blood pressure, LDL cholesterol, HDL cholesterol, triglyceride, nicotine consumption, body weight and HbA1c. In 130 patients, diabetes 2 was known and treated (A); in 62 (corresponding to 12.3% of the patients examined) diabetes was newly diagnosed (fasting blood sugar, fructosamine, HbA1c, double testing of fasting and 2-hour OGTT levels) (B).

Results: 18% of group A and 15% of group B were of normal weight (overweight: 65% / 61%, obese: 27% / 24%). Nicotine consumption: 12% of group A were smokers, 39% ex-smokers; 25% of group B were smokers, 53% ex-smokers. 62% of group A and 5% of group B received statin medication. Antihypertensive medication in per cent (A / B): ACE 72 / 65, ARB 17 / 31, betablockers 80 / 61, diuretics 63 / 55.
Target values for risk factors: arterial hypertension (AH) < 130/80 mmHg, LDL-C < 100 mg/dl, HDL-C > 45 mg/dl, triglyceride < 150 mg/dl and HbA1c < 6.5%

	A (known diabetes)	B (newly diagnosed diabetes)
	n= total / % controlled	n= total / % controlled
AH	108 / 28	32 / 16
LDL cholesterol	130 / 39	62 / 27
HDL cholesterol	130 / 58	62 / 61
Triglycerides	130 / 44	62 / 42
Hb A1c	130 / 18	62 / 35

Conclusions: In high-risk patients, glucose metabolism should be managed in order to prevent a manifest diabetes mellitus or an impaired glucose tolerance from being overlooked. In high-risk patients with type 2 diabetes mellitus, classic risk factor control is poor.

To observe the implementation of American Diabetes Association (ADA) guidelines for care of type 2 diabetics at Peripheral Diabetes Clinics in Karachi, Pakistan

F. Muzaffar[1], A. Hussain[2], A. Basit[3]
[1] *Baqai Institute of Diabetology & Endocrinology, Department of Research, Karachi, Pakistan*
[2] *Institute of General Practice and Community Medicine, Department of International Health, Oslo, Norway*
[3] *Baqai Institute of Diabetology and Endocrinology, Department of Medicine, Karachi, Pakistan*

Objective: To observe the implementation of American Diabetes Association (ADA) guidelines for care of type 2 diabetics at Peripheral Diabetes Clinics (PDCs) in Karachi, Pakistan.
Research design and methods: The study was performed using a retrospective medical chart review of 691 type 2 diabetic patients 20 years of age and older. All of these patients had a definitive diagnosis of type 2 diabetes and records were documented on their first visit. Four peripheral diabetes clinics in four townships of Karachi district which were in operation between 1 Jan 2005 to 29 Dec 2006 were selected.
Results: A total of 691 patients (332 males and 359 females) with type 2 diabetes had a mean age of 50.94 ±10.4 years. Mean BMI was 26.6 ± 4.77 kg/m^2 and 60% of these patients had a positive family history of diabetes. Comorbidities were largely present, 84.6% had hyperlipidemia, 59% were hypertensive, 31.3% had retinopathy, 22.6% had nephropathy and 18.6% had peripheral neuropathy.
On their first visit 86% had their blood pressure measured, 56% patients had serum creatinine measured, 45% had HbA1c measured, 31% patients had dilated eye examinations, and 25% had urine albumin screening. Of these patients, 44% had lower leg examination and 2% patients were suffering from diabetic foot ulcer.
Mean systolic blood pressure (SBP) was 138 ± 19.8 mm Hg, mean diastolic blood pressure (DBP) was 85.58 ± 9.6 mmHg. Mean fasting blood glucose levels was 194.32 ± 70.59 mg/dl, random blood glucose levels was 278.86 ± 100.75 mg/dl and mean HbA1c levels was 9.13 ± 1.6%. Mean cholesterol levels was 194.15 ± 42.79 mg/dl, mean triglyceride levels was 224 ± 118.12 mg/dl, HDL cholesterol levels was 39.16 ± 7.1 mg/dl and LDL cholesterol levels was 117.62 ± 31.16 mg/dl.
Management of type 2 diabetic patients was complex: 41% of patients on antiplatelet therapy; 27% on anti-hypertensive; 22% on insulin (includes oral hypoglycemic agent + insulin); 20.3% on angiotensin converting enzyme inhibitors and 15.6% on statin medications.
Conclusions: Family physicians were not adequately following the ADA recommended guidelines for comprehensive management of diabetes patients. Inadequate documentation of medical records may reflect poor diabetes care and comorbid conditions of hypertension and hyperlipidemia were not optimally managed according to ADA guidelines. In short, a wide gap exists between practice recommendations and delivery of diabetes care by peripheral diabetes clinics.

Characteristics and metabolic profile of patients with type 2 diabetes mellitus at a tertiary care centre in Pakistan

A. Rizwan[1], S.K. Hasnain[1], Q. Masood[1], N. Islam[1], A. Jabbar[1], L. Zuberi[1], J. Akhter[1], A. Sheikh[1], N. Haque[1], O. Ishtiaq[1], A. Ahmed[1], U. Majid[1]
[1] *Aga Khan University, Medicine, Karachi, Pakistan*

Aims: To assess the proportion of individuals reaching the recommended American Diabetes Association [ADA] goals for glycemic, lipid and blood pressure control.
Methodology: Data on patients presenting to the diabetes clinic, Aga Khan University and Hospital, between 2007 and 2008 were recorded. These included sociodemographic variables, physical measurements and presence of micro and macrovascular complications. Levels of HbA1C, blood sugars, lipid profile, urine microalbumin [UMA], and medications used were recorded. The chi square test of independence was used to assess the association between the categorical variables; the T test was used to compare means of continuous variables.
Results: 1814 diabetic patients were reviewed, mean age (±SD) was 53 (±13) yrs; mean duration of diabetes was 8 (±7) yrs. There were 52.1% males & 47.9% females. Using the Asian cut off values for BMI of 23 for overweight and 25 for obese, 12.5% were overweight, while 72.2% were obese: 76.4% females versus 68.4% males (p< 0.05). Of the overweight and obese individuals, 36.2% were hypertensive as compared to 25.2% of the normal weight individuals (p<0.05). Systolic blood pressure < 130 mmHg was achieved in 57.7%; diastolic blood pressure<80mmHg in 43.2%; HbA1C of < =7.0% in 44.8%; LDL < 100mg/dl in 55%: overweight/obese individuals, 53.9% had LDL> 100mg/dl, versus 35.7% in non overweight (p=0.04); 48.6% had a triglyceride level exceeding 150mg/dl: 54.2% females versus 44.4% males (p=0.018); 35.8% males had HDL > 40 mg/dl; 20.5% females had HDL > 50mg/dl. Normal urinary micro albumin levels were achieved in 63.4%. Microvascular complications were documented in 18.0% ; 38.0% had history of hypertension; 45.5% dyslipidemia; 9.7% heart disease; 1% diabetic foot; 4.7% had a history of depression. Statins were used by 39.2% patients; 24.3% were on insulin; 44% on sulphonylureas, 57.1% on metformin (59.6% overweight/obese were on metformin, and 38.5% normal weight individuals (p<0.05)), 20.7% on glitazones, 2.6% on acarbose; 19.9% on ACE inhibitors, while 12.0% were on angiotensin receptor blockers; 51.3% were on anti platelet agents.
Discussion/conclusion: The majority of diabetics were overweight/obese, with worse lipid profiles as compared to the non obese. Females had worse profiles as compared to males. The glycemic and lipid control were not at the ADA targets. Efforts are required to institute rigorous lifestyle measures and pharmacotherapy to clinch these targets.

Prospective study: application of technologies in the treatment and control of people with diabetes in rural areas

D. Veneros[1]
[1] *Vivir con Diabetes Center, Systems Management, Cochabamba, Bolivia*

Background: Diabetes is a chronic disease that currently has no cure, but it has been proven that education and adequate and timely information can help people with diabetes to lead a normal life and reduce the risk of complications. In countries like Bolivia access to diabetes education is very limited to some urban areas and is non-existent in rural areas for various reasons such as lack of trained health or specialized personnel, little emphasis in Education in levels of decision making in the health area.
The technology, which in Bolivia is throughout the entire republic, including the more remote rural areas, can be used to adequately promote and spread education, providing health care personnel and people with diabetes, simple and useful tools that by implementing an educational technology network with Vivir con Diabetes Center in the lead, to improve the quality of life for people with Diabetes in Bolivia.
Objectives:
- Find new ways for treatment of people with Diabetes.
- Provide more comprehensive care to people who are unable to attend regular check-ups
- Prevent complications in people with diabetes through improved monitoring of their blood glucose levels
- Improving quality of life of people living in rural areas through regular and personalized monitoring.

Sample: Control group: 2 groups of people with diabetes type 1 and 2 that are Vivir con Diabetes Center's patients who are living in rural areas of Cochabamba, Bolivia, and are unable to attend their controls due to economic issues.
Methods: Software development for rural areas that can connect with a system in the Vivir con Diabetes center.

- Database of people, their treatment, weight, BMI, Waist Diameter, Glycated Haemoglobin, Lipid Parameters, Arterial Pressure, Glucose levels and weekly control of the information of the patients.
- Educative software development headed to age groups and social-cultural level of people with Diabetes.
- Basic training in handling of this system to health personnel and community leaders of the rural area.

Expected results: That health personnel in rural areas are trained in Diabetes. That the Community leaders receive basic training in Diabetes and handle of basic computer packages to identify in their rural community people with diabetes.
That people with diabetes living in rural areas have better Management of their diabetes, understand the importance of education and are farthest from the complications.

Weekend psycho-educational groups to help families better cope with diabetes

C. Marín[1], P. Bodas[1], M. Belendez[2], F.J. Hurtado[3], I. Lorente[4], O. Sanz[5]
[1] Fundación para la Diabetes, Madrid, Spain
[2] University of Alicante, Communication & Social Psychology, Madrid, Spain
[4] Navarre Diabetic Association, Pamplona, Spain

Background and aim: Though the importance of providing psychological support for families as an integral part of diabetes care has – repeatedly - been highlighted, only a handful of such psycho-educational schemes are, currently, implemented in Spanish healthcare institutions.
To provide a service of this kind we propose that an innovative approach - consisting of weekend psycho-educational groups for families of children or adolescents with diabetes - be introduced.
Method: 4 fifteen-hour weekend-seminars on psychology in diabetes: participants were divided into 3 different psycho-educational groups, run by three clinical psychologists with expertise in diabetes care - one for parents of children <12 years, one for parents of adolescents and one for adolescents - with a final joint session.
Subjects: diabetes onset in childhood; diabetes in adolescence; impact of diabetes in the family; parent and child behavior; "Letter to My Diabetes"; daily problems and strategies applied in solving them; what you would ask your parents/child. The program for the adolescent group also included a 3-hour sports session, run by an expert in sports and diabetes.
Parents of children aged 0-18, from all over Spain, were invited by diabetes associations and www.fundaciondiabetes.org; the events were organized by Fundación para la Diabetes.
Results: The 141 parents (56 fathers, 85 mothers) and 46 adolescents who took part in the workshops meant that all four weekends were at 100% capacity.
After the seminar, participants completed a 10-item survey (item range: 1-7) to assess satisfaction levels regarding seminar content. Participants from each of the 4 weekends rated the psycho-educational groups very favorably. General scores for parents' of children<12 years were 6.5, 6.6, 6.8 and 6.64; parents of adolescents: 6.71, 6.7, 6.61 and 6.91; adolescent scores were 6.46, 6.82, 5.58 and 6.6.
Conclusions: Demand for psychological seminars by parents in Spain is high. Program content, organizers and speakers have all received very high marks.
Weekend psycho-educational groups give parents a chance to meet other parents, thus enhancing mutual support among families who face similar experiences.
Psychological support should be made a standard therapeutic component.

P-1706

Life style and obesity

M. Popoviciu[1], L. Demian[1], D. Aron[1], D. Sirca[1], S. Bungau[2], L. Faur[2]
[1] Bihor County Hospital, internal Medicine, Oradea, Romania
[2] University of Oradea, Faculty of Medicine Oradea, Oradea, Romania

Aims: The main goal of this study was to determine the existence of the correlation between life style and obesity.
Method: We studied 50 subjects with age between 28-74 years, hospitalized in Clinical District Hospital Oradea, between March -May 2008, each subject filled in a form regarding the life style inventory adapted by MacKenzie, which contained a number of eight questions, quantified from 0 to 6, and the body mass index was used for the determination of the weight status.We note in same time the age, sex, living environment.
Results: The studied batch was composed of 26 women (52,0%) and 24 men (48,0%) the ratio women/men being almost 1:1.The subjects came from both rural and urban environments in almost equal proportions (52,0%) urban and (48,0%) rural.The distribution in age groups showed a predominance for the group 42-50 years, followed by the age group 51-60 years. 86% of the subjects belong to the active population. Over 55% of the subjects are obese and only 10% are normal weight. 90% represent the overweight and obese, and they represent a high risk of several co-morbidites with serious implications in public health and in the life quality. Over 68% of the subjects consider that the obligations are higher than the satisfactions, spontaneity is missing almost completely at nearly 75% of the subjects, 60% of the subjects affirm that they increased the use of toxics.The reduction or giving up of hobbies at 84% of the subjects,an important percentage 26% have insomnia owing to the activites they carry out. Analyzing the obtained score from the life style inventory form, it resulted that 62,0% of the subjects have an unhealthy life style, 26,0% a medium one and only 12,0% a healthy one. A correlation between life style and the appearance of obesity has been determined after the statistical calculation, thus unhealthy life style can been seen in 20,0% of the normal weight subjects, at 52,9% of the overweight subjects and at 75,0% of the obese subjects. Obesity is present at 62,0% of the subjects with an unhealthy life style, at 26,0%of those with medium life-style and only at 7,1% of subjects with a healthy life style.
Conclusion: There is a correlation between life style and obesity, unhealthy life style is predominant in the study and it is necessary to intensify the efforts regarding health education

Type 2 diabetes is an etiologic factor in amenorrhoea and infertility

Z.C. Nwosu[1]
[1] Ebonyi State University Teaching Hospital, Chemical Pathology Unit Laboratory Services, Abakaliki, Nigeria

Amenorrhoea, the absence of menstruation in a previously menstruating woman of reproductive age, or absence of menarche in a female of 16 years and above, has been associated with many etiologic agents. However, one proposed etiologic mechanism is the role of insulin – a beta pancreatic islet cell hormone involved in glucose metabolism. In type 2 diabetes, the attendant insulin resistance influences the production of sex hormone binding globulins and insulin receptor signaling pathways as seen in polycystic ovarian syndrome, leading to high serum concentration of androgens in women. This pathophysiologic process, with the overwhelmingly increasing incidence of infertility, has compelled a review to elucidate some intrinsic biochemical relationship between type 2 diabetes, polycystic ovarian syndrome, and amenorrhoea. Infertility, a very disturbing outcome of amenorrhoea has traumatized many early marriages in recent times, with a vast majority of latter been characterized by social exclusion, antisocial behaviour, depression, and divorce especially in developing nations. A further understanding of the link between insulin resistance and amenorrhoea, would go a long way to make early detection of infertility possible. Also, the complexity of the process explains why estimation of serum insulin concentration should be employed as a part of the diagnostic algorithm in the assessment of infertility and in a guideline for monitoring type 2 diabetic patients that are experiencing menstrual disorders.

An adult diabetes specialist nurse perspective of a young person activity weekend, in the UK

D. Howarth[1]

[1] *Warrington And Halton Hospitals Foundation Trust, Diabetes Centre, Warrington, United Kingdom*

Aim: To engage and encourage young people with diabetes to embrace "normality".

Having diabetes can be psychologically catastrophic, but with little or no contact with others having the same condition, life for a young person with diabetes can be even more stressful.

Young people with diabetes aged between 14 and 17, are invited to an activity weekend in the Lake District, North West England, UK. Here they are able to interact with one and other, whilst sharing similar previous experiences.

Across the North West of England, paediatric diabetes teams are sent information regarding this well established weekend, which is overseen by an MDT of diabetes professionals. A pre-requisite being that their own diabetes team have discussed management and exercise, thus ensuring the young person can titrate, compensate and dose adjust etc as required for the strenuous activity one hopes they will embark on.

From the start of the weekend, all participants are encouraged to self manage their condition, however if this develops into a concern for the young person, professional help may be required. This is by no means a failure on the young person's part, more of a triumph in recognising that their current control may be beyond their own limitations.

The young people are divided into groups. These small groups gel throughout the weekend, and with the support and health promotion from the professionals, the "diabetes communion" is inevitable. Talks arise from within the smaller groups regarding control, insulin management, dose adjustment etc, for once, for many of the young people, providing a playground of new-found normality. Onlookers may observe these smaller groups and see a group of young people eating or drinking before getting onto a canoe, but one cannot help to see that deep down there is a group of likeminded, young people putting their own and even each others safety first, preventing what could turn out to be a disaster on board a one man kayak.

The young people report back the benefits of having such a high level of activity across the weekend. Re-energising oneself not just physically but emotionally and even psychologically. Many young people report that they don't know anyone else with diabetes of their age, not even realising the other young people at their clinic appointments may also have diabetes.

The weekend does not focus on diabetes management, but on reinstating normality in to what can be a very 'abnormal' life at home.

Diabetes: not a foe but a sweet unfaithful friend

M. Abd El-salam[1]

[1] *Faculty of Commerce Ain Shams University, Accounting, Cairo, Egypt*

Aims: Living with diabetes friendly. Spread awareness. Change Misconceptions about diabetes..Help other diabetics.

Methods: Listen to all specialized doctors. Tell my experience with diabetes. Listen to other diabetic's experience.

Results: I and diabetes become best friends and live safely with each other.

Discussion: My name is Marwa I'm 20 years old, living in Cairo-Egypt I'm not embarrassed to have Diabetes since 1995. I learned a lot from my doctor and I'll tell you my long experience with diabetes.

At the beginning: I felt that diabetes is a foe knocked my door, my family and I were extremely shocked worried and afraid, I started shooting anxious questions like why me!

Later: With my parents help I decided to accept to live with this tedious guest who landed in my life so. I'm taking my insulin shots regularly and in time. I do my best to eat moderately. To keep my weight. To avoid junk food. To eat vegetables and fruits on a daily basis. In the morning when I just wake up I say good morning to him by checking my blood sugar and accordingly I plan my day. I always follow my doctor instructions. All my blood tests results are great and my average HbA1c test is 6.4% so my doctor is always very proud of me He even asked me to help him to educate other diabetics in his clinic. I love swimming, riding horses and playing music.

I awarded following appreciation certificates in recognition of my accomplishments in social activities by: Air Force officer's ladies Association. Suzan Mubarak Library for my distinguished contribution in a Music Festival. Certificate of Merit from my high school because I ranked 'first' to the Republic in the authoring and playing music.

So diabetes did not stop me from living a normal life but on the contrary it helped me to be organized and scheduled.

Now when I grow up I study diabetes education and became a Founding member in diabetic youth care association DYCA to help other diabetics. I helped my doctor in the preparation of an audiovisual cartoon film as an education tool for children with diabetes.

The Following are some samples of my participation activities in DYCA events: I could initiate thousands signatures and E-mail messages from Egyptian student colleagues during the 2006 campaign (UNITE for Diabetes) to support UN resolution. I awarded Al Azhar University for coordinating a seminar about avoidance of diabetes complications. I participate in WDD.

Conclusion: I realized that helping other diabetics is a success for myself to defeat diabetes my unfaithful sweet friend. I do believe that living with diabetes needs facing, education and perseverance.

[3] *BIRDEM, Endochrinology, Dhaka 1000, Bangladesh*

[4] *East West University, Business Administration, Dhaka, Bangladesh*

Aims: The broad objective of the study was to examine "identify the need for and sources of financial support for persons with diabetes who have low-incomes". The specific objective was to determine: the most financially affected age group of person with diabetes according to occupational category, sources of treatment cost, need for financial aid, and the institution they look to for financial support.

Methods: The data was collected through structured questionnaire from 100 persons with diabetes (having monthly income less than BDT 5000; Exchange Rate: US$ 1 = BD Tk. 70, approximately) of Dhaka City, Bangladesh. Non-probability sampling technique is being used. The research was conducted using the convenience sampling technique. Quantitative and qualitative information related to financial impact of diabetes was developed through the analytical scanning effort. The statistical package (SPSS v.16) was used to conduct the various analyses of the study.

Results: The results show that among different age categories, persons with age 50 or more generally spend monthly BDT 3000 or more. Older persons (50+) with diabetes generally encounter diabetes-related other health complications and thus need higher medical/health related expenditure. The percentage is higher among the unemployed (46.7%), as many retired (normal or forced) people belong in that category. The unemployed spend more than BDT 3000 a month, where their two primary sources of funds/finance are relatives (33.3%) and family wealth (33.3%) respectively. 77.8% of the respondents, whose monthly expenditure for diabetes is more than Tk. 3000, either strongly agree or agree that their expenditure for diabetes is a burden for the family. These expenditures affect other costs of their family, namely food and clothing. Among the respondents, 60% of the unemployed and 35.7% of the housewives want support from Government in the form of monthly donation. They do not have any interest in seeking loan, e.g., micro-credit.

Discussion/conclusion: It is evident from the current study that in most of the cases the persons with diabetes are facing acute financial problems in one form or another. In order to support their recurring treatment cost they have to sacrifice other family and social priorities. It is also evident from the results that the respondents do not want to be entered into hard financial contract like micro-credit arrangement; rather they would prefer donation, medicinal support and other form of soft term financial mechanism to support their financial need owing to diabetes. Future research job would be to find out a support mechanism that is both socially and financially feasible for the numerous persons with diabetes.

Diabetes education and care in a developing country: observations from Karachi, Pakistan

M.A. Shakh[1], R. Hakeem[2], A.H. Shaikh[3]
[1] Dow University of health sciences, Medicine, Karachi, Pakistan
[2] Baqai Institute of Diabetes & RLAK CHE, Education, Karachi, Pakistan
[3] FUUAST, Education, Karachi, Pakistan

Introduction: Education and care are the cornerstones of diabetes management. Standards have been suggested by experts but in most of the low resource communities meeting those standards is not assured, not only due to lack of resources but also because of lack of awareness. Assessment of areas needing particular attention could assist in improving the situation. This study explored the kind of care that is being received by a sample of middle income group subjects with diabetes in Karachi.
Material and methods: Information was collected from 105 type 2 diabetics through a pre-tested self administered questionnaire distributed in two colleges to students having any adult with onset diabetes in the family.
Results: Proportion of male and females in the sample was comparable. Diabetes was being managed by diet alone by 37%, diet and insulin by 20% and by diet and OHA by 43% of the subjects. Several important assessments e.g. Lipids, OGTT, HbA1c, Urine albumin, feet check, had never been for more than 50% of the subjects. More than 90% subjects received information about diet and causes of diabetes; and more than 70 % had been informed about diabetes complications, foot care, dental care, self monitoring of blood glucose and testing sugar in urine, and 48% had been educated about insulin injections. For various aspects of diabetes education 70 to 90%subjects reported getting it from physician, 0 to 5% from nurse, 1-16% from dietitian and 4 to 15% from printed material. Only in 16% of cases dietary information was given by dietitian, Subjects also reported getting information about these aspects from family (57 to 88%), newspaper (25 to 50%), and television (31 to 62%) also.
Conclusion: It could be concluded that majority of subject had received information but because physician usually don't have time for detailed education and information is being supplemented by non professional sources its validity needs to be assessed. In terms of clinical assessment, situation needs to be improved as many suggested tests had never been done for a large number of subjects. The study needs to be replicated with a larger sample.

P-1712

Complex evaluation of quality of life in patients with type 2 diabetes

O. Shyshko[1], T. Mokhort[1], M. Zhemlo[1]
[1] Belarusian State Medical University, Endocrinology, Minsk, Belarus

Aim: to make complex evaluation of quality of life in patients with type 2 diabetes.
Methods: The subjects of the study were 50 patients (24 men and 26 women, age 52,57±5,09 years old) with type 2 diabetes for more than two years, and 32 healthy control subjects (14 men and 18 women, age 47,35±5,44 years old).
Complex evaluation of quality of life was estimated with nonspecific questionnaire MOS SF – 36 (Medical Outcomes Study 36-Item Short-Form Health-Survey). Nonspecific questionnaire «Feeling. Activity. Mood.» (FAM) was used to assess psychological status of patients. This questionnaire consists of 3 points, including 30 polar statements that reflect psychoemotional status. Specific (only for people with diabetes) questionnaire «The Self Efficacy or Diabetes Scale» consists of 8 points and is aimed to assess patient's level of confidence in grades 1 to 10.
Data analysis was conducted with applicable computer program STATISTICA 6,0. and presented in M±d.
Results: According to SF-36, patients with type 2 diabetes have worse quality of life over all 9 scales to compare with control group (Table 1).

Table 1 - Results study of quality of life by SF-36.

Rating scale	Patients with type 2 diabetes (M± d)	Control group (M± d)
Physical Functioning	23,6±3,76*	26,52±2,65*
Role Physical	5,54±1,68*	6.88±1,34*
Bodily Pain	6,84±2,13*	9,28±2,24*
General Health	2,0±0,75*	2,88±0,68*
Vitality	29,6±7,00*	36,00±6,33*
Social Functioning	7,56±1,73*	8,08±1,55*
Role Emotional	4,61±1,29*	5,98±0,98*
Mental Health	12,86±2,74*	14,48±2,12*
Change Health	2,72±1,03*	3,00±0,57*

*- p<0,05
According to SF-36 a better quality of life was both in women with diabetes type 2 and in control group, compared that in men (Figure 2).
According to results FAM it was revealed that psychoemotional status in type 2 diabetes group is lower than that in controls. This law is traced back in the analysis of well-being scale (Table 2).

Rating scale	Patients with type 2 diabetes (M± d)	Control group (M± d)
Feeling	44,22±12,98*	52,6±8,65*
Activity	47,43±10,88*	49,42±8,79*
Mood	50,77±9,92*	53,7±8,54*

*- p<0,05
Study results of quality of life according to SED revealed that confidence index in diabetic patients has mean range (5,41 to 7,88 grades). Patients are less confident in their physical capacity and self-test capability of glucose level during bodily exercises.
Conclusion: This study demonstrates worse quality of life in patients with type 2 diabetes. According to SF-36 quality of life was better among women than men, both with type 2 diabetes and controls. The results of all questionnaires improved dissatisfactory quality of life in patients with type 2 diabetes.

Diatletic: 1st edition of the Spanish half marathon championship for athletes with diabetes

C. Marín[1], P. Bodas[1], J.C. Gómez[1]
[1] Fundación para la Diabetes, Madrid, Spain

Objective
Diatletic is a team of athletes with diabetes founded by Fundación para la Diabetes and whose principal aims are:
- To promote balanced forms of physical exercise.
- To declare, as a statement of principle, that no person should abstain from doing sports simply because they have diabetes.
- To foster experience exchanges among athletes with diabetes.
- To do away with the idea that risk of severe hypoglycemia is a valid pretext in excluding people from specific jobs.

Method: Fundación para la Diabetes has sponsored participation by athletes with diabetes in the Granollers Half Marathon from 2006 to 2009.
Sponsorship comprises: covering registration fees, providing special assistance at supply points throughout the race, and offering Diatletic runners food and lodging, once the race is over.
Results: Diatletic Team athlete involvement in the Granollers Half Marathon has increased consistently, since 2006. In 2006, there were 14 athletes; 19 in 2007; 25 in 2008; 35 in 2009. In all, 57 different athletes with diabetes have taken part, over the 1,962 km. and 4 editions of the race: 48 men and 9 women. Average runner age was 37 (24-54), while mean duration of diabetes is 12 years (12-41). No severe hypoglycemic or ketoacidosis episodes were recorded.
2009 marked the first edition of the Spanish Diatletic Championship. The first of the 35 participants to cross the finish line did so in 1 hour and 17 minutes.
Conclusion: Though sport, generally, represents a challenge both for young DM1 patients and for the healthcare professionals who treat them, there are ways to make it safe, so long as motivated experts can provide people with the necessary level of information and training, and by introducing both adjusted pharmacological treatment and carbohydrate intake.
In addition to the direct physical and psychological benefits such sporting activities can bring, they also serve to change the negative perception of diabetics as people with limitations.

Type 1 diabetes in the have not children in India - project "Disha" and the free "insulin life line" program in the state of Karnataka, India: pseudoaltruism or real justice ?

P. Lakshman[1], P. Krishnamurthy[1], S.S. Srikanta[1]
[1] Jnana Sanjeevini Medical Centre, Endocrinology and Diabetes, Bangalore, India

The life of children and youth with diabetes in India, especially from the poorer sections of society, is full of unique additional struggles and hopelessness: 1. "Death before diagnosis" - lack of awareness and diagnostic facilities, especially in rural areas; 2. Unaffordability of insulin and medical care - costs often 25 – 50% of total family income; 3. Discrimination in education, future employment and family life 4. Non-existent governmental programs or even concern.

Since 1994, in a small attempt to improve this grave situation, Samatvam Trust - Jnana Sanjeevini Medical Center, has tried to support 500 children through charity Project DISHA and Insulin Lifeline Program (Karnataka State total population 53 million). The activities include: FREE Childhood Diabetes Clinic - first Sunday of every month, provision of FREE insulin and syringes, health education and counseling, social support – "Adopt a child", patient – parent support groups, residential health – recreation camps etc. Currently about 200 children are actively attending the clinic (rest untraceable or maybe dead). FREE insulin for this program has been procured through diverse sources, occasionally, strange sources: bulk purchased at discounted rates; pharmaceutical industry 'social' programs – often erratic and unfortunately business linked; short expiry and left over insulins from industry and hospitals; participation in limited time bound clinical trials; samples gifted by good samaritans (overseas friends, families of recently dead insulin using adults !!!) etc. During extreme scarcity of insulin stocks in the program, we were forced to implement rationing and reservation towards children of the lowest poverty rank order, even among the poor. SHBGM has been an unavailable luxury till recently (now 6 -10 blood glucose strips provided per child per month); HbA1c unaffordable; TSH measured only on strong clinical suspicion.

Distressingly, self realizing the grossly suboptimal care these youngsters are receiving, we often question ourselves whether we are justified in prolonging the misery of these children, just to let them succumb helplessly few years later (infections, hypoglycemia, DKA, renal failure etc), and disappear from this rather cruel and uncaring world

Diabetes in Africa: lessons from two lived experiences

V. Donnelly[1]
[1] QEII HSC Capital Health, Medicine/Geriatrics/Emergency, Halifax, Canada

Aims:

- Explore challenges and triumphs of managing diabetes in Tanzania, Africa, June-July 2008, while a student with the International Tanzania Study Tour, Dalhousie University, Canada;
- Building on experiences in The Gambia, Africa, July-September 2006 in developing and implementing diabetes education and prevention program, the lived Gambian diabetes experience is compared, contrasted to the lived Tanzanian diabetes experience;
- Relate similarities and differences from the African visits to clinical interactions as a Diabetes Case Management Coordinator in Nova Scotia, Canada, and how practice has changed as a result;
- Present a personal picture of the growing epidemic in Africa;
- Discuss the success of community based organizations (CBOs) in Tanzania in HIV testing, education and prevention and nutritional, financial, and spiritual support;
- Apply lessons learned and insights obtained from Gambian and Tanzanian travels to personal and professional growth as a nurse and global citizen.
- Methods: - Anecdotal, informal interviews with individuals living with diabetes in Tanzania;
- Discussion with healthcare professionals about managing diabetes in Tanzania, hospital and community, (monitoring blood glucose, using medications, adhering to a "diabetic diet");
- Personal reflection, journal writing;
- Literature review: managing diabetes in a resource-poor environment,
- Culture immersion: language, food, social connectedness.

Results:

- The lived experience of diabetes in Tanzania and The Gambia is similar to lived experience in Nova Scotia, Canada, despite differences in geography, economics and culture;
- Diabetes is a chronic disease affecting individuals, families, and communities because it is largely managed by diet and lifestyle, and thereby greatly influenced by culture and socioeconomics;
- Living in a resource-rich environment did not always ensure good glycemic control, and likewise, reasonable glycemic control is achievable in a resource-poor environment;
- Support (family, healthcare team, and community) are key elements for success in both a resource-poor and -rich environment;

Discussion/conclusion:

- Diabetes: a chronic disease, a global epidemic. Educating, preventing and managing diabetes in Africa impacts the world, as educating, preventing and managing AIDS in Africa impacts the world;
- Diabetes education centres in Tanzania are a successful model of care for resource-poor nations to follow;
- Adapting AIDS CBOs to diabetes is one community-minded strategy to prevent, educate and manage the diabetes epidemic, for resource-poor and rich environments;
- The world is a small place, we are all connected, and our commonalities are greater than our differences. We are all human.

Impact of a knowledge-sharing network of diabetic patients in Mali on quality of life: baseline survey

P. De Beaudrap[1], O. Keita[2], P. Guimet[3], E. Pasquier[3], F. Diko[2], N. Charpentier[2]
[1] Institut de Recherche pour le Développement, UMR145, Montpellier, France
[2] Handicap International, Mali, Bamako, Mali
[3] Handicap International, France, Lyon, France

Background: In Sikasso, Mali, a knowledge-sharing network was set up in May 2008 that aimed at bringing together diabetic and non diabetic patients, sharing knowledge through various activities and promoting social relationships.

Aims: To assess the efficiency of this network.

Methods: This survey is the baseline round of a quasi-experimental study. Face to face interviews were conducted in Bambara using a questionnaire made of 4 parts: (1) socio-demographic characteristics (2) assessment of the quality of life (QoL) through the WHO-QoL brief questionnaire (3) assessment of the social relationships (4) assessment of the impact of diabetes on health through 15 questions taken from the Diabetes QoL questionnaire.

Controls matched for age and sex were drawn from the association of diabetic patients of Sikasso.

Results: Of the 74 subjects included in this baseline study, 45 (61%) participated in the network and 29 (39%) were controls. The sex ratio, matrimonial status, educational level, age distribution and ethnic groups were similar between the two groups.

Clinical stage: 36% [21;50] of the network participants and 52% [33;71] of the control declared a clinical complication of diabetes (p=0.2). The most frequent complication was retinopathy.

QoL: The physical dimension of the QoL was greater for female than male (p=0.03), for people with a regular work (p=0.001) and for participants in the network compared to controls (p=0.02). The social dimension of QoL was also better for participants in the network than for controls (p<0.01).

Social relationships: Almost 90% of the participants and controls reported 1 or several close friends. The number of friends ranged between 1 and more than 6 without significant difference between the two groups (p=0.9) and the duration of friendship was most often longer than 2 years. The relationship with friends and their support were considered either as satisfactory or very satisfactory. Most of the subjects did not find that diabetes may limit their relationships (97% [94-100]).

Impact of diabetes on day to day life: Difficulties were reported for 75% [66;86] of the subjects and there was no significant difference between participants and controls. The most frequent difficulties were financial (62% of the case) following by physical (23%). Of the participants to this study, 10% [5-20] never disclosed their disease.

Conclusion: Whereas the two groups were similar according to their socio-demographic characteristics, a better QoL was found for the participants in the network. This could reflect an early effect of this program as well as a selected population.
Neither participants in the network nor controls reported difficulties related to their social relation. However, there was a significant impact of diabetes on their day to day life.

Thirty four years down the line with diabetes

G. Mohamed[1], F. Sherdel[2]
[1] Comprehensive Diabetes Centre, clinic, Nairobi, Kenya
[2] Avenue Healthcare, clinic, Nairobi, Kenya

Introduction: I am a Diabetologist in Kenya diagnosed with Diabetes 34 years ago.My life and experience with diabetes in Africa has been a case of "a tale of two cities" where in a resource poor setting I have graduated from using Bovine insulin to analogue insulin using an Insulin pump. I have moved from urine testing using benedict's solution to continuous glucose monitoring.
Diagnosis with Diabetes: The time period of my diagnosis seems rather vague, however the unquenchable thirst and fatigue is unforgettable. I vividly remember putting my mouth on a spout of a water tap to try and drink water to quench my thirst. I was first diagnosed with a urine infection and as my condition deteriorated an experienced expatriate General Practitioner in town was able to diagnose diabetes and I was admitted in hospital with Ketoacidosis. At the time of diagnosis I wasn't aware of what I was going through and the true reality of the disease process set in as I went through my teenage years
My Experience and challenges with Diabetes:
As I grew up I realized that most doctors had minimal knowledge and expertise in the field of Diabetes. There was no nutritional, diabetes education given. In my early years with Diabetes I was frustrated and confused with no real understanding of what was happening to me. Medical follow up was then erratic and unstructured. Doctors visits were only when I was unwell. I used glass and plastic syringes with reusable needles which needed boiling before each injection. Urine glucose testing when available was a laborious process using benedict's solution. Blood glucose meters were only available in the late 1980 and 1990 but the high cost of strips and infrequent availability of strips meant blood glucose monitoring was seldom done. Hypoglycemia was a great concern in my youth and it created a sense of loss of control of my body, and lifestyle.The fear of hypoglycaemia created anxiety and great concern to my family members and teachers.Insulin Shortages were a concern and an accidental breakage of an Insulin vial often meant that I would have to go for day or so without insulin. Over time I realized that effective management of Diabetes could only be achieved if I understood the disease and made necessary changes and adjustments. I was able to formulate realistic and attainable treatment goals.I was able to mould Diabetes round me rather than myself around Diabetes. I decided to pursue a career in diabetology to ensure I have the tools and knowledge to look after myself and also give back to the society my knowledge and experience.My experience 34 yrs down the line with diabetes is an indication that diabetics even in resource poor setting can have a fulfilling life and realize their dreams and objectives if given the necessary tools and support.

Cardiometabolic risk behavior among adults living with diabetes mellitus in Tanzania: a call for action

K. Leshabari[1], E. Licoco[2], R. Chunga[3]
[1] Amana Municipal Hospital, Internal Medicine, Dar es Salaam, Tanzania
[2] Muhimbili National Hospital/ Tanzania Diabetes Association, Internal Medicine, Dar es Salaam, Tanzania
[3] Muhimbili University of Health and Allied Sciences (MUHAS), School of Medicine, Dar es Salaam, Tanzania

Introduction: Diabetes mellitus is now a pandemic in distribution. However, inequities in the allocation of resources especially to the most remote areas of continental Africa have posed a big challenge to the health systems of most African nations. Awareness raising for cardiometabolic risk factors has proven to be an essential tool for preventive strategies against modifiable risk factors for metabolic diseases. However, not much is known of the extent of cardiometabolic risk behavior among people living with diabetes mellitus who regularly visit diabetes clinics for care.
Objective: To assess practices on cardiometabolic risk behavior among adults with type 2 diabetes attending a tertiary diabetes clinic in Dar es Salaam, Tanzania.
Methodology: A cross-sectional survey was done in July-Sept 2007 involving adult type 2 diabetes patients attending a tertiary diabetes clinic at Muhimbili National Hospital. Data were collected using semi-structured questionnaires. Data were analysed using epi-info version 3.3.2. Statistical significance tests included the usage of X^2 test to check for the association between different variables and P-value < 0.05 to account for the role of chance in findings.
Results: A total of 108 diabetes patients were surveyed. Out of whom, 66 (61.1%) were females. Significant amount (22.4%) of respondents declared to be regular alcohol drinkers with males outweighing females in frequency (P=0.05) Almost 10% of male respondents revealed to have smoked at least once within 24 hours prior to the survey time (P=0.0000). None among the study respondents revealed to perform blood/urine sugar on a daily basis. Long duration of diabetes state was strongly associated with higher frequency of blood/urine sugar tests (P=0.003). Significant number (87.75%) of respondents perceived eating practices to affect diabetes and its outcomes.
Conclusion: Significant amount of respondents were active smokers and alcohol users.
Recommendation: More education is needed on cardiometabolic risk factors especially among people living with chronic diseases like diabetes mellitus. There is a desperate need for a regular assessment of depressive illnesses among people with diabetes mellitus, and the extent by which depression influences early diabetes morbidity and mortality

P-1719

The effect of "GIDIUBE" on the glycemic control of its participants

S. Pereira Duarte Nunes[1], F. Andrade Avelar[1], F. Oliveira Magalhães[1], E. Espínola Leite[1], A. Lopes Cançado[1], A.C. Martins[1], D. Ribeiro M. C. Oliveira[1], R. Gimenez C. Bonfim[1], N. Mesavilla Ferreira[1], A. Paula da Silva[1], S. Messias de Freitas[1]
[1] Uberaba University, Uberaba, Brazil

The Gymkhana Diabetics of Uberaba - GIDIUBE, held in this municipality, has as main objective provide an education day for healthy individuals, diabetes patients and their family members about this morbidity, in commemoration of the world day of diabetes. In addition to the educative character, the event includes screening and control of some parameters correlated with diabetes and the metabolic syndrome in their participants, such as: levels of fasting glycemia and post-prandial, levels of cholesterol and triglycerides, in addition to the calibration of the values of blood pressure, of the weight and abdominal circumference of the same.
Methodology: Performed questionnaire, measured in fasting glycemia and post-prandial, weight, height. Data were analyzed by SPSS 14.0 program.
Results: Among 126 participants of the activity we have seen: 31% of diabetes. The average statistics – found: age 65.18 ± 1.3 years, fasting glycemia - 112 ± 5.4 mg/dl, glycemia post-prandial – 136.1 ± 6.8 mg/dl, body mass index (BMI) – 27.1 ± 0.6 kg/m^2. Among diabetics, 44.4% were fasting glycemia, 22.2% normal blood glucose between 100-125 and 33.3% fasting glycemia above 126 mg/dl. Five new diagnoses were made during the event (3.9%). In relation to post-prandial glucose 45.8% of diabetics maintained a normal level (2 h < 140 mg/dl).
Conclusions: The day educative may serve as a warning to the susceptible individuals to the development of diabetes mellitus, contributing to the reduction of the need of care with the disease, the complications associated with it; in patients with DM, involves the detection and prevention of early complications. In addition to the education program have a low cost compared with medicines and with the therapeutics specifies (hemodialysis, laser, hospitalizations, treatments of ulcers, amputation of limbs and cardiovascular problems) and be objective, it is primarily a reduction in the cases of diabetes in the future, obtained mainly with an improvement and/or control of ideal levels of blood glucose of participants.

P-1720

Living with diabetes

M. Miki[1]

[1] *Diabetes Association, Diabetes Association, Limbe, Cameroon*

When one is newly diagnosed with diabetes, one hardly believes that one will live with diabetes for the rest of one's life. If a patient's blood glucose is very high and this patient is placed on insulin, this patient has the impression that once the insulin is completely used, diabetes will be treated. In a situation where the patient is placed on oral treatment, the patient too has the impression that by the time the packet of drug gets finished, diabetes will be treated. Hardly will they know that diabetes is an illness he or she will be living with till death. As time goes on, EDUCATION starts to play a vital role in the patient's lifestyle. Diabetes is a METABOLIC SYNDROME.

What to do living with diabetes:

1. The patient has to monitor the blood sugar so as to maintain it under control.
2. The patient has to take his or her medications regularly.
3. Follow up a diet plan and moderate food items that carry up blood sugar.
4. Exercise regularly
5. The patient should watch out his or her weight.
6. Maintain good body hygiene so as to prevent infections.
7. Make regular check ups of the heart, eyes, kidneys, teeth and feet.
8. The patient should know the complications warning symptoms.
9. Living with diabetes is a major issue and a prime concern.

Insulin bank system

A. Joyo[1], *C. Opia Vicky*[1], *B. Abira C.Sally*[1], *D. Amade Paskal*[1], *E. Anguzu Patirck*[1], *F. Opar Bernard*[1]

[1] *Arua Diabetes Association, Health, Kampala, Uganda*

Introduction and background: Insulin is one of the most expensive anti diabetic's drugs without it, life can be meangless for children and adults, research has shown that, children without insulin their life span is a year and adults five years. Therefore insulin is one of the essential anti diabetic's drugs for managing diabetes both in type1and 2. In Uganda, particularly west Nile region, we have created insulin bank system. This is where insulin is brought in the districts of west Nile through the Arua Diabetes Association and the patients sells their Chicken, Beans, Matoke and come to buy the insulin at reduced price. The Associations are attach to District hospitals and health centers whereby the patients are able to access the medical services which are provided to them by trained health workers. The Diabetic nurses and educators provide information and give Diabetic education to the patients about how to keep insulin.

Method: The most assured way is by using the clay pots for keeping the insulin. This consists of;

1. Clay pot.
2. River sand.
3. Water.
4. Plastic cup.
5. Pot cover.

Water to be added to the river sand whenever necessary.

The trained health worker instructs the patient how to keep the insulin in the pot which is a halfway filled with the river sand. The pot stands on a basin of river sand. The coldness developed by the sand keeps the plastic cup cold and favorable for the insulin.

Then plastic cup is inserted in the pot half way, inside the plastic cup no water add and you now place your insulin in the plastic cup and keep it covered.

This is the safest way of keeping insulin in our set up, then when you want use it you pick your medicine, you inject and keep it back for the next time.

Results:

1. 90% of the patients have well controlled blood glucose level compared to 10% who don't follow the above method.
2. It is cheap and available for 100% patient who are on insulin.
3. It is affordable.
4. Most reliable way of keeping insulin.
5. It doesn't need electricity
6. It can be used in the rural set up of the village.

Conclusions: Most patients on insulin and following the above method have well controlled blood glucose level hence improving the quality of life.

Media, and public awareness

P-1722

Creating awareness and comparative screening for diabetes in rural (Isara) and urban (Sagamu) communities in Ogun State, Nigeria

C.O. Alebiosu[1], *F. Inofomoh*[1], *A. Inofomoh*[2]

[1] *Olabisi Onabanjo University Teaching Hospital, Medicine, Sagamu, Nigeria*

[2] *Olabisi Onabanjo University Teaching Hospital, Obstetrics and Gynaecology, Sagamu, Nigeria*

Background/aim: Non-communicable diseases account for a large proportion of morbidity and mortality in Nigeria. Diabetes mellitus is the most common endocrine disorder in Nigeria - within three decades, the prevalence rose six fold. The role of community participation in the prevention of diabetes and hypertension cannot be overemphasized. This informed the study, with the aim of creating awareness at the grassroot community level, emphasising preventive measures.

Methods: In 2007, a diabetes awareness campaign with free blood glucose screening, aimed at preventing diabetes was conducted within rural Isara community and urban Sagamu community in Remo division in Ogun state, Nigeria. Diabetes was defined as fasting blood glucose > 126mg/dl and random blood glucose > 200mg/dl. Hypertension was defined as blood pressure measurements > 140/90 mmHg. Obesity was also assessed using Body Mass Index and the waist – hip ratio. Data was analyzed using SPSS software version 13.

Results: In rural community of Isara, two hundred and forty respondents (18-80years) were screened during the campaign for diabetes and hypertension. The mean age, Body Mass Index and Waist-Hip ratio were 53.9±15.7years, 25.9±4.8 Kg/m2 and 0.91±0.08 respectively. The mean random blood glucose was 102.9 ± 25.5 mg/dl. The mean systolic blood pressure was 134.2±24.8 mmHg, while the mean diastolic blood pressure was 78.7±14.4mmHg.

In the urban Sagamu community, a total of 340 respondents were screened. The mean age, Body Mass Index and Waist-Hip ratio were 47.7±15.4years, 28.8±6.3 Kg/m2 and 0.99±0.1 respectively. The mean fasting blood glucose was 95.2±32.9 mg/dl. The mean systolic blood pressure was 128.8±18.6 mmHg, while the mean diastolic blood pressure was 82.1±12.4mmHg.

Conclusions: Our findings suggest that overweight and obesity are becoming a public health burden in the urban Nigerian community. Creating awareness on diabetes and hypertension and instituting lifestyle modification measures to curb non-communicable disease and obesity are of paramount importance.

Social networks in internet and diabetes divulgation

C. Dissat[1], *F. Garcia*[1], *P.C. Rodrigues-Pinto*[1]

[1] *Sociedade Brasileira de Diabetes, Communication/Press, Rio de Janeiro - RJ, Brazil*

Aims: To define and to list some of the main internet social networks, highlighting those linked to diabetes. To observe the growth of this kind of communication proving to be possible to use it to spread information about diabetes.

Methods: By analyzing the amount of virtual communities, blogs, fotologs, videologs, microblogs, etc; evaluation of related studies; evolution of behaviour in Brazil.

Results: Internet Social Networks are the relationship between persons in the communication mediated by computers. These systems work by social interaction, trying to connect people and allow their communication (Wikipedia). With the appearance of web 2.0 (in which the main point is the user participation) the interest of the users in expressing their opinion has increased. CGM - Consumer-Generated Media - is the term used for information communicated by the user and it is linked to comments, forums, discussion lists, blogs, fotologs, videologs, virtual communities, microblogs and wikis. All these ways of expression have grown in an incredibly fast manner. In 1999, 'The page of only weblogs', by Jesse James Garret, registered the existence of 23 blogs. In 2000, there were more than 102,499 only written in Spanish language. In a Google search combining the words blog+diabetes, the number of results is up to 5,600,000. In two of the most important social networks of the world – Facebook (most used in USA) and Orkut (most used in Brazil) – almost 1,000 communities were found, 530 and 408 respectively. The 5 first Orkut communities have together 16,979 members. In a research done in photo/image sharing social networks were found 37,000 photos in

Flickr and 108,000 in Picasa with the tag 'diabetes'. A recent research done by Nielsen has concluded that Brazilian web users (62.3 millions of web users according to IBOPE) are using the social networks more than the email (80% of Brazilians) and that 17 millions use Orkut. Dieese's report showed that in 2008 one computer was sold at each 3 seconds.

Conclusion: Social interaction that occurs in internet makes effective connections. Communication done this way makes thing less impositive and more spontaneous. The internet user turns to be more to the message. Entities related to diabetes couldn't be apart from this tool which can be developed with a low budget and with expressive results in the improvement of the quality of life of people with diabetes.

World diabetes day in Brazil in version web 2.0

C. Dissat[1], F. Garcia[1], E. Frick[2], C. Pupo[1], P.C. Rodrigues-Pinto[1], A. Dissat[1]
[1] *Sociedade Brasileira de Diabetes, Communication/Press, Rio de Janeiro - RJ, Brazil*
[2] *Sociedade Brasileira de Diabetes, Communication/Press, São Paulo - SP, Brazil*

Aims: To evaluate the use of internet and internet users' participation in publicizing World Diabetes Day activities in Brazil; use of social networks and how these strategies can reduce publicity costs.

Methods: By analyzing the number of visits and pageviews of the World Diabetes Day hotsite; amount of online forms filled with activities and with photos attached; and an evaluation of social networks.

Results: In 2008 the SBD website staff (journalism/photography/webmaster) proposed a hotsite creation exclusive for World Diabetes Day in which web 2.0 strategies would be used, that means an active participation of Brazilian internet users. The hotsite's first version - www.diamundialdodiabetes.org.br – was created in 2007 to publicize activities realized for the 14th November, but it was in 2008 that the community participation was higher. To make this happen, the hotsite worked with the Web 2.0 concept by creating alternatives to make the interaction between the website and the user. Forms were created for any person who wanted to send photos, texts and videos with the activities that happened in Brazil. To incentivize the community and SBD fellows the headlights on the hotsite homepage supported by the publicity on SBD website – www.diabetes.org.br – were done. The motivation was the publication of all the stuff that was sent to the newsroom. This is one of the strategies to make the user proud of the stuff sent by him. The hotsite had about 70,000 pageviews on November, 2008. Two hundred forms were filled up, as well as a lot of emails sent to info@diabetes.org.br. The journalism staff used a network called Flickr that has an excellent acceptance by Brazilian internet users. More than 260 photos were published in Flickr, which is a website defined as a social network whose objective is to store and to share photos. All photos can be tagged, making finding and web dissemination easier. A Flickr account was created (www.flickr.com/socbrasdiabetes) to publish the photos of the blue-lit monuments and activities in Brazil. The number of photo views was more than 20,000.

Conclusion: Diabetes websites can create strategies for the World Diabetes Day publicity can be done with regular investments using internet/web to call authorities, media and population attention.

Five years experience in "Healthy Run" promotion.

M. Tsang[1], J. leung[1], C.H. Chung[1], E. Li[1], T. Chan[1], C. Chau[1], G. Chu[1]
[1] *Diabetes Hongkong, Diabetes Hongkong, Hong Kong, China*

Obesity and type 2 diabetes mellitus (T2DM) represent major health concerns worldwide. The prevalence of diabetes mellitus is around 12% locally. However, burden of diabetes mellitus is projected to increase by 50-80% by 2025. A number of population studies, such as Finnish Diabetes Prevention Studies, Diabetes Prevention Programme and Da Quin Studies all support prevention of T2DM by life style modification. Since 2005, Diabetes Hongkong has been organizing yearly Healthy Run for the public. A subcommittee was formed and a coordinator was appointed to coordinate with various voluntary groups and helpers. The table below depicts the progress in the past five years. We concluded that it has been a successful programme in promoting public awareness of exercise in prevention of obesity and diabetes mellitus. Also, it has been important in promoting image of Diabetes Hongkong which is helpful in our fund raising program.

Year	Total	M<45	M>45	F<45	F>45	<18
2005	67	38	15	10	4	
2006	212	71	83	33	25	
2007	427	125	157	38	32	
2008	668	175	275	80	32	89
2009	1318	536	450	158	32	86

LATE-BREAKING ABSTRACTS

P-1726

The evolutionary paradox of the the polycystic ovary syndrome and the global diabetes epidemic: a Fertility First hypothesis

S.J. Corbett[1], A.J. McMichael[2], A.M. Prentice[3]
[1] *Centre for Population Health, Sydney West Area Health Service, Sydney, Australia*
[2] *Australian National University, National Centre for Epidemiology and Population Health, Canberra, Australia*
[3] *London School of Hygiene and Tropical Medicine, MRC International Nutrition Group Nutrition and Public Health Intervention Research Unit, London, United Kingdom*

The high global prevalence of the Polycystic Ovary Syndrome (PCOS), a heritable cause of ovarian infertility, is a stark evolutionary paradox which provides insight into the rapidly increasing prevalence of cardiovascular disease and diabetes in contemporary populations, particularly in the developing world. We propose that PCOS, Type 2 diabetes (T2D) and the Metabolic Syndrome (MetS) are modern phenotypic expressions of a metabolic genotype attuned to the dietary and energetic conditions of the Pleistocene - an era in which humans were hunter gatherers with a substantially meat-based, high protein, low carbohydrate diet. This metabolic "Fertility First" rather than "Thrifty" genotype persisted at high prevalence throughout the entire agrarian period – from around 12000 years ago until 1800 AD – because, we contend, in an environment defined by chronic and often severe seasonal food shortage, it helped to sustain ovulation, which, in humans, is exquisitely sensitive to energy balance and flux. Conversely, we argue that genetic adaptations to a high carbohydrate, low protein agrarian diet, necessary adaptations to, variously, population growth, climate change and megafaunal extinction, were constrained because they also compromised fertility by raising the lower bound of body weight and energy intake optimal for ovulation and reproduction. After 1800, the progressive attainment of dietary energy sufficiency released human populations from this adaptive constraint. This release, through the powerful mechanism of fertility selection, increased, in decades rather than centuries, the prevalence of a genotype better suited to carbohydrate metabolism. This putative mechanism for rapid and recent human evolution can explain the lower susceptibility to T2D of today's Europid populations. This hypothesis predicts that the increasing rates of diabetes and cardiovascular disease which typically accompany economic development will be tempered by natural, but particularly fertility, selection against the conserved ancestral genotypes which currently underpin them.

Insulin resistance temporarily induced in healthy male subjects results in increased postprandial GIP, but not GLP-1 responses

K.B. Hansen[1], T. Vilsbøll[2], J.J. Holst[3], F.K. Knop[2]
[1] *Glostrup Hospital, Clinical Physiology, Glostrup, Denmark*
[2] *Gentofte Hospital, Internal Medicine F, Gentofte, Denmark*
[3] *the Panum Institute, Biomedical Sciences, Copenhagen, Denmark*

Background and aims: Glucose-dependent insulinotropic polypeptide (GIP) and glucagon-like peptide-1 (GLP-1) are incretin hormones - with well documented insulin-releasing actions - secreted from the small intestine in response to feeding. GIP receptors are found in a number of peripheral tissues including adipocytes. GIP-R-mediated effects have been suggested to be a key link between consumption of high fat diets and the development of obesity, insulin resistance and type 2 diabetes. Obese patients with type 2 diabetes are characterised by increased postprandial GIP responses (promoting obesity

and insulin resistance) and reduced postprandial GLP-1 responses (promoting glucose intolerance). We aimed to determine the impact of insulin resistance on postprandial GIP and GLP-1 responses.
Materials and methods: Postprandial GIP and GLP-1 responses were measured using a 520 kcal-liquid meal test (58 g carbohydrate, 28 g fat and 10 g protein) in 10 healthy Caucasian male subjects without family history of diabetes (age: 23.9±3.1 years (mean±SD); BMI: 24.1±1.7 kg/m^2; fasting plasma glucose: 4.9±0.3 mM, HbA_1c: 5.4±0.1%) before and after induction of insulin resistance using high calorie diet, relative physical inactivity and administration of prednisolone (37.5 mg/day) for 10 days.
Results: The intervention had a significant impact on insulin resistance according to the homeostatic model assessment (1.4±0.1 vs 2.3±0.4, p=0.02) without affecting body weight. In line with this, fasting insulin levels (36±3 vs 61±6 pM, p=0.03) and insulin responses (area under curve) increased following the intervention (22±6 vs 43±13 nM·4h, p=0.03). The impaired insulin sensitivity had no impact on postprandial GLP-1 responses (1.5±1 vs 2.0±1 nM·4h, p=0.56), but postprandial GIP responses rose significantly following induction of insulin resistance (6.2±1.0 vs 10.0±1.3 nM·4h, p=0.002).
Conclusion: These data show that induction of insulin resistance using prednisolone, high calorie diet and relative physical inactivity results in increased postprandial GIP responses, suggesting that increased GIP secretion in obesity may occur as a consequence of insulin resistance rather than being a primary cause of obesity and insulin resistance. Additionally, our data suggest that insulin resistance is not directly responsible for the reduced postprandial GLP-1 responses observed in obese individuals with type 2 diabetes.
The study was supported by an EFSD/Novartis grant

P-1728

ATM protein kinase mediates full activation of AKT and regulates glucose uptake in response to insulin in muscle cells

D.Q. Yang[1], M.J. Halaby[1], J.C. Hibma[1], B.W. Kastein[1]
[1] Sanford Research/USD, Sanford Project, Sioux Falls, USA

Aims: Ataxia-telangiectasia (A-T) is an autosomal recessive disorder characterized by cerebellar ataxia and oculocutaneous telangiectasias. Patients with A-T also have high incidences of type 2 diabetes. The gene mutated in this disease, ATM (A-T, mutated), encodes a 370-kDa protein kinase. Previous results from our group and others have shown that cytoplasmic ATM is an insulin responsive protein (Yang et al, Nat. Cell Bio., 2000) that mediates full activation of Akt. Our recent results have shown that ATM stimulates GLUT4 translocation through regulation of Akt activity in muscle cells (Halaby et al., Cell Signal, 2008). The objective of this study is to further test the functional link between ATM and insulin-mediated glucose uptake in muscle cells.
Methods: We treated L6 muscle cells with a specific inhibitor of ATM, KU-55933, and a specific activator of ATM, chloroquin, and measured their effect on phosphorylation of GSK-3β and glycogen synthase. We also tested the effect of chloroquin on Akt activity in L6 muscle cells and in muscle tissue of high-fat-fed rats, an animal model of insulin resistance.
Results: We found that insulin-mediated phosphorylation of GSK-3β at Ser-9 in L6 myoblast was greatly reduced by KU-55933. In addition, a substantial increase in phosphorylation of glycogen synthase was observed in KU-55933 treated L6 cells. In contrast, treatment with choloroquin led to enhanced phosphorylation of GSK-3β and decreased phosphorylation of glycogen synthase, suggesting that ATM may positively regulates glycogen synthesis through inhibition of GSK activity. Next, a 2-deoxyglucose assay was performed to determine the effect of chloroquin on glucose uptake in L6 cells. In cells treated with both insulin and chloroquin, glucose uptake was 2.3-fold higher than that in cells treated with only insulin, suggesting that chloroquin is a potent activator of glucose uptake in L6 muscle cells. In addition, treatment of L6 myoblasts with chloroquin resulted in a marked increase in Akt phosphorylation at Ser473 as compared to cells treated with insulin alone. This result again confirms the role of ATM in the activation of Akt. To further study the role of ATM in insulin signaling in vivo, we tested the effect of chloroquin on Akt activity in high-fat-fed rats. We found that the inhibition of insulin-mediated Akt activity in muscle tissue of high-fat-fed rats was partially reversed when these rats were treated with chloroquin. The effect of chloroquin on phosphorylation of GSK-3β and glycogen synthase in this animal model is currently under investigation.
Discussion/conclusion: Our findings demonstrate that ATM, in addition to its role in regulating Glut4 translocation, also stimulates insulin-mediated glucose uptake by up-regulating glycogen synthesis. Chloroquin has been widely used as an anti-malarial drug. Our results suggest that chloroquin may also be used as a novel therapeutic agent targeting type 2 diabetes.

Increased diabetogenicity in a presumed low-risk cohort of pregnant Scandinavian women. A prospective longitudinal study (2002-2005 and 2005-2008)

E. Qvigstad[1], N. Voldner[2], C.M. Hoff[2], M.C.P. Roland[2], K. Godang[1], T. Henriksen[2], J. Bollerslev[1]
[1] Oslo University Hospital, Department of Endocrinology Rikshospitalet, Oslo, Norway
[2] Oslo University Hospital, Department of Obstetrics and Gynecology Rikshospitalet, Oslo, Norway

Aims: To monitor anthropometry, glucose and insulin metabolism and pregnancy outcome prospectively in a large cohort of pregnant women to elucidate mechanisms that influence glycemic control.
Methods: 1032 previously healthy pregnant Scandinavian women booked at our hospital, underwent 75g-OGTT at week 14-16 and 30-32, in addition anthropometry of mother and infant were done. Comparisons between the cohorts were done with t-test or chi square test, for overall trends, ANOVA was used.

Cohort characteristics mean (SD)	2002-2005 (n=553)	2005-2008 (n=479)	
Maternal age (years)	31,2 (4)	31,3 (4)	ns
Maternal weight (kg, week 14-16)	70,8 (12,1)	69,0 (11,9)	p<0,02
BMI (week 14-16)	24,9 (4,1)	24,1 (3,7)	p<0,001
Weight gain during pregnancy (kg)	10,6 (3,8)	10,4 (3,3)	ns
Fasting p-glucose week 14-16	4,19 (0,47)	4,46 (0,44)	p<0,001
Fasting p-glucose week 30-32	4,44 (0,49)	4,53 (0,51)	p<0,005
2 hour p-glucose week 14-16	4,42 (1,18)	4,50 (1,20)	ns
2-hour p-glucose week 30-32	6,08 (1,40)	5,95 (1,51)	ns
Birth weight (g)	3619 (570)	3556 (578)	p<0,08
GDM (%) week 14-16	1,9	1,2	ns
GDM (%) week 30-32	10.6	13.5	ns

Results: Maternal age and weight gain during pregnancy was unchanged, as well as gestational age at birth. For both periods the rate of gestational diabetes (GDM) is higher than previously reported in this region (12/1000/year). We found significant reductions in maternal body weight and BMI at inclusion, but no change in GDM rate between the cohorts.
Fasting and 1hour glucose levels increased during the study period, both in early and late pregnancy (p for trend <0.0001); however for 2 hour levels this shift was not significant between the two cohorts. The fasting and 1 hour glucose changes during OGTT occurred in spite of an unchanged GDM rate and a significant decrease in BMI at week 14-16 (p for trend <0.01).
Conclusions: This normal urban population demonstrated an unexpected high GDM rate. During longitudinal follow-up, there was in spite of decreasing BMI levels, unchanged GDM rates. The increasing dysglycemia during the study period indicates a rising level of diabetogenicity in these pregnant women.

Association between polymorphisms in SLC30A8, CDKAL1, TCF7L2 and gestational diabetes mellitus in the Chinese population

L.H. Zhang[1], Y.C. Hui[1], F. Ping[1], W. Li[1], M. Nie[1], M. Li[1], H.D. Xiang[1]
[1] Peking Union Medical College Hospital. Peking Union Medical College & Chines Academy of Medical Sceiences, Endocrinology, Beijing, China

Aims: New genetic variants associated with susceptibility to type 2 diabetes mellitus have been discovered in recent genome-wide association studies. We aimed to examine the association between gestational diabetes mellitus (GDM) and 3 of these diabetogenic variants related to pancreatic beta cell function.
Methods: The study included 1140 unrelated Chinese pregnant women (493with GDM and 647 non-diabetic controls). We genotyped the single nucleotide polymorphisms (SNPs) rs10946398, rs9465871, rs7756992 and rs7754840 in CDKAL1; rs2466293 and rs13266634 in SLC30A8. and rs290487,rs11196205 and 11196208 in TCF7L2 by using the method of ligase detection reaction. The genotype frequencies and related phenotypes in the GDM patients were compared with those in the non-diabetic controls.

Results: Compared with controls, GDM was associated with rs13266634 (OR 1.29, 95% CI 1.07-1.54, p = 0.008) in SLC30A8; rs10946398 (OR 1.59, 95% CI 1.27-1.96, p = 0.002) in CDKAL1; and rs290487 (OR 1.23, 95% CI 1.02-1.96, p = 0.042) in TCF7L2. The risk alleles of the SNPs rs13266634 in SLC30A8; rs10946398in CDKAL1; rs290487 in TCFL2 were associated with significant decreases in the Insulin Sensitivity–Secretion Index (ISSI) calculated by insulin and blood glucose or insulin AUC during a 100 g OGTT performed at the time of diagnosis of GDM.
Discussion/conclusion: Some of the type 2 diabetes-associated genetic variants that were discovered in the recent GWA studies are also associated with GDM in Chinese; this may support the hypothesis that GDM and type 2 diabetes are two of the same entity.

[9] *University of Medicine and Pharmacy of Craiova, Molecular Biology and Genetics, Craiova, Romania*

Introduction: Hyperglycaemia-induced superoxide overproduction seems to be the first and key event in the activation of all other pathways involved in the pathogenesis of diabetic nephropathy (DN). Glutathione peroxidase 1 (GPX-1) is one of the key enzymes in defence against oxidative stress at mitochondrial level. The aim of the study is to evaluate the effect of Pro198Leu polymorphism in GPX-1 gene on the risk of developing DN in type 1 diabetes.
Method: We studied 184 type 1 diabetic patients. They were divided into two groups: A – 91 patients with DN (proteinuria or ESRD) and B – 93 patients without microalbuminuria and more than 20 years diabetes duration. Genomic DNA was extracted from peripheral blood leucocytes using comercial Kit. Pro198Leu (rs=1050450) polymorphism was assessed by PCR followed by restriction with Apa I and electrophoresis (PAGE 8%). Association analysis was performed using DeFinetti computer program. In all cases P values < 0.05 were considered statistically significant.
Results: Hardy-Weinberg equilibrium was respected for patients with DN (F=0.19173, p=0.067406) and controls (F=0.09242, p=0.372773). At association test, homozygote patients for Pro allele had an OR=2.632 [95%C.I. (1.065-6.502), chi^2=4.56, p=0.03], the presence of one Pro allele conferred an OR=1.622 [95%C.I. (0.905-2.905), chi^2=2.66, p=0.10] for developing DN, while the presence of the homozygous Leu type variant was protective OR=0.380 [95%C.I. (0.154-0.939), chi^2=4.56, p=0.03] while the heterozygous patients for Leu allele had an OR=0.435 [95%C.I. (0.184-1.026), chi^2=3.75, p=0.05]. The allele frequency were significantly different, conferring the following ORs: OR_{Leu}= 0.607 [95%CI (0.392-0.939), chi^2=5.05, p=0.02] and OR_{Pro} = 1.648 [95%C.I. (1.064-2.552), chi^2=5.05, p=0.02].
Conclusions: Presence of the wild type - Pro variant for Pro198Leu polymorphism in GPX-1 gene may increase the risk of developing DN in Romanian type 1 diabetic patients while the mutant Leu allele seems protective. These results are very interesting because this is the first report of this polymorphism in diabetic nephropathy and allele frequencies are different from literature, which is why the results have to be confirmed in larger studies.

Relationship between compliance of self-monitoring of blood glucose (SMBG) and improvement in glycemic control in patients with type 2 diabetes

S. Harashima[1], Y. Nakahigashi[1], N. Inagaki[1], Y. Seino[2]
[1] *Kyoto University, Diabetes and Clinical Nutrition, Kyoto, Japan*
[2] *Kansai Electric Power Hospital, Diabetes and Clinical Nutrition, Osaka, Japan*

Background & aim: Self-monitoring of blood glucose (SMBG) is a useful tool for patients with diabetes to detect patterns of blood glucose control. However Japanese patients treated with oral hypoglycemic agents (OHA) usually do not perform SMBG because health insurance does not cover it. In addition, many patients treated with insulin are not willing to do SMBG frequently because of pain at blood sampling. Accordingly, SMBG is not fully applied in clinical practice. To approach this problem, we have designed a clinical research in order to examine advantageous effect that less painful blood sampling technique could improve glycemic control in patients with type 2 diabetes by increasing compliance of SMBG. In our preliminary questionnaire, 74% of 48 patients answered that palm blood sampling was less painful than fingertip one and the others answered that the pain was equal. From the result, we select two puncture sites, fingertip and palm, to evaluate glycemic control and compliance of SMBG.
Subjects & methods: A prospective, open, randomized, 24-week, single center study assesses the efficacy of SMBG on glycemic control in patients with type 2 diabetes. The study has been approved by the Institutional Review Board of Kyoto University Hospital. The primary objective is to evaluate glycemic control (reduction of HbA1c). The study has started since June 2009 and 120 patients newly treated with insulin and 180 ones treated with OHA alone are being enrolled. Insulin-treated patients are allocated to two groups; fingertip or palm, and OHA-treated patients are allocated to three groups; fingertip or palm or no SMBG, using a randomized, balanced design. Each subject is screened for eligibility, provided voluntary informed consent and basic demographic information and medical history. They also are given the One Touch Ultra Blood Glucose Monitoring System kit which allows both fingertip and palm testing. Subjects are required at minimum thrice SMBG at least three days a week in daily life and 7 times SMBG at least two days in a week before the next visit. Subjects visit every 6 weeks, and laboratory data including HbA1c and total number of SMBG are collected. They also are requested to fill in the questionnaire about SMBG at visit 3 (the first visit after the start of SMBG) and visit 6 (the final visit of the study). The study has been registered on University hospital Medical Information Network (UMIN) in Japan (UMIN000001525).
Results: Interim analysis about reduction of HbA1c and compliance of SMBG will be presented, comparing the fingertip group and the palm one in the patients treated with insulin or OHA alone. We also will report the result of the questionnaire about SMBG.

Eye based glucose meter – correlation tests

D. Daly[1], H. Simpson[2], P. Chatfield[3], M. Mukhtar[2], N. Reddy[2], T. Barber[2], E. Simpson[2], B. Cunningham[2], J. Sutton[4]
[1] *Lein Applied Diagnostics, Reading, United Kingdom*
[2] *Royal Berkshire Hospital, Centre for Diabetes and Endocrinology, Reading, United Kingdom*
[3] *University of Reading, Statistical Services Centre, Reading, United Kingdom*
[4] *Thames Valley Diabetes Research Network, Reading, United Kingdom*

Aims: This study compared glucose levels measured in the anterior chamber of the eye with glucose levels measured simultaneously in venous and capillary blood. Subjects had type 2 diabetes and no known eye disease. The ultimate aim is to produce a robust, non-invasive self glucose monitoring technique for people with diabetes.
Methods: Although the final goal is an eye glucose meter with the look of a mobile phone the prototype used in this trial was 25cm x 15cm x 15cm and was mounted on an ophthalmic stage. It used an eye safe 780nm laser to interrogate the anterior chamber of the eye and had received a notice of no objection from the Medical and Healthcare products Regulatory Agency (MHRA). The trial had ethical approval from the National Research Ethics Committee (NREC).
Thirty volunteers attended for 5 hours, each on one occasion. During the first hour they had an intravenous cannula inserted and were trained on the eye meter. Over the next 4 hours measurements of eye, venous and capillary

glucose were taken every 15 minutes. Capillary glucose was measured using Roche Accu-Chek, Lifescan OneTouch and Hemocue 201+ meters. Venous glucose was collected and centrifuged for subsequent laboratory analysis in a Johnson and Johnson Vitros 5.1.

Results: A statistical analysis was performed using the software package R to compare data from the eye with that from the gold standard meter (Vitros 5.1). Due to the requirement to get precise results at low blood glucose levels – when hypoglycaemia is a risk – the analysis was performed with the log of the blood glucose.

The anterior chamber dimensions were used as the model's target rather than the log blood glucose, as this allows the absolute dimensions to be used rather than normalised values.

A mixed model was used for the statistical analysis. This allowed us to determine which parameters, obtained during the measurement process, are important. The p-value relating to the log blood glucose term was calculated to be <0.0001. A p-value of less than 0.05 demonstrates that there is a correlation between the two parameters. Therefore, this is deemed to be strong evidence that blood glucose and anterior chamber dimensions are associated.

Conclusions: The study confirms that our eye based method for non-invasive eye glucose measurement correlates closely over a wide range of values with venous glucose without an obvious time lag. The next steps are to develop a predictive algorithm, build this into a handheld version of the meter and to test the technique on people with potential interferents.

P-1734

Therapeutic potential of glucagon-like peptide-1 agonists in insulin-treated diabetes mellitus

J. Dupre[1], T.J. McDonald[1]
[1] London Health Sciences Ctr, Medicine, London, Canada

We have reported that the glucagon-like peptide-1 agonist exendin-4 (E4) can greatly (>50%) reduce post-prandial glycaemic excursions in C-peptide (CP)-deficient (meal-stimulated CP < 0.2 mmol) diabetes, when injected subcutaneously before breakfast with usual insulin, during intensive insulin treatment (IIT). To test the hypothesis that greater glycaemic effects of E4 would be manifest in CP-positive (meal-stimulated CP ≥ 0.4 mmol) insulin-treated diabetes, we here used the same protocol and doses of E4 with diet-conforming breakfasts and with continuing IIT in 8 volunteers, age 45 ± 6 y, $A1_c$ 7.5 ± 0.4% $A1_c$, insulin dose 0.77 ± 0.08 u/Kg/d, peak meal-stimulated CP 0.62 ± 0.27 nM, duration of diabetes 11 ± 4 y. They received usual pre-breakfast insulin, without E4 (vehicle injection), or with 3-5 doses among 0.01, 0.02, 0.04, 0.06, 0.08 µg/kg body weight (BW), on different occasions, in varied order, with masking of E4 dosage in these 40 individual studies. Self-selected breakfasts were replicated for each subject. Blood levels of glucose, CP, free immunoreactive insulin (FIRI), glucagon and human pancreatic polypeptide (HPP, reflecting humoral and/or nervous entero-insular functions) were determined at 15-30 minute intervals through 240 mins. Changes of postprandial excursions from concentrations at 0 min were dose-related for glucose, HPP, and glucagon (correlations, r > 0.9, p < 0.04, anova) with estimated dosage for 50% attainable effect ('ED 50') 0.02-0.04 µg/kg BW E4, similar to our findings in CP-deficient diabetes. No effects of E4 on CP or FIRI were discernable, and no symptomatic adverse effects occurred with E4 < 0.08 µg/kg. E4 doses > 0.02 µg/kg reduced mean incremental plasma glucose levels into the range observed in concurrent studies in 8 normal volunteers who received 75 g carbohydrate breakfasts. We conclude that systemic delivery of ED50 dose E4 can powerfully enhance glycaemic control in insulin-treated diabetes, reducing the peak increments of plasma glucose postprandially by more than 50%, with equivalent effects in subjects with and without endogenous insulin secretion. This was demonstrated by means analogous to those employed in the original studies that defined insulin sensitivity in insulin-treated diabetes. Taken with the results in CP-deficient diabetes, the observations also show that portal delivery of endogenous insulin in low-normal amounts does not contribute detectably to observed effects on the glycaemic response. These observations indicate the need for, and enable, studies to assess the therapeutic potential of GLP-1 agonists as congeners with insulin for attainment of improved glycaemic control without adverse effect, and with possible reduction of insulin dosage, in people with insulin-requiring Type 1 or Type 2 diabetes.

P-1735

Effect of the dual endothelin receptor antagonist, bosentan, on untreatable ulcers in a diabetic patient

C. Luna Gomez[1], F. Álvarez Reyes[1], M. Brito Suarez[1]
[1] Hospital Universitario Nuestra Señora de La Candelaria, Rheumatology, Santa Cruz de Tenerife, Spain

Aims: Refractory skin ulcers are a major burden in diabetic patients. Their pathogenesis is multifactorial and increasing data implicate endothelin as a mediator of diabetic macrovasculopathy and microvasculopathy. We report here the resolution of refractory skin ulcers in a patient treated with the dual endothelin receptor antagonist bosentan.

Methods: An 85-year-old male with 30-year history of type 2 diabetes developed an ulcer on his right heel in November 2007 after prolonged heat exposure. Despite appropriate care, the ulcer increased in size and within 3 months the patient was unable to walk. He was admitted to hospital for congestive heart failure one month later. At time of admission, skin examination showed the heel ulcer to be extensive and in Wagner Grade III. It had evolved to expose the calcaneus, with an inflammatory aspect, limited granulation tissue, and a purulent, fetid exudate. The patient had also developed three Grade II decubital lesions on the sacral area, external malleolus and flexure of the right ankle. These were well delineated, of necrotic appearance, without granulation tissue and with purulent exudates. General examination showed congestive heart failure. The patient's diabetes remained well controlled. Standard therapy comprising mechanical and enzymatic debridement with aqueous gel dressing, combined with pentoxifylline 1,200 mg/day was administered during the next 5 months. Ciprofloxacin, followed by clavulanic acid plus amoxicillin, was also administered for 15 days during this time. The patient's response to this therapy was, however, disappointing. The heel ulcer remained in Grade III, affecting the total posterior face, with partial exposure of the calcaneus but sparing the Achilles tendon. The three decubital lesions remained in Grade II. In parallel, his general condition deteriorated. After this time he was treated with bosentan 62.5 mg/day for one week, up-titrated to 62.5 mg b.i.d thereafter, on a compassionate use basis.

Results: After 3 weeks of bosentan treatment the sacral ulcer rapidly healed, followed by the external malleolar ulcer. Marked granulation tissue became apparent on the heel and ankle ulcers. Following 21 weeks of bosentan treatment, all ulcers had healed and the patient was able to walk with assistance. No abnormalities were observed during monitoring of blood pressure, erythrocyte count, or alanine and aspartate aminotransferases, during bosentan treatment.

Discussion: This single case of an apparent beneficial effect and good tolerance of bosentan in a diabetic patient with refractory skin ulcers should be interpreted with care and merits further investigation. If confirmed, this observation would support a role of endothelin in the pathogenesis of diabetic skin ulcerations.

Factors accounting for variability in weight and HbA1c response to exenatide in the Association of British Clinical Diabetologists (ABCD) nationwide exenatide audit

R.E.J. Ryder[1], C. Walton[2], P.H. Winocour[3], A.B.C.D. nationwide exenatide audit contributors[4]
[1] City Hospital, Diabetes and Endocrine Unit, Birmingham, United Kingdom
[2] Hull Royal Infirmary, Department of Diabetes, Hull, United Kingdom
[3] Queen Elizabeth II Hospital, Department of Diabetes and Endocrinology, Welwyn Garden City, United Kingdom
[4] Many Hospitals, Diabetes Departments, Many Towns and Cities, United Kingdom

Aims: To learn from experience of exenatide in real clinical use in the UK, ABCD began a nationwide audit in December 2008.

Methods: An on-line questionnaire in a password protected area of the ABCD website for collection of anonymised patient data. UK diabetologists were persistently prompted by email to contribute.

Results: The first 3913 patients with data available for analysis were studied - mean (+/- SD) age 54.6 (+/-10.4) years, 2167/3913 (55.4%) male. In response to exenatide, mean (+/- SD) HbA1c, weight and body mass index fell as follows: HbA1c by 0.75% from 9.42 (+/- 1.19)% to 8.65 (+/- 1.22)% ($p<10^{-126}$), weight by 4.9kg from 114 (+/- 23.3) to 109.1 (+/- 22.6) kg ($p<10^{-}$

[15]), BMI by 1.74 from 39.89 (+/- 7.5) to 38.15 (+/-7.24) kg/m^2 ($p<10^{-16}$). The weight and HbA1c response showed considerable variability; to assess factors accounting for this variability, weight and HbA1c responses were each divided into 5 groupings. 5 weight groupings: weight increase; weight loss of 0-2Kg, 2-5Kg, 5-10Kg and >10Kg respectively. 5 HbA1c groupings: HbA1c rise >1% and 0-1%; HbA1c fall 0-1%, 1-2%, and >2% respectively. These groups were compared by analysis of variance with regard to initial HbA1c, weight, BMI, duration of diabetes, age, sex, insulin usage prior to exenatide and insulin discontinuation at exenatide start. Highly significant differences were found between the groups:

- Those whose weight increased after exenatide had higher initial HbA1c, but lower initial weight, BMI and age. They were less likely either 1) to have been on insulin or 2) to have had insulin stopped.
- Those who lost a large amount of weight (>10kg) after exenatide had a lower initial HbA1c, higher initial weight and BMI, and slightly longer duration diabetes. They were more likely 1) to have been on insulin 2) to have had insulin stopped.
- Those with the greatest falls in HbA1c after exenatide (>2%) had higher initial HbA1c.
- Those who experienced the greatest rise in HbA1c after exenatide (>1%) had a higher initial weight, were also more likely to be on insulin before being started on exenatide; when insulin was stopped at exenatide start, those whose HbA1c rose were more likely to have insulin restarted.

Conclusion:

1. Heavier patients with better glycaemic control lose the greatest amounts of weight on exenatide.
2. Some poorly controlled patients initially put on weight with exenatide as exenatide improves glycaemic control in patients whose weight has been lowered by poor glycaemic control.
3. Strict adherence to the current exenatide license in the UK, with discontinuation of insulin at exenatide start, may lead to considerable worsening of glycaemic control. This is more likely to occur in heavy patients whose diabetes is relatively well controlled by insulin.

Teneligliptin, a novel DPP-IV inhibitor, improves glucose intolerance and prevents diet-induced adiposity in obese animal models

S. Ishii[1], T. Takashina[1], K. Yoshida[1], T. Hatano[1], Y. Horai[2], A. Fukunari[2], K. Sakai[1]
[1] Mitsubishi Tanabe Pharma Co., Pharmacology Department II, Saitama, Japan
[2] Mitsubishi Tanabe Pharma Co., Advanced Medical Research Lab., Saitama, Japan

Background and aims: Dipeptidyl peptidase IV (DPP-IV) inhibitors improve abnormal glucose metabolism in type 2 diabetes by increasing the life-span of incretin hormones. DPP-IV knockout mice are characterized by lack of diet-induced obesity, enhanced energy expenditure and improved insulin sensitivity. However, the effect of currently available DPP-IV inhibitors on body weight is neutral. Teneligliptin (MP-513) is a novel chemotype DPP-IV inhibitor and is now under clinical development for the treatment of type 2 diabetes. The present studies were conducted to clarify the in vitro and in vivo pharmacological profiles of teneligliptin and anti-obesity potential in high-fat diet-induced obese mice.
Methods: The in vitro effect of teneligliptin was determined using recombinant human DPP-IV (rhDPP-IV). The plasma DPP-IV activity was evaluated in Wistar rats in vivo and the effect on postprandial hyperglycemia was examined in Zucker fatty rats. To assess the anti-obesity action, teneligliptin was administered to 60% kcal-fat-fed C57BL mice (DIO mice) via drinking water for 10 weeks and the mesenteric fat was pathologically examined.
Results: The enzyme activity of rhDPP-IV was inhibited by teneligliptin in a competitive manner with a Ki value of 0.4 nmol/L. In terms of IC50 values, teneligliptin is about 7 and 2.5 times more potent than sitagliptin and saxagliptin, respectively. In vivo, the plasma DPP-IV activity was persistently and potently suppressed by the teneligliptin-treatment compared to sitagliptin-treatment with an EC50 of 0.18 mg/kg in normal rats. Single oral dosing of 0.3 and 3 mg/kg elicited more than 50% inhibition of the plasma DPP-IV activity up to 15 hours, and improved glucose intolerance with increased insulin and active GLP-1 levels in plasma in the 12-hour interval carbohydrate loading tests of Zucker fatty rats. The 10-week treatment with teneligliptin inhibited the plasma DPP-IV activity by 65% throughout the study and increased the plasma GLP-1 levels by 4.1-fold in DIO mice. The body weight gain and visceral fat mass were significantly reduced by 36% and 41%, respectively (both $p<0.01$). The plasma insulin level was reduced by 41 % and pathological examination revealed suppression of the high-fat diet-induced adipocyte hypertrophy.
Conclusion: These results indicate that teneligliptin has a potential to be a once-daily DPP-IV inhibitor. Clinical studies have already demonstrated a long-lasting DPP-IV inhibition and improvement of HbA1c in patients with type 2 diabetes. The impact on visceral adiposity makes teneligliptin likely as a next generation DPP-IV inhibitor with beyond glucose benefits.

YH9425, a novel glucokinase activator with blood glucose-lowering activities in animal models

D. Lee[1], K. Min[2], Y. Kim[1], Y. Park[1], T. Han[1], J. Kim[1], B. Lee[3], W. Yi[1]
[1] Yuhan research institute, Drug discovery lab., Gyeonggi-do, Korea
[2] Yuhan research institute, Drug evaluation lab., Gyeonggi-do, Korea
[3] Yuhan research institute, Research management team, Gyeonggi-do, Korea

Aims: Glucokinase (GK) activator is expected to be associated with a dual mechanism for lowering blood glucose concentration – enhancement of insulin secretion from pancreatic beta-cell and glucose uptake in the liver. For new anti-diabetes agent, we discovered a novel GK activator, YH9425, and evaluated the mode of action in-vitro and the glucose lowering potential in animal models.
Methods: An enzymatic GK assay using purified recombinant human pancreatic and liver GK was used to evaluate the effect of YH9425. Selectivity against hexokinase 1 and 2 was tested also using enzymatic HK 1 and 2 assays.
Min6 cells, mouse pancreatic beta-cell line, were used for glucose dependent insulin secretion.
We examined the change of basal blood glucose levels and oral glucose tolerance (OGT) in non-diabetic (C57BL/J6) and diabetic (db/db) mouse model after oral administration. The level of blood glucose, HbA1c and OGT were measured in ob/ob mice after 2 weeks of once daily oral dosing.
Results: YH9425 raised human pancreatic GK activity (half maximum effective concentration-EC_{50} of 48.9 nM at 5 mM glucose) with a half maximum saturation concentration ($S_{0.5}$) of 1.36 mM glucose and maximum reaction rate (V_{max}) of 117 %. It activated human hepatic GK with an EC_{50} of 54.3 nM, same as pancreatic GK, and did not affect the hexokinase 1 and 2.
This compound increased insulin secretion from Min6 cells in a glucose dependent manner.
YH9425 also improved a dose-response OGT in C57Bl/J6 mice; for dosing 5, 15 and 50 mg/kg, area under the curve of blood glucose was decreased of 9, 26 and 38 %. Acute treatment of the compound in C57Bl/J6 and db/db mice elicited basal glucose lowering activity. In 14 day sub-chronic study with ob/ob mice, YH9425 showed significant decrease in HbA1c and blood glucose levels and no adverse effects on serum lipids or body weight have been observed.
Conclusions: YH9425 has potential as a therapeutic agent for type 2 diabetes mellitus. Currently, we are studying YH9425 and its analog.

Improvement in glycemic control after 12 week treatment with melogliptin, a novel DPP-IV inhibitor

J. Efthimiou[1], M. Patekar[2], N. Maharaj[2], S. Kalra[3], P.V. Rao[4]
[1] *Glenmark Pharmaceuticals Ltd., Clinical Research and Development, Oxford, United Kingdom*
[2] *Glenmark Pharmaceuticals Ltd., Clinical Research and Development, Mumbai, India*
[3] *Bharti Research Institute of Diabetes and Endocrinology, Consultant Endocrinologist, Karnal, India*
[4] *Nizam's Institute of Medical Sciences, Department of Endocrinology and Metabolism, Hyderabad, India*

Aims: Melogliptin is a novel, potent, selective, oral DPP-IV inhibitor. The primary aim of this study was to determine the change from baseline in HbA1c after 12 weeks of treatment with different doses/regimens of melogliptin. Secondary aims included safety and tolerability, and changes in metabolic parameters, including β-cell function.
Methods: This was a randomized, double blind, parallel group, placebo controlled study. The study consisted of an 8 week wash out period (including a 2 week placebo run in period), followed by 12 weeks of treatment. Patients satisfying eligibility criteria (HbA1c ≥7 ≤10%), were randomised to 1 of 5 treatment arms (ie melogliptin 25mg OD, 50mg OD, 50mg BD, 100mg OD or placebo). The study had 90% power to detect a treatment difference in HbA1c of 0.45%, assuming a SD of 0.9%, and α ≤5%.
Results: A total of 494 patients with type 2 diabetes mellitus [mean age 51 years (range 30-80 years), mean diabetes duration 2.8 ± 3.6 years] were enrolled in the study. A total of 41% patients were previously treated with diet and exercise alone, whilst 59% had been taking oral anti-diabetic monotherapy.
Significant reduction in HbA1c compared to placebo was observed in all melogliptin treatment groups [ie 0.55% (p<0.0001), 0.36% (p=0.0086), 0.75% (p<0.0001), 0.6% (p<0.0001) in the 25mg OD, 50mg OD, 50mg BD, 100mg OD groups respectively]. In the subgroup of patients with a higher baseline HbA1c of 8.5-10%, melogliptin showed mean placebo-subtracted reductions in HbA1c of 1.05% and 0.88% in the 50mg BD and 100mg OD groups respectively.
Significant improvement in homeostasis model assessment-ß cell function (HOMA-ß) was also seen in the 50mg BD group relative to placebo (p=0.004). Melogliptin exhibited a good safety and tolerability profile, with only two episodes of possibly drug related hypoglycemia throughout the 12 weeks of treatment and no drug related serious adverse events.
Conclusion: This 12 week placebo controlled study demonstrates that melogliptin is a safe and effective treatment for patients with type 2 diabetes at doses ranging from 25mg to 100mg, with a therapeutic index which compares favorably with other approved DPP-IV inhibitors.

Initial combination therapy with sitagliptin and pioglitazone: complementary effects on post-prandial glucose and islet cell function

M. Alba[1], B. Ahren[2], S.E. Inzucchi[3], Y. Guan[1], M. Mallick[4], L. Xu[4], E.A. O'Neill[5], D.E. Williams-Herman[1], K.D. Kaufman[1], B.J. Goldstein[1]
[1] *Merck Research Laboratories, Clinical Research, Rahway, USA*
[2] *Lund University, Clinical Sciences, Lund, Sweden*
[3] *Yale University School of Medicine, Section of Endocrinology, New Haven, USA*
[4] *Merck Research Laboratories, Late Development Statistics, Rahway, USA*
[5] *Merck Research Laboratories, Medical Communications, Rahway, USA*

The mechanism of action, efficacy and safety of sitagliptin 100mg (SITA) and pioglitazone 30mg (PIO) were assessed in patients (pts) with type 2 diabetes mellitus. Following a 6-week diet/exercise period (and washout if discontinuing an antihyperglycemic agent), pts with fasting plasma glucose of 7.2-14.4 mmol/L entered a 2-week, single-blind, placebo run-in period. Pts (N=211) were randomized (1:1:1:1) to SITA, PIO, SITA+PIO, or placebo (PBO). At baseline and after 12 weeks, pts were given a mixed meal and underwent frequent blood sampling for measurements of glucose, insulin, and C-peptide over 5 hours (h) and glucagon over 3 h. Disposition Index (DI, a quantitative measure of the relationship between b-cell function and insulin sensitivity), Φ_s (a measure of b-cell responsiveness to above-basal glucose concentrations) and insulin sensitivity (using a validated composite index, ISI) were also assessed.

see table 1

LS-mean differences in change from baseline were assessed at Week 12.
The 5-h total glucose AUC was lower with SITA, PIO, and SITA+PIO compared to PBO (p<0.001) and was lower with SITA+PIO compared to either monotherapy (p<0.01). The 5-h total insulin AUC was greater with SITA compared to PBO (p=0.005), PIO (p<0.001), and SITA+PIO (p<0.05); SITA+PIO increased insulin AUC more than PIO (p<0.05). SITA lowered 3-h total glucagon AUC more than PBO (p=0.002), and SITA+PIO reduced glucagon AUC more than PIO (p=0.01) and PBO (p<0.001) but not compared to SITA. DI was improved from baseline with all active treatments compared to PBO (p<0.02). Both monotherapy treatments improved Φ_s from baseline compared to PBO (p<0.05) and the combination SITA+PIO improved Φ_s more than SITA (p<0.05) or PIO (p<0.001). PIO, either alone or in combination with SITA, improved ISI compared to SITA (p<0.005) and to PBO (p<0.001). All treatment regimens were generally well tolerated. Through complementary mechanisms of action the combination of SITA+PIO reduced post-prandial glucose after a mixed meal more than either treatment alone. Both agents appear to enhance beta-cell function, whereas SITA additionally improves alpha-cell function.

Effect of yoga, diaphragmatic breathing,antioxidant rich diet on glycemic control, blood pressure control, anthropometry and oxidative stress: a randomised controlled trial in comparison with standard care in type 2 diabetes

H. Sreelakshmi[1], P. Adhikari[2], D. Sydney[2], D. Vivian[1], S. Kotian[3]
[1] Kasturba Medical College, Biochemistry, Mangalore, India
[2] Kasturba Medical College, Medicine, Mangalore, India
[3] Kasturba Medical College, Community Medicine, Mangalore, India

Oxidative stress is implicated in the pathogenesis of diabetes, beta cell dysfunction and complications Novel drugs are under development for inhibition of oxidative stress in Type 2 diabetes. Lifestyle interventions such as yoga are found to be beneficial in reducing oxidative stress. However controlled clinical trials are lacking. Similarly controversy exists on the role of antioxidants in diabetes.

Hence we aimed to study the effect of 3 different lifestyle interventions such as Yoga, diaphragmatic breathing (D.B.) and diet rich in antioxidants on HbA1c, blood pressure, anthropometry, oxidative stress and antioxidants.

Methods: 240 Type 2 diabetics were enrolled of which 60 had microvascular disease, 60 had macrovascular disease and 60 had neuropathy and 60 had no complications. Baseline assessment was done for all which included, FPG, PPG, HbA1c, Fasting lipid profile, BMI, waist-hip ratio, malondialdehyde (MDA) levels, Vitamin C, Vitamin E and SOD level. These patients were stratified according to complications and randomized in blocks of 12 to receive either Yoga, diaphragmatic breathing, diet rich in antioxidants, or standard care. All the three intervention groups also received standard care. Drug treatment, diet and exercise were kept constant throughout the study period. Supervised interventions were continued for 3 months and all the baseline parameters were repeated.

Results: There was no significant difference in the baseline characteristics of the four different groups. Yoga improved BMI (P=<.001),FPG (P=<.05), PPG (P=<.005),Systolic B.P. (P=<.05)and diastolic B.P. (P=<.05). D.B. improved Waist Hip ratio (P<.005,FPG (P<.005) and PPG. (P<.05). Antioxidant rich diet improved Systolic blood pressure (P<.005),FPG (P<.001) and PPG (P<.001), while with standard care there was significant increase in BMI (P<.005) and marginal decrease in waist circumference (P<.05) and increase in HbA1c (P<.005). Yoga and D.B. decreased MDA levels and oxidative stress significantly (P<.001) while diet rich in antioxidants decreased MDA levels (P<.005) and increased Vitamin C levels (P<.001), while standard care did not improve MDA or vitamin C.

Table showing Mean % difference ± S.D for groups

Intervention groups	BMI	WHR	HbA1c
Yoga	1.95 ± 2.88	1.36±5.56	0.65±16.06
D. breathing	0.42±3.3	1.66±3.48	1.77±10.03
Antioxidant diet	0.37±1.88	0.02±2.11	3.9±4.91
Standard Care	0.77±2.02	0.62±4.41	7.09±14.78
Significance (P)	<.005	<.005	<.005

Table showing Mean % difference for Oxidative Stress

Intervention groups	MDA	Vitamin C levels
Yoga	18.79±17.3	56.76±157.27
D. breathing	20.58±14.24	44.45±11.94
Antioxidant diet	5.05±11.85	63.55±80.74
Standard Care	3.72±15.3	9.79±56.14
P	<.001 <.005	

Yoga controlled BMI better while D.B improved WHR better while HbA1c improved better with antioxidant rich diet. Both Yoga and D.B improved oxidative stress better than antioxidant rich diet while antioxidants increased better with antioxidant rich diet

Conclusions: Yoga, D. breathing and antioxidant rich diet improved one or the other parameters of glycemic control, blood pressure and anthropometry and oxidative stress/antioxidants. It is useful to combine these multiple interventions as a part of life style modification in type 2 diabetes
